ABSTRACT

Child mortality become priority problem in Sustainable Development Goals (SDGs). High mortality rate of children under five is largely due to preventable causes. A comprehensive approach in solving these problems carry through Integrated Management of Childhood Illness (IMCI). Unfortunately the implementation is constrained by the lack of service accuracy and completeness of health service data, length of service time, and spatial monitoring problems. This study aims to show the effectiveness of Clinical Decision Support System (CDSS) in resolving management of sick children problems. This is a systematic review through analysis journal of child health services, especially management of sick children and CDSS. Article accessed from: Proquest, Ebsco, Google Scholar, and Science Direct. From a review of the literature found 26 related journals.The articles were published between 2014-2018. The result shows that CDSS escalate the accuracy of assessment and decision on medical actions, ensure the completeness of health service data, shorten service time, and overcome spatial problems in service monitoring that lead to improve child health services quality. CDSS able to overcome problems in management of sick children, therefore it can justify the use of CDSS in optimizing IMCI service.

Keywords: child health services, IMCI, CDSS

1. Introduction

The Convention on the Rights of the Child globally stipulated that every country must ensure the maximum survival, well-being, health and development of the children in its territory[1]. Therefore increasing child survival is a long-term international priority[2]. Paying attention to children's rights and the importance of children's health, the Sustainable Development Goals (SDGs) have targeted to end all preventable child deaths by 2030[3].

Child mortality is a burden for every country. In 2017, as many as 5.4 million children under the age of five died due to preventable causes[4], as many as 80% of children under five died at home[5], and moreover, many children still fail to reach their full potential in terms of growth and

development[6]. The major causes of child mortality include pneumonia, diarrhea, malaria, measles, malnutrition or a combination[7]. Some children may experience more than one problem / disease, so the care given must focus on the condition of the child as a whole, not only on the complaint submitted. This indicates the need for specific interventions that can overcome problems while simultaneously improving the quality of child health services[8].

In 1994, the World Health Organization (WHO) responded to child health problems by developing an integrative approach known as the Integrated Management of Childhood Illness (IMCI). IMCI was applied as a guideline for managing toddlers because it has 3 main components that are able to improve children's health, namely: (1) improving the capacity of the health workers, (2) strengthening the health system and (3) improving child care practices in families and communities. The curative, preventive and promotive aspects of the procedures make this form of management effective at improving the quality of health and reducing child mortality, especially for middle and lower income countries. Given the immense benefits of the IMCI and the high number of child deaths in Indonesia, the Ministry of Health of the Republic of Indonesia adopted the IMCI in 1996 with the development of guidelines and several pilot studies, where IMCI became a standard service in the management of health for infants and toddlers[6-9].

The implementation of IMCI has been running for more than 20 years, but in Indonesia, IMCI is still manual and constrained by the lack of service accuracy and completeness of the health service data, the length of the service time, and spatial monitoring problems. The analysis of children's health conditions in the districts is therefore less representative[7,10–12].

Several countries have used health information technology innovations in the form of Clinical Decision Support Systems (CDSSs) for their child health services, especially in the management of sick children. Research on the use of CDSSs has been carried out and these findings are promising. However, for them to be applied in Indonesia, a systematic analysis is needed that strengthens the possibility of using CDSS to optimize IMCI services[13–20].

The objective of this paper was to identify the effectiveness of a Clinical Decision Support System (CDSS) in resolving the management of sick child problems, which is expected to improve IMCI services.

This systematic review will summarize what is known from the existing research about child health services using CDSS. There are five main review questions:

1. What is the participant’s description that uses CDSS in their child health services?
2. What is the comparison between the use of CDSS applications and manual systems in child health services in other countries?
3. How does CDSS impact child health services?
4. What impact does the intervention have on optimizing IMCI and its outcomes?
5. What is the best study design/ methodology to use for revealing the benefits of CDSS in child health services?

2. Methods

The systematic review followed the Preferred Reporting Items for Systematic Reviews and Meta-Analysis guidelines to review child health management and CDSS articles to identify the effectiveness of CDSS in overcoming the problem of child health services, especially for sick children.

2.1 Data collection process

The data collection process was done independently by two reviewers obtaining and confirming the data from the investigators.

2.2 Data items

All of variables for which the data was sought were defined using PICOS. For the identification of the participants, we assigned the study, report and extractor identification details to each record. We included the type of publication and the country of origin. For the methodology, we noted the theories underpinning studies. We included the study design and setting. For the participants, we recorded the sample characteristics as defined by the author intervention characteristic. The article's inclusion criteria consisted of articles on child health services using CDSS or similar information systems in health services, while the exclusion criteria were abstract articles and the articles displayed not being the full text. For the intervention, we recorded the specific types of intervention that had been given in the study. For comparative characteristics, we described the characteristics as a reference point in a manner consistent with participant section and the control group as the foremost comparator. For the outcome, we explained the effect after the intervention was given based on the variable in the study. We represented the result for both qualitative and quantitative studies.

2.3 Risk of bias in individual studies

We explored variability in the study results by specifying the following hypotheses before conducting the analysis. We hypothesized that effect size may be diverse in concert with the methodological quality of the studies.

2.4 Summary measure

We accessed articles from Proquest, Ebsco, Google Scholar, and Science Direct. The articles were published between 2014-2018 with the keywords 'child health services', 'IMCI' and 'CDSS'. Articles that meet the inclusion criteria were collected and examined systematically. The search process obtained 167 articles which were then subsequently selected, extracted and analyzed. For the review, we used the results of the extraction process.

2.5 Risk of bias across studies

We examined the results from the available studies for indications that suggested that there may be missing studies (publication bias) or missing data from the included studies (selective reporting

bias). We compared the outcomes listed in the methods section with those for which the results were presented.

3. Result

Based on the search results, from the 167 articles, 26 related articles were deemed to be in accordance with the objectives of the study. The articles were then collected and screened for eligibility. After the process was completed, 10 eligible articles were obtained, which were then processed as part of a further review. The strategies and framework of the literature search can be seen in Table 1 and Figure 1.

Table 1. Strategy of the Literature Search

Search Engine	Proquest	Ebsco Host	Google Scholar	Science Direct
Search result	78	30	21	154

Eligible	1	1	4	4
Result		10		

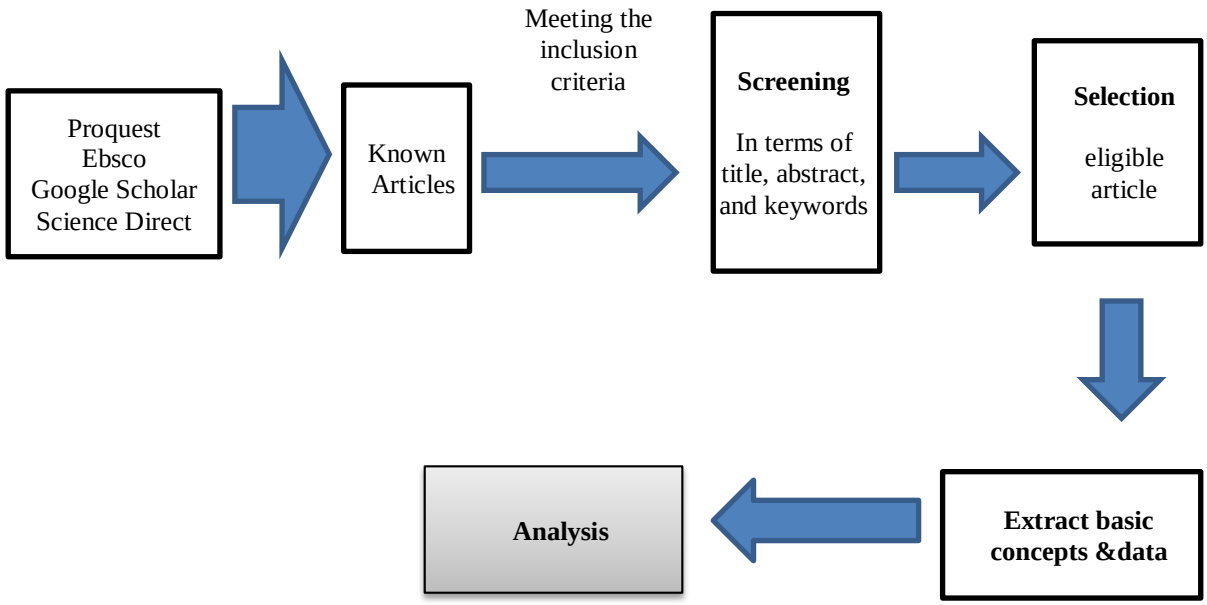

Fig.1 - Framework for the search strategy

After going through the selection process, the researcher then extracted the data from the 10 articles. The data extraction done by analyzing the data based on the name of the author, the title, purpose, research method and results, grouping the important data throughout the article. The results of data extraction are shown in Table 2.

Table 2. Extraction Data Results

No	Author, Year/ Country, Title	Participant, subject	Objective	Method	Result
1	Shao et al. (2015)/ Tanzania New Algorithm for Managing Childhood Illness Using Mobile Technology (ALMANACH): A Controlled Non-Inferiority Study on Clinical Outcome and Antibiotic Use in Tanzania[15].	Two nearby primary care health facilities (HF), similar in terms of natural environment, malaria prevalence, socio-economic status of the catchment population, and type of services available	The objective was to ensure that ALMANACH was safe, while keeping a low rate of antibiotic prescription.	Consecutive children aged 2–59 months with acute illness were managed using ALMANACH (2 intervention facilities), or standard practice (2 control facilities) in Tanzania. Primary outcomes were the proportion of children cured at day 7 who received antibiotics on day 0.	Management of children using ALMANACH improve clinical outcome and reduce antibiotic prescription by 80%. This was achieved through more accurate diagnoses and the better identification of children in need of antibiotic treatment. The building on mobile technology allows for easy access and the rapid updating of the decision chart.
2	Shao et al. (2015)/ Tanzania Can Smartphones and Tablets Improve The Management of Childhood Illness in Tanzania? A qualitative study from a primary health care worker's perspective[20].	40 primary health care workers from 6 public primary health facilities in the three municipalities of Dar es Salaam, Tanzania	This study investigated the constraining as well as facilitating factors that influence the uptake of a new electronic Algorithm for the Management of Childhood Illness (ALMANACH) among primary health workers in Dar es Salaam, Tanzania.	A qualitative approach was applied using in-depth interviews and focus group discussions with altogether 40 primary health care workers from 6 public primary health facilities	ALMANACH was assessed positively. The majority of the respondents felt comfortable using the devices and stated that the patient's trust was not affected. Most health workers said that the ALMANACH simplified their work, reduced antibiotic prescriptions and gave the correct classification and treatment for the common causes of childhood illnesses. Majority of the respondents stated that the devices increased the consultation duration compared to routine practice.
3	Khan et al. (2018)/ Saudi Arabia Health Quest: A Generalized Clinical Decision Support System with Multi-Label Classification[21].	5000health records, which were randomly selected from the dataset. Out of these 5000records, 4000 records were used for training and 1000 records were used for testing	The objective was to study the efficiency of the Health Quest in identifying multiple disease, accuracy and execution time.	Experimental design using 5000 records, which were randomly selected from the dataset. Out of the 5000 records, 4000 records were used for training and 1000 records were used for testing. Time of computation was used as well accuracy for disease	Health Quest capable to identify multiple diseases from a patient's health at a time. Extensive evaluation confirms its effectiveness and accuracy. It is able to identify first disease with 77% accuracy, whereas for the second disease Health Quest achieves an efficiency of 34%. Compared evaluation time noted that execution time decreases with the increase in computational capability. It can be highly beneficial

				diagnosis and the evaluation parameters.	in Medical Sciences for diagnosing disease correctly and assisting physicians.
4	Anand et al (2015)/ USA Pediatric Decision Support Using Adapted Arden Syntax[22]	Record of more than 44.000 patients between 2005-2014	To study the application of the Arden Syntax in a clinical environment	The Child Health Improvement through Computer Automation system (CHICA) screens patient families in the waiting room and alerts the physician in the exam room. Here described adaptation of Arden Syntax to support production and consumption of patient specific tailored documents for every clinical encounter in CHICA and describe the experiments that demonstrate the effectiveness of this system.	CHICA has been a highly successful CDSS and certainly the most studied decision support system in child health care. As of this writing CHICA has served over 44,000 patients at 7 pediatric clinics in the health care system in the last decade and its MLMs have been fired 6182,700 times in "produce" and 5334,021 times in "consume" mode. It has run continuously for over 10 years and has been used by 755 physicians, residents, fellows, nurse practitioners, nurses and clinical staff. There are 429 MLMs implemented in CHICA, using the Arden Syntax standard. Studies of CHICA's effectiveness include several published randomized controlled trials. The adaptation results show that the Arden Syntax standard provides an effective way to represent pediatric guidelines for use in routine care. It only required minor modifications to the standard to support the clinical workflow. Additionally, Arden Syntax implementation in CHICA facilitated the study of many pediatric guidelines in real clinical environment
5	Grout et al. (2018)/ USA A Six- Year Repeated Evaluation of Computerized Clinical Decision Support System User Acceptability [23].	Health workers (CHICA user) recorded 380 completed survey between 2011-2016	This study examined user acceptance patterns over six years of our continuous computerized CDSS integration and updates.	The users of Child Health Improvement through Computer Automation (CHICA), a CDSS was integrated into the clinical workflows used in several urban pediatric community clinics, completed annual surveys including 11 questions covering user acceptability. Responses were compared across the years within a single healthcare system and between two healthcare systems. We used logistic regression to assess the odds of a favorable response to each	Responses were significantly more favorable for all. Increasing system maturity was associated with improved perceived function of CHICA (OR range 4.24–7.58, $p < 0.03$). User familiarity was positively associated with perceived CDSS function (OR range 3.44–8.17, $p < 0.05$) and usability (OR range 9.71–15.89, $p < 0.01$) opinions.

				question by survey year, clinical role, part-time status, and frequency of CHICA use	
6	Sanmathi et al. (2018)/ India Computerized Decision Support System for Remote Health Monitoring: A Systematic Review[24].	52 included paper	The main objective was to outline the research on remote patient health monitoring system that constitutes the multimodal biosignal acquisition system, thereby providing multi-label classification and clinical decision support system (CDSS).	A systematic review was conducted with search terms such as multi-label classification, clinical decision support system, context-awareness and remote health monitoring. The study criteria included the randomized clinical trials evaluating the impact of efficient remote health monitoring system which incorporates CDSS for context-awareness systems by correlating several vital signs.	Several studies were effectively included which provides faster diagnosis for critically ill-patients. It is decisive for the critically ill-patients to be treated at the right time with proper and effective treatment which can be done efficiently using the CDSS and multi-label classification. The disease labels were classified as single and multi-labels where the multi-label classification included the disease labels for the correlated multiple vital signs and where single label classification included disease labels for individual vital signs. Furthermore, on developing the logical learning model using multi-label classification, the decision support system can be enhanced using context-awareness methods to predict the future vital signs, thereby providing an alert to the patients or doctors to take necessary actions.
7	Bernasconi et al. (2017)/ Afghanistan The ALMANACH Project: Preliminary Results and Potentiality from Afghanistan[25].	Record of 8047 children who has attending health facilities between May 2016 and September 2017	to improve the quality of care provided to children between 2 months and 5 years old.	IMCI's algorithms were updated in considering latest scientific publications, national guidelines, innovations in RDTs, the target population's epidemiological profile and the local resources available. Before the implementation of the project, a direct observation of 599 consultations was carried out to assess the daily performance at three selected health facilities in Kabul.	The review showed that with ALMANACH, malnutrition detection, deworming and Vitamin A supplementation increased respectively to 4.4%, 50.2% and 27.5%. Antibiotic prescription decreased to 21.83% and all children were examined and treated in compliance with the protocols. ALMANACH could establish as a powerful innovation for primary health care.
8	Wulff et al. (2018)/ Germany An Interoperable Clinical Decision-Support System for Early Detection of	16 pediatric intensive care patients with different demographic characteristics, diagnoses, courses of	Developing and evaluating an openEHR-based approach to achieve interoperability in CDSS	The design was an interoperable concept, which enables an easy integration of the CDSS across different institutions, by using openEHR Archetypes, terminology bindings and the	It was successfully designed and the population implemented a CDSS with interoperable knowledge bases and interfaces by reusing internationally agreed-upon Archetypes, incorporating LOINC terminology and creating AQL queries,

	SIRS in Pediatric Intensive Care Using Open HER[26].	disease and lengths of stay. The data was from a randomized trial with 807 PICU patients from the ward	by designing and implementing an exemplary system for automated systemic inflammatory response syndrome (SIRS) detection in pediatric intensive care.	Archetype Query Language (AQL). The practicability of the approach was tested by (1) implementing a prototype, which is based on an openEHR-based data repository of the Hannover Medical School (HaMSTR), and (2) conducting a first pilot study. The technical capabilities of the system were evaluated by testing the prototype on 16 randomly selected patients with 129 days of stay, and comparing the results with the assessment of clinical experts (leading to a sensitivity of 1.00, a specificity of 0.94 and a Cohen's kappa of 0.92).	which allowed retrieving dynamic facts in a standardized and unambiguous form. The use of openEHR archetypes and AQL was found to be a feasible approach to bridge the interoperability gap between local infrastructures and CDSS. The designed concept was successfully transferred into a clinically evaluated openEHR-based CDSS. To the authors' knowledge, this is the first open EHR based CDSS, which is technically reliable and capable in a real context, and facilitates clinical decision-support for a complex task. Further activities will comprise of the enrichment of the knowledge base, the reasoning processes and cross-institutional evaluations.
9	Roja et al.(2015)/ India Web Based GIS for Public Health Management in Andra Pradesh[27]	Public health center in Andra Pradesh	The main objective of the study is to create a web application which will be used as a decision support system in public health care and to make the effective utilization of GIS in Health sector for updating, storing and maintenance of spatial and non-spatial data of Health Centers for IDSP, HMIS & MCTS programs.	The information provided by Health department is used as an input to generate spatial layers in GIS environment. Influence boundaries of health centers like CHC and PHC are generated using administrative boundaries of Andhra Pradesh. The locations of Public health centers and hospitals were also created. Unique codes provided by Health department were assigned to each Cluster, PHC, Sub centre and Hospital, which acts as a primary key to connect to the Database. ArcGIS Server 10.2 and ArcSDE are to integrate geographic information query, mapping, spatial analysis and editing within a multi-user enterprise in DBMS environment, ArcGIS	The analysis revealed that the integration of statistical health data with GIS is helpful for analysis and display in the form of simple maps and reports which convey the information to the planners easily. The Health GIS web portal acts as a Decision Support System (DSS) to the health officials to take quick and effective decisions, display not only maps, but can also perform statistical analysis of geographic data, forecasting the predictions and cope up with new technologies.GIS can play a significant role in database management, periodical data comparison, geographic data comparison and data navigation. Comparison of present events to previous years will be helpful to take appropriate actions and precautionary measures. The study concludes that the Geographical information system has the capability to integrate data from different sources and gives single point access for health query and reports. The transitional data through internet will be helpful to access it anywhere and give instant information of incidents. GIS helps health managers to identify and

				API for Javascript as an interface, HTML5 and .Net programming for the web page.	monitor areas with discrepancies, by helping the community to overcome the problems
10	Hansoti et al.(2017)/ US SCREEN: A Simple Layperson Administered Screening Algorithm in Low Resource International Settings Significantly Reduce Waiting Time for Critically Ill Children in Primary Health Care Clinics	In Phase I, 1600(92.38%) of 1732 children presenting to 4 clinics. In Phase II, all 3383 of the children presenting to the 26 clinics during the sampling time frame	To determine the impact of SCREEN on the waiting times for critically ill children post-real world implementation in Cape Town, South Africa.	This is a prospective, observational implementation-effectiveness hybrid study that sought to determine: (1) the *impact* of SCREEN implementation on waiting times as a primary outcome measure, and (2) the effectiveness of the SCREEN tool in *accurately* identifying critically ill children when utilized by the QM and *adherence* by the QM to the SCREEN algorithm as secondary outcome measures. The study was conducted in two phases. The Phase I control (pre-SCREEN implementation- three months in 2014) and Phase II (post-SCREEN implementation in two distinct three month periods in 2016).	The proportion of critically ill children who saw a professional nurse within 10 minutes increased tenfold from 6.4% to 64% (Phase I to Phase II) with the median time to seeing a professional nurse reduced from 100.3 minutes to 4.9 minutes, ($p < .001$, respectively). Overall layperson screening compared to Integrated Management of Childhood Illnesses (IMCI) designation by a nurse had a sensitivity of 94.2% and a specificity of 88.1%, despite large variance in adherence to the SCREEN algorithm across clinics. The SCREEN program when implemented in a real-world setting can significantly reduce waiting times for critically ill children in PHCs, however further work is required to improve the implementation of this innovative program.

4. Discussion

In the limited resource condition, where skilled health workers are insufficient and there is a high number of child visits to health facilities, the length of service time in identifying and evaluating child symptoms and illnesses becomes a significant delay. This delay and long waiting time often causes other patients to leave the health facilities without being examined [11][16]. With limited time and abilities, the accuracy of the assessment in the IMCI services is reduced [12] and the documentation can't meet the procedures, so the health data obtained cannot describe the child's health condition in the area[10]. Meanwhile, geographical distance and a lack of monitoring tools leads to the weak monitoring of services [10][12].

The progress of information technology has enabled many diagnostic activities in health procedures to be carried out electronically[18]. Several studies show that the application of information technology in the form of the Clinical Decision Support System (CDSS) can improve health services. CDSS is a system that is used to support the clinical decision-making processes, therefore it was initially used to provide an alarm in the context of a clinical procedure. But in its development, this system has been applied in various health procedures and continues to evolve. CDSS has various types of use related to clinical decision activities. This system is based on simple rules using engineering knowledge to translate several clinical signs /symptoms into a form of diagnosis /classification[19][28][29]. In terms of the latest technology, CDSS integrated with the Electronic Health Record (EHR) can reduce the burden of documentation, ensure data completeness, and interpret the service data in a way that can affect health policies[26].

Based on a review of several items of literature, CDSS proved able to overcome the obstacles of time, distance, limited energy and it improved the accuracy and consistency of the clinical decisions[19]. In dealing with the spatial problems caused by geographical conditions, this system can be applied in the health world to support service monitoring [30]. Although CDSS has been applied in developed countries, some literature shows that low-middle income countries can also implement CDSS in their child health services and obtain similar benefits. This indicates that CDSS can possibily to apply in child health services in Indonesia with some adjustments.

The implication of these findings for the next research is the emersion of research in the formulation and application of CDSS or similar technology information systems in order to optimize IMCI and child health services generally in Indonesia.

5. Conclusion

CDSS is able to overcome problems in the management of sick children, therefore it is possible to justify the use of CDSS in optimizing IMCI services. With CDSS involved in the management of sick children, it can improve the quality of the children's health.

ABSTRACT

Tuberculosis (TB) is major community health problem in Indonesia. World Health Organisation (WHO report in 2017 shows that 6.4 million new TB cases were officially notified to national authorities, worldwide. Indonesia has 842.0000 cases and places it as the country with the third highest number in the world. The national program Directly Observed treatment, short-course (DOTS) started since 2014 has not able to handle TB cases comprehensively. Communities have important role in TB management. The aim of this study was to explore the existed condition of TB management and control. A descriptive qualitative study was conducted in Tandes Sub-district, which is an endemic area for TB and have the highest incident. Semi-structured interview was conducted to 13 participants which consist of sub-urban TB task force, community health volunteer, Community health Nurses and sub-district officer. Result reveal six themes: altruism as intentional caring factor, in adequate number of staff, the need to improve training skill, insufficient of resources, limited of financial support and social support. The conclusion, in order to be effective program, community-based TB management need to be improve in the availability of budget, staff, training and resources while maintaining the on going work of TB task force team.

Keywords: TB, community-based management, altruism, social support, descriptive qualitative

1. Introduction

The World Health Organization (WHO) states that Tuberculosis (TB) is a global emergency problem for humanity and that it is an important problem in various countries around the world. In Indonesia, although the Directly Observed Treatment Short course (DOTS) strategy has proven to be very effective for TB control, the burden of TB in the community is still high. This is because the implementation of the DOTS strategy and programs for handling TB in its application still encounter challenges and problems in the community. The main obstacle is the failure to mobilize all community capacities by involving and inviting the community members to participate. Unclear forms of contribution and who should be involved in the TB Handling Program activities affects the sustainability and effectiveness of the program[1].

The East Java Province is one of the provinces in Indonesia which still has problems when it comes to tackling tuberculosis with a prevalence of 110 per 100,000 population. In Surabaya, 16,616 people were suspected of TB and 2,330 people were found to be TB positive. Based on the data from the Surabaya Health Office 2015, the highest prevalence of TB was in the Tandes sub-district with 551 people suspected of having TB and 114 people were found to be TB positive[2]. In 2016, there were 109 new TB cases, with a total number of 170 TB patients and a success rate of 88.64% [2].

Modern society is more likely to solve problems independently through the various technological advancements that exist. Individual attitudes and the feeling of being capable of solving problems independently can have an effect on the awareness of living in society. As a result, people in society help each other through mutual cooperation and problems diminish, as depicted by the various individual actions that do not lead to a collective goal but that instead lead to a destination according to the individual's wishes. Coleman explained, in his ideas, about the individual actions influenced by the value of an event. Individuals will act based on the interests and benefits obtained from each individual[3]. If this condition is associated with handling TB cases, it can slow down the handling of the cases. If the ability of social management is understood as a social ability in forming nursing care by optimizing the health service system based on the culture of individuals, groups, families and communities, then an investment in community-based management is a useful strategy for increasing the community nursing care needed to treat TB[4].

Community-based TB management is believed to be able to increase the capacity of the community to work together in solving health problems because the basis of the management can be characterized in the form of individual willingness to prioritize community decisions to resolve health problems. Citizens who are in a community with good community management will form a level of cohesiveness that is interpreted by the existence of horizontal cooperation and the norms of reciprocity because they will also have high confidence when it comes to collaborating, cooperating and helping others[5].

This study aims to reveal how the community is making efforts to manage tuberculosis *with all of their ability and resources in place*.

2. Methods

2.1. Design

A qualitative descriptive study was conducted in Tandes, which is the sub-district with the highest incidence of TB in Surabaya[6].

2.2. Participants

The participants of this study were selected using the purposive sampling method including 1 official heads of the village, 4 directors of the community welfare and safety sub-district office, 2 community nurses who worked at the local public health center and 6 community health volunteers.

2.3. Data collection

The data was collected from January to May 2017 in Tandes, which has an especially high prevalence of TB. A total of 104 cases of TB were reported in 2016. The semi-structured interview questions focused on the influence of community-based management on TB prevention and control and any related experiences. The interviews focused on the participant’s existence, their role, experiences and connection to the community within TB prevention and control activities. The interviews lasted for 45 - 60 minutes for one time data retrieval. The community health workers were interviewed in their homes, and the sub-district officer and the community nurses were interviewed in their workplace to provide them with comfort and convenience. All of the interviews were recorded and transcribed as a part of the data analysis.

2.4. Data analysis

The interview data was analyzed using Uwe Flick[7]. The practical steps of analyzing and representing the interview data were performed. The data analysis began with (1) reducing the data to locate and examine the phenomena of interest. In this phase, the interviews were transcribed, and then the data was read and reread. The next phase was (2) reorganizing, classifying and categorizing the data, in which the researchers generated assertions about the topics by reassembling and reorganizing the data, codes, categories, and stories. The last phase was (3) interpreting and writing up the findings. In this phase, the researcher considered assertions and propositions in light of the prior research and theory in order to develop their arguments. The researchers developed stories that conveyed the main idea developed in the data analysis and they presented data excerpts or stories to support the assertions. The stories were sorted to examine the existence of community-based management for TB prevention and control.

2.5. Ethical considerations

The ethical approval to conduct this study was granted by the Institutional Review Board Ethical Committee of Airlangga University No. 630-KEPK, the Regional Department of Health (Surabaya, Indonesia) and the Regional Department of National Unity, Politics and Public Protection (Surabaya, Indonesia). All of the participants were provided with a participant information sheet written in Bahasa Indonesia, and they signed the consent form prior to participating in the study.

3. Results

Tandes is a sub-district in a suburban geographical area and it is the fifth largest area and highest population density in southern Surabaya. Tandes is located approximately 4 m above sea level. The overall site area is approximately 11.07 km2 and it is divided into six villages with a total population of 93.459. Below are the themes found from the data analysis.

3.1. Altruism as intentional caring factor

One of the forms of community-based management which plays an important role in the effort to eradicate TB is the volunteer. In the Tandes sub-district, six volunteers work in the two primary health centers (PHCs). The volunteers were responsible for the entire TB prevention and control program in the region and they implemented it in their own PHCs. In terms of overcoming the health problems, especially TB, at the government level there is an institution called the TB Task Force and for non-governmental TB elimination, there are the programs carried out by the Aisyiyah Organization. Both work together with puskesmas to conduct TB elimination programs. Social awareness is the basic foundation of working to reduce TB problems.

They said, *"We want life to be beneficial for others. The rest is so important that sincerity and maintaining sincerity is difficult."(P1)*

"We are also happy if we come to the patient. If the patient is happy, then we are also happy. Also the humans must be beneficial to others too." (P2)

"When I saw the patient not recovering and then when they had broken up the medication, I felt unsuccessful in carrying out my duties. I felt sorry when I could not make the person recover." (P3).

3.2. Inadequate number of staff

The nurse said, *"Yes actually it is lacking, because every RT must have counseling. Every RW must also have counseling, that is the target. I think it is still not possible" (P5).*

"in the field the program was not adjusted to the staff at the puskesmas, actually if it was only TB being finished one day it was not finished, we also doubled here and there so I did it"(P4).

"Firstly there was a shortage of cadres, then the work was not maximal. I did not even look at the curative nature of this puskesmas, whereas this health center should be more promotive and involve preventive activities" (PKM nurse)

The director of the sub-district of the community and safety office said, *"Yes, from those cadres, there were many who doubled this number. They also worked on PKK, while PKBM also worked on one working group and one PKK cadre" (P10).*

"The obstacle is that there are no more people… that's all. Looking for it is difficult, bro. Wong, the chairman of his defense cadre, is also old. So it's a bit less maximal but we try as much as possible mas" (P13)

The volunteers said, *"I was wrong because the officers were only one P1 (TB Cadre). Only one officer might not be able to see all patients" (P1)*

3.3. The need to improve the training skills

The problem of TB requires complex management involving all elements of the community and it also requires the evaluation of successful treatment for quite a long time. The treatment is complete once it has been conducted 6 months and the ease of transmission of the disease requires TB observers to carry out monitoring, mentoring and reporting. The number of TB programs must also be balanced with the skills of the human or human resources involved in implementing all of the TB programs.

The nurse Said, *"Yes, indeed there is a program, but I still remember that in my kelurahan, there were only 6 out of 6 who we tested the sputum of and the results were all negative. It should be really suspected if it is checked at all levels in the surrounding environment. It should be checked to see if the comparison of the suspect and BTA + puskesmas discovery numbers will decrease. If you don't find it, you will be asked what the screening process is and how the lab checks the process" P5 (Nurse*)

3.4. Limited financial support and social support

The Surabaya Health Office has provided free medical assistance to TB patients. In addition to the assistance of giving drugs without paying expenses, the TB patients also get free nutritional intake in the form of formula milk given when the patients take drugs at the puskesmas. Other parties who also provided material assistance for underprivileged TB patients were the Aisyiyah, in the form of 30,000 in cash. In reality, the support is still considered to be lacking.

The volunteers said, *"There are those whose economic condition is very difficult. The puskesmas also need to ride a pedicab, but there are also funds from the SSR available during treatment, only once," P1 (cadre).*

"Sometimes if you see something like that, the cadres' own initiative is mas, so we give you something, bro. The point is trying to be concerned. There is a distribution of basic necessities for the sick patient" P1 TB (cadre).

"Once, when I was OK, then I gave 25,000 people money. I didn't feel very happy". (P2)

The nurse said, *"Yes, we are still on a social mission, which we complain about. Usually we have*

a visit where we have not been able to give them transport money. We also usually hesitate if we have to ask" why haven't you visited this? "(P4)

In the Tandes sub-district, there are still no specific counseling programs about TB. This is because TB is still not a priority in the wider context of the community problems. The main TB program is the door knock program. This program is a program with a ball picking approach or where the task force members visit the community one by one to be give counseling and to look for TB suspects. With the constraint that not all communities receive TB health programs, not all levels of society get counseling about TB disease. So an effective way to provide counseling with the participation of many people is through community social groups.

The volunteers said that, *"In the recitation, PKK meetings and also at the puskesmas, when there is counseling for us to give out brochures about TB, later if they go back to the RW then they can transmit the knowledge that they get through the brochure." P3 (cadre, head of the task force).*

"Usually if there is an arisan RW, we hold counseling. Wherever we can hold counseling… if there is a task force. So far we have been at social gatherings."(P9)

"If there is an automatic posyandu… if there is a posyandu, then even though they are not active in the community activities, the posyandi is definitely going to participate, yes… The opportunity for us to provide information is also helped by the RT" (P11)

"I usually go to the sub-district head to ask for help regarding the problem of the residents who still don't know about the TB task force. When we move to the field, they don't know anything and ask 'what is this task?' Now, there are a lot of fraudsters, so now where do you take your SK from the sub-district? "P3 (cadre, task force head)

4. Discussion

Evidence from this study proves that community-based approved programs are also acceptable.
The WHO has issued community-based DOTs to complement health-based DOTs to deal with the high burden of TB in resource-limited countries [8]. Until the patient and community attitudes and the perceptions of the community and health facility-based DOT are discussed and calculated, this assistance will not be carried out with success.

The findings make the drug cadres and supervisors almost look over women and their family members. The responsibility of sick family members in most areas of Surabaya is defined as the role of women [9]. This is because families cannot participate because of DOT and this is because culture, family and family relationships were not proven in our study. Studies conducted elsewhere indicate that family members that are DOT-involved effectively support the treatment [10]. A study conducted in Indonesia did not show any benefits from using the patient's family members supporting DOT treatment [11].

The context in Australia may be different from that of Surabaya where large family members are an important part of one's social network. In Surabaya and Indonesia as a whole, the care of one's family members is important within the local culture [12]. Members of the caregiver's family help to care for their family members with chronic diseases such as HIV / AIDS. There is no reason not to believe that this phenomenon will be different for the TB cases [12]. Future studies should consider the impact of care on TB treatment and how it affects the family relationships.

Our study found the presence of support for the motivation and care put forward by the carers and

former TB patients for reasons of altruism. The majority of the patients also support other TB patients after completing their treatment. These findings are important for two main reasons. First, it shows the potential for using former TB patients in TB control activities. In one study, former TB patients were found to be an important source of information for TB Patients [13]. Former TB patients can also help current TB patients and the TB community by showing that they can be cured. This is very important in Tanzania where many people do not have enough knowledge of TB and delay seeking treatment. The national TB program needs to address this problem based on the available local resources[14].

5. Conclusion

Our findings provide valuable agreement on the effective implementation of relevant, sensitive and acceptable TB control interventions for the needs of the patients and society in general. Community-based TB programs are a viable option and they can be built based on health facilities in DOTS, especially in developing countries such as Indonesia where the health system is overwhelmed by the increasing number of TB and HIV / AIDS patients. Community-based TB Management must be seen of as a complement and perhaps as a substitute for a national TB activity program.

MENTAL HEALTH STATUS OF COASTAL POPULATION IN THE REGION OF CENTRAL JAVA'S CAPITAL

Betie Febriana[1], Dwi Heppy Rochmawati[1]
[1]Mental Health Department, Nursing Faculty, Universitas Islam Sultang Agung, Semarang
Email: betie.febriana@gmail.com

ABSTRACT

The development of coastal populations has not shown progress compared to other community groups. Indonesian statistics show that 25% of the poor are coastal communities. This condition has an impact on mental health which affects their quality of life. Therefore, this study aims to identify the mental health conditions of coastal communities in general, especially the symptoms of psychological stress. This research is an observational descriptive study with a survey approach on coastal communities in Kemijen as a population. The number of samples is 224 male population aged 20-55 years randomly selected. This study used Kesstler-10 to measure the level of psychological stress. It is known that 7% have moderate mental disorders and 18.7% tend to have mild mental disorders. The biggest symptoms detected are depression, anxiety, and restless. Another important finding from observations is that people tend to have violent behaviour both individually and in groups as coping with problems. This result illustrates that the community needs mental health education. It is necessary to conduct in-depth research on the findings of this study and also increase Government efforts for the welfare of the community by realizing mental health services for coastal communities.

Keywords: mental health, coastal populations, psychological distress

1. Introduction

Fishing groups in Indonesia need special attention in terms of health development efforts. Data from the Central Bureau of Statistics (BPS)[1] in 2018 showed that Indonesia has around 15.32 percent of its administrative areas at the village level in coastal areas. For development needs and policy making at the macro level, the residents living in areas on the seafront are often analogous to coastal communities. Coastal and marine areas have an important role as they form space structures in the Indonesian archipelago, as well as having economic and politic importance. They need to be harmonized and synergized so as not to cause conflicts of interest, environmental degradation and the inefficient and effective use of resources[2].

Some studies say that the problems of various fields - whether they be environmental, social, economic, inequality, climate and health - have plagued coastal communities [3,4,5] . Several studies [6],[7] state that physical environments such as the existence of healthy houses, the standards of the latrines and irregular waste disposal are a big problem and also sometimes the sea itself is considered to be a trash can. All of these factors will have an impact on both physical and mental health.

Economic problems and poverty which eventually have an effect on the emergence of criminality are increasingly high, which is also a part of the problem in coastal areas. Therefore, it can be concluded that crime, bad habits, the emergence of thuggery and other behavior deviations are responses to existing problems then make the fishermen's adaptability decrease and their resilience decline [4] .

The study conducted by Erik et al.[8] shows that coastal communities have a high level of anxiety and depression with problems of domestic violence due to economic factors. A low economy is often a broken circle of society where mental health is an important part of it.

The things mentioned above are the factors that can threaten and endanger individual welfare and trigger the emergence of psychological distress[9]. Psychological distress, according to Fawcett [10], is psychological and physical and it arises because of the inability to manage stress continuously. This stress, according to Lazarus and Folkman, is part of the relationship between the individual and the environment in which the individuals feel a pressure that is heavy or beyond the ability that is owned by them, so it threatens his well-being[11]. Therefore, stress arises as a psychological response to every situation that threatens him. If what emerges is a response that is a negative tendency, then this is called distress. This will result in decreased self-capacity [12]. This condition will greatly affect the community's welfare. Therefore, it is important to identify the psychological distress of coastal communities so then early prevention can be implemented. In addition, this is done to prevent the emergence of more severe consequences.

As an area located in the Coastal City of Semarang, Kemijen is often faced with the presence of tidal water (rob) inundating the surrounding settlements. Every five and ten years, the villagers have to pay for the raising of their houses because of the land subsidence process. The economy of the residents is in the lower middle level and on the poverty line. These conditions make them not really care about their environment properly. The absence of waste management facilities also contributes to disaster. The accumulation of plastic waste in the irrigation canals clogs the sewage water flow, causing flooding when it rains. In addition, the condition of the home environment is poorly organized and unsanitary, making it difficult for people to get clean water and other public facilities.

With a total population of 13413 habitants and an area of 120.90 km², this area is a fairly dense urban village. Kemijen is divided into two by Banger and the number of ponds / fish ponds along the edge of the railroad tracks leading to Semarang Tawang station. Overall, the profession of the people in this community is not only fishermen but it also includes entrepreneurs, drivers, freelancers, temporary employees, civil servants, laborers, scavengers, vagabonds, and pedicab drivers. This area has had a bad label attached to it, namely as being a village of pickpockets, thieves and bad boys.

2. Methods

This research was an observational descriptive study with a survey approach. The purpose of this study was to identify the mental health status of the coastal community of Kemijen, Semarang, Central Java, in 2018. The sample of this study consisted of randomly selected men aged 18-55 years. The research sample totaled 224. This study used the Psychological distress scale (K10) made by Kessler and Mroczek (1994). This measurement tool was used to see psychological distress in the

population. K10 consists of 10 items containing distress symptoms over the past month. The scores will range from 10 to 50. The higher the score, the worse the respondent's mental health. There are 4 categories including well mental disorder, mild mental disorder, moderate mental disorder and severe mental disorder. The analysis method of the data used was univariate[13,14].

3. Results

Table 1. Frequency and percentage of the mental health categories.

Category	Well	Mild	Moderate	Severe	Total
Frequency	164	42	15	3	224
Percentage (%)	73	18.7	7	1.3	100

[a]Feeling Tired Out For No Good Reason

[b]Can't Calm Down..

[c] Can't Sit Still Because Of Restless

[d]Feeling That Everything Takes Effort

[e]Feeling So Depressed That Nothing Could Cheer You Up

A total of 224 residents completed the K-10 questionnaire. Table 1 provides the grouping of the K10 scores based on the four mental status categories as well as the percentages. A total of 3 participants (1.3%) had a severe mental disorder but vice versa, most people (73%) are in a well condition regarding mental disorders; this is good news.

The responses from each of the K10 questions have been illustrated in Table 2. The responses to anxiety that received the most response (at all times) and that functioned as the highest negative screen in the area represents 10.7% of all participant responses (n = 24/224). Conversely, many participants reported that they never felt any symptoms. More than 68% reported never feeling tired for an unclear reason, 59% reported never feeling discouraged, 62.5% reported feeling calm, 82.5% reported never having felt so depressed that no one could comfort them, 63.8% reported never feeling that everything needed to involve effort and 87.9% reported never feeling worthless.

4. Discussion

Overall, this study found that 73% of people were in a well state regarding mental disorders, and those experiencing mild disorders was around 18.7%. However, the emotional mental disorders with the symptoms of depression, anxiety and restlessness were high in this region. Depression is far higher than the national average of 6.1 per 1000 population [15], while this region found that 6 out of 225 experience it. Anxiety was the most common symptom detected. This finding is reasonable due to the complexity of the problems in the area. The results of the interview stated that the thought of the topography of the region, the weather and the future of their family, especially their children, were the main reasons that gave them grave anxiety.

Anxiety was the most dominant symptom of psychological distress. This is in line with the study conducted by Asugeni et al., where almost all of the respondents (90%) reported that sea level rise affected them and their families and that it caused fear and concern both personally and within the community [16]. Four themes emerged from the qualitative analysis: experience about the physical impact of climate change, worry about the future, adaptation to climate change and the responses from the government to help them.

However, there are interesting things that can be seen from other symptom data such as hopelessness and worthlessness, which are not significant enough to be seen of as psychological distress. The interview results indicated that most said that they believe that God always guarantees sustenance, so they did not stop trying and still felt useful within their family. The finding of Alexandra's study was that the fishing community realize that their work depends on nature and the weather, so they feel powerless and unable to change the circumstances of their daily life[4]. On the other hand, there are many inhabitants who depend on the help of institutions and on the government. The residents think that waiting for and seeking help is one form of gaining money.

The residents of Kemijen Village also have varied jobs such as entrepreneurs, fishermen, drivers, freelancers, temporary employees and civil servants. The varied work conditions have a positive effect on their social condition. They can provide broad insights by allowing for the exchanging of ideas when gathering at the Ronda Post or in other non-formal activities. Therefore the symptoms of psychical distress are not very obvious.

The complexity of the problem does not create the tendency of the community to be depressive, but rather, it has an impact on violent behavior. Even though it cannot be generalized, it is noted that there are many juvenile delinquents in this village and that they are quite disturbing to the residents.

One of the ways that they manifest this trouble is by brawling. There are also quite a number of thugs and they are usually motivated by unemployed people and teenagers who are raised in broken homes. This group has a poor pattern of community relations because it usually carries out forms of violence against other citizens, both young and old. This is in addition to groups of thugs who cause unrest.

Research conducted by Hasanah found that the level of aggressiveness of coastal communities was higher than further inland[17]One of the trigger factors is an external factor in the form of the geographical environment [18]. Every individual has the potential to be aggressive but at different levels. Bus and Perry divided aggressiveness into four parts; physical aggression, verbal aggression, anger and hostility [19]. This is the same condition as occurred in this research area.

The economy factor and the low level of education triggers an increase in the crime rate. This situation is quite difficult to change because of the paradigm of the people who tend to be practical and pragmatic. The economic condition of the people of Kemijen, which has an average middle to lower education level, makes it difficult for every citizen to think of other things besides the economic condition of their families. Many teenagers drop out of school and end up consuming drugs and "ngelem" (breathing in glue vapor or other similar substances to gett a hangover sensation), which is common among school-age children. Among the parents (fathers), they like to drink, all of which has an effect on theft and fighting.

The above condition is called mass distress. This is because the response shown to the stressor produces negative consequences that are unhealthy and destructive [20]. Another negative thing is that the bad condition belongs to the community. Social relations disorders affiliated with unemployment contribute to the appearance of distress. Distress can reflect the individual's narrative about the problems faced and their interpersonal interactions in the socio-cultural context.

The study found that health problems in coastal communities are influenced by environmental, social and behavioral factors. This study found that the environment in coastal areas tended to be poor from almost all sides[21]. This is the reason why the bad factors will affect the mental health of the individuals there. Taylor explained that when individuals successfully deal with stressors, they will feel challenged and experience little stress, but when his ability is not enough to deal with the stress and when it requires a lot of effort to solve it, then he will feel a lot of stress[22].

Individual assessments related to things that have the potential to be sources of stress may vary. Individuals can consider the physical environment of their home as a source of stress, while other individuals consider it to be normal. Lazarus and Folkman mentioned that this is called secondary appraisal, which is the assessment of the individual’s coping ability in the face of challenging situations which in the end means that the stress experienced by a person is a balance between primary appraisal and secondary appraisal[11]. Primary appraisal is the determination of meaning when the individual is first exposed to environmental changes.

An interesting finding from this study is that the symptoms of distress were found more than the same characteristics in the same region, namely other coastal areas, according to a study conducted by Erik et al. in North Sulawesi[8]. This is reasonable, because the researchers considered that the area of

research at this time had a variety of problems that could affect the population's mental conditions, inclining them both toward depressive or violent behavior.

This study found that the mental health conditions of coastal communities in general were that 7% had moderate mental disorders and that 18.7% had mild mental disorders.. The biggest symptoms detected were depression, anxiety and restlessness. From this finding, it is necessary to conduct in-depth research on the findings of this study. There are community depressive conditions and violent behavior arising from the problems in coastal communities and also increasing the government efforts for the betterment of community welfare is important by realizing the importance of mental health services in health centers and their networks for fishing communities.

SBAR COMMUNICATION IN EMERGENCY DEPARTMENT: A SYSTEMATIC REVIEW

M. Hendri Haryono[1]
[1]Master Student, Faculty of Nursing, Universitas Airlangga, Campus C Mulyorejo, Surabaya, Indonesia
E-mail: hendrickerss@gmail.com

ABSTRACT

The Joint Commission International the second patient safety goal index comes from the large amount of incorrect data when doing documentation which leads to communication handover, especially in emergency departments that have a higher risk of medication error than other units in the hospital. The aim of this study was to collect evidence of SBAR (situation, background, assessment, recommendation) in the emergency department services. The main databases for reference include CINAHL Plus, Web of Science, MEDLINE, and PUBMED. Comprehensive search strategy for 6 months until February 2019 which presented empirical based studies keywords: 1) SBAR and 2) Emergency department. Data abstraction developed on each paper to the appraisal level of empirical evidence. Limitation study determines 2011-2019. The finding results from 11 articles reviewed dominated SBAR's superiority as a guideline for providing communication at the emergency department level by health professional. There is evidence of the Demonstrate effective communication with SBAR as a preferred data transfer tool related to the positive impact of the accuracy of data transfers significantly.

Keywords: SBAR, communication, emergency department

1. Introduction

The Joint Commission and Institute for Healthcare Improvement have mandated healthcare organizations to improve their professional effective communication [1]. The main problem of providing health services is that medical errors remain a reality. This cannot be overcome thoroughly in the field of health. Communication problems are sensitive and very challenging [2]. A very important reality in the emergency department (ER) is that it is where health care providers must stabilize, diagnose and treat patients very quickly while building a relationship and developing trust with the patients and their families [3], [4]. Poor communication between the health workers contributes a lot to the cases of medication errors that have the potential to slow down treatment and sentinel events. SBAR (Situation, Background, Assessment, Recommendation) handoff is known as one of the most common and effective transitions of communication services between multiple disciplines, especially for health care professionals [5], [6].

Complex images increase the risk of errors arising from the care provided and from the environment in the emergency unit during the information handover [7]. The communication of clinical handovers is an important component in preventing failures related to errors, side effects and patient hazards that can be avoided and to ensure the continuity of effective care [9], [10]. Before high-risk procedures are carried out, one should allow nurses to construct their own ideas for them to feel confident when talking with other medical staff members. This is then nursing communications can apply to the handover of nurse-to-nurse, while on the rounds, in doctor-nurse

communication, through changes in patient health status, in the directions before surgery by the surgical team, or in the communication between professional health care [14]. In another study, the training provider of SBAR communication techniques improved the effective communication and the interaction processes. They also relieved the stress related to communication and self-expression [15].

In the end, compliance with effective handover communication done using the SBAR technique has an important role in ensuring the accuracy, completeness and effectiveness of information delivery in the emergency department unit. In addition, the SBAR guidelines encourage many emergency department teams to carry out and have the same clinical standards. The review of this study aims to review the evidence base regarding the application of the SBAR technique as a handover communication intervention in the Emergency Department. The purpose of this systematic review was to review the use of SBAR as a communication tool for treatment at an emergency department. Practitioners in the emergency room use SBAR as a communication intervention strategy to provide improved communication and risk reduction for handover errors.

2. Research Method

2.1. Design

This study used a systematic design review that referred to the Preferred Reporting Items for Systematic Reviews and Meta-Analyzes (PRISMA) Statement [16]. The existing PRISMA guidelines adjust and combine from qualitative, quantitative and mixed method studies when conducting a review of this study. The PRISMA checklist is used as a reference for filtering the data articles including Eligibility (inclusion and exclusion) Criteria, Information Sources, Search Strategy and Study Selection.

2.2. Eligibility

The limitations of this study excluded study before 2011. The scope of this study was geographically international. Users of the communication method in the minimal emergency department loaded SBAR as a technique for effective communication. The evidence base of the existing articles was manually appraised by health professionals and expert researchers in determining the feasibility of the study material.

2.3. Search Strategy

The literature search database consisted of CINAHL Plus, Web of Science, MEDLINE and PUBMED. Comprehensive searches were conducted for 6 months until February 2019. In addition to mechanical searches, the reference list was searched and identified by health sciences professionals. When carrying out the identification process, we used the keywords as a reference. Emergency department keywords were used to search for information in including in the title, abstract, content and bibliography. In the next stage, the keywords in English were used to look for the relevant articles in the electronic database. The last step was to filter the results using PRISMA to determine the articles that were worth reviewing. This final step was finalized by limiting the studies to no older than 2011.

2.4. Study Selection

The paper went through 3 stages of screening in order to determine accuracy and to avoid duplicate titles, citations and abstracts. In the first stage, we filtered all of the relevant data based on the content. Second, we read all of the articles at least 3 times so then each article was assessed independently by the researcher. The last step of the researcher was to finalize the data to determine the appropriate articles before extracting and analyzing the contents.

2.5. Study Appraisal

The study appraisal used CASP to assess the feasibility of the articles reviewed and PRISMA for a framework guideline of the systematic review.

3. Results

The search strategy was conducted by generalizing the data with SBAR keywords and Emergency Department with the total initial results being 104 articles plus 7 articles sourced from the reference list found at the end of each study. A total of 38 articles indicated duplication in the titles and abstract were removed, leaving 73 articles total. In the final stage, 12 articles were screened according to the eligibility criteria and inclusion criteria set by the reviewer. The 12 articles included quantitative, qualitative and mixed method data.

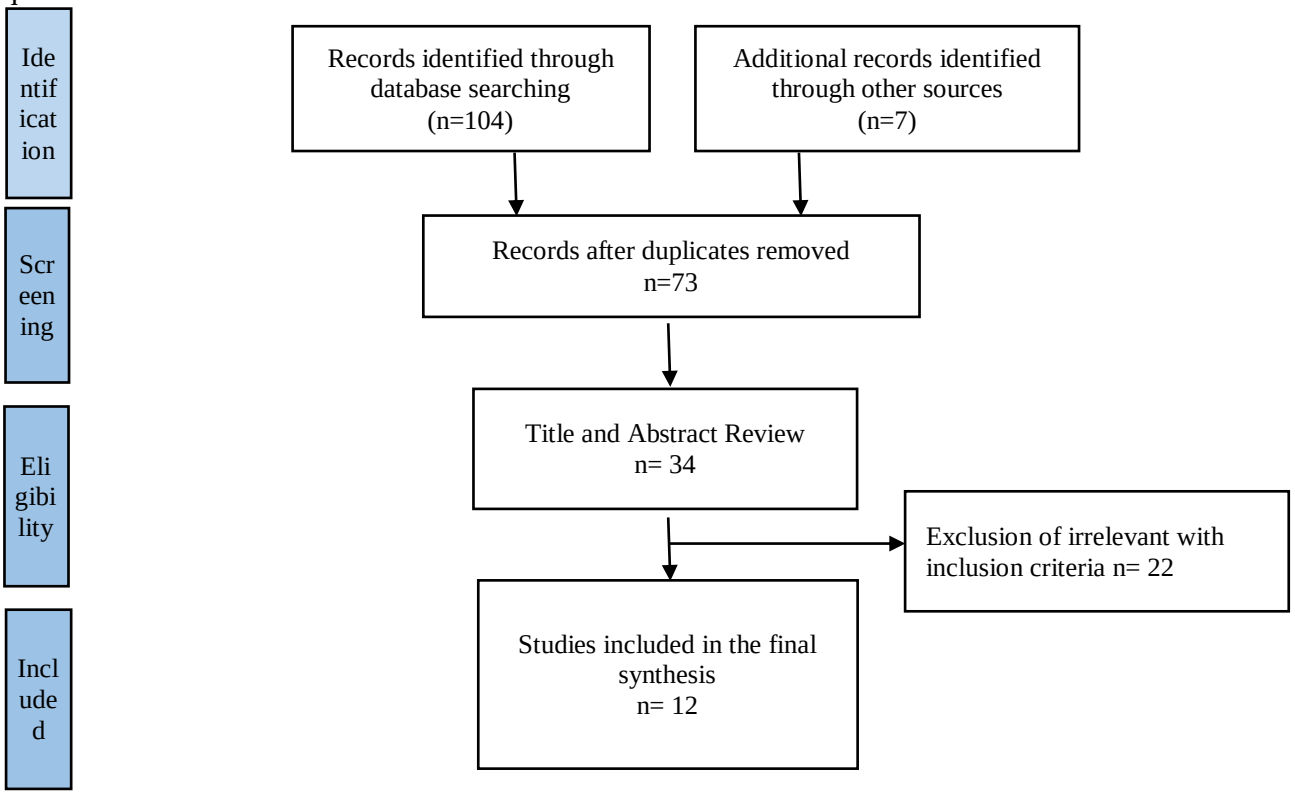

Figure 1. Flow diagram

3.1. *Quality Appraisal*

The assessment and evaluation of the feasibility of the 12 articles was done using the PRISMA and CASP Critical Appraisal Skills Program method with a percentage value of above 75% of the total maximum value of the tool used.

3.2. *Study Characteristics*

A total number of 12 articles were obtained from between 2011 and 2018. They had been carried out in several countries using qualitative, quantitative and development approaches and they involved mixed methods models. There were no criteria limits for the aspects of gender, marital status, the scope of emergency, country etc.

3.3. *Result of Synthesis*

The main components of the 12 articles to be reviewed have been shown below in Table 1. Readers easily get a systematic view of the sources found and the results of applying the SBAR in the Emergency Department which will be discussed. This allows the readers to identify the focus of each report. The importance of the various research methods or designs used has been clearly identified and this allows the readers to assess the suitability of the research designs.

In the study [17], the implementation of the SBAR-DR strategy resulted in an increase in verbal handoff quality. The agreement within a clear disposition plan is the most enhanced element, which is very important in describing maintenance responsibilities and streamlining ED throughput. SBAR communication and observation were also used to identify specific improvements. The results of the post-questionnaire showed increased satisfaction for both the staff and patients. The ED area benefits from the supervision of directors, managers and inpatient staff. In addition, the results show positive effects on the staff and patient satisfaction [18]. In another study, it explained the communication score in the increase in handover by increasing the knowledge of SBAR techniques. The experimental group showed greater post-intervention improvement in communication clarity relative to that observed in the control group [19].

The ISBAR standard tool is used to ensure high-quality handover delivery. The transfer of information between clinical teams can lead to improved performance without the need to reallocate resources and large data. Besides this, SBAR was reportedly useful at improving the quality of the information received and how it was adapted to the clinical context. It is very important that all doctors in the ER receive all of the information needed and that they ensure that the patient delivery is comprehensive and safe. Routinely using these instructions can lead to an increase in the quality of patient surrender. The introduction of standard submission tools, combined with education, can improve compliance with these tools. Lack of education knowledge in submission can cause current findings to be short-lived [6], [20]. The paramedics and ED participants agreed that being open to each other's knowledge can reduce the risk of injury or missed signs. This will prevent the occurrence of side effects and help with the patient's health care plan [20].

Other results show that nurses found the SBAR bedside reporting method easy to use and that it prevented a loss of patient information more effectively than pre-intervention practices. Post-intervention, the nurses found the SBAR handoff method easy to use and they found that it prevented a loss of patient information. The nurses declared that handoffs in the bedside context increased mutual responsibility and that it had the opportunity to increase situational awareness by looking at the patients and their surroundings, reviewing orders and discussing care plans with patients and their families [21].

SBAR can be accepted by first-year EM residents, and it is followed by an increase in the ability to apply SBAR in case of simulations and follow-up sessions. This format is feasible to use as a training method and it is well received by resident doctors. This significantly increased their ability to implement SBAR on simulated case presentations. SBAR's approach is the most commonly used approach to improve clinical case communication and it is more adaptable to the emergency department environment more than other complex models [22]. However, the active involvement of senior staff during the planning and implementation stages of the project is recommended. The introduction of 'M' to SBAR's handover tool has led to an increase in the number of prescription drugs that were examined. The time demands in the ER need to be considered when introducing changes to the current practices [23].

Psychometric tools based on the SBAR format were developed and validated to identify and improve the overall quality and value of education from surgical M & M conferences. The SBAR M & M tool is easy to use and requires little training to be used by evaluators. It potentially applies to other specializations [24]. Transfer documentation from a Residential Elderly Nursing carer, paramedics and ED triage nurses does not always contain comprehensive information. Better SBAR communication between non-affiliated organizations is needed to improve the timely maintenance that is appropriate for the residents of RACF (Residential Aged Care Facilities), through to ambulances and the emergency departments [25].

Structured communication techniques, such as the huddle and SBAR framework, promote improved communication between staff members. The joint evaluation followed by huddle was found to be a feasible and effective step to be taken to determine that the patient care plans have the potential to improve patient safety in the emergency department [26]. SBAR protocol support is an effective tool at improving communication through an alignment format and information reporting process. Standardization has been proven to improve the nurses' social orientation and critical thinking processes. Every time the protocol is used, the nurses will have a blueprint of the population assessment process and data collection [27].

SBAR can also be introduced into the nursing curriculum as a part of educating individuals living with chronic diseases to improve their self-care management. This can also be included as a part of return teaching for individuals who are excluded from the emergency unit or inpatient unit. Another ideal time to teach SBAR is when most people come for care. In addition, SBAR can be included in the transition program when individuals move into adult care [28].

4. **Discussion**

This systematic review is the first evidence published intended to improve the handover of patients using SBAR. It also intends to produce an in-depth understanding of SBAR's communication intervention strategies that lead to improved effective communication, in addition to improved accuracy, speed and quality in the services in Emergency Departments. Until now, the nurse communication and multi-disciplinary relationship carried out using the SBAR technique had a very good impact on the delivery of data in order to cope with the incidence of medication errors, patient safety and the length of treatment [15], [18], [26]. The review of this study provides information on the potential of the SBAR technique for the transition of information in ensuring that patient transfers are efficient, accurate and accountable, and that they avoid mistakes. The SBAR technical standard research base ensures that the information results in clear expectations. This reflects that an

emergency department is a land where large risks and significant sentinel events require great responsibility. The risks and sentinel events can be solved by applying the SBAR communication techniques [2], [24]. Ultimately, the approach to SBAR communication techniques in care ensure that the patient expectations and needs are communicated, making Emergency department care more responsive to patient needs and accuracy.

The increased recognition of communication at handover is an initial tool to improve part of the support process involved in the Joint Commission Index Patient Safety Goals. It is clear that the adoption of effective communication using SBAR has a better impact. The results of this systematic review indicate that SBAR communication technique interventions tend to be effective at improving the quality of the weighing and completeness of patient information in the emergency department. Of the 12 articles studied, there are different types of research designs. Most of them used quasi-experiments and others were epidemiological studies that were cross-sectional. This results in an interpretation that cannot be generalized.

5. **Conclusion**

SBAR communication techniques, as a communication tool in the wider scope of emergency, improve the accuracy and clarity of patient data information. The efforts of the WHO, by developing SBAR, have contributed greatly to the communications made by health workers in the emergency department. The continuous improvement of the current guidelines is still very important, especially in the process of patient safety. The use of the SBAR effective communication technique in the emergency department mentioned above is evidence that the adoption of SBAR is a reference for the communication of health workers in the emergency department according to the existing settings. The development and adoption of improved communication protocols in patient processing is not only continuous documentation of an effective handover in the current guidelines but it also involves ongoing modifications to adjust the specific rules to prevent medication errors in patient safety practices through SBAR communication. Further research can summarize the communication skills in emergency cases, with specific emergencies related to each scope of the disease in the Emergency Unit. This reflects on the effective communication practices to ensure that the individual communicates well. Thus, one should consider using SBAR or other standard communication tools to support the practices in the Emergency Department.

Appendix

Table 2. Summary of the results

Title & Authors	Design of the Research	Number of Participants (n)	Results
Situation, Background, Assessment, And Recommendation (SBAR) May Benefit Individuals Who Frequent Emergency Departments: Adults with Sickle Cell disease (2011) [28]	Pre-post implementation	34 Nurses	Eighty-three percent of patient encounters included a joint evaluation. A huddle structured with SBAR was conducted 86% of the time. Registered nurses and nurse practitioners verbalized the patients' treatment plans in 89% of cases and 97% of cases respectively. Improved teamwork, communication, and nursing satisfaction scores were demonstrated among the nurse practitioners and registered nurses.
SBAR M&M: a feasible, reliable, and valid tool to assess the quality of, surgical morbidity and mortality conference presentations (2012) [24]	Prospective observational study	9 residents	A psychometrically robust assessment tool based on the SBAR format was developed and validated to identify and improve the overall quality and educational value of the surgical M&M conference. The SBAR M&M tool is easy to use and requires little training for use by evaluators and it is potentially applicable to other specialties.
Situation-Background-Assessment-Recommendation (SBAR) and Emergency Medicine regarding the Residents' Learning of Case Presentation Skills, (2012) [22]	Educational study	25 EM Residents	There was a statistically significant improvement in the resident scores in the pre-test/post-test of the first case (P =0.001). There was no difference between the post-test of the first case and the pre-test of the second case (P =0.34), suggesting a retention of the material. There was a statistically significant improvement between the pretest and post-test scores on the second case (P =0.001). The survey yielded good reliability for both sessions (Cronbach's alpha =0.87 and 0.89, respectively), demonstrating statistically significant increases for the perceived quality of training, presentation comfort level, and the use of SBAR (P =0.001).

Caring For Inpatient Boarders In The Emergency Department: Improving Safety And Patient And Staff Satisfaction (2014) [18]	Mixed Method	204 staff members	Situation-background-assessment-recommendation (SBAR) communications and direct observations were also used to identify specific improvements. The post-questionnaire results indicated improved satisfaction for both the staff and patients.
Situation, Background, Assessment and Recommendation – Guided Huddles Improve Communication And Teamwork In The Emergency Department (2015) [26]	pre- and post-implementation surveys	N=34 (32 Nurse and 2 Nurse Practitioner)	Eighty-three percent of patient encounters included a joint evaluation. A huddle structured with SBAR was conducted 86% of the time. Registered nurses and nurse practitioners verbalized the patients' treatment plans in 89% of cases and in 97% of cases, respectively. Improved teamwork, communication, and nursing satisfaction scores were demonstrated among the nurse practitioners and registered nurses.
Using SBAR to Decrease Transfers from Longterm Care to the Emergency Room (2013) [27]	Develop and Implementation Project	140 residents	The implications of social change will include increasing the effective communication, as well as critical thinking skills by building the potential for increasing the satisfaction of the nurses and doctors that have the potential to increase job satisfaction, and to increase recruitment and retention. Positive results increase when care is given by those who are familiar with the patient's norms and settings.
Continuity matters: Examining the 'information gap' in the transfer from Residential Aged Care through an ambulance to emergency triage in southern Tasmania (2017) [25]	Retrospective cross-sectional transfer narratives	80 residents	The inclusion of elements from SBAR was inconsistent across the transfer. Rather, the written narratives focused on the concerns relevant to the immediate priority, the type of information imposed by the document(s) in use and the clinical role of the author.
Clinical Information Transfer between the EMS Staff and Emergency Medical Assistants during the Handover of Trauma Patients (2017) [6]	Clinical audit	178 and 168 Medical records	Clinical audit of the current situation in the ED showed that the clinical handover process does not follow standard ISBAR (0.0%). However, after training, 65.3% of clinical handover processes were performed in accordance with ISBAR. In the current study, there was an increase in all parameters of the ISBAR tool after training, most of which increased significantly compared to the first

			phase of the study (before the intervention).
Impact of an education session on clinical handover between medical shifts in an emergency department: a pilot study (2018) [23]	A pilot study: pre- and post-intervention design using qualitative and quantitative methods	24 doctor	The educational intervention led to an increased focus on checking medication charts, but it had a minimal effect on changing other aspects of clinical handover at the doctors' change regarding shift times. Perceived increased time spent on handover using the new system was seen of as a major barrier to the implementation of SBARM. The addition of 'M' to 'SBAR' heightened awareness of checking the medication and fluid charts.
Implementing Bedside Hand-off In The Emergency Department: A Practice Improvement Project, (2018) [21]	Pre Post Implementation	230 Registered Nurses	The results showed that the nurses found the SBAR bedside report method easy to use and that it helped to prevent the loss of patient information more effectively than pre-intervention practices.
Evaluation of a Novel Hand-off Communication Strategy for Patients Admitted from the Emergency Department, (2018) [17]	Mixed method	560 for the pre- post-test and 110 for the qualitative conversation	The composite quality score improved in the post-intervention phase (7.57 + 2.42 vs. 8.45 +2.51, p=.0085). Three out of the 16 individual scoring elements also improved, including time for questions (70.6% vs. 82.7%, p=.0344) and confirmation of the disposition plan (41.8% vs. 62.7%, p=.0019). The majority of emergency and internal medicine physicians felt that the SBAR-DR model had a positive impact on patient safety and hand-off efficiency.
Effectiveness of a role-play simulation program involving the sbar technique: a quasi-experimental study	A quasi-experimental study	Non-equivalent control-group pretest-posttest quasi-experimental.	The intervention group showed higher SBAR communication scores ($p = 0.003$), communication clarity scores in doctor notification scenarios ($p < 0.001$) and SBAR education satisfaction scores ($p < 0.001$) relative to those of the control group. There was no significant difference in the handover confidence between groups ($p = 0.054$).

E-mail: emkazaen@gmail.com

ABSTRACT

Communication can influence the quality of relationships and nursing care implementation. Successful communication are by nurses' knowledge and skills in therapeutic communication. Moreover, the factor that influence the quality of nurse and patient relationship is nurse spirituality. Spiritual-based therapeutic communication (SBTC) knowledge and skills are expected to improve nurses' abilites in intrapersonal, interpersonal, and transpersonal relationships. This study aims to analyze the effect of SBTC training on nurses' knowledge and skills that are useful to improve the quality of nurses and patients relationship. This was a quasi experimental to the nurse in Bangil hospital East Java Indonesia. The assessment procedure was carried out before and after in the intervention group and control group. The results found an increase knowledge and skills of SBTC in nurses who were given training.. The highest increase was the knowledge about communication and skills, especially positive emotional regulating skills, dimensions of response, and spiritual experience. Spiritual-based therapeutic communication training can improve nurses' knowledge and skills in communication. From the results of this study it is recommended that SBTC training must be carried out continuously.

Keywords: Spiritual, Therapeutic communication, Nurse, Training

1. Introduction

The results of communication will affect the subsequent relationship process. Nurse communication in the implementation of nursing care known as therapeutic communication. Therapeutic communication is a process carried out by the nurses of influencing consciously or helping the patients in their verbal and nonverbal communication (1). Psychologically, therapeutic communication is intended to build trust and cooperation between the nurses and patients (2).

Not all nurses in charge of health services are capable of good therapeutic communication. Aktas and Karabulut (2017) found that 46% of nurses experienced difficulties in their therapeutic communication with patients, especially in non-verbal communication (3). Chan (2017) reported that 58.7% of patients considered the frequency of information provided by nurses to be unsatisfactory (4).

Based on this data, it is necessary to increase thte nurses' knowledge and skills in therapeutic communication to increase patient confidence in the nurses. Therapeutic communication is not just the implementation of communication between nurses and patients. It includes the ability of the nurses to foster therapeutic relationships (5). Therapeutic relationships are influenced by personal quality, facilitative communication, responsive dimensions, action dimensions and therapeutic barriers (6). If there are disturbances in any these factors, then the fabric of the therapeutic

relationship will not have the maximum results possible (7). The personal quality factors of the nurses in therapeutic relationships are nurse-originated factors including self-awareness, value classification, altruism, feeling exploration and the exploration of their abilities and weaknesses (8).

The abilities related a nurse's personal qualities can be influenced by many factors, one of them being spiritual (9). Spirituality is something that is related to the spirit, and to the enthusiasm tfor beliefs, hopes, and the meaning of life (10). Spirituality is a tendency to make a meaning of life through intrapersonal, interpersonal and transpersonal relationships to overcome various life problems (11). Spirituality includes an awareness of conscience, the internalization of values, actualization, and sincerity as actual manifestations of relations with God (12). Spirituality is also referred to as something that is felt about oneself and in one's relationships with other people, good actions, friendliness, and respect for everyone to make someone happy (13).

Vlasboom (2011) revealed that the nurse's spiritual care ability is able to increase self-confidence, emotional control, and sincerity when performing health services that have an impact on increasing the patient trust in nurses and helping the patients find meaning from suffering due to their illness by increasing patient optimism (14).

Spiritual abilities, in addition to increasing individual abilities in interpersonal relationships, will also help someone to understand the meaning of life, sincerity, and the acceptance of any conditions that occur both in him, others, and the environment (15).

The addition of spiritual elements in the therapeutic communication of nurses is related to implementing nursing care to patients (16). This can be used as a means to improve the nurses' ability to understand the meaning of life, sincerity, patience and to increase positive emotions in relationships that are intrapersonal, interpersonal and transpersonal. Based on the chronology of the problem, it is necessary to provide SBTC training to nurses, which is useful for improving the nurses' knowledge and communication skills so as to improved nurse communication knowledge and skills.

2. Methods

2.5 Design

A quasi-experimental pre-test and post-test with a control group design was used (17). This study was used to investigate the effects of spiritual-based therapeutic communication. To find out the effect of SBTC training, we divided the participants into two groups by giving a pre-test and post-test to both groups.

2.6 Participant

The participants in this study were nurses who served in the adult inpatient room at the Bangil hospital, East Java, Indonesian. The population of nurses were serving in the adult inpatient room and totaled 120 nurses divided into 8 rooms. From that number, the samples were chosen to be made into two groups, namely the intervention group and the control group. Each room consisted of 14 nurses, so the number of samples for the intervention and control groups was 28 nurses per group.

2.7 Instrument

The instrument used was the width of the respondent's identity, the questionnaire used to measure knowledge about SBTC and the self-evaluation questionnaire used to measure the nurses' skills in SBTC. The knowledge questionnaire consisted of 25 questions in the form of questions with multiple

choice answers, while the self-evaluation questionnaire used a Likert scale. Before the questionnaire was applied to the participants, the questionnaire was measured for reliability and validity first. The self-evaluation questionnaire initially consisted of 40 items. After being tested for validity and reliability, this was reduced to 27 items. The questionnaire measurement results were in the form of interval data for both the knowledge questionnaire and self-evaluation questionnaire.

2.8 Intervention

This research was carried out after an ethical review process was carried out in RSUD Bangil number 445.1/570.1/424.202/2019. The implementation of SBTC training was carried out for the intervention groups by providing modules, lectures, role-play and direct practice. The spiritual-based therapeutic communication training lasted for 3 days and consisted of three stages: classroom training (1 day) and direct practice with mentoring (2 days).

2.4.1 Definition. Spiritual-based therapeutic communication is a combination of therapeutic communication within the spiritual dimension. The basic elements of therapeutic communication are formed from five elements that influence therapeutic communication and four spiritual dimensions, which are personal quality, facilitative communication, response dimensions, action dimensions, therapeutic barriers, the meaning of life, positive emotions, spiritual experiences and rituals.

2.4.2 Training Objectives. It is expected that after the training, the participants will be able to implement the SBTC techniques in nursing care to their patients, making it easier to help the patients overcome any problems and to improve their abilities.

2.4.3 Part of SBTC training

2.4.3.1 Part 1 Classroom Training. The classroom training was carried out in the form of a lecture, discussion and role play about SBTC for one day consisting of 9 sessions.

Table 1. Topics and methods in the SBTC training in the classroom

Session	Topics	Methods
1	Training Contract	Lecture
2	Why spiritual-based therapeutic communication?	Lecture
3	Who am I? Who is he? (Pre-interaction phase)	Role-play
4	The first impression is so tempting (Orientation Phase)	Role-play
5	Implementation time (Working Phase)	Role-play
6	Say goodbye (Termination Phase)	Role-play
7	Flashback	Discussion
8	Action plan	Discussion
9	Closed	Lecture

2.4.3.2 Part 2 Direct Practice with Mentoring. The participants were invited to practice directly with patients through mentoring. This stage was carried out for 2 days

2.9 Measurement

The respondents' measurements were taken by filling out the respondents' identity details and

questionnaire. The filling in of the respondent's identity and pre-test questionnaire was conducted at the beginning of the study in both the intervention and control group. The post-test was conducted after the 7th day adjusted to the end of training and to the implementation of SBTC in the intervention group.

2.10 Analysis

The respondent's identity data has been described as a table by grouping it together. The results of the pre- and post-test of knowledge and skills in the intervention group and the control group were analyzed using a simple paired t-test. To compare the knowledge and skills between the intervention group and the control group, this was done using an independent t-test.

3. Result

3.4 Characteristics of the Respondents

The characteristics of the respondents between the intervention and control groups was almost the same.

Table 2. Characteristics of the Respondents

Characteristics of the Respondents	Intervention Group n = 14	Control Group n = 14
Age in years		
20 - 29	5	4
30 - 39	7	9
40 - 49	2	1
Sex		
Male	4	3
Female	10	11
Job Experience in years		
1 - 5	4	5
6 - 10	8	8
11 - 15	2	1
Education		
Diploma of Nursing	13	13
Bachelor of Nursing	1	1
Job Status		
Government Employees	4	3
Not Government Employees	10	11
Religion		
Islam	14	14
Others		

3.5 Measurement SBTC knowledge and skills intervention group and control groups

The measurement results of the pre-post test of the knowledge of intervention group showed as being very significant (0,000), while in the control group, it showed as not being significant (0,828).

Table 3. Measurement of SBTC Knowledge in the Intervention and Control Groups

		Mean	Std. Deviation	t	df	Sig. (2-tailed)
Pre – Post Test	Intervention Group	-5.64286	2.59013	-8.152	13	.000
Pre – Post Test	Control Group	-.07143	1.20667	-.221	13	.828

Table 4. Measurement of the SBTC Skills in the Intervention and Control Groups

		Mean	Std. Deviation	t	df	Sig. (2-tailed)
Pre – Post Test	Intervention Group	-11.286	7.405	-5.702	13	.000
Pre – Post Test	Control Group	-.214	3.142	-.255	13	.803

3.6 Comparison of SBTC knowledge and skills between the intervention group and control group

The results of the comparison of knowledge and skills in the post-test intervention group and control group showed as being significant (0,000). This means that there is an effect of providing SBTC training to increase knowledge and skills about SBTC.

Table 5. Comparison of SBTC knowledge between the intervention and control group

		Levene's Test for Equality of Variances		t-test for Equality of Means			
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference
Result Post Test	Equal variances assumed	.030	.865	6.842	26	.000	5.643
	Equal variances not assumed			6.842	25.940	.000	5.643

Table 6. Comparison of the SBTC skills between the intervention group and control group

		Levene's Test for Equality of Variances		t-test for Equality of Means			
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference
Result Post Test	Equal variances assumed	.000	.995	4.408	26	.000	11.357
	Equal variances not assumed			4.408	25.924	.000	11.357

3.7 Distribution of SBTC Elements in The Intervention Group

After the SBTC training, there was an increase in SBTC skills, especially with the most prominent improvement being in the difference in scores before and after training of ≥ 2.00. For the response dimension it was 2.86, for positive emotions it was 2.00 and for the spiritual experience, it was 2.43..

Table 7. Distribution of the SBTC Elements in the Intervention Group

No	Element of SBTC	Mean		Difference
		Pre Test	Post Test	
1	Personal Quality	8.50	9.29	0.79
2	Facilitative Communication	6.14	6.57	0.43
3	Response Dimension	10.50	13.36	2.86
4	Action Dimension	9.71	10.14	0.43
5	Therapeutic Barriers	6.29	6.71	0.43
6	Meaning of Life	7.50	8.29	0.79
7	Positive Emotions	7.64	9.64	2.00
8	Spiritual Experience	7.43	9.86	2.43
9	Rituals	9.93	11.07	1.14

4. Discussion

The results of this study indicate that the nurses trained in SBTC increase their therapeutic knowledge and communication skills more than untrained nurses. SBTC training methods are carried out in the form of lectures, role-playing and direct practice, which is a combination of learning with the stimulation of the cognitive, affective and psychomotor aspects. Allen & Ph (2010) revealed that learning methods for increasing a health workers' knowledge and skills can be improved by providing learning through the three aspects of cognitive, affective, and psychomotor (18).

Increasing the knowledge and skills of theparticipants in this study was in accordance with the theory of learning methods by adjusting to one's own learning style. Everyone has their own learning styles. An effective learning model that can be accepted by the learner is to adjust the learning style of each individual. Individual learning styles can be in the form of visual, auditory and kinesthetic. In SBTC training, a combination of all learning methods is carried out so then any learning styles

that the trainees have allow them to be ble to receive the new information well and to increase their knowledge and skills (19).

The training in this study also aims to provide knowledge and training through visual and auditory media (modules and lectures) and kinesthetic modules (role play and direct practice). It also has the potential to further enhance one's knowledge and skills, because in receiving information and stimuli from outside, someone will pass through a system representation that is visual, auditory, kinesthetic, olfactory and gustatory (20).

The knowledge and skills of the nurses after SBTC training was increased. Increased knowledge and skills in each element of SBTC can make the nurses better understand the meaning of their intrapersonal, interpersonal and transpersonal relationships. Elements of the meaning of life will mean that the nurses try to be role models for others, help spontaneously, hold their promises, forgive themselves and others, be honest, and prioritize harmony and togetherness. The element of spiritual experience will make the nurse feel close and friendly with the universe, they will feel the presence of God in every event, and they will feel a special impression on all of the events they experience (21).

The manifestation of increasing the elements of positive emotions can make the nurses more optimistic, able to control themselves, happy when they are doing good, happy with the happiness of others, and able to make peace under any condition. The ritual element will mean that the nurses feel the love of God, feel a dependence on God, feel calm, fear to do evil and are sensitive to goodness (21).

Increasing the personal quality element of the nurse will make the nurse better know and control themselves, able to be an example of their role, altruism and to have a good sense of ethics and responsibility for what they do. In the element of facilitative communication, it plays a role in increasing the nurses' abilities in terms of verbal communication, non-verbal communication, communication techniques and developing motivational interviews (6).

The dimensions of response include respect for others, sincerity, empathy, and openness. Elements of the dimension of action are confrontation, immediacy, self-disclosure of nurses and emotional catharsis. As for overcoming the therapeutic obstacle elements in the form of resistance, transferring, transferring, and encroachment, the nurses will be better able to act through the knowledge and abilities ifrom SBTC that have been studied and practiced in the SBTC training.

In this study, all of the elements have increased. There are several prominent elements that increase the value of the dimensions of response, positive emotions, and spiritual experience which are the response dimensions, positive emotion, and spiritual experience. The increased response dimensions indicates that the nurses responded to the stimuli given by the patients better. This is in accordance with the aspects of SBTC training including the provision of knowledge and skills in empathy, sincerity, the understandingthe patients and spirituality. Good responsive conditions are very useful for the nurses in the application of therapeutic communication, especially the work phase and termination phase (6). Increased response dimensions can also increase the mutual trust between nurses and patients and this can make the nurses better understand themselves and thi+er patients(6).

Increasing the positive emotions in nurse communication skills is in accordance with what is expected in SBTC training. Combining therapeutic communication elements with spirituality can improve the ability of the nurses to manage their own emotions by accepting whatever happens both in terms of the conditions experienced and referring to the conditions experienced by the patients.

Increasing positive emotions means that nurses are more sincere in helping their patients, with the patient, when facing any situation, receptive to all conditions that occur (22)

Increasing the spiritual experience can make the individuals calmer and closer to God. Every incident that happens is always associated with The Creator, which means that all good or bad events are the will of The Creator and there must be a meaning behind the incident. Increasing the spiritual experience is very useful to keep emotions stable (21).

Broadly speaking, SBTC training is a new communication model in which therapeutic communication has been oriented to increasing the intrapersonal and interpersonal relationship skills, with added spiritual elements that are useful to increase the skills of transpersonal relationships so then communication, especially when in relation to nursing care, does not only involve the element of self themselves and others but it also involves God in every activity of giving nursing care.

5. Conclusion

SBTC training is a training method that combines elements of therapeutic communication with a spiritual dimension that aims to improve the ability of the nurses in therapeutic communication that is useful to increase the nurses' skills in terms of establishing relationships with their patients when providing nursing care.

The provision of SBTC training has been shown to have an effect on increasing the nurses' knowledge and skills in therapeutic communication, especially related to the response dimensions, positive emotions, and spiritual experiences.

UTILITING SOCIAL MEDIAS AS A HEALTH PROMOTION TOOLS TO ENGAGE MILLENNIALS : A SYSTEMATIC REVIEW

A N Izzati[1], Z 'Ulya[1], I Choliq[1], and S Tauriana[1]
[1]Faculty of Nursing, Airlangga University, Surabaya,
Indonesia Email: aisyah.nur.izzati-2108@fkp.unair.ac.id

ABSTRACT

Social media has become the most important component of everyone's life in this digital era. It can't be denied that social media has changed the ways people seek about health information. The aim of this study was to assess the effectiveness of health promotion using social media to change health behaviour, awareness, and health outcomes. ProQuest, Scopus, NCBI, and SAGE database was searched for existing literature on social media development to delivering health promotion. The search returned 423 journals, and 15 journals met the eligibility criteria following review of full-text documents literature result. Studies shown social media is effective in increasing health knowledge, awareness, and prevention behaviour. Furthermore, other studies stated social media can enhance their sense of community among patients with chronic disease and thus help people attain healthier lifestyles. This review highlights that social media has a lot of roles in changing people's perception and behaviour, it a useful yet cost effective strategy that have to be considered by health workers to use it as a health promotion tool and engage millenials.

Keywords: social media, social networking, health promotion, behaviour, prevention, awareness

1. Introduction

Social media platforms such as Facebook, Twitter, and Instagram are increasingly becoming a central part of daily life [1]. This transition of technology has created an environment in which everyone has the ability to comment, participate, and contribute toward the sharing of information, especially for healthcare. Social media has become an important health resource, and not just for millenials. Nearly 90 percent of older adults have used social media to seek and share health information [2]. Social media is a gathering place. People gather together to share things, learn, and to engage in conversations regarding things that are important to them [3].

Global Digital 2018 reported that over the past 12 months, the number of social media users in each country has increased by almost 1 million new users every day. Astonishingly, each person is spending around two hours on social media every day. Although they use it as a form of social interaction and self-actualization, social media platforms seem to also be used for seeking

information [4]. It is unsurprising that now, online health information seeking plays an increasingly important role in a user's online activities. According to the report of European Citizen's Digital Health Literacy survey published in 2014, over 60% of Europeans reported using social media to look up health information. From all of the phenomena above, it can be defined that it may be worthwhile for healthcare professionals to find a way to engage millenials by doing health promotions using social media.

We live in a time where, due to the popularity of the smartphone, we have almost instantaneous access to a wealth of specialist information at our fingertips. There is an expectation that health information diffusion will follow suit and that health care organizations are turning to social media. For example, Public Health England has responded to the changing landscape of social media and health communication by engaging with digital technologies and switching to an "always on" approach rather than traditional annual campaigns [5].

Social media is an efficient platform for the user to access information via, including access for help, advice, and information from another user. In other words, social media is a key place to share breaking information during a health crisis. This kind of information sharing and social support in online communities may affect their health behavior. Health promotions in social media enable the users to have a great control over, awareness of and to improve the health outcome through behavior changes.

In this review, we systematically reviewed the literature regarding the effectiveness of health promotions using various forms of social media to change health behavior and health outcomes. This work will facilitate any health professionals, policymakers and organizations to identify any effects, pros and cons from doing health promotion on social media.

2. Methods

2.1 Literature search strategy

The review was based on the results of a search of the research on Scopus, ProQuest, NCBI and SAGE. The keyword terms used were 'social media' or 'social network' or 'Instagram' or 'vlog' and 'health promotion' or 'health awareness' or 'health behavior' or 'health prevention'. The search returned 423 journals, but all of the results were reviewed and evaluated using the following criteria, and we selected the 15 most relevant final studies (Figure 1).

2.2 Inclusion and exclusion criteria

2.2.1 Study Design. The study designs included random controlled trials, exploratory descriptive, analytic observational, an exploratory study and a cross-sectional study. The heterogeneity design provided a different context that may answer whether social media is effective for health promotion or not.

2.2.2 Population. The participants in the study were men and women of any age. This was in order to look at engagement levels at multiple ages.

2.3 Intervention

In the treatment group, the action given to the participants was shown and they were given health education through posts on different social networking platforms. In the control group, the health education was given alongside the usual side-to-side process in which the users can interact with each other and share information.

2.4 Clinical outcomes

The results of the intervention measured after the action included the level of the participant's knowledge, their awareness and their behavior.

3. Results

3.1 Selection Criteria and Process

We used the selected terms on a broad spectrum such as "social media and health promotion" to search the literature. It returned 423 studies and all of the results were reviewed and evaluated using the following criteria. It was found that there were 15 selected items of literature that met the criteria.

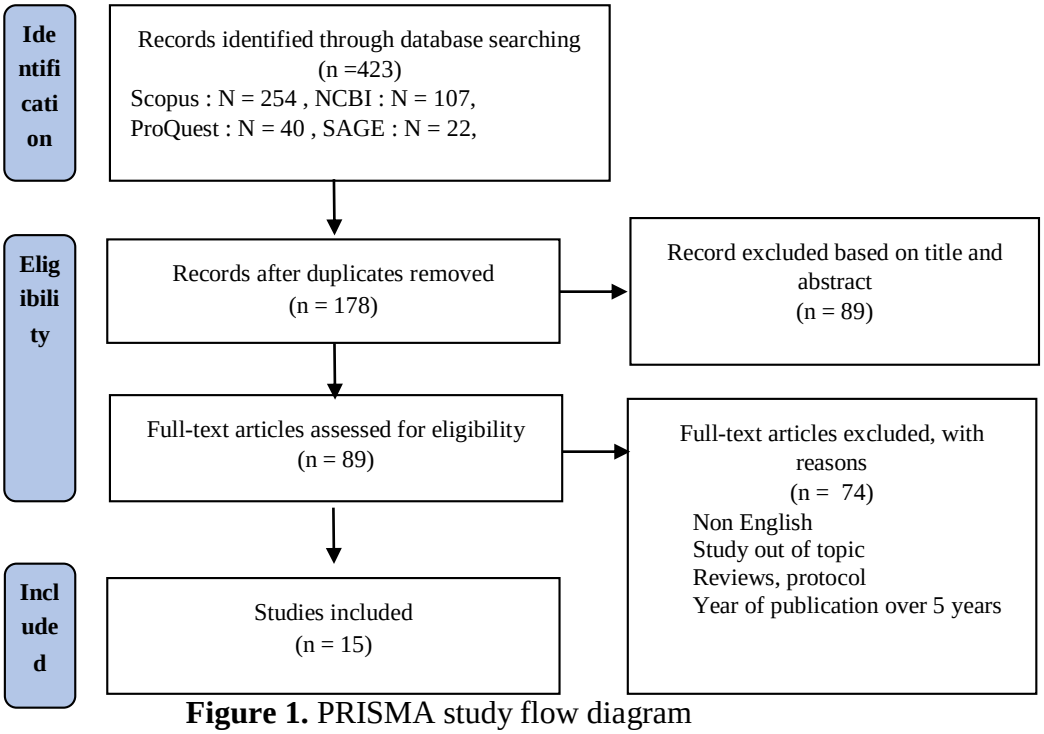

Figure 1. PRISMA study flow diagram

3.2 Kind of Intervention

The interventions were given according to the literature including a Youtube-style video, stimuli public post on Instagram and Twitter, mentoring via a Facebook Group, Twitter and Facebook posts, a website and interactive social media.

3.3 Result Measurement

The measurement tools used on the literature items were exercise motivation, activity, self efficacy, physical activity, knowledge, awareness, and prevention behavior, risk behavior, body mass index, strokes scale and vaccination status [10].

Table. 1 Type of Study in the Setting Up of the *Systematic Review*

Author	Type of Study	Participants	Intervention	Outcome
(6)	Exploratory descriptive Study	146 participants	135 adolescents in British Columbia Canada.	Videos via social media are a promising messaging strategy for raising awareness about tobacco exposure as a modifiable risk factor for breast cancer.
(7)	Exploratory descriptive Study	346 participants	Participants were invited to participate in the creation of a health-promotion intervention on diabetes by expressing their opinions through an online questionnaire posted on Facebook, Twitter, and Instagram.	Social media potentially increased the diabetes patients' engagement and satisfaction with health-promotion interventions, enhancing their sense of community, and thus helping people attain a healthier lifestyles.
(8)	Cluster randomized trial	229 people (99 male, 130 female) from a liberal arts college	Participants viewed a series of 40 actual social media posts across the 4 conditions (individual post with images, corporate post with images, individual post with images, and corporate post	Stimuli with images from individual accounts were more motivating than stimuli with images from corporate accounts, $t(228) = 3.57$, $p < .001$, $d = .24$,

			without images) in a randomized order.	
(9)	RCT	238 adolescents (46.32% boys; M age=12.17, age range: 11–14 years) divided into 2 groups (118 intervention , 120 control)	The influencer agents, based on their closeness centrality within the social networks, used an innovative approach to train the influence agents via smartphones for 5 weekdays and 2 weekend days.	Social network intervention didn't have any effect on the physical activity level of the adolescents.
(20)	AnalyticalObservation	782 participant	Participants were shown a unique random set of 20 tailored messages per day over five days via social media platforms.	There were no statistically significant changes in knowledge and prevention behaviors from the baseline through to post-survey among study participants.
(11)	Cross-Sectional	95 participants	Participants reported their sources of information about contraception and human immunodeficiency virus/sexually transmitted disease such as TV/movies, parents, and social media.	Youths who were exposed to sexual health messages on social media were 2.69 times more likely to have used contraception or condoms the last time they had intercourse.

(12)	Experimental	360 participants	Subjects experiment utilized a 2×4 factorial design, varying the type of social media and the message communicator used to deliver a cancer risk reduction message.	YouTube led to higher comprehension and stronger attitudes toward cancer risk reduction than Twitter and Facebook. The form of social media used to deliver content can have an effect on persuasive outcomes
(13)	Exploratory Descriptive	34 young adults (male 7, female 27)	Eight focus groups (m=4.25 participants per group) were scheduled in-depth-semi-structured interviews using multiple approaches in qualitative research.	The majority of young adults in this study perceived that social media use does have an influence on young adult health behaviors
(14)	Exploratory Descriptive	100 participants Facebook (n=60) Twitter (n=40)	Identifying active Facebook and Twitter profiles undertaking sexual health promotion through a previous systematic review, and assessed profile activity over a one month period.	Key strategies to promoting sexual health promotion by social media are regular individualized interaction with users, encouraging conversations, uploading multimedia and relevant links, and highlighting celebrity involvement
(15))	RCT	556 participants	Participants in the HIV intervention were randomly	Development of peer-mentored social media communities seemes to

		(278 control, 278 intervention)	assigned to 2 peer leaders within their group who would attempt to interact with them about the importance of HIV prevention and testing, while those in the control group received an enhanced (incorporating social media) standard of care.	be an effective method to increase HIV testing among high-risk populations
(21)	Quasi-experimental	64 participants	Interventions of eHealth Self Management (eHSM) based on community for 24 weeks	Self-efficacy, self-care behavior, and social support increase in the intervention group
(16)	RCT	Overweight and obese individuals with a body mass index (BMI) between 25–40 kg/m2 and aged between 21 and 65 years	One group received the program within a Facebook group, along with a support network within the group. The other intervention group received the same program in a booklet. The control group was given standard care.	The Facebook group reported a 4.8% reduction in initial weight, significant compared to the CG only ($p = 0.01$), as well as numerically greater improvements in body mass index, waist circumference, fat mass, lean mass, and energy intake compared to the Pamphlet Group and the Control Group.
(17)	Analytic Observational	620 survey participants	The participants were asked on average how	Several health promotion programs via social media have

		aged 16 to 29 years	many hours per day they spent using SNS, and they were asked to rate their level of comfort receiving information about sex/sexual health from different sources, including traditional sources (school, doctor), older media (mainstream media, websites), and social media.	demonstrated efficacy. However, many young people are not comfortable with accessing sexual health information through these channels.
(18)	RCT	60 participants	Youths in the Internet intervention immediately received emails with links to online HIV/STI prevention websites and YouTube videos. Researchers sent the participants 8 HIPPA compliant emails (containing 2–3 links each) twice a week over 4 weeks	Youths who received links to publicly accessible online prevention content by email showed a significant improvement in HIV self-efficacy and a significant reduction in unprotected vaginal or anal sex.
(19)	RCT	80 participants	5 promotion attempts were made by email, a website,	Social networks and websites can be as effective as traditional methods of advertisement in order

			LinkedIn, Twitter and Facebook	to reach patients for stroke rehabilitation protocols.
(9)	RCT	888 participants	Single-center RCT of vaccine information and social media interventions designed to reduce under-vaccination among infants of women recruited during pregnancy.	Providing web-based vaccine information with social media applications during pregnancy can positively influence parental vaccine behaviors.

3.4 Analysis of Intervention

3.4.1 Youtube Videos. YouTube-style videos shown to the participants raised awareness among adolescent girls and boys about tobacco exposure as a modifiable risk factor for breast cancer [7]. Tailored, gender-specific messages for use on social media hold the potential for cost-effective health promotion and cancer prevention initiatives targeting youths. YouTube led to higher comprehension and stronger attitudes toward cancer risk reduction than Twitter and Facebook [13]. YouTube is the best method for delivering health messages, especially for particularly complex risk reduction messages.

3.4.2 Public Post on Instagram, Facebook and Twitter . Effectiveness of social media content in promoting exercise motivation differed across the general categories of content type (with images or without images) and account type (individual or corporate). From the literature, we've determined that stimuli with images from individual accounts were more motivating than stimuli with images from corporate accounts. Content with images may simply be more accessible and offer more information relevant to making social comparisons rather than content without an image [9]. The promotion on Facebook and Twitter through segmented profiles was more effective than traditional posting on these social networks [20].

3.4.3 Facebook Group Mentoring. The development of peer-mentored social media communities via Facebook Groups seems to be an effective method to increase HIV testing among high-risk populations [16]. On the other hand, Facebook Groups can assist overweight and obese individuals with dietary and physical activity modifications for weight management [17].

3.4.4 Website and Interactive Social Media. Web-based vaccine information and social media intervention had a positive impact on early childhood immunization. Pregnant woman exposed to the

social media were more likely to vaccinate their infants on time than the other participants [10]. Interactive, informational intervention on social media can improve vaccine acceptance.

4. Discussion

There were 15 articles about utilizing social media as a health promotion tool that we reviewed. There were 2 studies that proved that social media had no impact on the physical activity of adolescents and there were no statistically significant changes in the knowledge and prevention behaviors related to cervical cancer [20],[9]. The rest of the studies stated that a health promotion intervention through social media had an impact of health quality, such as breast cancer awareness, diabetes patients' engagement and satisfaction, sexual transmitted disease awareness, cancer risk reduction, young adult health behavior, increasing HIV testing, weight management program, HIV self efficacy, stroke rehabilitation protocol, and vaccine behavior.

The four types of interventions found in this review had a significant effect on knowledge, awareness, and behavior change. However, the effectiveness of social media as a health promotion tool needs to be maximized through interactions with the users, encouraging conversation, image and video uploading and the involvement of social media influencers. Health professionals need to be strategic if they want to make a health promotion through social media. They will need to learn about the social media platforms on which they can engage with their clients, and also having social media ambassador/influencer on board makes the health promotion far more likely to spread.

Furthermore, the limitation of social media is that the readers need to be wary of the health information posted. This is because there is no filter to screen for reliability, and whether it is credible or not. To ensure the accuracy, quality and credibility of the health information, it needs to be evaluated. Social media is low cost and broadly accessible, which made it holds more potential opportunities than just advancing traditional health promotion in this era. The study designs in this systematic review are likely to be heterogenous and this can affect the bias quality assessment. These findings may not generalizable to other regions where people have less access to social media.

5. Conclusion

We reviewed the evaluation of literature search conducted focused on health promotion using social media for breast cancer prevention, vaccine acceptance, stroke rehabilitation, HIV self-efficacy, and physical activity. Successful research has been done using Youtube videos, public posts on Instagram and Twitter, through Facebook group mentoring, websites and interactive social media. Creating health promotions through social media has had a variety of effects which caused by the different types of social media platform, the promotion intensity, and also the promotion's duration. More research is needed to explicitly discuss the theoretical framework. This systematical review has implications for how these technologies might be utilized by health professionals to make a health promotion. In the disruptive era 4.0, it is necessary to bringing health promotions into a modern context. The increasing amount of social media users suggests that health professionals need to make the step forward to engaging millenials.

CONFLICT IN HEALTH CARE: A LEGAL STUDY ON NURSE PRACTIONER AUTHORITY AT INDEPENDENT MEDICAL CLINIC IN INDONESIA

Astutik, Prilian Cahyani
Faculty of Law, Criminal Law Department, Airlangga University
tutik9833@gmail.com; prilian@fh.unair.ac.id

ABSTRACT

Indonesian Nursing Law allows and authorizes nurses to establish an independent medical clinic (IMC). The legal problem on this authority arises in relation to the partnership between medical doctor (MD) and nurse practitioner (NP). This study uses a legal doctrinal method which employs statutes and conceptual approach. The purpose of this study firstly is to examine the laws and regulations concerning to the authorizations given to NP to establish an IMC. Secondly, to elaborate the scope of NP authorities both in medical health service and IMC. The result of this study shows that the limitation of authority between medical doctor and nurse is vague, so it potentially causes the conflict in authority. It triggers competition between MD and NP and bring some confusion for the community. As a conclusion, the law needs to be amended and addressed the clear boundaries of authority between MD and NP. It will also enable community to distinguish between MD service and NP service when they need to access medical service and health treatment.

Keywords: Authority, Clinic, Doctor, Nurse, Health, Treatment

1. Introduction

The health service effort is a part of the health subsystem components. The health service effort consists of the individual health efforts (UKP) and the public health efforts (UKM). UKP is an activity carried out by the government, society and the private sector to maintain and improve health, to prevent and to cure diseases and to restore personal health. UKP includes promotion, prevention, restorative and rehabilitation efforts. UKM is an activity carried out by the government, community or private sector to maintain and to improve public health, and to prevent and overcome health problems which arise in the community. Health workers have an important role to improve the health services for both individuals and communities.

Health workers are those who devote themselves to the health sector. They undergo professional training and have graduated from formal health education. According to Article 1 paragraph (1) Law No. 36/2014 concerning Health Workers, the health workers also have the authority to carry out health efforts. Health workers are divided into health workers and health workers' assistants. Furthermore, based on the Article 11, health workers consist of medical personnel such as doctors, dentists and nurses. In practice, doctors and nurses often collaborate to provide health services in public health service facilities or in an independent health practice. In the past, nurses were merely positioned as the assistant of the doctors. Currently, nurses are the doctor's partner in the health services.

According to Law No. 38/2014 on Nursing, nurses have a wide authority such as to provide health services to the community. Moreover, nurses are divided into several levels based on the level of education that they have achieved. Law No. 36/ 2014 allows nurses to have an independent practice. However, the Law is not equipped with a clear explanation of the duties and authority of nurses in the independent practice. Law No. 36/2014 has neither adequate information nor does it differentiate between the nurse's duties/authorities in independent practice and in the health care facilities. The incompleteness of information on the duties and authorities of the nurses and doctors, especially in the independent practice, has caused a conflict of authority in the health care service.

Therefore, it is necessary to explore the government's rationale for issuing independent practice licenses to nurses. Besides, the vagueness of the law regarding to the limitation the authority between doctors and nurse in independent practice is pivotal to be examined. The medical practice carried out by nurses needs to be examined to determine who is responsible for any loss suffered by the patient. This article focuses on the basic considerations required to allow the nurses to conduct independent practice and the limitations of the nurses' duties as well as that of the authorities in independent practice.

2. Method

The type of research used in this article was normative legal research, in which this study used the provisions of positive law or legislation as the most important reference to resolve legal problems that arise and that have caused unrest in the reality of life in society. Peter Machmud Marzuki, a professor of Law from the Faculty of Law, Airlangga University, in his book entitled 'Legal Research', has clearly stated that Socio-Legal Research is not a form of Legal Research. The research team in the context of this legal research does not use the term Socio-Legal Research and the rules of Socio-Legal Research have not been used in this legal research.

The approach used in this study was the statute approach and the conceptual approach. The legislative approach (statute approach) that was used in this approach is where the author conducted research to seek out, examine and understand the laws and regulations relating to the regulation of the practice of independent nursing. The conceptual approach (conceptual approach) is an approach where the writing team feels that it is very necessary to use the conceptual concept of the concept of independent nursing practice.

3. Results

The authority of the nurses to practice independently is regulated in the Law No. 36/2014 on Nursing. The consideration to grant permission to the nurse to conduct independent practice is based on several laws and regulations.

3.1. Basic consideration for nursing independent practice permits

3.1.1. The 1945 Indonesian Constitution . This is the basis and philosophical foundation for granting nurses to establish independent practice. It is stipulated under two articles. They are Article 28A: 'Everyone has the right to live and has the right to defend his life' and Article 28H: 'Every person has the right to live in physical and spiritual prosperity, to live, and to get a good and healthy environment and the right to obtain health services'.

3.1.2. The Law No. 44/ 2009 on Hospital Law. Article 13 of the Hospital Law stipulates that certain health workers who work in hospitals must have a license in accordance with the statutory provisions and that they must work according to professional standards, hospital service standards, applicable standard operating procedures, professional ethics, respecting patient rights and prioritizing patient safety.

3.1.3. The Law No. 3/ 2009 on Health Law. Article 22 of the Health Law requires health workers to have certain minimum qualifications. Based on these qualifications, health workers are authorized to provide health services. In administering health services, the health workers are required to have permission from the government, as stipulated in article 23 (3) of the Health Law. Health personnel who have been granted permission to exercise authority must meet the provisions of the code of ethics, professional standards, health service user rights, service standards and standard operating procedures as stipulated in article 24 (1).

3.1.4. The Law No. 36/ 2014 on Health Workers. Article 46 regulates the issue of licensing for health workers as follows. Every health worker who practices in the health service must have a permit. Permits as referred are given in the form of SIP; SIP is given by the district / city regional government on the recommendation of the authorized health official in the district / city where the health worker carries out their practice. To obtain this, the health workers must have a valid STR and a recommendation from professional organizations and practice sites. Furthermore, the provisions are stipulated in article 47, in that health workers who carry out independent practices must install a practice signboard. Health workers who are given practice permits must carry out their duties in accordance with the authority granted based on their competence, as stipulated in article 62 of the Law on health workers. Furthermore, it is explained that what is meant by competency-based authority is the authority to carry out independent health services in accordance with the scope and level of competence, among others, for nurses authorized to carry out nursing care independently and comprehensively, and for there to be a collaboration between nurses and other health personnel according to their qualifications.

3.1.5. The Law No. 38 of 2014 on Nursing. Nursing is the activity of giving care to individuals, families, groups, or communities, both in a sick and healthy condition (article 1 paragraph (1) of the Nursing Act). A nurse is someone who has passed through nursing education, both domestically and abroad, which is recognized by the government in accordance with the provisions of the legislation. Article 19 of the Nursing Law regulates licensing for nurses states that nurses who carry out nursing practices must have permission. Permits as referred to in paragraph (1) are given in the form of SIPP. The SIPP as referred to in paragraph (2) is given by the district / city regional government on the recommendation of the authorized health official in the district / city where the nurse carries out his practice. Furthermore, in the provision of Article 20 of the Nursing Law, it formulates that the SIPP is only valid for 1 (one) place of practice and that it is given to the Nurse at most for 2 (two) places. Particularly for nurses who carry out independent practices, they must put up a sign of nursing practice as stipulated in Article 21 of the Nursing Law.

Regarding nursing practice, article 28 regulates the nursing permits that can be carried out in health care facilities or independently. Nursing practices carried out in health care facilities must be based on a code of ethics, service standards, professional standards and standard operating

procedures. Independent nursing practices must be based on the principles of health service needs and / or nursing in a region. Based on the legislation mentioned above, the independent practice permit granted to the nurses has been regulated in a number of rules, starting from the highest rules, namely the 1945 Constitution through to the most specific rules, namely Law No.38 of 2014 concerning Nursing. Permission is given to the nurses with consideration to further improve the quality of health services as supported by the health resources, one of which is a nurse. Nursing services are given independently based on the delegation of authority, assignments in certain circumstances of limitations, assignments in emergencies or in collaboration. Thus, giving permission to practice independently to nurses is a part of fulfilling human rights, especially the right to health, which is the responsibility of the state which is manifested in the form of health development directed at improving the welfare of individuals, families and communities by promoting healthy living habits.

3.2. Nurses 'authority in independent nursing practice

Nursing is an integral part of health services, which are an essential service to increase the lives of individuals, families and communities. A nurse is someone who has passed through nursing education, both domestically and abroad, that is recognized by the government in accordance with the provisions of the Laws and Regulations.

The nurse has the authority to carry out nursing. Nursing is a form of professional health service and it is an integral part of health services based on knowledge and the nursing skill in the form of a comprehensive biopsy-socio-spiritual service, shown to individuals, families, and communities both sick and healthy which covers all related processes. According to the results of the 1983 national nursing workshop, nursing is 'a form of professional service that is an integral part of health services based on science and nursing tips, in the form of comprehensive bio-psycho-socio-spiritual services, aimed at individuals, families and communities'. Furthermore, based on Article 1 paragraph 1 of the Law on Nursing, the notion of nursing is "the activity of giving care to individuals, families, groups, or communities, both in sick and healthy conditions".

4. Discussion

Nursing services are carried out as an effort to achieve health improvement, disease prevention, healing, recovery and health care. This is in line with the goals of nursing which include helping individuals to be free from the health problems faced by inviting the individuals / families to participate in improving their health and helping individuals / families to develop their potential to maintain health as optimally as possible so then they do not always depend on others in maintaining health.

The function of the nurse consists of independent functions, interdependent functions and dependent functions. The independent function means that the nurses do not need a doctor's command in carrying out their nursing duties. The nurse is independently responsible for the consequences arising from the actions taken. Examples of nurse actions in carrying out dependent functions are assessing the entire health history of the patient / family and physically testing them to determine their health status, identifying possible nursing actions to maintain or improve health, helping patients in carrying out their daily activities and supporting the patients to behave naturally.

The interdependent function of the nurses is based on collaboration with other health teams. Therefore, this interdependent function appears when people collaborate with other health workers,

such as doctors, when seeking patient recovery. In this collaboration, patients become the main focus of the health services. The nurse's dependent function occurs when the patient acts to help the doctor in providing medical services and special treatment, as the authority of the doctor. Examples of nurse dependent functions are to give infusions and injections, as well as the administration of drugs. Therefore, the responsibility for action is in the hands of the doctor.

The roles of the nurse includes implementing nursing services, managing the field of nursing services and nursing education institutions, improving the education in the science of nursing, and conducting research and development in nursing science. Implementing nursing services brings in the consequence of the nurses being responsible for providing nursing services both simple and complex to individuals, groups and communities. The role of care as a manager in the field of nursing services and nursing education institutions makes the nurses accountable in terms of nursing administration in managing the nursing services for individuals, families, groups and society. The role of nurses in education and in nursing science makes the nurses accountable in terms of education and nurse teaching for other health workers. The role of nurses as researchers and as the developers of nursing science makes the nurses have an obligation to do research to develop care science and to improve the practice of the nursing profession, especially service, education and nursing administration.

Based on the Law on Nursing, nurses have the authority to establish an independent practice. The definition of nursing practice is regulated in Article 1 paragraph 4. It is stated that "nursing practice is a service organized by nurses in the form of nursing care." The notion of nursing care is regulated in Article 1 paragraph 5 of the Nursing Law. The law defines nursing care as "a series of nurse interactions with clients and their environment to achieve the goal of fulfilling the needs and client's independency in caring themselves". Furthermore, based on Article 18, nurses who conduct nursing care are obliged to have STR. The STR is issued by the Nursing Council. Meanwhile nurses who want to carry out independent practice have the obligation to have a license or SIP, as stipulated under Article 46 paragraph 1 of the Law on Health Workers. In addition, based on article 46 paragraph 3, a license is issued by the district/city government on the recommendation of an authorized health official in the district/city. The obligation to have license is also regulated in the Nursing Law. Article 19 points 3 and 4 stipulate that for establishing an independent nursing practice, it is mandatory for nurses to have license or SIPP. SIPP is issued by the district/Regional Government.

In carrying out independent nursing practices, nurses have several authorities as stipulated in the Nursing Law. The authority given to the nurses comprises of (1) Conducting treatment for common diseases under the circumstances that the medical personnel is not available; (2) Referring patients based on the framework of the referral system; and (3) Carrying out limited pharmaceutical services under the circumstance that the medical personnel is not available.

The authority of nursing practices has also been regulated in the Regulation of the Minister of Health of the Republic of Indonesia No. HK.02.02 / Menkes / 148 / I / 2010 concerning the Permit and Implementation of Nurse Practices. This regulation states that the authority of the nurses is "the right of autonomy to carry out nursing care based on ability, level of education, and position of health facilities." Based on the Minister of Health's Regulation, nursing care covers perinatal, neonatal, child, adult and maternity nursing care.

There are fifteen categories of authority in carrying out nursing practices. They consist of (1) conducting basic assessments of individuals, families, groups and communities in health facilities; (2) carrying out further studies on individuals, families, groups and communities at health facilities; c. conducting data analysis to formulate further nursing diagnoses for individuals, families, groups and communities at health facilities; (3) planning simple and complex nursing actions for individuals, families, groups and communities at health facilities; (4) performing nursing actions according to the level of difficulty, such as basic nursing actions in categories I, II, III and IV; (5) conducting complex nursing actions in categories I, II, III and IV; (6) conducting health education: (7) arranging extension programs with simple methods for individuals, families, groups and communities; (8) conducting counseling on individuals, families, groups and communities; (9) conducting health counseling activities for individuals, families, groups and communities; (10) conducting medical actions as delegation of authority / abundant tasks based on their abilities; (11) conducting outside authority in life-threatening emergency conditions in accordance with the applicable provisions (standing order) at health facilities; (12) under certain conditions, when there are no competent personnel, nurses are authorized to take health actions outside their authority; (13) to conduct nursing evaluations; (14) to conduct simple nursing evaluations in the community; and (15) to conduct complex nursing evaluations on individuals, families, groups and communities at health facilities.

Meanwhile, in carrying out nursing practices, they will be granted authority based on their competencies. These competencies comprise of independent competencies, namely the ability of professional nurses to practice based on their level of ability. There are also delegation competencies that are delegated abilities from the professional nurses to vocational nurses and the delegation of abilities from the medical personnel to the nurses. Expanded competency is the ability of the professional nurses to take certain actions after the person concerned has received special training and experience.

Related to the duties and authority of nurses as stipulated in the Nursing Law, the limitations of the authority between the nurses who perform tasks in health care facilities and the duty of the nurses who carry out independent practices are very important. The limitation is pivotal because it has implications on the doctor's authority who grant the authorization to practice independently. In addition, it has legal implications on the patients when the health services provided are detrimental to the patients. Who will be criminally responsible when the medical actions conducted either by the doctors or nurses have caused losses or injury to the patient? Based on the concept of criminal law, criminal responsibility is personal responsibility. It cannot be delegated to doctors or other health service workers.

5. Conclusion

In Indonesia, the legal basis for nursing practice is regulated under the Indonesian 1945 Constitution as well as Law No. 38/2014 on Nursing. The consideration to provide independent nursing practice licenses is to improve the quality of health services in Indonesia through the support of health workers, such as nurses. The health services provided by the nurse are derived from the delegation of authority. Nurses are allowed to deliver health service practices in certain circumstances and under limitation. For example, during emergency circumstances as well as in collaboration with doctors or dentists. Thus, giving the nurse authority to have an independent practice is a part of the state's responsibility to fulfill the public's right to health.

The authority to carry out independent nursing practices is regulated under Law No. 38/ 2014 on Nursing. Nurses have several authorities as stipulated in the Nursing law. The authorities include: a. conducting treatment for common diseases in the case where there is no medical personnel; b. referring to patients according to the terms of the referral system and c. carrying out limited pharmaceutical services in the case where there is no medical personnel. There are no regulations specifically regulating the authority of independent nursing practice. In the future, there needs to be special rules that regulate the practice of independent nursing.

A SYSTEMATIC REVIEW ON HOSPITAL: DEPENDENT FACTORS THAT INFLUENCE OF DISCHARGE PLANNING

E A Rahayu[1], Nursalam[2], Fitri Chandra
[1]Master Student, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
[2]Lecturer, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
E-mail: elmirahayu04@gmail.com

ABSTRACT

Discharge planning is a routine activity in the health care system that aims to reduce the length of stay in the hospital, and to improve coordination of services after being discharged from the hospital to home or to other units. The purpose of this study was to analyze factors that influence implementation of discharge planning in the hospital and to give recommendation of monitoring and evaluation discharge planning. The journal had searched multiple databases: DOAJ, Sage, Proquest, Medline, Google Scholar, and Science Direct. It used limited time in January 2013 to December 2018. From 1315 article, only 15 articles that suitable with the inclusion criteria. Systematic reviews obtained from 15 medical journals showed various factors that influence the application of discharge planning in hospitals. These factors include factors from health workers or nurses and factors from patient also their family.

Keywords: discharge planning, nurses, patient, patient's family, hospital

1. Introduction

Discharge planning is the development of a personalized plan for each patient who is leaving the hospital with the aim of containing costs and improving patient outcomes (Gonçalves-Bradley et al, 2016). Areas of discharge planning that are frequently missed by nurses include the patient's admission assessment, the coordination of the completion of different discharge planning elements, referral to allied health and community services, and communication within the multidisciplinary team and the patient and their family (Graham et al, 2013). Discharge planning should ensure that the patients leave the hospital at an appropriate time in their care and that, with adequate notice, the provision of post-discharge services will be organized. In its implementation, there are still obstacles in the process of discharge planning, namely communication problems, the limited family capacity to care for patients at home, and plans for follow-up and commitments that are less effective between the health workers, the patients and also their families.

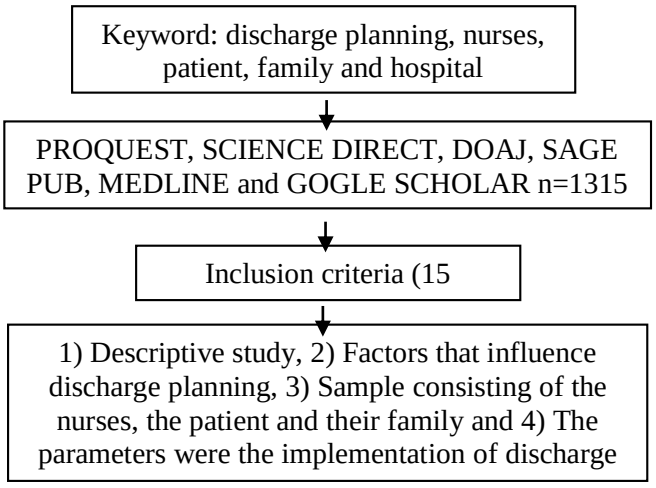
For simple discharges carried out at the ward level, the process should be standardized throughout the entire hospital. The key to making this or any process work consistently in an organization is to adapt it to fit the existing systems and processes. It is helpful to involve the patients and their families in this process. In elective care, planning can commence before admission and it may take the form of a screening tool, risk assessment or care pathway. The principle is to anticipate potential delays and to manage these in a proactive manner. With the advent of the care pathway and the renewed focus on end-of-life issues, care pathways exist to facilitate rapid discharge for patients at the end of life on admission to acute services.

In an emergency and in terms of unscheduled care, advance planning is not possible. Therefore robust systems to gather patient information must be in place - pivotal sources for such include the general practitioner, the primary care team and the carers.

2. Materials and Methods

The purpose of this study was to analyze the factors that influence the implementation of discharge planning in the hospital and to provide recommendations for the monitoring and evaluation of discharge planning. The journals were searched for from within multiple databases: DOAJ, Sage, ProQuest, Medline, Google Scholar, and Science Direct. The search used a limited time frame for inclusion from January 2013 to December 2018. From the 1315 articles, only 15 articles were suitable according to the inclusion criteria for the article. The inclusion criteria was as follows: 1) descriptive study, 2) factors and variable that influence the discharge planning, 3) the sample consisted of nurses, the patient and their family and 4) the parameters were the implementation of discharge planning at the hospital. The papers were critically reviewed and the relevant data was extracted and synthesized using an approach based on the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA).

Figure 1 - Summary of the Literature Search



3. Result

The systematic review obtained 15 medical journals that showed the various factors that influence the application of discharge planning in hospitals. The purpose of this study was to analyze the factors that influence the implementation of discharge planning in the hospital and to provide recommendations for the monitoring of discharge planning. Nurses have significant factors associated with them to provide the best discharge planning for patient and their family. The factors from the nurses include knowledge, attitude, skill, psychologists and experience.

4. Discussion

Waring (2014) said that workplaces are where different professional and stakeholder perspectives are brought together in discharge planning and that value face-to-face and interpersonal interactions have been found to involve a better shared understanding about patient care and coordination. It also has the ability to generate a more comprehensive discharge plan [1]. General internal medicine (GIM) units have a high volume of patient admissions given the concomitant pressure of patient in- and outflow [2]. These units have been characterized as extremely busy workplaces with high professional stress, burnout and time pressures present [3]. Discharge planning in GIM units can be particularly complex given the multi-faceted and challenging nature of the patients' healthcare needs and the range of healthcare professionals involved in their care.

Over the last few decades, healthcare systems in Western countries, such as Australia, Canada, the United Kingdom and the United States have witnessed an expansion of management influence over professional activities. A managerial approach that has emphasized task completion and outcomes in the pursuit of evidence-based, cost-effective and efficient care is dominant. This approach affects the range of professional groups in GIM and healthcare more broadly, as they defend or adapt their professional boundaries and roles to these demands.

The other factors that impact successful discharge planning are the patient and their family. The other factors include motivation, attitude, anxiety, psychologists, knowledge, the ability to learn, and their level of education.

Combining with sound patient care and follow-up mechanisms, a discharge-planning service can be complete and effective for patient care. The following studies supported the view. Phillips (2004) said that comprehensive discharge planning plus post-discharge support can reduce medical costs, reduce the rate of re-hospitalization and improve quality of life, but not for all causes of mortality or in relation to all initial lengths of stay for older patients with congestive heart failure by meta-analyzing eighteen studies [4]. The discharge planning intervention in the patients with a percutaneous transluminal coronary angioplasty can increase patient satisfaction and reduce the fourteen day risk of post-discharge readmission, the fourteen days post-discharge risk of emergency treatment, and an increased hospital length of stay [5]. A systematic review showed that telephone-based post-discharge nursing care can decrease the re-admission rate in patients with heart failure [5]. The thematic-analysis of nineteen randomized controlled trials (RCTs) also supported that heart failure management programs with nurse-driven pre-discharge interventions had the potential of reducing hospital re-admission [6].

Except for the objective indicators "post-discharge readmission, post-discharge with an emergency treatment, and the hospital length of stay", the subjective indicator "the satisfaction of patient or caregiver" is also important in the effective assessment of discharge planning. For the caregivers of the home-care clients, the items of dissatisfaction were financial aid (income tax reductions, living cost subsidies, medical expenses, fees for aides and medical devices), services (rehabilitation, nursing consultancy when needed, and transportation) and the information and skills

needed to support caring [7]. Higher levels of patient satisfaction are achieved by offering more nursing teaching, medical transfer and social services [8].

After controlling for the other variables, the adoption of a care plan and the discharge locations were the factors associated with the re-admissions of stroke patients. Increasing home nursing resources to meet the demand for wound nursing care may reduce re-admission [9].

It was also concluded that coaching chronically ill older patients and their caregivers to ensure that their needs are met during care transitions may reduce the rate of subsequent readmission. A Discharge Decision Support System was helpful to use to identify high-risk patients who are recommended for post-acute referral services. This resulted in a reduction in the rate of readmission [10]

The parameters used to evaluate the application of preceptorship were obtained from the questionnaire instruments, checklist observation sheets, and interview sheets. The phenomenon from within many journals indicates that discharge planning in hospitals requires special attention in its implementation. Optimizing the various factors that influence the effectiveness of the application of discharge planning can increase the effectiveness of communication between the nurses and patients and also their family to increase the quality of the health services.

5. Conclusion

Comprehensive discharge planning plus post-discharge support can reduce medical costs, reduce the rate of re-hospitalization and improve quality of life. Discharge planning is a complex activity, particularly in the context of new services offered outside of the hospital like intermediate care, and having a population of increasingly older people who often have extremely complex care needs. Preparation for discharge is a multidisciplinary effort. Nursing staff have the primary responsibility for discharge teaching, which consists of the educational interventions used to prepare the patient and their family members or caregiver with the knowledge and skills needed to assume care as the patient transitions from the hospital to their home.

THE RELATIONSHIP BETWEEN SPIRITUAL INTELLIGENCE AND LEVEL OF STRESS ON OLDER ADULT

A D D B Anggraini[1], Supriyadi[1]
[1] Faculty of Nursing, StiKes Surya Global, Yogyakarta, DIY, Indonesia
E-mail: syaliva@gmail.com

ABSTRACT

Older adult is those who has each age 60 years. In that period, feeling comfortable will be gained by those who possess a sense of acceptance of their present condition. The aims of this study was to reveal the relationship between spiritual intelligence and the level stress on older adults. This research used Quantitative Descriptive with Cross Sectional approach as research design. The sample of this research was taken by applying Sampling Purposive technique and using inclusive criteria for age, susceptibility, education, will to be a respondent, active speaking Indonesian, good physical health, active religious activities and exclusive criteria. The sample size was 40 respondents. The data were analyzed by Kendall Tau test. The instruments of this research was Spiritual Intelligence Self Report Inventory (SISRI) and questionnaire Depression Anxiety Stress Scale (DASS). The result of Kendall Tau correlation test 0,000 ($p<0.05$), which means that there was a relationship of Spiritual Intelligence with Level of Stress by Elderly. It is found that there was a relationship of spiritual intellegence towards the level of stress for Elderly. The high level of spiritual intelligence will reduce stress levels in older adult.

Keywords: spiritual intelligence, level of stress, elderly

1. Introduction

According to the Republic of Indonesia No.12 of 1998, an older adult (elderly) is someone who has reached an age that is above 60 years old. The WHO data also estimates that 75% of the world's elderly population in 2025 is in developing countries. The results of the 2010 population census showed that Indonesia is among the top 5 countries with the largest number of elderly population in the world.

One of the ways to increase stress immunity is religion. Someone who is religious should not just be more formal, but they should be someone who is more capable of living and practicing his religious beliefs, so he gains strength and calm from him. A religious activity that is associated with decreasing the return of stress is a psycho-religious approach. For the followers of religion (Islam), this can be done by carrying out the obligatory prayer 5 times, coupled with the evening prayer (tahajud) accompanied by prayer and dhikr[1]

The results of a preliminary study conducted in the congregation of Asem Legi Sragen Islamic Boarding School on December 21st, 2015 were gained by interviewing 10 elderly people in Asem Legi Islamic Boarding School Sragen. From the interviews with the 10 elderly individuals, data was obtained; 9 elderly said, "*I could not sleep when this problem I faced*." 5 elderly people said, "*I was easily angry because of small and trivial things after getting into a problem that I told*." 4 elderly

people said, "*I feel sad about what happened to me*." 4 elderly people said, "*I feel embarrassed because of the incident*. "3 elderly people said, "*I feel suspicious and easily offended by other people. I feel they are talking about me*." And 2 elderly people said, "*I am afraid to face people and meet many people because of my shame*. " The data is related to the feelings of the elderly when the problem first arises. The symptoms of stress experienced by the elderly are being unable to sleep, and feeling anxious, suspicious, irritable, and afraid.

After facilitating the interviews related to the problems faced by the elderly, the author gave an interview related to the spirituality that the elderly worked on, especially praying, remembrance and acceptance of God Almighty. From the results of the interviews, data was obtained; 10 elderly said to the effect of, "*I diligently prayed 5 times. I diligently took part in the recitation at AsemLegi Islamic Boarding School. I feel comfortable with dhikr and praying which makes me feel close to Allah SWT.* Then, 9 elderly people said,"*I began to accept the problems I faced*." 6 elderly people said," *I started self-introspection after experiencing the problem.* "10 elderly people said, "*Maybe this is a trial from God to his servant*." 4 elderly said, "*This is a warning that God gave me*." 2 elderly people said, "*I began to be careful in acting*." 8 elderly people said, "*God will test his servant to adding to goodness*. Finally, 9 elderly said that," *By praying, praying and dhikr is my strength in facing problems and being more patient*.

The elderly are vulnerable to psychiatric disorders and tend to experience stress. This is in accordance with the theory of [2**],** in that the problem that commonly occurs in the elderly in psychological aspects is stress. Based on [3]'s theory, it was stated that religious approaches can increase immunity to stress.

Based on the above background, the researcher was interested in researching further with the title "The Relationship of Spiritual Intelligence with Stress Level in the Elderly in the Congregation of Asem Legi Sragen Islamic Boarding School."

2. Material and methods

2.1 Research design, population, sample, and variables

The design was quantitative descriptive with a cross-sectional design. The population in the study were the subjects (for example, humans, also known as clients) who met the criteria that had been set [4]**.** The population in this research were all of elderly who were worshipers in Asem Legi Islamic Boarding School. The sample obtained 40 respondents through purposive sampling. This research was conducted at Asem Legi Islamic Boarding School of Sragen in Central Java in January 2016. The inclusion criteria in this research was as follows: 1) Elderly aged 60 years – 70 years, 2) Elderly whose last level of education was junior high school – senior high school, 3) Elderly who could communicate in the Indonesian language active and fluently, 4) Elderly were routinely attending religious activities and 5) Healthy. The exclusion criteria were 1) Elderly were hospitalized, 2) Elderl was travelling and 3) the elderly has a chronic disease. The independent variable was spiritual intelligence and the dependent variable was the level of stress.

2.2 Instruments

Spiritual intelligence was measured using a questionnaire whose name was SISRI. SISRI consisted of information about *Critical Existential Thinking*, *Personal Meaning Production*, *Transcendental Awareness* and *Conscious State Expansion* as written by [5] which was modified by [6] and

translated into the Indonesian language. The number of questions totaled 24 to be answered using a Likert scale. This questionnaire was tested for validity and reability with a Cronbach's alpha level of 0.92. The instrument for level of stress was the DASS questionnaire by [7], modified by [8] and translate into the Indonesian language. The number of questions totaled 42 items to be answered using a Likert scale with a score of low 0-14, middle 15-28 and high 29-42. The questionnaire was tested for validity and reability with a Cronbach's alpha result of 0.91.

2.3 Research procedures and analysis

This research was conducted in Asem Legi Islamic Boarding School to find out the correlation level of stress and spiritual intelligence in the elderly. The first study in this research was carried out by conducting a preliminary study. The second time around, the researchers interviewed the elderly. Third, the questionnaires were distributed to measure spiritual intelligence and the level of stress in the elderly. The data was analyzed using SPSS and Kendal Tau with an alpha of 0.05.

3. Result

The characteristics of the respondents in [Table 1] showed that all of the respondents were elderly and that the majority were female. The majority of the respondents had their last level of education as being senior high school. All of the respondents were staying in Asem Legi Islamic Boarding School and they routinely attend religious activities. During the interview session, the eldery shared about the changes when they routinely attended the religious activities (dzikr, prayer, khutbah). There is deep tranquility that you can use to control the stressful thoughts that are felt by getting closer to Allah.

The majority of the respondents in the Asem Legi Islamic Boarding School who were respondents in this study were 60 - 65 years old. Those in the vulnerable criteria totaled 24 people or 60%, while those aged 66 - 70 years who were vulnerable totaled 16 people or 40%. Those who were male made up as many as 19 people or 47.5%, while the female sex made up as many as 21 people or 52.5%. Furthermore, the criteria for junior high school education was so for as many as 17 people or 42.5%, while high school education totaled 23 people or 57.5% [Table 1]. The distribution of the elderly spiritual intelligent as in [Table 2] showed that the respondents have a low spiritual intelligence level of 10% or as many as 4 people, moderate spiritual intelligence of 77.5% or as many as 31 people, and high spiritual intelligence of 12.5% or 5 people. The distribution of the elderly level of Stress on [Table 3] showed that the majority of respondents have low stress levels of 100% or 40 people.

The result of the analysis of spiritual intelligence and level of stress using the Kendal Tau test as in [Tabel 4] showed that the result was significant $0.000 < 0.05$. It can be concluded that there is a significant correlation between the variables. The correlation coefficient was -.467*, so the value (-) of the correlation coefficient explains that the variables are contras. When the spiritual intelligence is high, then the stress level will be low. If the spiritual intelligence is low, then the level of stress will be high.

4. Disscusion

The spiritual intelligence of the elderly in the congregation of Asem Legi Islamic Boarding School in the high category totaled 5 elderly (12.5%), the moderate category totaled 31 elderly (77.5%) and the low category totaled 4 elderly (10%). This means that the spiritual intelligence of

the majority of the elderly was of a high and moderate condition. The spiritual intelligence of the majority of the elderly was high and medium because religious activities were carried out in Asem Legi Islamic Boarding School. The elderly approach God Almighty and strengthen themselves in worship such as through prayer, dzikir, and listening to da'wah.

The results of the research by [9] providing cognitive behavioral therapy that leads to spirituality. He stated in his journal that cognitive behavioral therapy can improve spiritual well-being; it would help the elderly to accept their sadness and emotional depletion when the elderly were in mourning. [10] said that the relationship between spirituality and old age occurs through the capacity to bear the limitations, difficulties and disadvantages that are inherent in the process. The nature of living a spiritual life is observed to be heterogeneous, while all have the same recognition of the importance of living in old age with a good quality of life.

[11] said that if there was a basic intervention in terms of security for the elderly in the nursing home, then there would be a difference. It can be seen from the depressive symptoms that there shoud be an increase in the quality of life of the elderly who are in a nursing home. In this study, the intervention given was a recital of Al Quran and a sermon.

The level of stress in the elderly in the congregation of the majority of AsemLegi Islamic Boarding School was in the low category, which totaled 40 elderly (100%). The stress level of the elderly is low due to a sense of acceptance and being able to adjust to the changes that they are experiencing with a positive attitude. Besides that, judging from the characteristics of education, it supports the mindset of the elderly who are able to choose better coping methods when solving their problems.

[12] conducted a study stating that the one in two parents experience at least one mental disorder during their lifetime. [13] said that the elderly generally experience anxiety which can lead to depression. The conclusions in his study indicate that there is a higher prevalence of anxiety and somatic symptoms in Indonesia than in the elderly among Indians.

The research conducted related to stress levels in the elderly with a low majority is in line with the research conducted by [14], which states that elderly parents have low and moderate stress levels because the elderly make the health problems or changes in their physical condition or problems in the family as a pressure on their life and thus this can interfere with their level of independence.

5. Conclusion

The elderly in AsemLegi Islamic Boarding School did regular religious activities during the religious process resulting in the elderly feeling happy. The elderly felt that they didn't have it as tough as before. The elderly had a feeling of surrendering to Allah and believing that their life is arranged by Allah. The elderly executed dhikr, prayer and listened to dakwah. They were patient and tolerant. Stress in life that is not balanced with spirituality will have a negative impact on the elderly. When the elderly have high spiritual trust in Allah, then their stress will decrease.

THE ROLE OF GOOD WORK ENVIRONMENT TO DECREASE BURNOUT SYNDROME: A SYSTEMATIC REVIEW

F N Putra, R T Ardiansyah, and H Soebagiyo
Master Student, Faculty of Nursing Airlangga University, Surabaya, Indonesia
Email: fetreonegeo@gmail.com

ABSTRACT

Nurse are the largest component of health care who have the important role. Stressor in nursing profession sometime make them fatigue until they falls in burnout condition. Burnout syndrome is the effect due to the fatigue of work both physically and mentall. Required actions or policies to lower the burnout syndrome in nurse because it can impact in health care quality. Environment is an important aspect in organization to make a good work performance. Important to make sure that is an organization have a good environment. This paper present a systematic review that examined the role of work good environment for decreasing employee's burnout syndrome. The database namely Scopus, SAGE, Proquest, Science Direct, PubMed were accesed to get relevant study with keyword good work environment, burnout syndrome, nursing workload. This search identified 15 relevant research article published between 2014-2019. The Result showed that good work environment have an important role to decrease burnout syndrome in nursing profession. Eight for 15 article said that good environment plays a important role to decrease burnout syndrome. Good work environment make nurse comfort and enjoy to do there job so it can make reduce statistic of burnout syndrome in nursing profession.

Keywords: good work environment, burnout syndrome, nursing workload

1. Introduction

Nursing is one profession that is not easy to do. Nurses seem to be especially vulnerable to stress and burnout because they often work in a particularly stressful environment that it is related with people's lives and safety[1]. In a study focused on nurses from nine countries, it showed that 33% to 60% of nurses reported a high level of burnout syndrome. Thailand had reported the highest level of burnout syndrome at 41% out of all nurses in Thailand. A study in Shanghai, China, showed that 527 nurses from 41 hospitals reported high emotional exhaustion, moderate depersonalization and low reduced personal accomplishment. The magnitude of this workload could grow when not supported by the working environment, health institutions and where the wage policies add to the problem. The burden must be shouldered by a nurse that has a good coping system, otherwise burnout syndrome will happen[2][3].

Burnout syndrome is conceptualized as the feeling of emotional exhaustion, depersonalization and reduced personal accomplishment that can occur among individuals who work with people in some environments or organizations[4]. High levels of stress in a nurse can be caused by an exhausting work routine, the number of patients who have to be serviced and pressure from their manager who

sometimes adds to the burden that causes the declining performance of the nurses. The nurse's role is very important in primary health care services in the hospital, where a nurse must be able to adapt quickly to high pressure, and they should not be confused when providing services[5].

The consequences that can arising from burnout in the nursing field are very diverse, including emotional exhaustion, depersonalization and a loss of the personal accomplishment[6]. Practically, this can be seen in everyday nursing practices. One example is the length of working hours (shift) that a nurse has to handle as well as a large number of patients. The longer the working hours of the nurses, then the risk of the occurrence of an error or accident the work will grow. One of the studies showed the impact of burnout on family conflicts which, when elaborated on further, shows that the conflict caused by the dimensions of time, stress and changes in behavior[7]. Therefore, there needs to be action or regulation to minimize the occurrence of burnout.

Almost one-third of our lives is spent in the workplace, where much of our interactions with other people can make for a stressful situation[8]. Stress is defined as a relationship or transaction in terms of adaptation and the interactions between a person and the setting or environment that can place a burden on individual well-being and lead to psychological disorders, unhealthy conducts and ultimately, disease [9]. The nursing work environment has been studied for decades. The existing research confirms that a safe, positive work environment is related to improved patient outcomes, staff satisfaction and retention[10]. A safe work environment for a nurse is characterized by, among other factors, good professional relations, a supportive management style, a balanced work schedule, concordance between the nurses' increased workload and the nurses' skill-mix, adequate enough time to meet the patient's needs, professional autonomy, adequacy of the resources and opportunities for professional advancement.[11]

In several studies, it has been reported that a positive work environment is associated with fewer occupational injuries, less burnout and increased job satisfaction. On the other hand, a negative nurse work environment may lead to poor patient outcomes, such as increased mortality and complications and increased healthcare costs.[12]

2. Research Methods

2.1 Search Strategies

The writer in this study chose burnout syndrome as the topic. Factually, this specific condition is an unsolved problem in the management of nursing studies up until now. Furthermore, we determined some of the keywords to make easy to find the literature we were looking for. The keywords were: good work environment, burnout syndrome and nursing workload. Qualified international journals were involved to provide some of the information, including Scopus, Science Direct, Elsevier, Proquest, Pubmed and SAGE. The studies focused on were those published between 2014 and 2019 on the topic of nursing management as the limitations.

2.2 Selection Criteria

The inclusion criteria of the article that we chose in the systematic review were as follows: 1) international journals in which the studies were published in English, 2) studies on the effect of a good work environment on nursing burnout syndrome, 3) the subject of the study was nurses and health workers and 4) The location of the studies was in a hospital.

2.3 Data Extraction

In the next activity, we explored 1034 articles and decide to deeply explore 15 articles according to the inclusion criteria. They had to be studies published in English, research studies (prospective, cross-sectional, systematic review and meta-analysis) and studies that wrote about nursing burnout syndrome and the effect of a good work environment on burnout syndrome.

3. Results

In total, 1034 articles were found from searching the literature, of which 935 articles were excluded after we reviewed the title. Following the review of the abstract, a further 66 articles were excluded. Then we reviewed the full text of the articles. Finally we choose 15 articles according our inclusion criteria. A further 15 articles were included after we reviewed their full text. This systematic review included two descriptive correlational studies, one systematic review, one meta-analysis study and six cross-sectional studies.

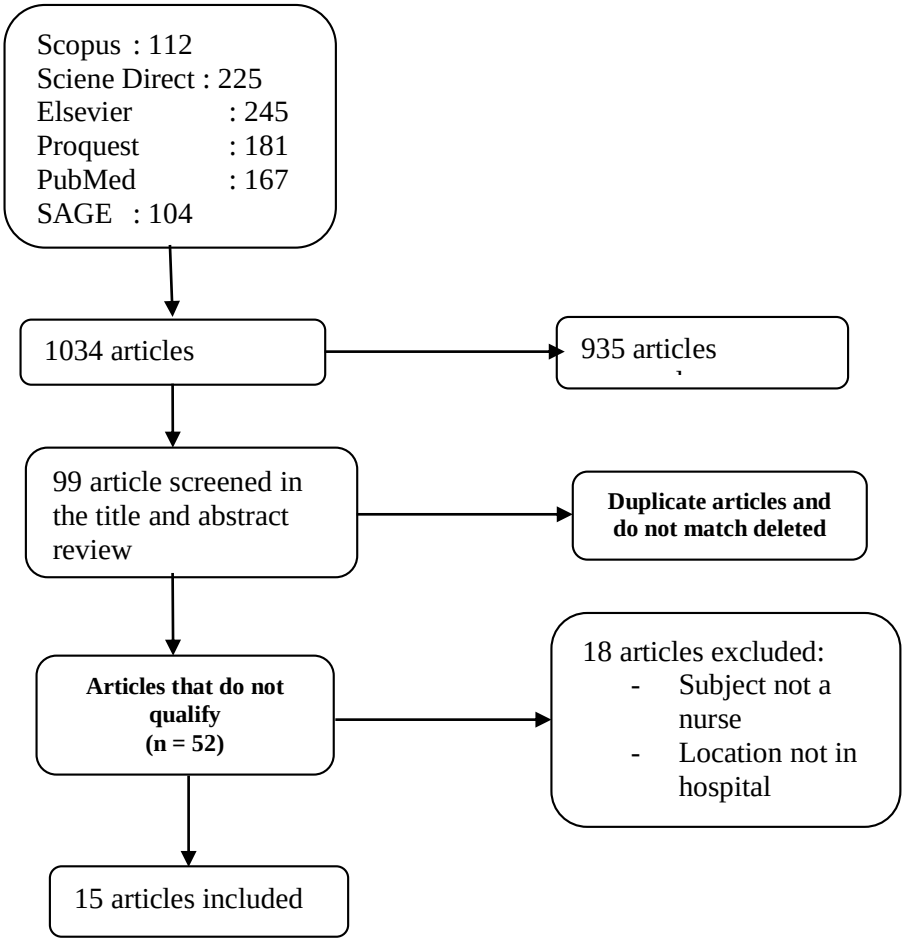

Figure 1. Flow chart of the literature search process

Title, Author, Year	Study Design	Sample	Measurement/Instrument	Reliability Cronbach's	Validity	Analysis
Nursing unit teams matter: Impact of unit-level nurse practice environment, nurse work characteristic, and burnout on nurse reported job outcomes, and quality of care, and patient adverse events-A cross-sectional survey (Peter Van Bogaert, Olaf Timmermans, Susan Mace Weeks, Danny van Heusden, Kristien Wouters, Erik Franck, 2014)	Cross-sectional design with survey	1108 nurse assigned to 96 nursing units	The Nursing Work Index Revised (NWI-R), adapted for our samples, tapped into three dimensions of nurse-physician relations (3 items), nursing management at the unit level (13 items), and hospital management and organizational support (15 items)	Cronbach's alpha of 0.05	Cronbach's alpha	Descriptive statistics and intra-class correlation coefficient (ICC)
Burnout syndrome and demotivation among health care personnel. Managing stressful situation: The Important of teamwork (J.Garda-Campanyo, M. Puebla-Guedea, P. Herrera-Mercadal, E. Dauden, 2016)	Descriptive analytical study	Data was collected by survey focused on the condition of quality of life at work in the European union	To measure burnout syndrome, this article used Maslach's Burnout Inventory (MBI)	Not Reported	Nor Reported	Not Reported
The association of the Chinese hospital work environment with nurse burnout, job satisfaction, and intention to leave (Li-feng Zhang, phD, 2014)	Retrospective secondary analysis	The study was conducted on 9698 nurses in 181 hospitals in China	The intervention provided was by providing a questionnaire where instrument fatigue nurses were measured using the Maslach Burnout Inventory (MBI), while nurse satisfaction was	Cronbach's alpha of 0.05	Not Reported	Chi-square test was performed to examine the percentage difference of high

			measured using nine questionnaire items with 4 point Likert-type scales (1 = very satisfied, 2 = satisfied, 3 = slightly disappointed, 4 = very disappointed)			burnout, job dissatisfaction, and intention to leave inn hospital with poor, mixed, and good work environment, then logistic regression models were performed to estimate the influence of hospital work environment on nurse burnout
Burnout among nursing professionals in tertiary care hospitals in Delhi (Yashika Negi, Rajni Bagga, 2015)	Descriptive study	A total of 200 staff nurses from two randomly selected hospital in New Delhi	Questionnaire. To measure burnout syndrome, this article used the Maslach Burnout Inventory (MBI)	Reliability test was performed on the five constructs using Cronbach's alpha values, and the values were 0,05	The validity test was performed using an independent t-test and one-way analysis of variance (ANOVA)	The data was analyzed using the statistical package for social science (SPSS) version 17
An examination of the correlation between the nurses' organizational trust and burnout levels (GonulOzgur, Pinar Tektas, 2018)	Descriptive and relational study	This study used 155 nurses as the sample who accepted to participate in the study and who had been working in the	Data collection was conducted by two questionnaires; the Organizational Trust Scale (OTS) and the Maslach Burnout Inventory (MBI)	Cronbach's alpha of 0.05	Not reported	ANOVA, t-test, Pearson correlation coefficient, and Poisson regression via SPSS 20.

		institution for at least 1 year				
Practical environment scale of the nursing work index: a reliability generalization Meta-Analysis	Meta-Analysis	This study used 157 articles which were independently reviewed by the primary and secondary authors of the meta-analysis	Questionnaire survey about healthy work environment using the Practice Environment Scale of the nursing work index (PES-NWI)	Cronbach's alpha ranged from 0.904 to 0.936	Not knowing	The comprehensive Meta-analysis version 2.0 (Borentein, Hedges, Higgins, & Rothstein, 2005)
Relationship between authentic leadership and nurse intent to leave: The mediating role of work environment and burnout (Huan-Fang Lee, Hui-Yin Chiang, Hui Ting Kuo, 2017)	Quantitative research method - cross sectional	The total respondents were selected purposely from among 946 nurse from three different levels of hospital (medical center, regional, district)	The Authentic Leadership Questionnaire (ALQ) was used to measure the nurse's perception of their leaders' authentic leadership and the Practical Environment Scale of the Nursing Work Index (PES-NWI) was used to examine the nurse's perception of the environment in the hospital-based setting	Cronbach's alpha scores were 0.96 overall. 0.91 for self-awareness, o.90 for relational transparency, 0.85 for internalized moral perspective and 0.87 for balance processing	The indicator of validity was CFA, which resulted in 0.97 for CFI and 0.06 for the standardized root mean square residual (SRMR)	Descriptive statistic, correlation, and tests of reliability were conducted using SPSS (IBM, 2014a), chi-square and t-test were used to compare differences between junior and senior group
Psychological work environment and suicidal ideation among nurse in Taiwan (Wei-shan chin, Yi-chuan chen, 2018)	Quantitative research method - cross sectional	The total number of respondents were selected purposely among 2734 eligible questionnaire were returned	The Practical Environment Scale of the Nursing Work Index (PES-NWI) was used to examine the nurse's perception of the environment in the hospital-based setting. Maslach's burnout inventory (MBI) was used for measuring burnout syndrome	Not reported	Not reported	Descriptive statistic, logistic regression was used to examine the association between the covariates and suicidal ideation

Effect of work environment on patient and nurse outcomes (panagiota copanitsanou, Nikolaos fotos, hero brokaki, 2017)	Systematic Review	10 articles that contain information about the work environment and the effect of the outcome	Using PRISMA and including criteria for determining the articles	Not reported	Not reported	Not reported
Job Stress and burnout syndrome among critical care health care workers (Noha Selim Mohamed Elshaer, 2017)	Cross-sectional study	The 82 nurses and healthcare who practice in critical care room were selected Using simple random sampling	Data was collected by an interview questionnaire using selected subscales of the NIOSH Generic Job Stress Questionnaire and the Maslach Burnout Inventory of Health and Human Services Questionnaire	Not reported	Not Reported	The collected data was analyzed using STATA statistical software-version 14
Does the nurses' self-concept mediate the relationship between job satisfaction and burnout among Nigerian nurses (Chidozie E.Nwafor, Euckie U Immanel, Harry Obi-Nwonsu, 2015)	Cross-sectional study	The study was conducted on 170 nurses in 2 health care facilities in Nigeria, where the respondents were nurses in the morning and evening shifts who have 22-50 years old, consisting of 160 female nurses and 10 male nurses	The measurement of self concept used the Nurses' general self-concept (NGSF) which is an instrument developed by Corwin (2000). The questionnaire consists of 6 items and it is arranged into points 1-8, while nurse fatigue was measured using the Maslach Burnout Inventory Human Services Survey (MBI) instrument. -HSS) consisting of 22 items used to measured 3 components of burnout	Not reported	Not reported	Statistical analysis of the data was done using the SPSS software (version 19) and the Pearson r correlation
The Effect of Emotional Intelligence on Burnout in Healthcare Professionals (Laura-Elena,	Cross-sectional research study	The study was conducted on 120 male and female doctors and nurses in	The intervention provided is by providing a questionnaire, where workload and fatigue are measured using the Maslach burnout inventory (MBI),	Not reported	Not Reported	Analyzed by SPSS 11.5 using descriptive statistics;

Anca Daniela, 2015)		Romania who have 26-52 years old	whereas emotional intelligence was measured using the emotional intelligence scale (EIS)			
Effect of personal and work stress on burnout, job satisfaction and general health of hospital nurses in South Africa (Natasha Khamisa, Karl Peltzer, Dragan Ilic, Brian Oldenburg, 2017)	Cross sectional study design	The study was conducted on 895 nurses from 1200 nurses in southern Africa's hospital, where participants comprised 46% black nurses, 85% female nurses, 59% nurses private hospital, 28% nurses aged over 50 years, 72% nurses with diploma diplomas and 27% nurses with experience more than 25 years	Participants were given 6 questionnaires consisting of the Socio-Demographic Questionnaire (SDQ), Chronic Burden Scale (CBS), Nursing Stress Inventory (NSI), Maslach Burnout Inventory-Human Services Survey (MBI-HSS), Job Satisfaction Survey (JSS), and General Health Questionnaire (GHQ-28	Not Reported	Not Reported	SPSS Statistic version 20 which included hierarchic al multiple linear regression
Moral distress and its contribution to the development of burnout syndrome among critical care providers (Renata Rego, Gustavo Adolpho, Andrela de Fatima and Jose Mauro Vieira, 2017)	Cross-sectional study	The study was conducted on 289 out of 389 care providers in the Intensive Care Unit (ICU) and Step Down Unit (SDU) rooms attended by a care team consisting	Interventions were carried out by giving a questionnaire where the measurement of work fatigue data was done using the Maslach Burnout Inventory (MBI) instrument, and the Moral Distress measurements were taken using the Moral Distress Scale-Revised (MDS-R)	Not reported	Not reported	Descriptiv e analysis was performed using mean and SD to compare the variables with a Chi-square test, student t-test, and

		of nurses, doctors and respiratory therapists				Wilcoxon rank-sum test
Structural empowerment, job stress and burnout of nurses in China (JiajiaGuo, MD, Juan Chen MD, Jie Fu MD, Xinling Ge MD, Min Chen MD, Yanhui Liu phD, 2015)	Descriptive and Inferential Research	Sample as many as 1080, but a number of nursing questionnaire that returns a 1002. Samples taken from a tertiary hospital in Beijing, Tianjin, Shanghai, Hangzhou, Changsha, Chongqing of China	Structural Empowerment is measured using Conditions for Work Effectiveness-II (CWEQ-II), Burnout syndrome measured by Maslach's Burnout Inventory	Not reported	Not reported	SPSS 17.0 was used to conduct descriptive and inferential statistic analyses. Structural equation modeling (SEM) AMOS 7.0 statistical program was used to analyze the hypothesized model

4. Discussion

This systematic review looked at the existing studies referring to the effect of a good work environment on decreasing burnout syndrome and increasing the quality of the nursing service. The systematic review showed that there is a positive effect gained from a good work environment from the fifteen articles that met the inclusion criteria from the literature search. A good work environment for nurses is not just meaning good available materials and a clean workplace, but it is characterized by other factors like good professional relations, a supportive management style, a balanced work schedule, and fewer occupational injuries, adequate time to meet their patients, adequate resources and opportunities for professional advancement. Other research said that a good work environment includes adequate resources, good colleagues, and relationship and management support. Another study said that a better work environment was associated with lower burnout, higher job satisfaction and less intention to leave[7].

Almost a third of our lives are spent in the workplace, so it is very important to make sure that our working environment can make the employee feel comfort and enjoy working there, especially in a health worker environment that involves high pressure in the job. The health workers are faced with people with varied problems and from different culture. In a health worker and especially in a nursing environment, we demand a place to be able to concentrate and perform with consistency. This is because patient safety and people lives are at stake, but sometimes the high work burden in the nursing environment puts the nurses at risk of burnout syndrome. This can cause the nurses to lose concentration, become angry at the patient and experience depersonalization which can effect patient safety, so it is important to research and study the literature to know how the relationship between a good work environment and burnout syndrome in nurses works[11]

The purpose of this systematic review was to analyze the studies in which the effects of the nurse

work environment on the nursing burnout and nursing job satisfaction. The majority of our literature showed that nurses who work in a good working environment can enjoy and show good performance. There are three major points that can explain what a good work environment is: 1) physical good work environment, 2) good teamwork and relations and 3) good culture and management. It is important to make sure that the workplace can make an employee enjoy their work and feel comfort annually every time they are there, because almost third of their time is spent in a workplace of one sort or another. The items that are included in a physically good work environment include a clean room, good materials available and a machine in room[1]. Interactions with other people in the same place over a long time can make for stressful conditions if the relationship that the nurse has with other people is not good. Communication and teamwork are the best way to make sure that we can adapt and spent our time positively in the workplace[13]. The management maintains all of the policies in an organization. Their decisions determine the culture and purpose of the organization. Good management can make all of those in the organization, especially the work environment, increase employee performance and decrease burnout syndrome[14].

5. Conclusion

The results show that a good work environment means that the nurses enjoy their job and find comfort in their workplace. They have the desire to grow and learn, and to work more professionally in improving the quality of nursing care. Of the fifteen articles reviewed, all showed positive results that a good work environment can improve service quality and decrease burnout syndrome. A supportive environment for the nurse, good teamwork with other nurses and motivation from the management can make increase the work motivation and performance, which impacts on job satisfaction, and decreases resilience and burnout syndrome in the nurse and the working environment. This is so then patient safety and patient satisfaction can be materialized.

EXCLUSIVE BREASTFEEDING AFFECTS THE BEHAVIOR OF PICKY EATER IN PRESCHOOL CHILDREN

U N Rohmah[1], H Arifin[1], N Ningsih[2], and D Wahyuni[2]

ABSTRACT

Picky Eater is characterized by a little eating behavior, choosing the preferred food, reducing the amount of food, and worried to try other foods. The aim was to determine the factors associated of picky eater behavior in preschool children. Research with cross-sectional design. Sample obtained 132 mothers of preschool children with simple random sampling. Independent variable were interaction when eating, mother's eating behavior, complementary food, history of exclusive breastfeeding and birth weight while dependent variable was picky eater behavior. Data were analyzed by chi-square and regression logistic. The results were obtained that the history of exclusive breastfeeding (p=0.001; OR=3.149) was the most influential factor with picky eater behavior in preschool children. Interaction when eating, mother's eating behavior, and complementary food were other factors that influenced picky eater behavior. Parents need to pay attention to the behavior of picky eater in children seriously, because the worst things caused disruption of growth and development in children due to lack of adequate nutritional intake. Parents can stimulate by make interesting food and teach to eat good food through direct examples, because children will imitate what parents do.

Keywords: picky eater; preschool; feeding practice

1. Introduction

Feeding that is of a good quality and amount can promote the optimal growth and development of children. Nevertheless, children in the growth and development period are not always fed perfectly. Problems often arise mostly in improper feeding. Improper feeding can affect many organs and systems in the child's body [1]. In various studies, the parents often find this behavior difficult to manage and by the time that the children reach 3 years of age, a proportion of the children start from 6% up to 50% of what they should be [2].

Picky eating can be a serious health problem when the child is growing. Picky eating usually indicates having strong food preferences, consuming an inadequate variety of foods, restricting the intake of some food groups, eating a limited amount of food or being worried to try other foods[3]. In other hand, picky eaters are very selective at choosing their food [4].

The prevalence of picky eaters in the Netherlands in a study population of 4018 children was 26% for children aged 18 months, 27.6% for those aged 3 years and 13.2% for those aged 6 years [5]. Another study stated that the results of study with 120 children between 2 to 11 years old showed that between 13% - 22% of the children were picky eaters [6]. In China, 937 healthy children aged 3-7 years old were approved as being picky eaters, making up to 54% in preschool [7]. Picky eating occurs at 2.5 to 4.5 years of age and there is twice the risk of children aged 4.5 years old of

experiencing a lack of normal weight compared to children who are not picky eaters [8]. The prevalence of experiencing eating difficulties in children in Indonesia who were aged under five years old was 23.9%, of which 45.5% among them were picky eaters [9].

Picky eating behavior in children can cause stress in the family which can worsen the relations between children with a family and the food itself [9]. Picky eaters also had poor weight gain, a lower intake of a variety of foods, a lack of important nutrients, and even failure and delays in their growth and development [10]. The possible cause of picky eating is a reduced duration of breast-feeding and a late introduction to complementary feeding have been shown to predict it [11]. Picky eating can cause parental practices related to feeding that include pressuring a child to eat more than they want to and using food as a reward [12]. However, the research on picky eating has still not been widely done.

2. Research Methods

2.1 Research design, population and samples, and variables

This study was correlational with a cross-sectional approach. The population in this study was all of the mothers of the preschool children at Ittifaqiah Kindegarten Indralaya, which totaled 198 respondents. With the inclusion and exclusion criteria applied, we obtained 132 respondents. The inclusion criteria in this study included 1) the mothers of children aged between 3 - 6 years old, 2) good communication, 3) the mother willing to be a respondent and 4) healthy children. The exclusion criteria included 1) mothers with mental disorders, 2) mothers who cannot read or write and 3) mothers who were not cooperative during the research process (refused to be a respondent in the middle of the research process). The sampling technique used in this study used simple random sampling. The independent variables were interactions when eating, the mother's eating behavior, a history of complementary food, a history of exclusive breastfeeding and birth weight. The dependent variable was picky eating behavior.

2.2 Instruments

The picky eater questionnaire in this study was modified by [13].The questionnaire consist of 18 items statement. Each item was scored from a minimum of 1 and up to a maximum of 5. The statement was assessed using a Likert scale with a value of 1 (never), 2 (rare, 1-2 times/week), 3 (sometimes, 3-4 times/week), 4 (often, 5-6 times/week), 5 (always, every day).The results of the validity and reliability test of the picky eater questionnaire shown that 17 statements were declared valid and reliable with Cronbach's alpha values of 0.795 but 1 statement was not valid. The researcher tested for reliability and validity in Al Kautsar Kindegarten, and all of the items were found to be valid and reliable.

Interactions when eating were measured by a modified version of the Child Feeding Questionnaire (CFQ) [14]. This instrument consisted of 30 items. Each item was assessed using a Likert scale with a value of 1 (never), 2 (rare, 1-2 times/week), 3 (sometimes, 3-4 times/week), 4 (often, 5-6 times/week) and 5 (always, every day). The results of the validity and reliability test for the CFQ questionnaire indicated that all questions were declared to be valid and reliable with values of 0.866.

The questionnaire in this study about the mother's eating behavior related to picky eating children consisted of 7 statements using a modified Comprehensive Feeding Practices Questionnaire (CFPQ) [15]. The answer choices were marked on a Likert scale, going from 1 (strongly disagree), 2 (disagree), 3 (neither), 4 (agree) through to 5 (strongly agree).The results of the validity and reliability

test on the Comprehensive Feeding Practices Questionnaire (CFPQ) showed that 24 statements were declared to be valid and reliable with values of 0.827.

The history of complementary food was assessed by answering a questionnaire with the answers falling into 2 categories. The answers consisted of less than 6 months and 6 months or over. The history of exclusive breastfeeding was answered by filling in a questionnaire with 2 answer categories, namely exclusive breastfeeding and non-exclusive breastfeeding. Birth weight was examined using a questionnaire with 3 answer categories, namely low birth weight, normal birth weight and over-birth weight.

2.3Research procedures

The initial process of the data collection was done using simple random sampling by selecting prospective respondents according to the inclusion criteria in Al Ittifaqiah Kindergarten Indralaya. This research passed approval with the letter No. 2774/UN9.1.4/PP/2016 as given by the Headmaster of Ittifaqiah Kindegarten. The data was collected by the mothers of preschool children. The researcher explained the purpose and benefits of the study while asking for approval from the prospective research respondents by requesting that they fill in the informed consent sheet and provided a signature as proof of their approval. After the respondent was confirmed as being willing, the researcher then distributed the research questionnaires to the respondents. At the time of the data collection, the researcher accompanied the respondent so then if there were respondents who did not understand the research questionnaire, then the respondent could immediately ask the researcher. The researcher asked for the help of 3 nurse colleagues to assist in taking the research data. The researcher explained and gave direction to the nurses related to technical research. The researcher guaranteed the confidentiality of the respondent's identity and ensured that no other party other than the researcher would know the things that the respondent wanted kept secret.

2.4Analysis of research

The statistical analysis consisted of two stages, namely descriptive and inferential analysis. The descriptive analysis included the distribution of picky eating, interactions when eating, the mother's eating behavior, complementary food, a history of exclusive breastfeeding and birth weight. The inferential analysis used a Chi square test and regression logistic statistics to determine the relationship between the independent and dependent variables.

3. Results

The majority mean for the mother’s age in this study were aged 33 years old (late adulthood). The age of the youngest respondents was 24 years old and the oldest was 42 years old. The majority of the respondents (49) had children who were 6 years. In this study, the respondents with working experiences made up 61 participants, and they were housewives. The majority of the mother's last obtained education was senior high school, for as many 58 participants [Table 1].

The majority of children, 57.6%, were picky eaters. Interactions when eating was found to be 50.8%, with the majority of mothers restricting their eating and pressuring their children while eating. The majority of mothers had good eating behavior, totaling 56.8%.The majority of children had a history of complementary feeding, totaling 52.3% by 6 months. The majority of children had a 51.5% history of exclusive breastfeeding. The majority of children, at 83.3%, had a normal birth weight [Table 2].

The majority of participants, referring to interactions when eating, were in the bad category with 44 participants being picky eaters. In addition, there were also good interactions when eating for as many 32 of the 67 participants, but their children were still picky eaters. The results of the Chi square tests showed that there was a significant relationship ($p<0.05$) between interactions when eating with picky eating behavior in Ittifaqiah Kindegarten Indralaya. The results of the statistical tests showed there to be a correlation ($p=0.032$) [Table 3].

As many as 40 respondents with bad eating behavior for the mother were picky eaters. In the minority of for good mother's eating behavior, as many as 36 out of 75 participants had picky eating behavior. The results of the Chi square showed that there was a very significant relationship ($p<0.05$) between the mother's eating behavior with picky eating behavior in Ittifaqiah Kindegarten Indralaya. The statistical test results also showed as being significant ($p=0.018$) [Table 3].

This study found there to be a majority for a history of complementary food at less than 6 months for as many 44 of 63 participants with picky eating behavior. The children that had a history of complementary food at 6 months and who were picky eaters totaled 32 of 69 participants. The results of the Chi square test showed that there was a significant relationship ($p<0.05$) between a history of complementary food with picky eating behavior in Ittifaqiah Kindegarten Indralaya. The results of the statistical tests also had

a correlation ($p=0.011$) [Table 3].

For the 67 participants who were non-exclusive breastfed, 64 participants were picky eaters. In total, 29 of 68 participants had a history of exclusive breastfeeding and picky eating behavior. The results of the Chi square test showed that there was a significant level relationship between a history exclusive breastfeeding on picky eating behavior in Ittifaqiah Kindegarten Indralaya. ($p=0.001$) [Table 3]. The regression logistics showed that the determinant factor associated with picky eating in preschool children was a history exclusive breastfeeding ($p=0,004$), with more than the other variables in the results with a value (Exp (B)=3.149) that reported exclusive breastfeeding as effecting picky eating by 3.149 times in preschool children [Table 4].

According the results of this study, 7 of 16 participants had a lower birth weight when they were picky eaters. In conclusion, 66 out of 110 participants had a normal birth weight and were picky eaters, while for those with an increased birth weight, as many as 3 out of 6 participants were picky eaters. The results of the Chi square test showed that there was no significant level relationship ($p=0.437$) between birth weight and picky eating behavior in Ittifaqiah Kindegarten Indralaya [Table 3].

The majority of children, 57.6%, were picky eaters. Interactions when eating for the children was 50.8% for the negative, with the majority of mothers restricting their eating and pressuring their children while eating. The majority of mothers had good eating behavior, by 56.8%.The majority of children had a history of complementary feeding, totaling 52.3% for 6 months and over. The majority of children, 51.5%, had a history of exclusive breastfeeding. The majority of children, 83.3%, had a normal birth weight [Table 2].

4. Discussion

The results show that 56% of the sample were picky eaters, totaling 49 children aged six years old. Picky eating will often survive to when they are over 2 years old [6]. Preschool children begin to show the uniqueness of their existence and ego by making decisions that can be the opposite of their parents. Children can begin comparing the food menus at home with the food eaten by their friends at school and on the advertisements shown on the television. At this age, they are picky eaters that love eating snacks outside. This phenomenon is also caused by the mothers having a sufficient level of knowledge, so this makes the feeding problem more serious. Knowledge is an important domain related to establishing behavior in an individual. If the feeding is based on bad knowledge, then it will make the decisions and behavior taken also not appropriate [16]. Persistent picky eating has been identified as a risk factor for subsequent anorexia nervosa, predicted pervasive developmental problems, but not behavioral or emotional problems [11].

Interactions when eating by the mother were bad for as many 67 participants. Interactions when eating include restrictive eating and the pressure to eat. There were 75 mothers who practiced restrictive feeding and 68 mothers who pressured their children to eat. Restrictive feeding as a form of food control is popular when used with children [17]. Fisher and Birch said that groups that are not free to access snacks prefer snacks over those who are free to access snacks. Not only that, but restrictions on eat can induce the children to be forced to eat their food even though they are not hungry. At the same time, pressuring a child to eat does not always show in the form of force. Sometimes it used in the form of reinforcement, which includes praises and rewards. Parents seek to enhance the quality and amount of their children's intake. Furthermore, the pressure to eat child has a negative effect on their eating habits because the children will associate the negative experiences with food [17].

There were cases of the mother's having bad eating behavior for as many as 75 participants. In this study, the majority worked as housewives, rather than following government employments, or being a teacher, entrepreneur or trader. Even though the mothers are busy, as the mothers consume healthy food such as vegetables and fruits, and serve various foods at the dining table, so they can be role model for their children. Korkmaz said that the factors associated with healthy eating behavior were economic status, social status, education level, income level and health facilities [18].

History of complementary foods after 6 months totaled 69 participants. Feeding complementary food will contribute to optimal growth and development if given appropriately. The results of this study showed that half of the participants had the knowledge about starting to feed their children complementary food appropriately. If the mothers have good knowledge about complementary food, then good feeding behavior will appear. The right time for feeding complementary food is at the age of 6 months, because if complementary food given before or after this time then it will put the child at risk of developing a poor digestive system regarding their intestines and enzymes, and it will increase the risk of chocking, asthma, allergies and obesity [19].

There were 68 mothers whose children were exclusively breastfed. This was caused by maternal factors. The mothers in Ittifaqiah Kindegarten Indralaya were aged between 24 - 42 years old, and they worked as housewives, civil servants, traders and entrepreneurs. Similarly, this study found that the mothers who were housewives had higher odds of exclusive breastfeeding than non-housewives [20]. Not only that, but the mothers with higher levels of education knew about the nutrition-related health outcomes of exclusive breastfeeding. Employment status was not an obstacle because there are facilities for feeding rooms in a lot of places, and the government can provide facilities to help with a lack of workplace accommodation for breastfeeding mothers [21]. The older someone is, the higher their maturity level, and the more strength that a person has will result in them being more mature in their thinking and working. Age and employment status can be related to the mother's practices of exclusive breast feeding. Being of an older age affects a person's ability to receive information and there will be more positive behaviors. Working mothers have a double role that will have impact on their health, safety, and on the education of their children in the future.

The majority of the birth weights recorded in Ittifaqiah Kindegarten Indralaya were normal, between 2500 - 4000 grams. The results of the study showed that the education level was low, that the age of the mothers was that of an old adult and that most worked as a housewife. The statement agreed with birth weight being associated with maternal characteristics such as parity, ethnic region and education level [22]. Activities that are a risk during pregnancy include high stress, heavy lifting

and standing for a long time, which will be a risk for the child being of a low birth weight (<2500 grams). The fertilization process for older mothers or for those not of productive age will increase the risk of experiencing growth disorders, which can cause a low birth weight [23].

The Chi square results showed there to be a significant relationship (p=0.032) between interactions when eating and picky eater behavior in Ittifaqiah Kindegarten Indralaya. There was a positive relationship between interactions when eating with being pressured to eat and restricted eating in children with picky eating behavior. Restrictive feeding may affect the child's eating behavior by creating a context in which the child's refusal of food might be a response to both restriction and pressure feeding conducted by the parents to control the food intake of their children [24]. This interaction means that when the child eats, it becomes unpleasant. Restrictive feeding practices related to fast food are because the children want fast food again when there is access to fast food. This caused the children to feel unpleasant, which affected their food intake [17]. Not only that, bad interactions when eating will mean that the children always associate food with the negative experience (cognitive aversion), causing them to create bad memories about food in a specific condition. They will have bad experiences with new food and feel the same when they try other food in the future, with a high severity of this causing food neurophobia [25]. Finally, the role of the parents is important to the children. The frequency of eating family meals is associated with better psychosocial outcomes for both children and adolescents. This is because frequent eating with the family was inversely associated with disordered eating, alcohol and substance use, violent behavior, and feelings of depression [26].

The correlation between the mother's eating behavior and picky eating was strongly significant. Bad eating behavior in the mother caused picky eating in the children. The parents can be a role model when it comes to the consumption of healthy food; the children imitate the feeding practices of their parents. In another study, it showed how a mother's good eating behavior was associated with body mass index in preschool. This is because good and healthy eating behavior in the mother (modeling) can promote positive experiences with food and reduce picky eating behavior in the children [25]. The consumption of fruit and vegetables in young children who reported the modeling role of the parents in relation to healthy food was very useful for introducing bitter foods such as vegetables or food items that are less favored among children. Therefore, the mother's eating behavior can partly show the quality of their children's food behavior [27]. For example, children who experience food enjoyment may be more responsive to parental modeling. Children who are less picky may be more able to duplicate the eating behaviors of their parents, including the behaviors that the parents are less aware that they are exhibiting [28].

The results reported that there was an association between picky eating in children who have a history of complementary food being given after less than 6 months of breastfeeding. If the children are introduced to complementary food before they are 6 months of age, then they have a 2,5 times greater risk of being a picky eater than children given complementary food when they were 6 months old [13]. Beuchamp showed that introducing complementary food at 4 months would make the chance of picky eater behavior higher than introducing complementary food at 6 months. Too early a time introducing complementary foods can increase the risk of digestive disorders and food allergies because the digestive system is not yet mature. If children have negative experiences after consuming complementary foods, then in the future there will be greater occurrence of food neuphobia and the limiting of some foods [29]. The early feeding of complementary food can allow

for the entry of various types of microbe. When an infant is less than 6 months old, the cells around the intestines are not yet ready to receive solid food, so offering food can make a path for microbes to enter the body and this can also cause an allergic reaction followed by a reduced immune system [30]. The same as feeding complementary food under 6 months, the late introduction of foods that need to be processed by the tongue's movement from side to side is associated with a poorer acceptance food and there is a sensitive period for obtaining chewing abilities. The poor introduction of fruits and vegetables with complex food textures can cause more eating difficulties by the time the child is 7 years old [31].

The determinant of being a picky eater was a history of exclusive breastfeeding. This research reported that exclusive breastfeeding affected picky eating in preschool children 3,149 times. Other studies reported that when comparing children who were exclusively breastfeeding up until age 4 - 6 months and up to 6 - 10 months for children who were breastfed for 0 - 1 months only, the former were less likely be picky eater [32]. Children who were exclusive breastfeeding for 6 months and who were introduced to complementary foods after 6 months reduced the incidence of picky eating at an early age. Breastfeeding and the introduction of complementary foods should not be overlooked, especially in the development of healthy eating behavior. Breastfeeding can encourage them to learn many tastes in relation to the foods consumed by the mothers and this can have a protection affect against picky eating in infancy [33]. Similar to the statement that breastfeeding is associated with picky eating behavior, exclusive breastfeeding had a positive relation with umami flavor acceptance. The initial eating impression can have an important impact on food intake and flavor. The first taste recognition in children is breastfeeding [34] and if they are not breastfed, then this will establish and encompass malnutrition, and underdevelopment. An appropriate duration of breastfeeding is recommended to maximize the health benefits for both the infant and mother [21].

There was no correlation between birth weight with picky eating (p=0,437). This is contrast with the study of Dubois et al, who reported that picky eaters aged 2.4 - 4.5 years tended to have a low birth weight (<2500 grams) compared to children with a normal birth weight (2500- 4000 grams). This is caused by children with a low birth weight experiencing changes in their metabolism while in the wombs, so the children are born with the risk of being a picky eater but this requires further research [35]. Another study reported that birth weight was not associated with eating behavior, but that low birth weight was associated with metabolic syndromes that secondarily influence dietary habits through an altered secretion of adipokines that control energy balance and increase the risk of obesity further [36]. According to the researcher, birth weight has no impact on the children's eating behavior but the risk of malnutrition and the incidence of picky eating also does not align with their birth weight. This is caused by the influence of other factors on the digestive system related to birth weight.

5. Conclusion

The majority were picky eaters who were preschool children. Interactions when eating for children were found to be bad, especially regarding restrictions with eating and the pressure to eat. The mother's eating behavior was good. The majority of children had a history of complementary feeding from 6 months and a history of exclusive breastfeeding. The children had a normal birth weight. History of exclusive breastfeeding was the most influential factor regarding picky eating

behavior in preschool children. Interactions when eating, the mother's eating behavior and complementary food were the other factors that influenced picky eater behavior. Parents need to pay attention to the behavior of picky eating in children. This is because it can cause disruptions in their growth and development due to a lack of adequate nutritional intake. Parents can stimulate their children by making interesting food and teaching them to eat good food through direct example. This is because children will imitate what their parents do.

Health care professionals are expected to optimize health information as a health promoter to the parents and society about healthy eating behavior by providing a setting and collaborating with other health professionals such as doctor, nutritionists and a psychologists to provide counseling on healthy food and to motivates the parent to modify their bad behavior in front of the child when eating together. The next researcher is expected to further explore the factors related to picky eating and the self-management of diet. This is to better determine how the factors have an impact on the nutrition of children.

ANTENATAL EDUCATION INCREASING THE PRENATAL ADAPTATION AMONG PRIMIGRAVID MOTHERS

ABSTRACT

Lack of adaptation to changes that occur during pregnancy, particularly the first pregnancy, can lead to many mental health problems. Therefore, this study aimed to identify the effects of antenatal education on the prenatal adaptation. A randomised controlled trial involving 78 primigravid mothers (Intervention=38, Control=40) was conducted at the Tengkera Health Clinic, Melaka. The intervention group received two antenatal education sessions for 45 minutes per session while the control group only received the regular health education provided by the clinic. The prenatal adaptation was measured before and after the intervention using the Prenatal Self Evaluation Questionnaire. Data were analysed using the independent t test, Mann-whitney, Wilcoxon signed test and paired t test. Overall, the prenatal adaptation increased significantly after the intervention ($t = 2.818$, $p = 0.008$). Similar findings were also found for the three subscales of the prenatal adaptation; acceptance of pregnancy ($z = -4.742$, $p = 0.000$), identifying mother's role ($z = -5.000$, $p = 0.000$) and relationship to husband ($t = -2.055$, $p = 0.047$). The delivery of antenatal education in this study has led to a more positive prenatal adaptation. The antenatal education of this study is recommended to help increasing prenatal adaptation among pregnant women.

Keywords: antenatal education; prenatal adaptation

1. Introduction

Pregnancy is a condition where a woman becomes a mother. There are various physiological and mental health changes that may occur during pregnancy [1]. These may include back pain, frequent urination, heartburn, nausea and severe vomiting [2]. A lack of adaptation to these changes may result in anxiety, depression, seclusion or internal conflict during the period of pregnancy [3]. Anxiety can then be associated with the incidence of complications in obstetrics where it increases the stress hormone (catecholamines and corticotrophin releasing hormone), stimulating blood constriction which can lead to fetal distress or delayed uterine contraction and eventually it can cause a prolonged labor process and uterine atony [1].

Antenatal education is important for pregnant women, especially primigravida mothers, as a preparation to adapt to the physiological and mental health changes and thus to enable them to take part in self-care during pregnancy and after the birth [4-5]. The aim of antenatal education is to influence the mother's health behavior [6], to provide space for the mother to identify the essentials

for labor [7], to increase the mother's confidence in her ability to deliver her baby[8] and to provide a better preparation for women and their spouse related to the birth and their role as parents [9].

There are many studies that have been conducted to examine the effectiveness of antenatal education on prenatal adaptation [10-14]. These studies have shown that the mothers who received the antenatal education demonstrated a better prenatal adaptation compared to those who did not receive it [11-12,14]. The aspect of the differences included concern for the well-being of the self and baby, preparation for labor and a fear of pain, helplessness and a loss of control [12]. In addition, the level of prenatal adaption increased significantly after the mothers received the antenatal education [14].

However, the effectiveness of the antenatal education in improving prenatal adaptations among pregnant women in Malaysia is unknown since there have been no previous studies conducted in Malaysia. The findings of the studies conducted in other countries may not be appropriate to be generalized to the context of Malaysian pregnant mothers due to the differences in culture and religion. Therefore, this study was conducted by the researcher to examine the effectiveness of the education on the prenatal adaptation of primigravida mothers in Malaysia. This study hypothesized that the mothers who received the antenatal education improved their prenatal adaption.

2. Materials and methods

2.1. Design

A randomized control trial design was utilized to conduct the study. It involved two groups; the intervention and control. The intervention group was given the antenatal class by the researchers whereas the control group only received the routine health education (see Table 1).

Table 1. Routine health education.

Contents	Schedule
✓ Breast self-check up ✓ Common problems during pregnancy ✓ Problems of PIH/GDM/Anemia during pregnancy ✓ Importance of counting baby's movement ✓ Preparation for labor ✓ Breastfeeding ✓ Postnatal care for mother and baby ✓ Knowing your Baby's Health Book at Home ✓ Child immunization	✓ Every Monday and Thursday according to a named list of nurses arranged by the nursing supervisor. *Not all pregnant women get the same health education as it depends on the topic given on the day and time set out in the schedule, *e.g.* breastfeeding and child immunization.

2.2. Participants

The study participants were primigravida mothers who received their routine antenatal check-up at

Tengkera Health Clinic, Melaka. They had not attended any antenatal education program organized by any other organization or private agencies and they were 20 to 24 weeks pregnant. However, the mothers were exempt from this study if they experienced any complications in their pregnancy. This study received ethical approval from the Universiti Kebangsaan Malaysia Medical Centre (UKMREC) (Reference number: UKM PPI/111/8/JEP-2017-802) and from the Malaysian Ministry of Health (Reference number: KKM.NIHSEC/P18-287(5).

2.3. Intervention

The antenatal education provided by this study was based on the antenatal education developed by Sercekus & Mete[12]. Every mother in the intervention group was given the antenatal education package twice. The first session was given at 20 - 24 weeks. The second session was given after four weeks from the date of the first session where the gestational age was between 24 - 28 weeks. It took 30 to 45 minutes to deliver each session. The researcher used various teaching aids such as a doll, female pelvic trainer, video and PowerPoint. Detailed information of the intervention along with its contents has been presented in Table 2.

Table 2. Antenatal education of the study.

Content	Time	Duration
Session 1 (45 minutes)	Week 20 – 24 of gestation	
• Anatomy and physiology of the female reproductive system • Physiological changes during pregnancy. At the end of the topic, an open discussion was conducted to allow		10 minutes
• The growth and development of the fetus. At the end of the topic, an open discussion was conducted to allow the mothers to discuss their feelings about the baby's condition		10 minutes
• Requirements for laboratory testing and routine examinations - Blood, urine and ultrasound tests. - Importance of antenatal follow-up visits. At the end of the topic, an open discussion was performed in order to allow the mothers to state their acceptance (mother and spouse) of		10 minutes
• Changes during pregnancy and how to overcome it. At the end of the topic, an open discussion was conducted to allow the mothers to express her anxiety and capability to overcome her		15 minutes
Session II (45 minutes)	Week 24 – 28 of gestation	
• Nutrients during pregnancy An open discussion was conducted to allow the mothers to share her issues related to cravings, weight gaining and self-image		20 minutes
• Labor management - First, second and third stage. - Labor mechanisms - Pain management during labor – pharmacological and non-pharmacological. After the teaching session – discussing the mother's feeling about giving birth. An open discussion was performed to allow the mothers		25 minutes

2.4. Measure

This study measured the prenatal adaptation using the Prenatal Self Evaluation Questionnaire (PSEQ) developed by Lederman (1979). The reliability of this questionnaire was α 0.84. It was comprised of 79 items dividing into 7 sub-scales; acceptance of pregnancy (14 items), identification with the motherhood role (15 items), concern for the well-being of the self and for the baby in labor (10 items), preparation for labor (10 items), fear of pain, helplessness and a loss of control in labor (10 items), their relationship with their mother (10 item) and their relationship with their husband (10 items). The response format for all items was a five-point Likert scale. The scores of all items in each subscale as well as scores of all 79 items were totaled up (minimum 79 to maximum 316). The lower the score, the more positive the mother's prenatal adaptation was and vice versa. PSEQ was measured twice; at 20-24 weeks just before the first intervention and 4 weeks after the second intervention at 28 to 32 weeks.

2.5. Sample size

The calculation of the sample in this study was performed using two mean formula methods based on the mean and standard deviation (SD) as reported by Sercekus & Mete[12]. Based on this calculation, a total of 70 people were required in this study; 35 for the intervention group and another 35 for the control group. However, in order to overcome the possibility of a reduction in sample size due to attrition, an additional 10% was needed. Therefore, the total sample needed was 80 (40 samples for each group).

2.6. Randomization

All primigrivida mothers in the health clinic that fulfilled the study criteria were given an explanation of the study and they also given the information sheet to read. Those who were interested in participating in the study were given an informed consent form. The mothers who completed and signed the consent form were randomized into either the control or intervention group according to the number allocated to them in a sealed envelope.

2.7. Data Analysis

All of the data analyses in this study were conducted using IBM SPSS version 20. First, the demographic characteristics of the mothers between the intervention and control groups were compared by conducting an independent t test for age and using the Chi-square test for the other demographic variables. The demographic data for race, level of education and occupation were first reduced to two categories (race=Malay vs. non-Malay, level of education=school vs. higher education, and occupation = professional vs. non-professional) before conducting the Chi-square test in order to meet the test assumption[15].

The inferential analyses for the main study variables involved both parametric and nonparametric statistics due to the non-normal distribution in some of the study variables. In particular, when comparing the intervention and control group in the pre-intervention, the independent t test was utilized for two of the prenatal adaptation subscales (concern for wellbeing of self and baby in labor and preparation for labor) whereas others were tested using Mann-Whitney test. Post-intervention, the independent t test was used for three subscales (preparation for labor, fear of pain, helplessness, loss of control and relationship with husband) whilst the other subscales and overall adaptation was tested using the Mann-Whitney test. For the comparative analyses of the prenatal adaptations pre-

and post-intervention, the Wilcoxon signed rank test was used to examine the four subscales of the prenatal adaptation (acceptance of pregnancy, identification with a motherhood role, fear of pain, helplessness and loss of control and relationship with mother). Other subscales and the overall adaptation between pre- and post-intervention were compared using the paired t test because the data distribution was normal. $P<0.05$ was set to determine the significance of the results. The effect size was also calculated for all significant results.

3. Results

3.1. Participation and retention of study subjects

A total of 98 primigravida mothers who met the study criteria were invited to participate in the study. However, only 80 of them were interested and signed the consent form. Of this total, two subjects from the intervention group dropped out from the study before the post-intervention data was measured due to moving out and having important office-related work to do that took priority. Therefore, these subjects were excluded from the analyses involving their post-intervention data; see Figure 1 for details.

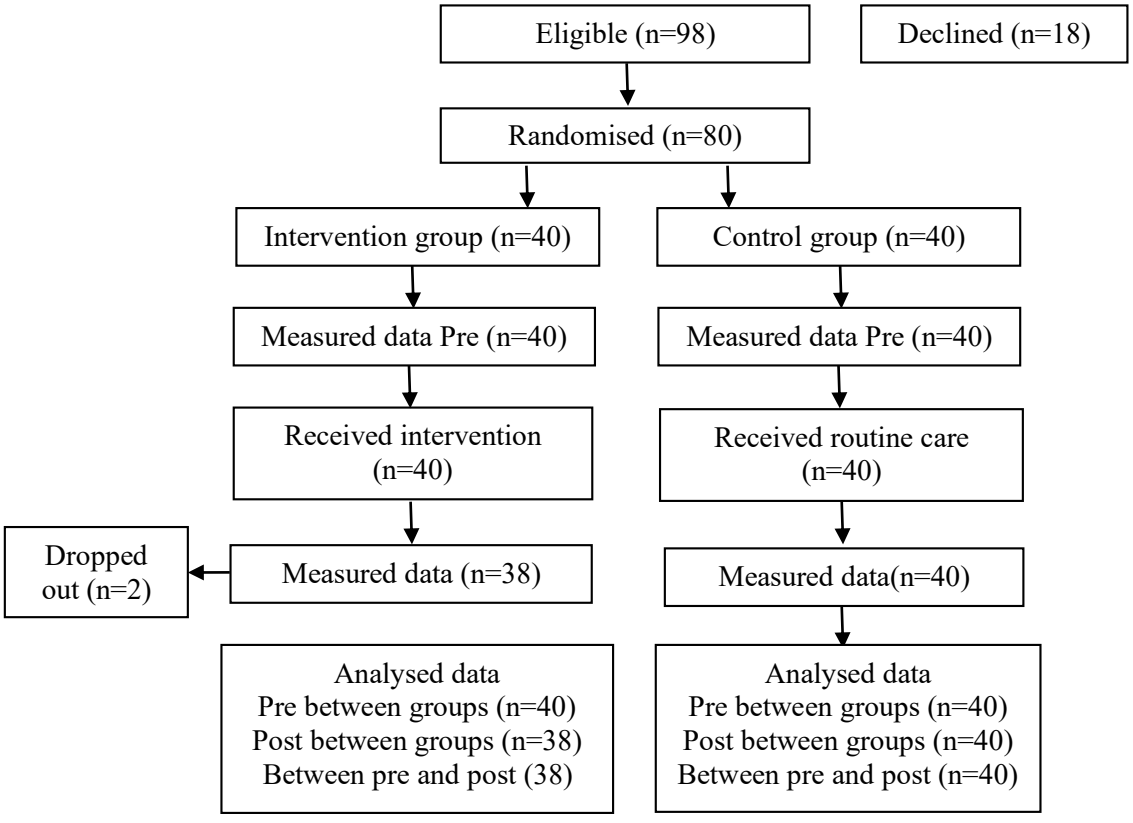

Figure 1. The recruitment and retention of subjects.

3.2. Socio-demographic data

As shown in Table 3, in this study, the subjects in both groups were aged 22 years on average (Intervention: SD = 1.74,Control: SD = 1.81), were comprised of 87.5% Malay (n=35) and most of

them had attended school as their highest level of education (Intervention: 65%, n=26; Control: 62.5%, n=25%). For the occupation, 80% (n=32) of subjects in the intervention group were non-professional workers whereas in the control group, almost half were professional workers (42.5%, n=17). About two-thirds of the subjects in the intervention group earned an income between RM3,001-RM5000 (65%, n = 26) whilst only 45% (n = 18) of subjects in the control group earned the same income. Almost all subjects in both groups stated that they wanted the pregnancy (n=36, 90%). Comparative analyses showed that there was no significant difference in the demographic characteristics between the intervention and control groups (p> 0.05).

Table 3. Demographic data.

Variables	Intervention (n=40) Mean (SD)/n(%)	Control (n=40) Mean (SD)/n(%)	Statistics	*p*

3.3. Prenatal adaptations between intervention and control group

Table 4 shows the differences in the prenatal adaptations between the intervention and the control group at the beginning of the study. Of all the variables, only the prenatal adaptation of the relationship with the husband showed a significant difference between the intervention (Md=17.50, n=40) and the control group (Md=19.50, n=40); U=535.500, z=-2.559, *p*=0.01. This difference, however, was small (*r*=0.29) [16]. Post-intervention, none of the prenatal adaptations differed significantly between the mothers who did receive and those who did not receive the study intervention (*p*> 0.05) (see Table 5).

Table 4. Prenatal adaptations between the groups pre-intervention.

Prenatal adaptation (pre-intervention)	Intervention Median/ Mean(SD)	Control Median/ Mean(SD)	Statistics	*p*
Acceptance of pregnancy	31.50	34.00	-0.926[a]	0.354
Identification with the motherhood role	29.00	33.00	-1.069 [a]	0.285
Concern for the wellbeing of the self and for the baby	21.15 (4.21)	22.28 (6.50)	-0.919[b]	0.361
Preparation for labor	18.80 (5.14)	18.48 (5.17)	-0.282[b]	0.779
Fear of pain, helplessness, loss of control	22.00	25.00	-1.835[a]	0.066
Relationship with their	18.00	16.50	-1.726[a]	0.084
Relationship with their	17.50	19.50	-2.559[a]	0.010

Relationship with their	19.11 (3.20)	17.80 (2.99)	1.86[b]	0.067
Overall prenatal adaptation	152.00	140.50	-0.845[a]	0.398

[a] = Mann-whitney U test; [b]=Independent t test

3.4. Prenatal adaptations between pre and post intervention

The differences in the prenatal adaptations before and after the mothers received the antenatal education have been presented in Table 6. The results showed that the two subscales for the prenatal adaptations had significantly reduced after the mothers received the antenatal education; acceptance of pregnancy (Md = 31.50 (pre)vs. Md = 25.50 (post), z = -4.742, p = 0.000 and the identification with the motherhood role (Pre: Md = 29.00 vs. Post: Md = 23.00), z = -5.000, p = 0.000. Both of the reductions had a large effect size (r = -0.53 and 0.57). The overall prenatal adaptation also had a significant reduction post-intervention; pre: Mean = 159.63 (SD = 21.45) vs. post: Mean = 146.87 (SD = 22.59), t = 2.818, p = 0.008. The eta-squared statistics for this difference was 0.11, indicating

a moderate difference in the overall prenatal adaptation. On the other hand, the prenatal adaptation of the relationship with the husband increased significantly post-intervention; pre: Mean =17.84 (SD= 2.96) vs. post-intervention: Mean =19.11 (SD=3.20), t=-2.055, p=0.047. The eta-squared statistics for this increase, however, was small (0.06), indicating that the difference is small [16]. Other adaptation sub-scales, however, did not show any significant differences between pre- and post-intervention (p> 0.05).

Table 6. Prenatal adaptations for the intervention group.

Prenatal adaptation	Pre (N=38) Median/ Mean (SD)	Post (N=38) Median/ Mean (SD)	Statistics	*p*
Acceptance of pregnancy	31.50	25.00	-4.742[a]	0.000[*]
Identification with the motherhood role	29.00	23.00	-5.000[a]	0.000[*]
Concern for the wellbeing of the self and their baby when in	21.00 (4.17)	21.39 (4.96)	-0.418[b]	0.678
Preparation for labor	18.58 (5.18)	18.53 (5.23)	0.051[b]	0.959
Fear of pain, helplessness and a loss of control	22.00	24.00	-1.197[a]	0.231
Relationship with their mother	18.00	18.00	-0.798[a]	0.425
Relationship with their	17.84 (2.96)	19.11 (3.20)	-2.055[b]	0.047[*]
Overall prenatal adaptation	159.63 (21.45)	146.87 (22.59)	2.818[b]	0.008[*]

4. Discussion

To the best of the researchers' knowledge, this is the first study that has examined the effectiveness of antenatal education on the prenatal adaptations among primigravida mothers in Malaysia. At the beginning of the study, the mothers who did and did not receive the antenatal education were not significantly different in all of their prenatal adaptations except for the relationship with the husband. After the intervention, none of the prenatal adaptations in the mothers who received the antenatal education differed significantly to those of the control group. Nevertheless, the mothers' prenatal adaptations in the acceptance of pregnancy and in their identification with the motherhood role and the overall prenatal adaptation reduced significantly after the intervention, indicating that they had a more positive adaptation after receiving the antenatal education. Their adaptation related to the relationship with their husband, on the other hand, increased significantly or became less positive after the intervention.

Previous studies have demonstrated that pregnant mothers who received the antenatal education had more positive prenatal adaptations in relation to the identification with the motherhood role[11], concern for the wellbeing of the self and their baby in labor, preparation for the birth, a fear of pain, helplessness and a loss of control, their relationship with their husband [12]and the overall adaption than those who did not [14]. These findings contradict the findings of the current study. The non-existence of significant differences in any of the prenatal adaptations between the intervention and control group in this study could be due to the occupational background of the study subjects in

the control group. This group had more mothers who were professional and semi-professional workers than those in the intervention group. These mothers may have been exposed to knowledge about the adaptation to pregnancy and labor through various sources such as the internet and magazines. Therefore, their levels of adaptations were no different than those of the intervention group even though they did not receive the antenatal education.

In addition, the contradicting findings could also be due to the difference in implementing the antenatal education. In this study, the intervention was divided into two sessions in which all of the pregnancy-related topics (three topics) were given in the first session whilst the rest were provided in the second session. In contrast, the previous studies delivered each topic in a separate session[12,14]. This may have caused the study subjects to better understand the topics taught and thus their adaptations differed to those of the control group. Furthermore, the data for the post-prenatal adaptations in these studies were collected at 7[14]and 25 weeks after the first prenatal adaptations were measured [12], whereas in the current study, they were measured just 4 weeks after the pre-intervention test. The mothers in this study may not have had sufficient time to develop a better adaptation than the control group. Moreover, the previous studies provided written information to the mothers whereas this study only used PowerPoint, a video and a pelvic trainer and then delivered the education orally. According to Walker [17], written education is more effective than oral.

However, it was unexpected that the adaption in the relationship with their husband by the mothers in the intervention group was significantly more positive than in the control group at the beginning of the study. It became non-significant after they received the intervention. Most surprisingly, although the scores not significantly different, the score indicates that the control group had a more positive adaptation related to their relationship with their husband despite them not receiving the antenatal education. According to Weis & Lederman [13], staying with their husband is important during the adaptation process of their relationship with the husband. It is important to note that there were two subjects in the intervention group who dropped out from this study post-intervention. It would be possible to assume that the two subjects were those who contributed to a more positive prenatal adaptation than the mothers who remained in the study. Therefore, when they dropped out from the study, the score for the relationship with the husband became higher or less positive.

On the other hand, a previous study also found that the overall prenatal adaptation was positive in the mothers who were given the antenatal education[14]. Similarly, mothers in the current study also had an overall positive prenatal adaptation after receiving the antenatal education. According to Aba & Komurcu [14], the timeliness and appropriate content of the education may create a positive adaptation. However, Aba & Komurcu [14] did not compare the differences in each of the sub-scales of prenatal adaptation pre- and post-intervention. Therefore, the positive prenatal adaption found in the acceptance of pregnancy and identification paired with a motherhood role found in this study after the intervention cannot be compared. It should be noted that the acceptance of pregnancy and the identification with the motherhood role subscales consists of pregnancy-related questions whereas the other three subscales that did not differ significantly between pre- and post-intervention (concern for the well-being of self and baby during birth; preparation for labor; fear of pain, helplessness and loss of control) comprised of labor-related questions. The post-prenatal adaptations of the participants were measured at 28 - 32 weeks of pregnancy. Sercekus & Mete [12] suggested

that pregnant mothers may focus more on birth-related topics when they are about one month prior to their birth.

Furthermore, the findings on the adaptation's effect on the relationship with their mother was that it remained the same even after they received the antenatal education. This can be for several reasons. First, the score was already been low before the intervention (mean 18, range 10 - 50). This indicates that the mothers may have had a positive adaptation to the relationship before they participated in the study. Their mothers probably shared their pregnancy and birth experiences with their daughters. Second, the study subjects were primigravida mothers of a young age (22 years old), which this may have led their mothers to frequently ask about their daughter's health, pregnancy and also the birth. Therefore, whether the antenatal education was given or not, the relationship between the mother and pregnant daughter can be positive.

Unlike adaptations in reference to the acceptance of pregnancy, identification with the role of motherhood and the overall prenatal adaptation, the results of the adaptation in reference to their relationship with the husband became less positive after receiving the intervention – this is beyond expectations. According to Weis & Lederman[13], pregnant women should stay with their husband in order to ensure that there is a good level of adaptation in the relationship between them. However, in this study, the samples were not limited to primigravida mothers who stayed with their husband. It is well known that long-distance marriage is not uncommon in Malaysia. Since this study did not include staying with the husband as the eligibility criteria, the reason why the relationship with the husband had become less positive after the antenatal education was conducted was unknown.

Adapting to pregnancy is necessary in order to avoid mental health problems in pregnant mothers[13]. The results of this study should be given attention by the midwives or nurses involved in providing services to this population, especially the primigravida mothers. The midwives or nurses may consider providing the antenatal education package used n this study in order to help their primigravida mothers in terms of prenatal adaptation. The nursing management should also consider integrating the antenatal education into the standard clinical practices of nursing in antenatal clinics. The courses should also be provided to equip them with knowledge on the importance of antenatal education as well as its implementation. This is to ensure that the antenatal education is delivered in an effective way in order to assist the pregnant women going through the prenatal adaptation process [3].This study, nevertheless, warrants further investigation to include written information in the intervention and samples from those living with their husband as a part of the study criteria. The intervention should also be implemented longer so then each topic can be delivered in an independent session.

5. Conclusion

The antenatal education in this study has resulted in an increase of positive prenatal adaptation in relation to the aspects tied into the acceptance of pregnancy and the identification with a motherhood role as well as the overall adaptation. Midwives or nurses who are involved in health education at the antenatal clinics are encouraged to consider antenatal education for pregnant mothers. Future studies that deal with the limitations inherent in this study should be undertaken.

ABSTRACT

Breast cancer is the second cause of death on women. Therefore, one method is needed to detect breast cancer earlier, one of that is by breast-self examination (BSE). The aim of this study was to determine the effect of health education on early detection of breast cancer using demonstration methods and poster as media against knowledge of teens which poster was displayed for fifteen days in each bedroom's teens. This study using pre-post experimental test design without control group. The population in this study was the teens in 11th grade on senior high school of North Indralaya with sample of 35 teens. Data retrieval for this research conducted on 11-25 May 2016. Analysis of experimental data using paired t-test. The results showed the average knowledge of the teens has increased from 12.20 (pretest) to 14.57 (posttest) with p-value 0.000 (<0.05). This result shown a very significant positive relationship between health education using demonstrations method and poster as media on increasing knowledge BSE for teens.

Keywords: breast self-examination, Ca Mammae, knowledge, poster, education

1. Introduction

Breast cancer is a global health issue and it is ~~a~~ leading cause of death among women internationally [1]. The World Health Organization reports breast cancer as being the most common cancer in women, both in the developed and developing world [2]. In Indonesia, it is the most common type of cancer and the second leading cause of cancer death for women, with an incidence of 1,4 cases per 1000 inhabitants. Mortality rates are the highest for women aged 20 - 59, followed by women aged 60 - 79 and those older than 80 respectively [3].

It is currently not possible to prevent breast cancer. However, early diagnosis is vitally important to improve outcomes [4]. The most effective ways to make a diagnosis are by breast self-examination (BSE), mammograms which are the gold standard for early diagnosis, and clinical breast examination (CBE) [5]. Women who regularly perform BSE have a greater awareness of their breasts, and if they detect any changes in their breasts, then they should immediately report to a health-care-professional [6]. Studies on BSE in Indonesia have showed that the rate of women having adequate knowledge and who do BSE regularly is extremely low [7].

The promotion of self-care, an attitude fostered early in life, may pay lifelong dividends. The adolescent period is a time of rapid change that provides teaching opportunities for shaping health

behaviors into adulthood. For example, teaching breast self-care may encourage positive behaviors such as performing breast self-examination (BSE) and attending regular professional breast examination[8]. Health behaviors such as BSE can help to empower women to take control and responsibility over their health promotion [9]. For adolescents, BSE education and adherence are a gateway to health promotion behaviors which sets the stage for the adherence to clinical breast examination and mammography screening later on in life [8].

Educational programs play an important role in breast cancer preventive behavior, and educational interventions have a positive impact on the knowledge, practices, early detection and health beliefs related to breast cancer [9]. Health education activities are more effective among younger groups such as students as they show a more positive attitude toward health education on breast cancer and early screening [10]. Educating young women about the early diagnostic methods of breast cancer is critically important to increase their awareness. Acquiring the behavior and practice of BSE at an early age is also likely increase the probability of continuing it later [5].

The early detection of breast cancer provides women with more treatment choices and a greater chance of long-term survival [11]. Breast self-examination is a simple and non-invasive screening method. In developing countries, BSE remains the method of choice for the early detection of breast cancer because of resource constraints [9]. Unfortunately, there have been only a few studies on the awareness of breast cancer and the practice of BSE among Indonesia women. This points to a lack of knowledge of breast cancer among women [7].

Traditionally, health education is imparted via didactic lectures using audiovisual aids. However, studies have proven that hands-on experience using mannequins and simulations is more a effective learning tool for skill development [12]. Hence a BSE training using a hands-on training experience could be more effective at imparting the skill of Breast Self-Examination, but there are no studies available in the previous literature that have tested this approach. The aim of this study was to determine the effect of health education on the early detection of breast cancer using the demonstration method and a poster as media.

2. Research method

2.1. Research design

This study was carried out using a pre-post test without a control group on a sample of female students from SMAN 1 North Indralaya. This was carried out from April to May 2016.

2.2. Sampling

The target population included all female students in the 11th grade in SMAN 1, North Indralaya. The participants were recruited through purposive sampling with the following inclusion criteria: 1) willing to be a respondent in the research study as shown by signing an informed consent form; 2) female students who were in the 11th grade and in good health; 3) female students who never obtained information about breast self-examination previously and 4) attended from the beginning of the pretest until the end of the post-test.

2.3. Sample size

The study sample included 39 female students who were according to the inclusion criteria.

2.4. Data collection instruments

The data was collected using a structural and validated questionnaire and planned teaching program using posters designed by the researcher. The questionnaire regarding adolescent knowledge about the BSE steps was developed by the researchers as well. A structured questionnaire consisting of 18 Multiple Choice Questions (MCQ) was developed to assess the knowledge about BSE. Each correct answer was 1 and each incorrect answer was 0. The total possible score was 18. The knowledge scores were assessed using a ratio scale. There was no level of knowledge because we could only see the score changes before and after the intervention.

The validity of the tools was established and administered to 20 females students from another school. The results of the validity test for the 18 items in the questionnaire showed that all of the questions were valid with an r value >0.444 ($\alpha = 5\%$) and a t value of >0.561 ($\alpha = 1\%$). The reliability was established by administering the questionnaire to 20 female students from another school. The reliability coefficient of the knowledge questionnaire was established using Cronbach's Alpha. The reliability coefficient was found to be 0.841.

There was also a planned teaching program. The lesson plan with the poster was given and it contained basic anatomy and physiology information, information on the risk factors for breast cancer and the steps of BSE. This was continued with a demonstration of the steps of BSE using a doll.

2.5 Data Collection Procedure

Administrative permission was obtained from the Principal of the selected school. Written consent was obtained from the study participants. The questionnaire was administered to them in the classroom setting. The data was collected by administering the knowledge questionnaire on BSE and the planned teaching program was also introduced to them. The teaching program consisted of demonstrating the steps of BSE using a doll for around 30 minutes and after finishing the intervention, we gave them a poster to stick on their bedroom wall. The students could therefore practice the steps of BSE upon seeing the poster in their bedroom. On the 15th day, a post-test was done by administering the same tool. The post-test score explained that the adolescents understood the steps of BSE from the teaching program and due to seeing the poster for 14 days.

2.6 Data Analyses

The data was analyzed using SPSS package version 16.0. The data was analyzed using descriptive and inferential statistics based on the objectives. Paired t-test analysis was conducted to find out the differences in knowledge before and after the intervention was given.

3. Result

At the time of the study, there were 4 respondents who dropped out; 2 respondents did not attend the post-test and 2 more respondents did not following the intervention because of getting an assignment from school. The sample size in this study was therefore reduced to 35 respondents.

The data presented in Table 1 shows that among the 35 samples, the majority (80%) of the samples were in the age range of 15 - 16 years. Only 14.26% of them had heard about BSE and 2.86% of participants (only one participant) had practiced BSE only once at the time of the study.

Table 1: Sample Characteristics

Demographic variables	(n= 35)	F	%
Age	15-16 years	28	80
	17-18 years	7	20
Age of first menstruation	<11 years	3	34.29
	11-14 years	32	65.71
	>14 years	0	0
Family history of cancer	Yes	1	2.86
	No	34	97.14
Have you heard/read about BSE?	Yes	5	14.26
	No	30	85.74
Have you ever performed BSE?	Yes	1	2.86
	No	34	97.14
If Yes, how often?	Once	1	2.86
	>1	34	97.14

The description of the knowledge scores pretest (Table 2) showed that the average knowledge of female students was 12.20 with a standard deviation of 1.907. The lowest score was 9 and the highest score was 15. The interval estimation results indicate that 95% were in the range of 11.55 to 12.85.

Table 2: Average knowledge of the female students before the intervention

Variable	**N**	**Mean**	**Median**	**SD**	**Min-Max**	**95% CI**
nowledge before intervention	35	12,20	12,00	1,907	9-15	11,55-12,85

The description of the knowledge scores post-test (Table 3) showed that the average knowledge of the female students was 14.57 with a standard deviation of 1.520. The lowest score was 10 and the highest score was 17. The interval estimation results indicate that 95% were in the range of 14.05 to 15.09.

Table 3: Average knowledge of female students after intervention

Variable	**N**	**Mean**	**Median**	**SD**	**Min-Max**	**95% CI**
nowledge after intervention	35	14,57	15,00	1,520	10-17	14,05-15,09

The paired t test was computed to test the effectiveness of health education on the early detection breast cancer using the demonstration method and posters as media (t= -7.170) as shown in Table 4. This shows that health education related to early detection breast cancer was very effective.

Table 4: Computation of the effectiveness of health education on the early detection of breast cancer

Variable	N	Mean	T	df	*p-value*
ɾe-intervention	35	12,20			
			.170	34	000
ɔst-intervention	35	14,57			

4. Discussion

Developing proper health habits in adolescence could lead to the maintenance of good health in adulthood. These habits can have profound long-term ramifications on health. One of these habits is breast self-examination [8]. This study provided important data about the breast health awareness of high school students in Indonesia. The adolescent females were found to have poor knowledge of breast cancer and BSE.

In the present study, the knowledge scores about breast cancer increased significantly at the 14 day follow up after the intervention. This finding demonstrates that breast cancer health education can improve the level of knowledge about breast cancer and the knowledge of early detection by BSE. Similar to the findings of other studies, the education highlighted the positive impact of the breast cancer knowledge including symptoms, risk factors, and early screening methods [10].

Only 14.26% of the students reported to hear about BSE and 2.86% of students had performed BSE. Almost half of the students reported that their main source of information on breast cancer and BSE was the media, consistent with the results of the study by Kara and Acikel (2009) [11]. These findings indicate that the media has continued to be one of the most important sources of information about breast cancer and BSE and that it highlights the cooperation between the public health educators and the media in dissemination breast cancer information and BSE.

The improvement of the knowledge about breast cancer may be attributed to the well-designed intervention. First, this study involved 2 hours of intensive training, consistent with Ludwick Gaczkowski and Budakoglu et al., who showed that short and one-time education was highly effective at improving the knowledge of breast cancer [1]. Second, in this study, color pictures in a combination of posters and written materials could make the participants better informed about the risk factors of breast cancer, the signs of breast cancer, the benefits of early screening methods and the steps of BSE. This result was consistent with that of Leslie et al., who stated that using the video kit was also very useful to improving the knowledge of breast cancer, but it is not convenient when in the form of written material [13]. These findings indicate that the health education conducted using a poster as a media could improve the participants' attitudes to breast cancer and BSE.

Since the sample of this study included the students of a high school, the results of the study cannot be generalized to a larger population in Indonesia. The variables in this study were singular, so the results of the study are limited to knowledge only. Some participants dropped out so the sample size was not as expected by the researcher.

5. Conclusion

The health behaviors that are formed during adolescence can enhance future health and have implications on the entire life course. Female high school students have little knowledge of the risk factors of breast cancer. The students were also not familiar with BSE. The results of this study may provide important baseline information about the awareness of breast cancer risk factors and the practice of breast self-examination among high school students. There is a need to increase the knowledge of the adolescent females about the risks of breast cancer and the benefits of early detection. Health care professionals should develop effective breast health programs in adolescence to help adolescent females to acquire good health habits in their youth. The nurse plays an important role in health promotion and this is only possible when she teaches or educates her client. However, the teaching of BSE can help women to be alert to any abnormal changes in their breasts and to seek medical advice immediately.

THE EFFECTIVENESS OF SCHOOL-BASED SMOKING PREVENTION PROGRAM: A SYSTEMATIC REVIEW

R Pujiyanti[1], B Utomo[2], Padoli[3]
[1] Faculty of Nursing, Universitas Airlangga, Surabaya [2] Faculty of Medicine, Universitas Airlangga, Surabaya [3] Polytechnic of Health, Ministry of Health, Surabaya Email: riny.pujiyanti-2017@fkp.unair.ac.id

ABSTRACT

Smoking behavior in children is a behavior that can cause health problems or chronic diseases in adulthood. The risk of illness and death will increase if smoking behavior starts at a young age. In addition to causing a burden of disease, smoking can also cause social, economic, and environmental burdens for themselves and other as passive smokers/secondhand smoke. Smoking prevention program is one of the efforts that can be done to reduce the number of smokers and novice smoker. The systematic review aimed to identify the effectivity of school-based smoking prevention program in preventing smoking behavior (cognition, knowledge, attitude, skills, etc). This review conducted database in Scopus, ScienceDirect, Medline, and CINHAL with inclusions are randomized control trial study determined from 2012 to 2018 and related to smoking prevention. The analysis from the article searches is resulted 15 suitable articles with the term required. School-based programs can increase knowledge, attitudes/perceptions of adolescents about smoking, and reduce cigarette use approvals. A school-based program can be a program of controlling and preventing smoking in adolescents/school children.

Keywords: smoking prevention, school-based program, adolescent

1. Introduction

Smoking behavior in children is a behavior that can cause health problems and chronic diseases in adulthood [1]. The risk of illness and death will increase if the smoking behavior starts at a young age. In addition to causing a burden of disease, smoking can also cause social, economic and environmental burdens for themselves and other as passive smokers and due to secondhand smoke [2]. The developments in the stages of smoking behavior star from someone who does not find it easy to smoke through to becoming a person who is vulnerable to smoking behavior, and then finally becoming a smoker[3]. Data from the Surgeon General states that since cigarettes were first marketed in the United States in 1964, twenty million people have died from smoking both as active and passive smokers[4]. Smoking is the cause of death for

nearly 6 million people each year and it is estimated that by 2030, this will increase to 8 million people every year[5].

The factors that can affect children and adolescents related to smoking are wanting to try the "taste" promised by cigarette advertising, wanting to look cool and "slang", being considered an adult by others, being loyal to their friendships, having the wrong perception of cigarettes (cigarettes can reduce or eliminate stress), and the environment they are exposed to cigarettes in[2]. Adults who smoke in the same social environment as children and adolescents indirectly will shape their perceptions, motivations and how they learn about smoking. Close friends can be an important factor in changing the behavior of children and adolescents towards tobacco use[4].

Control programs have been improved, but the usage and hazards that arise remain at a high level [6]. Schools are places that can be used in smoking prevention programs for children and adolescents because most of those in the early age range of smoking are still in the school environment[3,7]. Schools have a tobacco control policy that means that the school community does not to use tobacco products (cigarettes) in the school environment[3]. The school becomes an institution that can determine the quality of life and behavior of adolescents, and this has a profound effect on their lives. Therefore, schools can be a good place to prevent high-risk behaviors that occur during adolescence[8].

School-based smoking prevention programs offering broad and effective interventions that can reach groups of children and adolescents[9]. Various school-based tobacco controls, programs and policies have been implemented with varying degrees of success in terms of reducing the prevalence of smoking among students[3].

The goal of the school-based smoking prevention program is to improve the smoking prevention behavior in childhood and adolescents. Thus, the purpose of this study was to examine the benefits and to identify the school-based smoking prevention programs for children and adolescents.

2. Methods

This systematic review was reported in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) Statement.

2.1 Data Sources and Searches

The results obtained were drawn from the Scopus database, ScienceDirect, Medline and CINHAL, from 2012 until 2018. The articles were searched according to the following keywords: school-based program, smoking prevention and adolescents. Every article that was included in this systematic review has received ethical clearance approval.

2.2 Study Selection

The papers went through 3 stages of screening to determine their accuracy and to avoid duplicate titles, citations and abstracts. In the first stage, filtering all of the relevant data was based on the content. Second, the researcher read all of the articles at least 3 times so then each

article was assessed thoroughly and independently by the researcher. The last step was where the researcher finalized the data to determine the appropriate articles before extracting and analyzing the data itself.

2.3 Data extraction and quality assessment

All citations retrieved from the electronic databases were imported into the Mendeley Program. Two reviewers (AY, YSA) independently analyzed the titles and abstracts of every study retrieved from the literature search to identify which were potentially eligible. The full text of the remaining studies were obtained for further examination. The last review was conducted by the first reviewer (TPD).

The research data included the author's name, year of publication, sample size, research design, the general characteristics of the participants (age) and any interesting results from the school-based smoking prevention programs. A detailed description of the intervention of the school-based smoking prevention program included the characteristics of the intervention (type, duration, and frequency) and the impact of the smoking prevention efforts on the students (children and adolescents).

6. Results

From the article and journal search, 11.510 papers were found from within four databases, including 1040 articles from CINHAL and Medline, 473 articles from Scopus, and 9.997 articles from ScienceDirect. The detailed identification and selection processes of the papers can be seen in Figure 1. The results of the paper selection were according to the inclusion criteria and they were then given a sequence number to facilitate the review process (Table 1).

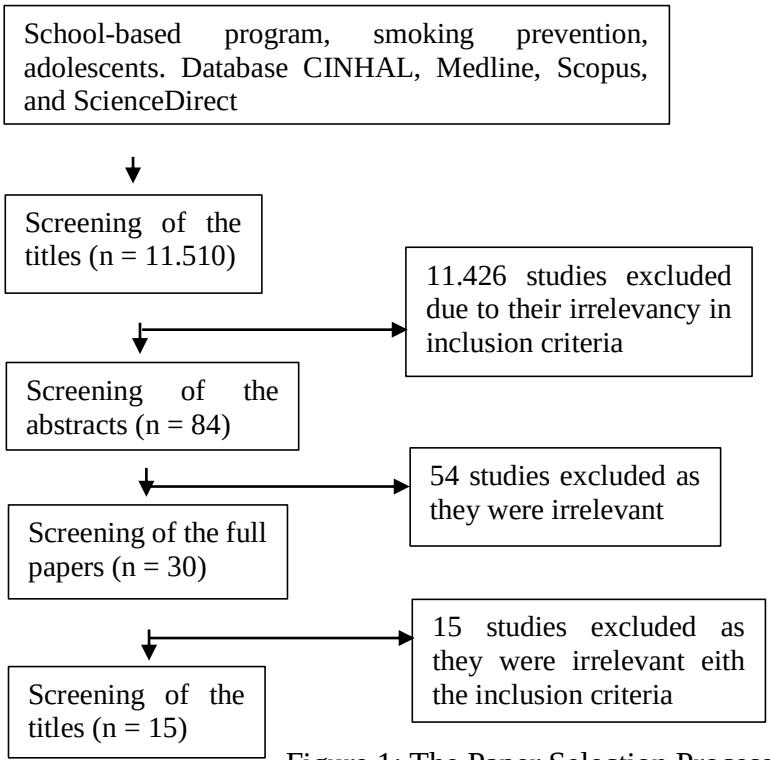

Figure 1: The Paper Selection Processes

For the results of the study conducted by Tahlil et al[6], the intervention given was that the students were taught about the prevention of smoking from an Islamic perspective including smoking behavior in Islamic societies, Islamic views on health, the effects of smoking, national regulations and rules in relation to Islamic teachings about smoking behavior, skills in rejecting smoking invitations and healthy living techniques. It was given using interactive teaching methods (group discussions, brainstorming, role play and storytelling). School-based programs can provide long term benefits for the Indonesian adolescents' smoking knowledge and attitudes.

Based on the research done by Cole, Qian and Leatherdale[3], six tobacco programs or policy interventions had a significant positive influence on the student's susceptibility to smoking.

The X: IT programs conducted by Bast et al.[7] included non-smoking school yard programs, smoking-free curriculums, and parental involvement, contracts, and dialogue. The results show that a higher level of implementation will increase the effect of the intervention itself.

The results of the study conducted by Midford et al.[9] used DEVS intervention. The DEVS program was carried out for 3 years with the result that there was an increase in knowledge about smoking, talking more about smoking with their parents, smoking did not increase, and positive changes were seen in the effects of smoking. These results are in line with the results of Al-sheyeb et al.,[17] using the TAJ intervention (Triple A-Adolescent Asthma Action) and TAJ-Plus (smoke-free classes) by increasing both smoking knowledge and perceptions. TAJ consisted of 3 steps in the intervention, namely training the senior students (peer leaders) and facilitating program implementation (education for juniors in 3 sessions, quizzes and role playing).

Chun, Bae, and Min[16] used 6 sessions adapted from the cognitive behavioral model and the sessions were conducted for 45 minutes 3 times a week in the intervention group (2 schools, n = 35 students) and there was a 1 hour regular education session in the control group (n = 45 students). The research conducted by Rafiee et al.,[8] used an educational intervention to improve self-efficacy in 53 students consisting of 27 students in the intervention group and 26 students in the control group. The education given consisted of 5 sessions a week that covered stress management, an awareness of smoking risks, decision-making management and problem-solving skills, effective and interpersonal communication, and being courageous and the skill of saying no.

The results of the study conducted by Kolovelonis, Goudas, and Theodorakis[15] promoting sports as an alternative to smoking consisted of 8 sessions every week. The program was called "I do not smoke, I exercise". The intervention was carried out on 338 elementary and middle school students (135 elementary school students, 203 middle school students).

4. Discussion

The prevalence of smokers in the world continues to increase every year, as do smokers who are adolescents [14]. Smoking behavior can be influenced by many factors including the desire or curiosity of adolescents, environmental influences, and high cigarette production, and

so on. This of course can affect the health of a child or teenager in the future [4]. Therefore, a way that can improve smoking prevention behavior is needed. There are many researchers looking for ways to overcome the problems that exist related to children and smoking. For the methods or ways to overcome the problems that are found include school-based smoking prevention program.

School-based smoking prevention is a program that is based on the curriculum in schools using the objectives of the school students using various methods and media [7]. The purpose of using this program is to be able to increase the students' knowledge of behavior and the impact of smoking on health, changes in the attitudes / perceptions of smoking risk, normative expectations, resistance skills and refractive self-efficacy efforts [10]. In addition, school-based prevention programs are also a method to train the students as peer-leaders to influence the people around them.

Fifteen journals used school-based smoking prevention programs utilizing several methods and media including group discussions, education, quizzes, role playing, storytelling, extracurricular activities, brainstorming, active learning and short videos, which all showed a significant effect on improving the knowledge, perception, attitude and skills involved in rejecting smoking invitations, motivation, self-management, and quality of life.

5. Conclusions

School-based smoking prevention programs using education, training for both the students and teachers, extracurricular activities based on the school curriculum as well as policies and regulations on smoking in schools are both reliable and effective at improving knowledge, attitudes, self-efficacy, motivation, refusal skills, and self-management in smoking prevention.

PHP-668

Author	Title	Design	Sample	Intervention	Frequency/ Duration	Results
Tahlil et al., 2015 [6]	Six-months follow-up of a cluster randomized trial of school-based smoking prevention education programs in Aceh, Indonesia	RCT	476 students (11 and 14 years)	The intervention given is based on Health-based intervention program (historical perspective of tobacco smoking and smoking behaviors in Indonesia, tobacco smoking effects, national regulation about tobacco smoking, refusal skills, assertiveness, and stress management) and Islam-based intervention (smoking prevention from an Islamic perspective, and this included information about Islam; tobacco smoking among Islamic society; Islamic view about, health, tobacco smoking, and healthy living techniques) adapted to the culture and education curriculum. We used teaching methods such as group/class discussions, brain storming, role play, and storytelling.	Eight two-hour sessions.	Health and Islamic-based programs provided stronger effects and while the separate health and Islamic-based approaches showed similar effects, tailoring the intervention components to the participants' religious background might be useful in improving the long-term effectiveness of school-based smoking prevention programs. School-based programs can provide long term benefits on Indonesian adolescents' smoking knowledge and attitudes
Cole, Qian and Leatherdale, 2017 [3]	Changing the Smoking Trajectory: Evaluating the Impact of School-Based Tobacco Interventions on Changes to Susceptibility to Future Smoking	COMPASS (a school-based	Students in Grades 9 to 11 (8.834 students)	Six tobacco program or policy interventions (enforced smoking bans with fines, giving letters to the parents of students who smoke, smoke prevention training)	2012-2014	Few interventions in this study had a significant positive influence on student susceptibility to smoking.

		cohort study design)				
Bast et al., 2016 [7]	High impact of implementation on school-based smoking prevention: The X:IT study-a cluster-randomized smoking prevention trial	RCT	Grade 7 pupils (mean age 12.5 years) and 4141 students	The intervention included three components: (1) smoke-free school grounds, (2) smoke-free curriculum, and (3) parental involvement, contracts, and dialogues.	2010-2012	Implementation assessment includes the adherence to the intervention, the dose, quality of delivery, and participant responsiveness. Schools, which were implemented in the intervention in close accordance with the aim and directions of the intervention program, were found to be highly effective at preventing smoking among the adolescents compared to the control schools. There was a graded negative association between implementation fidelity and smoking

						prevalence among adolescents. The smoke-free curriculum was implemented with high fidelity in the first year but this dropped markedly the second year. Parental involvement, based on the contracts and dialogues, was implemented with high fidelity and stability during the intervention period.
López et al., 2015 [5]	Efficacy of a smoking prevention program in Catalan secondary schools: a cluster-randomized controlled trial in Spain	RCT	1128 students in 29 school 11–15 years of age	The program consists of seven modules that use a different approach to smoking habits including activities, work-shops and/or class sessions.	Consists of 9 sessions over 3 years 1-hour in-class sessions	The school-based intervention reduced the risk, prevalence and incidence of smoking by 25 and 26% respectively, but this was not statistically significant ($P \geq 0.170$). The session given must include a minimum of 10 sessions to get a significant

						program effect.
Midford et al., 2016 [9]	Smoking Prevention for Students: Findings from a Three-Year Program of Integrated Harm Minimization School Drug Education	RCT	13-15 years 1163 students (DEVS program) and 589 students (control)	The intervention was given across 18 lessons consisting of 10 lessons in 2010 and 8 lessons in 2011 using the existing curriculum resources including student workbooks, trigger videos and teacher manuals.	18 lessons consisting of 10 lessons in 2010 and 8 lessons in 2011	Intervention students smoked fewer cigarettes and experienced less smoking related harm, than those in the control. The school drug education program, delivered by specifically trained teachers and employing participatory, student-centered pedagogy, benefited the students who choose to smoke cigarettes, while they did not encourage the uptake by non-smokers
Carreras et al., 2016 [10]	Mediating factors of a school-based multi-component smoking prevention intervention: The LdP cluster randomized controlled trial. Health Educ Res	RCT	14-15 years 989 students	This intervention included the 'Smoking Prevention Path' (SPP), an educational intervention delivered by trained educators, in the context of a community Health Promotion centre. The classroom component consisted of a 2-h in-depth school lesson on one of the SPP sessions. A life-skills peer-led intervention. The enforcement of a school tobacco policy.	SPP was divided into four 40-min sessions. The classroom component consisted of two 2-hour meetings. A life-skills peer-led intervention trained in three 2-h sessions at	The program was also shown to significantly increase risk perception and smoking knowledge, even though these mediators had no effect on smoking. The LdP intervention directly reduced

					school plus one meeting	smoking in school areas.
González et al., 2018 [11]	Role of smoking intention in tobacco use reduction: A mediation analysis of an effective classroom-based prevention/cessation intervention for adolescents	RCT	685 adolescents aged 14 – 20 years	The Project EX curriculum was closely adapted from the original program developed in the United States, included strategies to quit smoking and learning skills for non-smoking maintenance, with an interactive methodology based on motivation.		Project EX can reduce the students' intention to smoke after 12 months. Efforts can be made such as making a commitment about not using tobacco for a long time.
Maruska et al., 2015 [12]	The Role of Substance-Specific Skills and Cognitions in the Effectiveness of a School-Based Prevention Program on Smoking Incidence	RCT	Students in Grades 5 and 6.	This program focuses on improving skills (coping with emotions, stress, and problems and on teaching) or modifying skills and cognition (attitudes toward smoking and risk perception, smoking-related knowledge, normative expectations concerning adult and peer smoking, resistance skills, and the self-efficacy to refuse cigarette offers).	The program is comprised of 14 units, most of which were 90 mins in duration, and two workshops, that were four to six class hours each.	Substance-specific skills and cognitions targeted by the social influence curricula seemed to contribute not only to the effectiveness of the programs in modifying current use but also in preventing adolescent smoking onset.
Mohammed et al., 2016 [13]	**Effects of a randomized controlled trial to assess the six-months effects of a school-based**	RCT	1416 student in Grade 8 (13-15 years) in 19 schools	The five-week program was implemented in December 2008 and January 2009. This program comes from a smoking prevention program in the Netherlands which was then adjusted to the culture and norms in Saudi Arabia. It used a	Five lessons; each lesson took 45 min to be implemented	The students who were exposed to the program had stronger Non-smoking attitudes, a higher self-efficacy to cope with peer and

	smoking prevention program in Saudi Arabia			led peer video, followed by group work and active learning.		social pressure, more action planning and a lower intention to smoke in the future. Smoking initiation at the 6 month follow-up was significantly lower in the experimental group than in the control.
Thurston et al., 2018 [14]	Randomized controlled efficacy trial of a smoking prevention program with Grade 8 students in high school	RCT	Grade 8 students (13-14 years old) 881.55 for the intervention and 992.7 for the control.	Dead Cool was delivered by the teachers and was comprised of four lesson plans consisting of five sessions held for 4 weeks with a duration of 40 minutes/session. The intervention was given using DVD media in the form of short video clips.	Five sessions for 4 weeks (40 minutes/ session)	Multi-level modeling indicated that the program prevented smoking initiation in Grade 8 students.
Kolovelonis, Goudas, and Theodorakis, 2016 [15]	Examining the Effectiveness of the Smoking Prevention Program "I Do Not Smoke, I Exercise" in Elementary and Secondary School Settings	RCT	338 Greek students (135 elementary and 203 secondary students)	For each session, a student book in PDF file form was available that included information about smoking and exercise (e.g., short- and long-term consequences of the smoke on the human body) and examples of activities (e.g., puzzles, drawings, interviews, and slogans). The implementation of the program was mainly based on alternative teaching methods (e.g., brainstorming, role-playing, discussion groups, problem solving). Short lectures were also included. Furthermore, 10 physical education games combining sporting activities with	8 sessions implemented weekly	The results showed that the program had a significant effect on the elementary students' attitude toward smoking, the intention to smoke, subjective norms, the attitude toward the application of the program, and the knowledge of the health consequences of smoking. For the secondary students,

				smoking prevention exercises were available.		significant effects were found in relation to the students' perceived behavioral control and their knowledge about the health consequences of smoking. Very few students reported as having a smoking experience before and after the intervention.
Chun, Bae, and Min, 2012 [16]	Effectiveness of a smoking cessation program for male adolescents in South Korea	RCT	80 male middle school students	This intervention program is based on the cognitive behavior model that has been modified according to the characteristics and cultural factors of Korean students. In session one, they explained the objectives and encouraged the students to introduce themselves and their expectations. In session two, the students performed self-monitoring to better understand themselves, to analyze the pros and cons of smoking, and to anticipate the positive changes associated with quitting smoking. The third session provided each participant with an opportunity to identify their strengths and sources of support for improving self-efficacy. In the fourth session, the participants examined their stressors and	This program consisted of 6 sessions conducted over two weeks with a duration of 45 minutes per session	In conclusion, the significance of this study was that we were able to develop and verify the effectiveness of a shorter smoking cessation program combined with the biological measurement of cotinine and CO in the Korean adolescents.

PHP-668	talked about the causes of stress and potential resolutions. The fifth session involved learning techniques for abstaining from smoking, and for dealing with various situations in order to achieve the goal of becoming a nonsmoker. The students took part in situational role-play (called "Angels and Demons") to practice refusing an offer to smoke a cigarette. In the sixth session, thte students wrote plans to stay away from smoking and they reviewed the measures and techniques that they had learned in the previous sessions.

CORRELATION OF WORK SCHEDULING TOWARD QUALITY OF NURSE WORK LIFE: A SYSTEMATIC REVIEW

R Zunaedi[1], W Washilah[1]., and M P Kaonang[1] [1]Master of Nursing Student, Airlangga University E-mail: roslyzunaedi@gmail.com

ABSTRACT

Employee scheduling problems are often found in the hospital. The quality of nurse work life is describing how nurses satisfied with their personal and work needs through participation in the workplace. The sttudy aimed to know the correlation of work scheduling toward quality of nurse work life. Scopus, ProQuest, and Google Scholar databases. Published articles are identified in January 2014 - December 2018. The keywords are "work schedule" AND "QNWL" OR "Quality of Nurse Work Life" AND "Nurse". Articles with observational cross sectional case-control, prospective or retrospective cohort studies and quasi-experimental design. There were 18 articles reviewed from 516 articles found using keywords in the database. The results of the review found that the work shift was related to the quality of nurse work life. Work scheduling can affect nurses activities outside their working hours and nurses feel difficult to socialize. There is a correlation between work scheduling and the quality of nurse work life. To maintain a good quality of work life, nursing management can develop a transition rotation schedule, coordinate the work patterns, improve work shift hours, propose an increasing sallary and recognize workplace characteristics

Keywords: work schedule, quality of nurse work life, QNWL, nurse

1. Introduction

Employee scheduling problems are often found in the service industry, one of which is in hospitals. Most nurses have working hours scheduled as shifts. A job shift is defined as the organization of daily working hours where different people or teams work sequentially to cover more than 8 hours in a normal day[1]. Nurses, in providing comprehensive nursing care to patients in hospitals, will experience a lot of pressure because of the environmental situation that requires optimal performance, dissatisfied patients who are being treated and an uncomfortable feeling because the shift disrupts their sleep and rest cycles. Nurses in the treatment room will provide optimal nursing care so then the patients can recover. This condition can cause a crisis that occurs due to changes in the environment while treating patients in hospitals.

The most common problems related to work shifts were psychological disorders (96.4%), followed by social life (84.5%) and digestive problems (81%)[2]. Work schedules affect the nurses when it comes to them carrying out activities outside of work. Additionally, 25% of respondents who worked the afternoon and evening shifts found that their work shifts sometimes made it difficult for them to socialize with the environment outside of their work[3].

Quality of work life is a fairly broad and general concept, so the quality of work life is beginning to be developed in accordance with the field of work it is focused on[2]. The quality of life of the nurse's work or Quality of Nursing Work Life (QNWL) can be defined as the extent to which a nurse feels satisfied with both their personal needs and work through participation in the workplace to achieve the organizational goals[4]. Research on the factor analysis from QNWL shows that there are 4 valid factors including work context, support system (home and work), work design and employment system[5].

The development of structural empowerment models using the indicators of resources, support and information have a direct influence on psychological empowerment, which reduces fatigue syndrome in nurses[6]. In the end, fatigue syndrome, as an indicator of personal achievement, can affect the Quality of the Nurse's Work Life (QNWL). Hospitals that pay attention to the quality of the work life of the nurses (quality of nurse work life or QNWL) will be able to improve their service quality[7]. In addition, the quality of work life of the nurses, which includes the relationship between their work life and household life, work shifts, workload, the number of nurses, autonomy in decision making, supervision, relationships with colleagues, career development opportunities, salary, and compensation, can affect their commitment to the organization[8]. QNWL indirectly affects the intention to stay through job satisfaction and commitment[7]. The recommendation to increase the intention to stay is to develop good work life quality, job satisfaction and nurse commitment. There are 3 benefits from applying the quality of work life of nurses principles, namely increasing their commitment to the organization, in addition to their work productivity and work effectiveness[7].

The purpose of this systematic review was to find out the impact of work scheduling on the quality of the nurse's work life.

2. Research Methods

This systematic review used a guide based on the Preferred Reporting Item for Systematic Review and Meta-Analysis (PRISMA) (Liberati et al, 2009). The systematic review was followed by screening and removing duplications, and then conducting title and abstract-based screening for the elimination of articles with topics that were inappropriate / irrelevant. The articles obtained were then identified based on the inclusion criteria (eligibility criteria) that had been determined by reading the whole text. Articles that were appropriate according to the criteria were used to prepare the systematic review.

2.1. Literature inclusion criteria

The inclusion criteria were: 1) Observational design; cross-sectional case-control, prospective or retrospective cohort studies with a quasi-experimental design; 2) Published in English; 3)

Participants were nurses; 4) Outcome: work shift - quality of nursing work life (QNWL) and 5) Published between January 2014 and December 2018.

2.2. Resources

The literature used in this systematic review was acquired through searching 3 (three) electronic databases: Scopus, ProQuest and Google Scholar.

2.3. Literature search

The keywords used were “work schedule” AND “QNWL” OR “Quality of Nurse Work Life” AND “Nurse”. The standard protocol for selecting the research used a guide based on the Preferred Reporting Item for Systematic Review and Meta-Analysis (PRISMA) (Figure 1).

A total of 13 articles were identified to be included in the systematic review. Searching through Scopus, ProQuest and Google Scholar databases found 516 articles. After duplication screening, topic suitability, research design, English-language publications, and irrelevant outcomes were assessed, there were 13 articles that met the criteria for the review. In total, 10 of the selected articles used a cross-sectional design, 2 consisted of prospective cohorts and 1 article used a survey design.

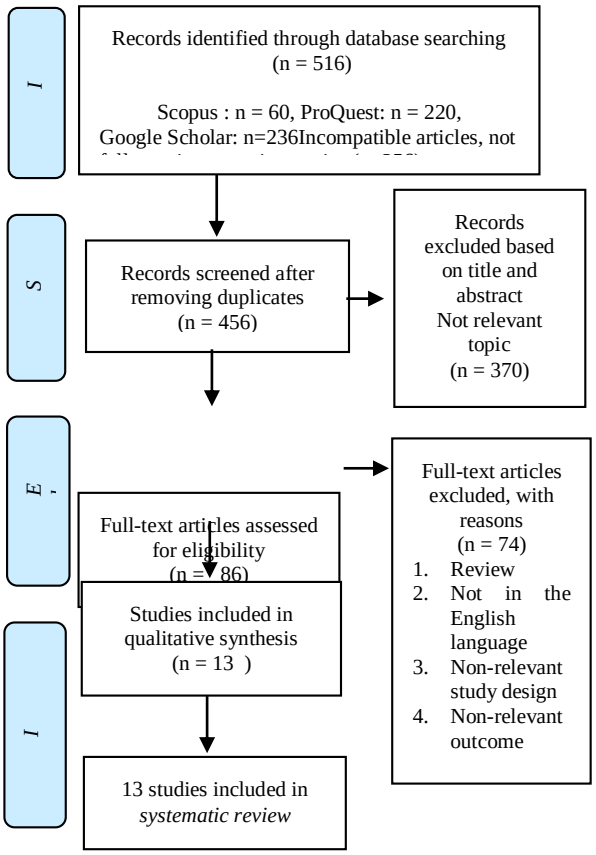

Figure 1: Flow Diagram

2.4. Data Collection

The data was extracted from each study. The articles that were obtained have been included in Table 1 and described. The articles were described by title, author and year, research design, population, the variables involved, the instrument, the outcome and results. Describing the articles made it easier for the author to review each article that was obtained.

3. Results

Work scheduling relates to the life of the nurse both in the work environment and in their personal lives, such as changing their activities outside of work and encountering the difficulty of socializing in the environment outside their work.

There are several impacts that can be identified from the articles. Night work and work rotation take turns not being related to the potential of anxiety or depression. The nurses that work in turns reported higher levels of mental pressure and lower levels of job satisfaction. In some parts, stress in social relations occurred higher in nurses who work in shifts.

Shift workers reported that working shifts had a negative impact on their life outside of work. Despite the negative effects, the participants generally thrived when working shifts.

Table 1. Information on the 13 articles showing the impact of work scheduling on the quality of the nurse's work life

Among the six subscales of NASA-TLX, frustration and mental demand had the lowest and highest scores, respectively. Temporal demands, frustration, and effort levels were significantly correlated with QNWL.

4. Discussion

The nurse's official schedule in nursing management theory is the activity of staffing. The nursing staff arrangement methodology must be regular, systematic and rationally-based, applied to determine the number and types of nursing personnel needed to provide nursing care to the standards set beforehand related to a group of patients in a certain situation[18]. The shift workers reported that working shifts had a negative impact on their life outside of work. The opportunities for participating in spare time activities and encountering difficulties when trying to fall asleep after their shifts were the main issues for the evening-shift workers, whereas physical symptoms such as headaches and mood swings were more dominant among the night-shift workers. Despite the negative effects, the participants generally thrived on working shifts[18].

The work life – home life dimension is the correlation between the life experience of the nurses in their place of work and when they are at home[4]. In their working life or dimensions of the nurse's home life, it was found that the organization has a flexible leave policy, but the nurses have difficulty balancing their responsibilities at work and at home. Most of the nurses feel tired because they do a lot of tasks that they have to do both at home and in the work place[19]. In the work life/home dimension, the main factors causing dissatisfaction among the nurses in this study included the work life– home life balance, the system of working hours, the availability of child care facilities and the organizational policies for vacations. One-third of the respondents were not able to balance their work and home life and they reported not having energy after work. The increased workload often results in exhaustion and the nurses will have no energy left after the work is done. This often results in an imbalance between their work life and home life. Similarly, nearly one-third of the respondents stated that rotating shift schedules affect their life negatively. Inflexibility in the working schedule is highlighted as a strong predictor for quality of work life and job satisfaction in numerous studies[20]

Work shift settings are needed in nursing because they can affect the physical and mental health of the nurses as well as their ability to care for their patients. The level of concentration and the cognitive abilities of the nurses were both found to decline after carrying out the night shift[21]. This decrease can affect work efficiency and consequently, serious errors can occur. Working in shifts or taking turns is also related to work stress, which can have an impact on physical fatigue[2]. There are differences in the workload between the nurses' work shifts. The inappropriate division of work shifts is related to the workload of each nurse. This then directly affects the quality of life and the nurse's work[22].

The nursing implications from this research are that by improving the quality of the nurse's work life with a shift schedule, the nursing management can develop a transition rotation schedule, coordinate the list of nurses' names to consider shift work patterns, improve the work shift hours, propose intensive improvements for the nurses in terms of shift services and recognize workplace characteristics.

Shift workers experience family and social life dysfunction, as well as a lack of harmonization between the irregular working hours of shift workers and other day workers, thus affecting their participation in terms of regular meetings and other social activities, for which the individuals need to discuss with their family or friends the need for bedtime in the afternoon the day after night shifts. Besides that, it should also be wise to choose social activities that will be carried out so as not to disturb their hours of sleep or resting after night duty.

5. Conclusion

The results of a systematic review of 18 articles about the relationship between work scheduling and the quality of life of the nurses found that the nurse's work scheduling did not directly affect the quality of the nurse's work life. However, the scheduling system has an influence on a number of points in the theory of the quality of work of nurses. The highest impact of the nurse's work scheduling on the quality of the nurse's work life was in the work life - home life dimension and the work design dimension.

Further study needs to be carried out in several countries with larger communities involved. This is so then the research results can be generalized. This is in addition to identifying the other factors that influence the quality of the work life of the nurses.

THE EFFECT OF TRADITIONAL GAME OF "DAM-DAMAN" TO DECREASE RATE OF DEMENTIA ON ELDERLY IN KEDIRI

Wimar Anugrah Romadhon[1], Joni Haryanto[1], and Ira Suarilah[1]
[1]Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
E-mail: wimar.anugrah.romadhon-2018@fkp.unair.ac.id

ABSTRACT

Elderly at risk of dementia caused by decrease in cognitive function, one of the treatments that is safe with no side effects is the reminiscence therapy with traditional game of "dam- daman" to increase cognitive function. The purpose of this study is to explain the effect of traditional game of "dam-daman" on elderly with dementia. The total sample were 20 respondents in Kediri whom were inclusion criteria with Quays Experimental design. The sampling technique was multistage random sampling method. Data were collected using MMSE questionnaires and analysed using Paired t-test with a significance level of $\alpha \leq 0.05$. The study was conducted at 8 sessions in 2 weeks. The duration of each session is 60 minutes. The result was indicating a therapeutic effect of traditional game of "dam-daman" to decrease rate of dementia on elderly ($p=0.000$). The second data analysed using Independent T-test with a significance level of $\alpha \leq 0.05$. The conclusion is traditional game of "dam-daman" improves cognitive function elderly with dementia.

Keywords: dam-daman, cognitive impairment, dementia, elderly

1. Introduction

Aging is the process of slowly decreasing the ability of the tissue to repair or replace itself, to maintain its normal structure and function so then it can no longer survive against injury (including infection) and to repair the damage suffered at the age of 30 - 70 years [1]. The aging process will be experienced by all humans and most of them experience dementia or senility in their old age. This condition is a challenge to maintaining the health and independence of the elderly so then they do not become a burden for themselves, their families and society [2]. There is still no specific treatment for dementia but there are treatments for the symptoms. One of them is by introducing reminiscence therapy with the traditional *dam-daman* game. *Dam-daman* is one of the traditional games that can train the cognitive function of the elderly brain. The intervention of traditional games as a defense against the prevention of increasing dementia still needs to be studied.

There were 37 million people in 2010. This will increase in 2025 to as many as 65 million out of the total world population of 7.3 billion million [3]. It is estimated that the number will continue to increase to around 131.5 million in 2050 and the proportion of poor and developing countries will reach 58%. Indonesia is among the ten countries in the world that had the most dementia sufferers in 2015, which was 2.7 million or around 15% of the total number of elderly people in Indonesia [3][5]. In East Java, the number of people with dementia reached around 634,500 million people [6]. Kediri Regency is included in the top 5 districts in East Java which has the largest number of elderly people

in 2014 with 165,061 people; around 24,759 are suffering from dementia [7]. The number of people with dementia will continue to increase if it is not immediately addressed or dealt with further.

The preliminary study looking at 5 out of 287 elderly people was conducted in Purwokerto village whose population was ranked 3rd out of the 16 large villages in the Ngadiluwih sub-district on May 14th 2016 using the MMSE questionnaire. This resulted in data showing that 3 out of 5 experienced temporal orientation disorders, 3 out of 5 experienced a spatial orientation disorder, 3 out of 5 people experienced attention / calculation disorders; 4 out of 5 people could not remember well, 4 out of 5 people experienced interference with their verbal commands and 4 out of 5 people experienced language disorders. In the preliminary study, it can be concluded that 4 out of 5 elderly people experience dementia.

Dementia is a clinical syndrome characterized by a loss of intellectual function and memory, and other thinking power that significantly disrupts the activities of daily life [5]. Dementia attacks the elderly around the age of 65 years, and with an increase in age, the greater the chance of suffering from dementia. This is characterized by a decrease in physical endurance. Physical and behavioral changes can occur in all people when they reach a certain chronological development stage [2], [5].

Things that can reduce the risk factors for dementia include learning activities whose function is to maintain the sharpness of the memory and to exercise the brain function [8]. In overcoming the problem of decreasing cognitive function that has a negative impact on the elderly, nurses as health workers can use methods to reduce the level of impaired cognitive function in the elderly. One of which is the method of remembering and talking about things in the past. This method is used for the elderly who experience cognitive impairment and loneliness for psychological recovery [9]. Therapy for remembering the past or playing games from the past can be given to elderly as individuals, with their families and in groups [10]. The *dam daman* game is a type of traditional Javanese game that has been played in ancient times and when the elderly were young. The traditional game of *dam-daman* will train the brain to think and it will train the elderly to determine the strategies that were done in ancient times when they first played it [11], so the elderly will remember. The purpose of this study is where the researchers looked at the intervention of a traditional game on the increase in dementia in the elderly in Kediri Regency.

Based on the above background, the researchers are interested in conducting research looking at the influence of a traditional game on the decline in dementia levels in the elderly in Kediri Regency. This is to find out how far the influence of the traditional draughts game extends in lessening the cognitive decline to reduce dementia in the elderly.

2. Research Methods

2.1 Research Design, population, sample, and variables

The research design was quasi-experimental. The target population in this study was the elderly with dementia according to the criteria set by the researcher, which was according to the demographic data. The population in this study was the elderly with dementia in Kediri District (26 Sub districts), totaling as many as 24,759 people. The inclusion criteria in this study was the elderly with the Clock Drawing Test (CDT) score ≥ 3 (L. Yang et al., 2016), the elderly who were able to communicate, the elderly who had played or could play *dam-daman* and the elderly who were cooperative. The exclusion criteria in this study were the elderly who were deaf and illiterate, those who experienced mental disorders and those with impaired physical mobility.

The method used in the site selection was multistage sampling, which randomly selected the representative place of the sample in the study. The researcher chose one of the sub-districts in Kediri Regency out of the 26 sub-districts, followed by choosing one village at random. The sample selection used simple random sampling to represent the population determined by the researcher. This study had a sample size of 20 people, consisting of 10 in the control group and 10 in the treatment group from the elderly population of Purwokerto Village in Kediri Regency. The independent variable in this study was the traditional game of *dam-daman*, while the dependent variable was the level of dementia.

2.2 Instruments

The instrument used to regulate the dependent variable in this study was the Mini Mental State Examination (MMSE) in the pretest and post-test (Pond et al., 2016). MMSE as a whole consists of 30 test points covering 7 domains, namely temporal orientation consisting of 5 points, spatial orientation consisting of 5 points, registration consisting of 3 points, attention and calculation consisting of 5 points, short term memory consisting of 3 points, language consisting of 3 points and verbal commands consisting of 6 points. The highest score possible was 30 points. The interval interpretation was 1 - 30.

2.3 Research procedures and analysis

The research passed the ethical review and obtained Ethical Approval certificate *No. 126-KEPK issued by the Health Research Ethics Committee of the Faculty of Nursing of Universitas Airlangga. The research location was in Purwokerto Village, Ngadiluwih District, Kediri Regency. The study was conducted on June 11 - 25 2016, and it involved 8 sessions over 2 weeks. The duration of each session was 60 minutes. The pretest was performed on each client who became a respondent in both the treatment and control group. Traditional games were carried out in the treatment group and the researchers observed each intervention using a log book. After the *dam*-daman intervention was given for 2 weeks, the next step was followed by the post-test to determine the final condition of the dementia level in the elderly, both in the control group and in the treatment group. The researcher then compared the results of the pre-test and post-test before and after the intervention and they also compared the levels of dementia between the treatment and control groups.

The collected data was processed by assessing the results of the MMSE questionnaire, and then executing coding, data tabulation, and data analysis using a paired t-test and independent t-test.

3. Results

The characteristics of the respondents as shown in Table 1 showed that the respondents in the control and treatment groups were between 60 - 75 years old. Most of the respondents had elementary school, junior high school and undergraduate education levels at 30% and in the control group, most had an elementary school education level of 40%. The sex distribution of the respondents in the treatment group and the intervention group were comparable. The treatment group had 2 working seniors and 8 of the elderly did not work. In the control group, there were 3 working elderly and 7 elderly who did not work. The results of the independent t-test stated that the response characteristics were $p > 0.05$, meaning that there were no differences in the characteristics of the respondents between the treatment and control groups.

Table 1. Characteristics of the respondents

Age	Treatment group		ɔntrol group	
	f(x)	(%)	ɤ)	ɔ)
60-75 years old	10	100	)	)0
76-90 years old	0	0		
>90 years old	0	0		
Total	10	100	)	)0
Level of Education	Treatment group		ɔntrol group	
	f(x)	(%)	ɤ)	⅙)
No school	0	0		
Elementary School	3	30		)
Junior High School	1	10		)
Senior High School	3	30		)
Bachelor degree	3	30		)
Total	10	100	)	)0
Independent t-test	p=0,226			
Gender	Treatment group		ɔntrol group	
	f(x)	(%)	ɤ)	⅙)
Male	4	40		)
Female	6	60		)
Total	10	100	)	)0
Independent t-test	p=0,673			
Job	Treatment group		ɔntrol group	
	f(x)	(%)	ɤ)	ɔ)
Work	2	20		)
Does not work	8	80		)
Total	10	100	)	)0
Independent t-test	p=0,628			

Based on Table 2, the lowest pretest was 19 and the highest dementia value was 26 with a mean of 21.6 and a standard deviation of 2.01. For the post-test, the lowest dementia value was 26 and the highest dementia value was 30 with a mean of 28.20 and a standard deviation of 1.31. In the pretest for the control group, the lowest dementia value was 16 and the dementia value was the highest at 25 with an average of 19.40 and the standard deviation was 3.27, while in the post-test, the lowest dementia value was 16 and the highest dementia value was 24 with a mean of 18.70 and a standard deviation of 2, 66.

Table 2. Results of the pre- and post-test for the dementia levels in both the control and treatment groups

No. Respondent	Treatment group			Control group		
	Pre	Post	Δ	Pre	Post	Δ

1	23	27	+4	23	22	-1
2	20	27	+7	25	24	-1
3	22	29	+7	18	18	0
4	26	30	+4	17	18	+1
5	23	30	+7	18	17	-1
6	21	28	+7	18	17	-1
7	21	29	+8	24	21	-3
8	19	26	+7	17	17	0
9	20	28	+8	18	18	0
10	21	28	+7	16	16	0
Mean	21,6000	28,2000	+6,6	19,4000	18,7000	-0,6
SD	2,01108	1,31656		3,27278	2,66875	
Paired t-test	p=0,000			p=0,066		
Independent t-test pretest	p = 0,870					
Independent t-test post-test	p=0,000					

The results of the analysis using the paired t-test statistical test in the group obtained a p value = 0,000 so p <0.05. This means that the difference in the value of dementia was significant during the pre-test and post-test. The control group obtained p = 0.066, so p> 0.05, which means that there is no significant difference in the value of dementia in either the pretest or the post-test.

The results of the analysis using the independent t-test statistic when pretest was p = 0.870, so p> 0.05. There was no significant difference in the value of dementia levels between the control group and the treatment group before the intervention of the *dam-daman* game. The results of the analysis using the independent t-test statistical test in the post-test obtained a value of p = 0,000 so p <0.05, which means that there is a significant difference in the value of dementia between the treatment and control groups after providing the traditional game of *dam-daman*.

4. Discussion

The results of this study indicate that the respondents from both the control and treatment groups were all aged between 60 - 75 years. The data shows that the respondents were in the elderly age group. The problem of dementia that occurs in the respondents is a degenerative process, the

aging process, which is the gradual disappearance of the tissue's ability to repair itself and maintain its normal function. This is experienced by humans age over 60 years old. The risk of dementia increases every 5 years from the age of 65 due to the increasing number of neurons in the brain becoming tangled (neurofibrillary tangles) and gain plaque [5].

Based on the results of the study, there was a change in the value of the dementia level in the treatment group before and after the intervention of the *dam-daman* game, whereas in the control group, there was no significant change in the value of the dementia level. This shows the influence of playing the traditional *dam-daman* game as an intervention to lessen the level of dementia in the elderly.

All of the respondents in this study were known to experience a decline in their cognitive level, which is one of the symptoms of dementia. The presence of an impaired cognitive function can be one of the main indicators of dementia. The traditional *dam-daman* game intervention which was given 8 times over 2 weeks proved to be able to increase the cognitive value of the elderly, which was marked by an increase in the score in the MMSE (Mini Mental State Examination) questionnaire [12]. The scientific explanation of cognitive-assisting games in view of past games is that the traditional game of *dam-daman* could improve cognitive function in the elderly who could lessen the risk of dementia in the elderly [5], [13].

In the MMSE (Mini Mental State Examination) questionnaire, the treatment group in the temporal orientation domain was worth 5 points and it was found that 9 out of 10 received a score of ≥ 3, while only one elder got a score <3. The same was found in the temporal orientation domain, where 9 out of 10 seniors got a score of ≥ 3, while only one elder got a score <3. In the registration domain, it was worth 3 points; i.e. 7 out of 10 elderly got a score of 3, while 3 other elderly got a score <3. In the short-term memory domain worth 3 points, the researcher determined that 6 out of 10 elderly could not answer the question at all with a score of 0, while 4 other elder individuals only got a score of 2. In the language domain, the value was 3, and 9 of 10 got a score that was ≥ 2. Only one elderly person got a score that was 1. The verbal domain was worth 6 points; 7 out of 10 elderly got a score of ≥ 4, while 3 other elders had a score of ≤ 3.

From the explanatory data, it can be concluded that the average elderly individual with dementia has impaired short-term memory domains according to the MMSE questionnaire. After the treatment using a traditional game, there was an increase in the scores of each domain, especially in the domain of short-term memory. From the post-test data in the treatment group, it was found that 6 out of 10 elderly people can answer the short-term domain memory questions perfectly and they got a score of 3; 4 other seniors got a score of 2, which means there was a significant increase before and after the treatment. Similar to the control group, the results of the pre-test depicted the elderly people with dementia as experiencing disruption in the short-term memory domain. The post-test results were different from those in the treatment group. There was no score increase in MMSE in any domain and some even decreased in each domain.

Based on Table 2, the value of the dementia level in the treatment group decreased after the traditional intervention and it also reactivated cognitive function in the elderly. The *dam-daman* game is one of the games that are quite popular among respondents who can prevent senility and improve their cognitive function by stimulating their kinesthetic and visual functions by remembering the strategy of the game.

According to the Indonesian Ministry of Health in 1999, the criteria for cognitive decline includes forgetfulness or the memory not functioning properly. This is because the elderly rarely carry out activities related to cognitive function or memory that can stimulate their kinesthetic and visual functions [14].

Research proves that by remembering events / things in the past by playing, they can improve cognitive decline in the elderly with dementia aged 65 and above [4]. According to [15] and [16], they explained that remembering events in the past through play therapy is one of the effective approaches that can be used to reduce the level of dementia. This therapy is used for the elderly who experience impaired cognitive function by stimulating their kinesthetic and visual functions.

Traditional games are one way for the elderly to play; they think of past game strategies which stimulates the brain to improve or maintain the cognition related to the visual and kinesthetic functions. The traditional *dam-daman* game is a game performed on a board or carton with the strategy of eating the opponent's fruit / pawn and keeping their fruit / pawn itself so then it is not consumed by their opponent. This game stimulates the kinesthetic function of the elderly. The relationship between kinesthetic function and cognitive function occurs in the brain through the limbic system, namely the amygdala and hippocampus. The brain will be stimulated to remember strategies / past events that will be captured by the efferent nerve fibers and this signal will be transported by the afferent nerve fibers to the central nervous system. The process will be integrated into a reticular formation which functions to focus the attention so then movement occurs through a spindle muscle contraction so then the kinesthetic functions work.

The traditional game of dam-daman also stimulates the visual function of the elderly. Visual function originating from the retina stimulates the optic nerve with regard to pawn movements. The prefrontal lobe receives stimulation from the optic nerve to work and think by planning strategies that are to be used in play that have been done in the past. The existence of thoughtful thinking activities related to the past stimulates the cognitive functions to reactivate, which can slow down the decline in cognitive function and prevent an increase in dementia in the elderly.

The process of kinesthetic and visual functions is included in the cognation and regulator subsystems in Roy's adaptation theory. Roy's adaptation theory explains that the relationship between input, the process of subsystem cognation and the regulator, and the output must be balanced so then they will produce an adaptive response in the individual.

Dementia is a symptom experienced by the elderly which means that the elderly cannot respond adaptively. This can affect every aspect of the life; physiological, psychological, social, and spiritual. Roy's Adaptation Theory explains the importance of responding in an adaptive manner to maintain the integrity of the body in defensive against a range of physical and mental illnesses due to the state of the surrounding environment. The adaptive response can work well if the regulator and cognation components are included in the subsystem of Roy's adaptation model and if they are processed through the appropriate inputs. The appropriate input in this study is to intervene using a traditional game to improve cognitive function, mood and behavior in the elderly with dementia so then the elderly can respond adaptively.

Based on Table 2, the H1 results were received. That is, there was an influence from traditional damages on the decline in the level of dementia in the elderly. There was a difference in the level of dementia in the treatment group in the pre-test and post-test through the paired t-test statistical test.

The independent t-test statistical test showed that the intervention of traditional games of draughts provided by the researchers was effective at reducing the level of dementia in the elderly.

From the discussion, the role of the nurses in research on dementia in the elderly is that the nurses are able to carry out the nursing process from the assessment, through to diagnosis, planning, implementation and finally, evaluation. The assessment process occurs when the nurses, in this case the researchers, conduct an assessment of the initial data on the elderly, namely by asking about the characteristics and lifestyle of the elderly. The assessment process was completed and the results obtained which stated that the elderly had dementia. Their nursing diagnosis showed a nutritional imbalance, memory impairment, the barriers to social interaction, verbal communication barriers and ineffective coping according to NANDA 2015. The next actions taken by the researcher were to run the process of planning and implementation. Planning and implementing the appropriate measures to reduce the level of dementia were done using the traditional game of *dam-daman*, so the nursing diagnoses appeared to be overcome. Then we evaluated the results starting from the assessment to implementation. Then the results were evaluated from assessment to implementation.

5. Conclusion

The conclusions are based on the results of the study referring to the influence of a traditional game on the decline in dementia in the elderly in Kediri Regency. Dementia is influenced by age, sex, the type of work that the person had and their level of education. The role of the nurse is needed in the settlement of the risk factors for dementia by conducting a study of the characteristics of the respondent. Then a nursing diagnosis needs to be conducted so then the nurse can carry out the interventions in accordance with the diagnosis obtained. Based on the discussion in the previous chapter, the level of dementia in the elderly before they were given the intervention consisting of the traditional game of *dam-daman* still did not show a difference or vice versa after the intervention was carried out with a decrease in the level of dementia. The implications and the role of the nurses in this study focused on dementia in the elderly is that the nurses are able to intervene to reduce the level of dementia by introducing traditional games such as *dam-daman* to help them remember the past.

AN UPDATE ON DOMINANT RISK FACTORS FOR BREAST CANCER: A SYSTEMATIC REVIEW

N M M Myint[1], T G Sesaria[1], H Widodo[1], M R Maulana[1]
[1]Faculty of Nursing, Universitas Airlangga, Kampus C, Mulyorejo, Surabaya, Indonesia
E-mail:nyein.moh.moh-2018@fkp.unair.ac.id

ABSTRACT

In the modern era, risk factors become a serious problem for breast cancer. Breast cancer is the most common cancer in women, with 1.67 million new cases of breast cancer diagnosed in 2012 and 522,000 thousand deaths reported. The higher developed countries, the higher incidence rate of breast cancer compared with developing countries. This systematic review aims to explore various risk factors that cause breast cancer based on various international studies and literature reviews. Authors searched the articles in database; Ebscho, Science Direct, Springer, Scopus and ProQuest between 2014 and 2019. Then the authors assessed eligibility of studies based on the inclusion criteria namely breast cancer and all risk factors on various ages, demographics. Then, 18 articles relevance with inclusion criteria are chosen for this systematic review**.** The risk factors can be categorized as the reproductive factors, food related factors (inadequate intake of vegetable and fruits, high intake of fresh red meat, and processed meat and vitamin B), genetic factors (gene mutations), lifestyle related factors (less physical activity, sun exposure, active and passive smoking, drinking alcohol, sleep duration) and histology. Identification of these risk factors may be useful for development of prevention strategies decreasing breast cancer incidence.

Keywords: Breast Cancer, Cancer, Risk Factors

1. Introduction

The risk factors of breast cancer are a serious problem in the modern era. Higher developed countries have a higher incidence rate of breast cancer when compared with developing countries[1]. Community misconception about the cause of cancer is very important to consider in formulating strategies of cancer prevention [2]. Breast cancer is a cancer that is often diagnosed in the world [3]. It has not yet been clarified how many cases are affected by the influence of the risk factors for breast cancer [4].

Cancer is the leading cause of death in the world and it is the biggest health problem in the world[3]. The increase in global demographic and epidemiologic transitions have resulted in an increasing cancer burden over the past few decades, especially in low and middle income countries. It has been estimated that more than 20 million new cancer cases will occur each year until the beginning of 2025[5]. Breast cancer is the most common cancer in women, with 1.67 million new cases of breast cancer diagnosed in 2012 and 522,000 thousand deaths reported [6]. Moreover, Asia, the world's largest continent comprised of about 3/5^{ths} of the human population, is where breast

cancer is the most common type of cancer and the second leading cause of cancer-related deaths among women, accounting for 39% of all breast cancers diagnosed worldwide[7].

The risk factors that occur in breast cancer cases are not only genetic. There are many other factors. An unhealthy lifestyle such as smoking, obesity, the low consumption of fruits and vegetables, alcohol consumption and a lack of physical activity are some of the risk factors for the occurrence of cancer[2]. The reproductive factors that can prolong the woman's exposure to hormones, such as early menarche and late menopause, are also risk factors for breast cancer [8]. The risk factors for breast cancer are a little bit higher in post-menopausal women than in premenopausal women[4]. Nutritional factors such as the effects of vitamin B, diet and some protein precursors can also influence the incidence of breast cancer [6],[9].

The purpose of this study was to conduct a systematic review of the various risk factors that increase the risk of breast cancer. The findings originate from various international studies, systematic reviews and literature reviews. The results of this systematic review are expected to be able to highlight the important information about the risk factors involved in breast cancer to the community. This systematic review has been presented in the form of articles consisting of an abstract, introduction, method, results, discussion, conclusions and the bibliography.

2. Method

This systematic review was followed by the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist.

2.1 Searching

The search strategy was developed to identify the published studies describing the risk factors of breast cancer. The search was conducted between 2014 and 2019. Four databases (Scopus, Springer, Pro-Quest, and Science Direct) were searched using different combinations of the following keywords: "cancer", "breast cancer", and "risk factors". The following inclusion criteria guided the search efforts to identify all of the relevant studies.

2.2 Inclusion criteria

The inclusion criteria consisted of the following:

1. Publication in English

2. Study sample comprising of a population of any age and any sex for the breast cancer cases

3. Focus on the risk factors of breast cancer

4. No restrictions on the research design

2.3 Screening

At first, the authors identified 742 articles and then removed any irrelevant topics, duplicated articles, any that were over the time limitation (2014 - 1019) and where the language used was not English. Second, 24 articles are remained. Six articles were excluded again because they did not focus on the risk factors of breast cancer. Finally, 18 articles were chosen for this systematic review.

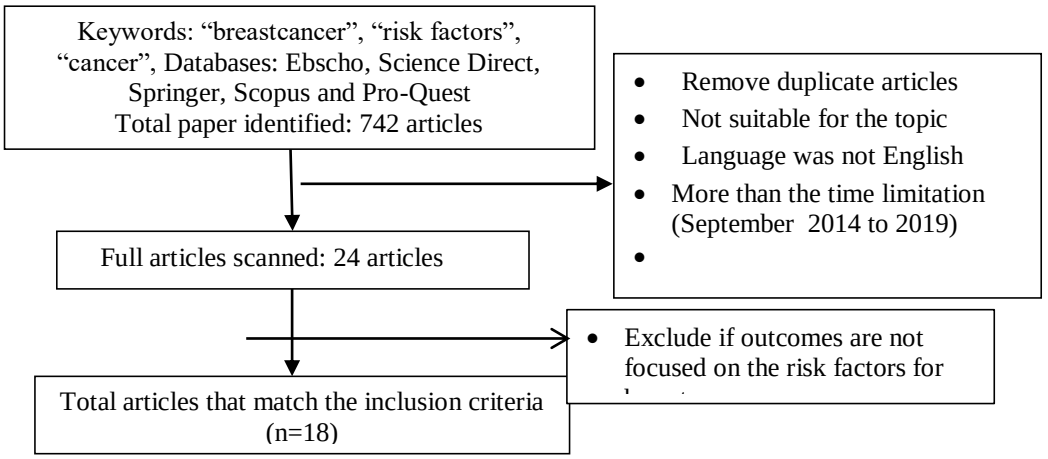

Fig.1. Flowchart of the research on the risk factors of breast cancer

3. Results

All of the studies were published between 2014 and 2019 and the study areas were Sweden, the United States, France, Norway, the UK, Canada and the Kingdom of Saudi Arabia. The four authors analyzed the results. A total of 21 risk factors of breast cancer were identified and classified into 5 important categories: genetic predisposition, histology, reproductive, diet and lifestyle.

3.1. Genetic predisposition

The study by Antoniou et al (2014) aimed to determine the risk factors of breast cancer in women derived from PALB2 (partner and localizer of BRCA2) mutations compared with populations at the age younger than 40 years old, aged 40 - 60 years old and in those aged over 60 years old. The occurrence of the PALB2 mutation in women with breast cancer was 40%. The risk factors for breast cancer were influenced by age ($P < 0.0001$) and by the family factors ($P = 0.04$). The risk factor for breast cancer from the PALB2 mutation came from women aged 70 years old at 33% while the absence of a family history of breast cancer was 58%. The PALB2-associated breast-cancer risk depends on both genotype and family history[10].

The research by Dossa et.al (2018) stated that women who have pathogenic mutations in the BRCA 1 and 2 genes are at a high risk of breast and ovarian cancer[11].

3.2. Histology

Another study conducted by Rice et al (2018) stated that a high percentage for mammographic density (MD) or the proportion of dense breast tissue on a mammogram can be a risk factor for invasive, ER+ , PR+ and HER2 breast cancer[12].

Research by Rehman and Husnain (2014) explained that the excessive accumulation of Fe, Cu and Zn in breast tissue are risk factors for breast cancer. Bowen H (1988) in Rehman and Husnain (2014) stated that iron is important in the regulation of cell growth and that is an important part of many proteins and enzymes. If there are excessive amounts of certain metals, then they may be shunted into very large proteins, such as iron into ferritin. This may have an association with malignancy in the tissue. Copper is also needed to form new blood vessels and cancer needs new

blood vessels in order to grow. Therefore, copper can affect carcinogenesis by acting as a cofactor for angiogenesis[13].

3.3 Reproductive/ hormonal risk factors

The research conducted by Arthur et al (2017) suggests that the use of *hormone replacement therapy* (HRT) and having atypical hyperplasia are both associated with an increased risk of breast cancer among women with benign breast disease (BBD)[14]. Another study by Elebro et al (2014) aimed to determine the potential risk factors for androgen receptor status breast cancer. The androgen receptors from 467 tumor cases (90.5%) were positive while those from 49 tumor cases (9.5%) were negative. Having their first child in old age and the use of oral contraceptive were both risk factors reated to the negative androgen receptors engaged in breast cancer[15]. Naser et al (2014) reported that using HRT doubles the chance of developing the disease among Arab females[16].

A study by Engmann et al (2017) aimed to determine the population at risk of pre-menopausal and post-menopausal breast cancer. Of the 18,437 women with breast cancer, being 40 years of age pre-menopause and 60 years of age post-menopause was also a risk. Additionally, 4,743 women (89.8%) pre-menopause and 12,502 women (95.1%) post-menopausal who were overweight and obese had the risk factors for breast cancer[4]. Moreover, early menarche age (≤13 years), nulliparous, late age at first live birth and a high reproductive interval index were all significantly associated with an increased BC risk in both the pre-menopausal and post- menopausal period[17]. Furthermore, Khaliset al (2018) described that women who were younger than 20 years old at their first full-term pregnancy were associated with a decreased risk of breast cancer. On the other hand, Khaliset al (2018) reported that there was no significant association with breast cancer risk concerning the irregularity of the menstrual cycle, age at menopause, a history of miscarriages and abortions, the duration of breastfeeding per child and their history of oral contraceptive use [18].

3.4. Diet and nutrition

The research on nutrition by Egnell et al (2017) aimed at investigating the association of vitamin B in alcohol consumers and breast cancer risk. This study showed that vitamin-V (thiamine, riboflavin, niacin, pantothenic acid, pyridoxine, folate and cobalamin) supplemental intake in non-to-low alcohol drinkers was inversely associated with breast cancer risk but not in heavier drinkers. This is because the alcohol intake interfered with the vitamin B transport (especially folate), absorption and metabolism

[6].

The study results from Kippen et al(2017) described that the inadequate intake of vegetables and fruits are one of risk factors for breast cancer[2]. Similarly, a research conducted among Jordanian women stated that the good or optimal intake of fruits and vegetables decreases the risk of breast cancer[19]. Another research study by Ji Hyun Kim (2017) aimed to investigate the dietary factors (food, habits) with Korean women's breast cancer risk factors. The participants were aged 30 years or older and they were recruited by the National Cancer Center in Korea between August 2002 and May 2007. In this study, grilled meat, a high-cholesterol food intake and irregular eating habits are significantly associated with breast cancer. Grilled meat increased the risk of breast cancer due to the carcinogenic mutagens such as heterocyclic amines (HCAs) and polycyclic aromatic

hydrocarbons (PAHs) which are highly abundant in meat cooked at high temperatures, especially that which is grilled or barbecued. When cholesterol is converted to cholesterol metabolites at 27HC, it may induce ER+ breast cancer growth [3]. Taking calcium supplements (>3 times a week) was associated with an increased risk of breast cancer. However, this result is not yet clear and needs to be investigated in further studies[19].

Research by Jing Wu et al (2016) proved that various proteins have different effects on the occurrence of breast cancer. In this article, the authors explained about milk. Milk contains fat, calcium, vitamin D, conjugated linoleic acids (CLAs) etc. that can have an effect on the inhibition of cell cycle progression, including the induction of apoptosis, the inhibition of angiogenesis, and the differentiation of the mammary cells. Moreover, soy food is an important food in Asian countries. Soy food contains numerous fibers and phytoestrogens, which can arrest the cell cycle, induce apoptosis, and inhibit angiogenesis. On the other hand, red meat and processed meat are a high risk cause of breast cancer because of (a) the carcinogenic byproducts that can change at a high temperature, (b) the fat, heme iron, and animal sugar molecules of N-glycolyneuraminic acid that enrich the red meat, which could promote inflammation, oxidative stress and tumor formation and (c) the hormone residues used for the stimulation in the growth of cattle. Hence, a higher soy food and skimmed milk intake may reduce the risk of breast cancer. Poultry, fish, egg, nuts, total milk, and whole milk intake are not associated with breast cancer, while red meat, fresh red meat, and processed meat have a risk of breast cancer[9].

3.5. Lifestyle

A cohort study by Dossus et al (2014) proved that both active and passive exposure to cigarette smoke increases the breast cancer risk. However, it depends on the duration of smoking or exposure, the amount of cigarettes and the level of physical activity[20]. Similarly, less physical activity is an increased risk of breast cancer[19]. Likewise, research by Kippen et al (2017) explained that more than 90% of the 3,301 respondents identified the sun exposure factors and active smoking, while around 80% identified passive smoking and 40-60% identified the risk being due to having an overweight body or obesity and drinking alcohol[2].

Research by Naser et al (2014) explained that in the sample of 1,172 women from Arabia, 24% were aged less than 35 years, married and obese (BMI ≥25) and they had increased risk factors for breast cancer. Overweight/obese women exhibit more than 2-times the increased risk of breast cancer compared to women with a normal BMI[16]. Furthermore, a study by Al-Ajmi et al (2018) explained the results of a 9-year study of total breast cancer cases. Being pre-menopause, having a low BMI and a low waist to hip ratio can increase the risk of breast cancer whereas a high BMI can increase the risk in post-menopausal women[17].

Sleep has been closely linked to the risk of breast cancer. Both a short sleep duration (<6h) and a long sleep duration (>9h), in addition to poor sleep quality, were associated with an increased risk of breast cancer progression, especially in pre-menopausal women. Short sleep duration altered melatonin release, immune function, oxidative stress, and the inflammatory pathways, which then consequently influenced the breast cancer progression[21]. A cohort study conducted on 10,802 Mexican American adults aged 20-60 years showed that sleeping for less than 6 hours per night was significantly associated with an increased breast cancer risk [22].

Table 1 List of the risk factors for cancer that form the basis of making this systematic review

No	Author	Type of Study	Sample size	Outcome

4. Discussion

The study of this systematic review was about the risk factors that influence the occurrence of breast cancer. The studies took place in the U.S, Morocco, Arabia, the UK, France, South Korea and Canada. Based on the 18 articles, there are four reproductive risk factors, namely menstruation, pre-menopause, post-menopause, menopause, and contraception. There are three food related risk factors, including diet, protein and vitamin B factors. The presence of risk factors due to gene mutations was found in two articles. The lifestyle related risk factors included sun exposure, active and passive smoking, obesity, drinking alcohol and the inadequate eating of vegetables and fruits as found in four articles. One article mentioned the factor of tissue changes in the breast, and one article referred to a mammogram. Another article identified obesity as being a risk and two articles described relating the risk with sleep duration. The identification of these risk factors may be useful for the development of prevention strategies to decrease the breast cancer incidence. The most common risk factors found in relation to the incidence of breast cancer are the reproductive factors and lifestyle factors.

There are premenopausal, postmenopausal, menopausal and contraceptive menstruation factors. The use of contraception, the influence of hormones and changes in Fe, Cu, Zn in the breast tissue also affect the occurrence of breast cancer [13]. The risk factors in the field of reproduction are where menarche is too early, where there is a late age for the first live birth and nullipara [18].

Another risk factor that is very influential on the occurrence of breast cancer is a unhealthy lifestyle, including exposure to the sun, smoking, drinking alcohol, consuming low vegetables and fruits and obesity [2]. Obesity is also emphasized as a factor that greatly affects the occurrence of breast cancer in Arab women[16]. Sleep duration (>9 hrs and <6 hrs) is also related to the breast cancer risk[21,22].

The risk factors in the nutrition field say that consuming vitamin B supplements and high calcium supplements can be risk factor for breast cancer. There is a relationship between consuming grilled meat, as and contains a lot of cholesterol, and the occurrence of breast cancer [3][19]. Lifestyle and reproductive factors are the most common risk factors for breast cancer.

5. Limitation

One limitation of this study was that the search strategy was intentionally very broad, as the authors were attempting to identify all of the possible risk factors for breast cancer. Another potential limitation related to the inclusion criteria for this study is the language restrictions used. Some potentially relevant articles may have been excluded. It is believed that the overall impact is minimal.

6. Conclusion

Based on the 18 articles, the authors found there to be various risk factors that influence the occurrence of breast cancer. There were reproductive factors, food related factors (inadequate intake of vegetables and fruits, high intake of fresh red meat, processed meat and vitamin B), genetic factors (gene mutations), lifestyle related factors (less physical activity, sun exposure, active and passive smoking, drinking alcohol, sleep duration) and histology identified. The most common risk factors found in correlation with the incidence of breast cancer were reproductive factors and lifestyle. Changes in diet and lifestyle can be used as a basic consideration in the promotion of breast cancer prevention. Moreover, people with a family history and genetic predisposition should emphasize

regular check-ups for early diagnosis and timely treatment. Therefore, the identification of these risk factors may be useful for the development of prevention strategies for breast cancer.

ABSTRACT

Changes in the balance of fluids and electrolytes in patients of End Stage Renal Disease (ESRD) resulted in changes in the composition and flow of saliva [1]. In addition to changes in the composition and flow of saliva, ESRD patients also undergo changes dry mouth (xerostomia) caused an increase in the blood concentration of ureum [1]. Xerostomia is also influenced by the drugs used by patients ESRD undergoing hemodialysis (HD). This study aims to find out the effectiveness of chewing gum against xerostomia and the flow rate of saliva in patients undergoing hemodialysis. Search literature begins with the determination of the topic then continued with the search articles using keywords that have been determined by some English-language journals database i.e. Scopus, Pro Quest, Ebscho and Scholar with the limitations of the year publication of 2005 up to 2018. After getting the appropriate journals by keyword and then selected 15 journals that comply with the criteria for inclusion in this study. In General, all the articles that do review give the results that the chewing gum to give benefits to the change of xerostomia and increased flow rate of saliva in patients undergoing hemodialysis. Chewing gum is an effective way, cheap, simple and well tolerated for xerostomia changes and an increase in flow rate of saliva in patients undergoing hemodialysis.

Keywords: chewing gum, xerostomia, salivary flow rate, hemodialysis

1. Introduction

Changes in the balance of fluids and electrolytes in patients with End Stage Renal Disease (ESRD) results in changes in the composition and flow of saliva [1]. In addition to changes in the composition and flow of saliva, ESRD patients also undergo changes resulting in a dry mouth (xerostomia) caused by an increase in the blood concentration of ureum. Xerostomia is also influenced by the drugs used by the patients ESRD undergoing hemodialysis (HD). Some studies show xerostomia can be experienced by the patient's ESRD when they are undergoing hemodialysis [2,3,1,4,5,6,7].

Several studies show there are interventions when it comes to stimulating saliva and minimizing xerostomia, namely sugar free chewing gum or sucking on sugar-free candy to stimulate the flow of saliva, sucking ice cubes, drinking water while eating to assist in the chewing and swallowing of food, the use of an alcohol-free liquid gargle (mouthwash), the avoidance of

carbonated beverages (such as soda), caffeine, tobacco, and alcohol, using a lanolin-based lip balm for the lips when they are cracked or dry, acupressure, electrostimulation, the use of pilocarpine and cevimeline (mouthwash) and drugs that target angiotensin[8,9,10,11,12].

In general, the prevalence of xerostomia in patients undergoing hemodialys is about 33 - 76% [5]. In Indonesia, the research conducted by Widati et al in RSU Haji Surabaya showed that the prevalence of xerostomia in patients with chronic kidney disease who underwent hemodialysis end stage as many as 35 out of 60 patients (58.3%) [6]. Besides, the research conducted by Gowara et al in Cipto Mangunkusumo hospital showed that the main complaint was xerostomia in patients with chronic kidney disease who underwent hemodialysis in the end stage, which was 77 (82.8%) of the subjects [7].

Xerostomia will occur when the flow of saliva decreases to 50% of the normal secretions. A decrease in saliva causes precipitation in the above-mentioned composition of the saliva such as the level of bicarbonate, phosphate and urea being reduced, thus causing a decrease in the capacity buffer of the saliva producing a decreased pH [13]. In the event of an increase or decrease in the volume of saliva, it will be followed by an increase or decrease in the pH of the saliva of 78.5%. The increased secretion of saliva causes an increased volume and dilution of the saliva needed to proceed with both ingestion and lubrication. The increased secretion of saliva also increases the number and arrangement of the content of saliva, such as bicarbonates which can increase the pH. Conversely, the decreased secretion of saliva will lower the number and arrangement of the content of saliva that can cause a decrease in the pH of the saliva in turn [14]. The research done by Khoerunnisa and Dralfoldman shows that in the more severe degrees of xerostomia, it will lower the pH of the saliva [15].

The impact of xerostomia in patients undergoing hemodialysis (HD) is related to difficulties swallowing, chewing, tasting, and speaking; an increased risk of disease, including oral mucous lesions, gingiva and those of the tongue; bacterial and fungal infection such as candidiasis, dental caries and periodontal disease; an interdialytic body weight resulting from an increase in fluid intake and a decrease in quality of life[12].

Therapies without any side effects are necessary to prevent xerostomia from happening. The research conducted by Mansouri and Ali, Vahed and Shahraki, Shahdadi, Mehr and Arbabisarjou said that chewing gum without sugar has more of an effect when it comes to reducing xerostomia in patients undergoing hemodialysis compared to candy without sugar [3]. In addition, the sweets without sugar were also found to significantly lower the xerostomia in some patients who underwent hemodialysis. The research done by Said and Mohammed concerning the influence of chewing gum on xerostomia, haus and interdialytic weight gain in patients on hemodialysis pointed out that the use of chewing gum reduces thirst, xerostomia and that it significantly reduces interdialytic weight loss and increases the flow rate of saliva in the HD patients[4]. In addition, Bots et al foud that chewing gum for a short period of 2 weeks reduces thirst and xerostomia, which is more effective than a comparison of saliva, with the best improvement seen in patients who also increase their chewing of gum as a useful therapy[16].

There are several scientific articles found about interventions used to treat xerostomia in patients undergoing hemodialysis, namely chewing gum, chewing gum with chewing gum, chewing gum and Straw, chewing gum containing CPP-ACP, massaging the salivary glands and gum chewing, sweetgum (Happydent White Chewing Gum) and sugar-free gum (Happydent White

Xylitol Chewing Gum), chewing different flavored gums, sugar-free chewing gum and xanthan gum-based artificial saliva. Therefore a systematic review is needed to identify the effect of chewing gum effectiveness on xerostomia and the salivary flow rate of patients undergoing hemodialysis. This study aimed to find out the effectiveness of chewing gum against xerostomia and the flow rate of saliva in patients undergoing hemodialysis.

2. Method

The review of the journals was done using the guidelines in the form of the checklist of Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISM) and the PICO framework.

2.1 The Search Strategy Article

As many as 336 articles were found. The results came from four databases: 102 articles from Scopus, 87 articles from Proquest, 61 articles from Ebscho and 86 articles from Scholar. The results of the article selection according to the inclusion criteria of 15 articles, then they were given a serial number and article analysis was done to facilitate the review process. The articles were taken from 2005 to 2018. The keywords used in the journal search were chewing gum AND xerostomia AND Saliva and Hemodialysis Flow Rate.

2.2 Selection Criteria of the Article

The inclusion criteria specified were (1) English-language journals, (2) the intervention given was in the form of chewing gum, (3) the research subjects were patients experiencing xerostomia and a decreased salivary flow rates and (4) the results of the study stated that chewing gum is needed to reduce xerostomia complaints and to increase the salivary flow rate. The exclusion criteria were journals that did not discuss gum chewing interventions, the research subjects were patients undergoing head and neck therapy and the year of publication was before 2005.

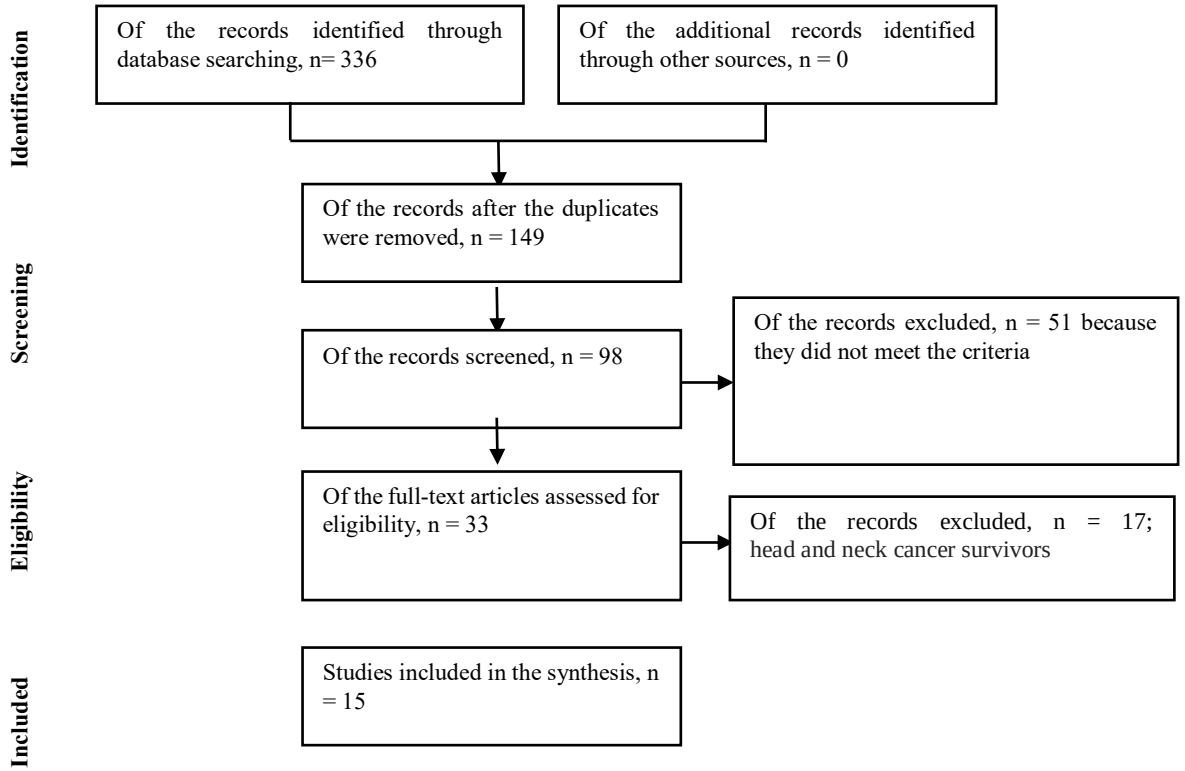

Figure 1. PRISMA Flow Diagram

2.3 Assessment Of Articles

This systematic review was not limited to studies with randomized controlled trial research designs. For the desired outcome, it was stated that a gum chewing intervention is needed to reduce the xerostomia and to increase the salivary flow rate. For the stages, methods and duration of the intervention and the number of samples in this systematic review, there are no restrictions.

Our review has some limitations. First, there is the potential for the incompleteness of the evidence reviewed to have restricted the validity of the results. Second, biased publication and location can also affect the results of this systematic review. Third, the number of trials included in the review and analysis of the US and the total sample size was too small to allow for a definite assessment. Fourth, the collection of statistics is not possible because of the heterogeneity of the studies that were included and the lack of adequate raw data reporting.

3. Results

From the search results using predetermined keywords, the researcher found 336 journals which were then screened by looking at the title and reading the abstract; 33 journals were obtained. Of the 33 journals, 15 journals were selected that met the inclusion criteria. Some journals were not selected is because they did not meet the inclusion criteria. Of the 15 selected journals, all discussed about the intervention of chewing gum to reduce xerostomia and to increase the salivary flow rate.

Table 1. Analysis of the Literature

Title	Research Design	Sample and Sampling Technique	Variable	Research Measurement Tool	Analysis	Outcomes
The Null Effect of Chewing Gum During Hemodialysis on Dry Mouth[2]	Randomized, controlled, single-blind, crossover experimental study	Sample: 61 patients on hemodialysis. Technique: Random sampling	Variable independent: Chewing gum Variable dependent: Dry mouth and its symptoms	Dry mouth symptoms were assessed using the Visual Analog Scale [VAS]	1. Normal distribution was assessed using the Shapiro Wilk test 2. To test the effects of chewing gum on the flow rate of saliva pH, saliva, and the symptoms of dry mouth, set points in time of 0-4 hours were measured using the Wilcoxon signed rank test 3.To determine the effects of chewing candy, we used the Friedman test	There were significant differences ($P < 0.05$) between chewing gum with no chewing gum against the pH of saliva but it does not increase the flow rate of saliva and it does not control the dry mouth symptoms. However, it was also reported that most of the patients (68.9%) have a positive opinion about chewing gum, which is likely related to its ability to refresh the mouth.
A comparative study on the effect of sugarless chewing gum with sugarless candy on xerostomia in	Semi-empirical study	Sample: 61 patients on hemodialysis Technique: Random sampling	Variable independent: Chewing gum with candy without sugar Variable dependent:	Xerostomia determined using the Xerostomia Index (XI). The duration of dialysis use was also looked at	- To measure the duration of a comparison group of patients in thirst related to gum consumption before and after the intervention	There was a significant difference in xerostomia patients before and after the interventions in both the intervention group and the control group ($p < 0.05$).

Title	Research Design	Sample and Sampling Technique	Variable	Research Measurement Tool	Analysis	Outcomes
patients undergoing hemodialysis[3]			Xerostomia	(DTI). To measure the intensity of thirst, VAS was used	was used via the Wilcoxon test - Average and standard deviation of the duration of the haus in three groups were compared before and after the intervention using the Kruskal-Wallis test	The results of this study showed that the average index of xerostomia for the chewing gum without sugar and for the sweets without sugar was higher than the control group. The average deductions for the xerostomia group for chewing gum without sugar were higher than the groups with candy without sugar.
Study on the Clinical Significance and Related Factors of Thirst and Xerostomia in Maintenance Hemodialysis Patients [1]	Observational study and crossover trial	Sample: 61 patients undergoing hemodialysis Technique: Random sampling	Variable independent: - Chewing gum - Straw Variable dependent: - Thirst - Xerostomia	Thirst was assessed using visual analog scales (VAS) and the Dialysis Thirst Inventory (DTI). Xerostomia was assessed using VAS and Xerostomia	The data was analyzed using ANOVA and the correlation coefficients were used to assess the correlation between the continuous variables. The results of the crossover experiment were investigated using two T-test samples	Xerostomia was significantly reduced by gum use (P = 0,000) and thirst was reduced with straw use (P = 0.016)

The management of xerostomia in patients on hemodialysis: comparison of artificial saliva and chewing gum, [16]	Crossover trial	Sample: 65 HD patients	Variable independent: Sugar-free chewing gum and xanthan gum-based artificial saliva Variable dependent: Xerostomia	The level of xerostomia was assessed with the Xerostomia Inventory (XI)	To assess the overall treatment effect of each therapy with the repeated multivariate analysis of variance (MANOVA). Furthermore, we investigated the effects of each therapy compared to the BASELINE for the level of xerostomia using the General Linear Model of the design of repeated ANOVA actions, followed by a paired t-test as a post hoc procedure if appropriate. Differences between the VAS scale data were analyzed using non-parametric tests and the other data from the questionnaires was analyzed using the Chi-square test.	Chewing gum and artificial saliva could play an important role in the palliative care of xerostomia in HD patients

3.1 Intervention

The results of a journal review of the research that has been done on chewing gum showed that the reduction of the xerostomia release and the increase of the salivary flow rate indicates that the duration, amount and frequency used for the administration of interventions varied. The duration of the interventions was between 2 weeks to 3 months and the amount of gum given was between 6 and 10 seeds per day according to the consideration of the researcher.

3.2 Characteristics Summary of Studies

The research conducted by Duruk et al. with 60 hemodialysis patients as the sample stated there were significant differences ($P < 0.05$) between chewing gum and no gum chewing against the pH of saliva but that this did not increase the flow rate of saliva and that it did not control dry mouth or the symptoms[2]. However, it was also reported that most of the patients (68.9%) had a positive opinion about chewing gum, which is likely to be related to its ability to refresh the mouth. In this study, the patients were asked to chew gum every hour for 15 minutes during a session of hemodialysis while in the other studies, the patients were asked to chew gum six times a day for at least 10 minutes [2]. The differences between the scores of all of the subjective dry mouth symptoms (VAS) at the 0- and 4-hour time points in the day when gum was not chewed and on the day when the gum was chewed, the results were found to be significant (P G .05), except for the scores for the "amount of saliva" and "burning sensation in the mouth". Because this was a single-blind study, the symptoms of dry mouth (VAS), the salivary flow rate and the pH were assessed by a nurse who was not included in the study team with the aim of avoiding bias. The nurse collecting the objective data did not know which patients had completed gum chewing. The nurse was instructed by the researchers about how to record the symptoms on the VAS, how to measure the amount of saliva in the graduated tube and how to read the pH value. Because this was a single-blind study, the symptoms of dry mouth (VAS), the salivary flow rate and the pH were assessed by a nurse who was not included in the study team with the aim of avoiding bias. The nurse collecting the objective data did not know which patients had completed the gum chewing. The nurse was instructed by the researchers about how to record the symptoms on the VAS, how to measure the amount of saliva in the graduated tube and how to read the pH value.

The research conducted by Fan *et al*. was where a total of 11 MHD patients were enrolled and randomized across two groups: chewing gum and straw for 2 weeks respectively. There was no significant difference in age, gender, time on HD and the parameters of biochemistry, hemoglobin, Kt / V and nPCR between the two groups. What's more, no obvious difference was found in the level of xerostomia, thirst, IDWG and blood pressure. However, significant treatment effects were observed for thirst and xerostomia. The use of chewing gum decreased the VAS thirst score (70.7 ± 17.1 to 61.1 ± 22.0, $P = 0.038$), DTI (19.3 ± 3.4 to 14.3 ± 4.8, $P = 0.000$), VAS xerostomia score (54.6 ± 19.6 to 44.6 ± 20.0,$P = 0.001$) and XI (32.2 ± 9.4 to 27.3 ± 11.7, $P = 0.001$). The use of straw also had a positive overall effect on the DTI ($P = 0.016$) and VAS thirst score ($P = 0.003$) during the crossover clinical trial. When the patients were treated with chewing gum, the IDWG2d decreased from 2.78 ± 0.66 kg to 2.43 ± 0.70 kg ($P = 0.009$) and IDWG3d decreased from 3.17 ± 0.89 kg to 2.88 ± 0.65 kg ($P = 0.017$). IDWG3d also decreased by the use of a straw to control the water intake ($P = 0.049$). Treatment with chewing gum and straw did not influence UWS, PC-SWS, MAP, SBP, and DBP during the crossover clinical trial. Compared with the treatment of straw during the crossover clinical trial, the VAS xerostomia score significant decreased through the use of chewing gum ($P = 0.06$). Between the two interventions, no difference was found in DTI, VAS thirst score, XI, UWS, PC-SWS, IDWG, MAP, SBP and DBP [1].

The research conducted by Mansouri et al., according to the Wilcoxon test, showed that there was a significant difference between xerostomia before and after the intervention in the chewing gum group ($p = 0.001$) and the candy group ($p = 0.001$). There was no significant difference in the control group ($p = 0.44$). The mean and standard deviation of xerostomia in the patients across the three groups were compared before and after the intervention using the Kruskal-Wallis test. The results showed that there was no significant difference between the three groups before the intervention ($p = 0.72$). The results after intervention showed that there was a significant difference between the mean xerostomia index of the patients in all three groups ($p = 0.001$). By considering the mean and standard deviation obtained for each group, it can be concluded that the mean of the xerostomia index in the chewing-gum group was less than the other two groups and that it was smaller in the candy group when compared to the control group[3].

The research conducted by Said & Mohammed showed that the age of the studied sample was divided into two categories, which was most prevalent in the age group of (<50) years in both the study and control group (60.0% & 53.3% respectively), followed by the category of (50+) years. The gender distribution was almost equal between males and females with a slightly higher preponderance of males in both groups. Regarding the duration of hemodialysis, about 40% of the study group and 33.3% of the control group had received hemodialysis for more than 4 years. Regarding the dry weight, the mean for the study and control group was (74.94±5.13) and (72.92±3.7) respectively. There were no statistically significant differences revealed among the two groups for any of the characteristics. There was a statistically significant difference among the patients in the study group throughout the six sessions in relation to xerostomia, thirst, salivary flow rate (ml) and interdialytic weight gain (kg). There was a decrease in xerostomia, thirst and interdialytic weight gain from 4.6±0.6,4.3±0.6 and 4.4±1.2 to1.8±0.8, 1.9±0.7 and 1.8±0.7 (respectively) through the six sessions. There was an increase in salivary flow rate (ml) from 0.4±0.1 to at 0.8±0.2 through the sixth session. Statistically significant differences among the patients in the control group throughout the six sessions were in relation to xerostomia, thirst, salivary flow rate (ml) and interdialytic weight gain (kg). There was an increase in xerostomia, thirst and interdialytic weight gain from 3.3±0.7, 2.3±1.1 and 1.8±0.5 to 4.0±0.9, 4.4±0.8 and 3.0±1.5 (respectively) through the six sessions. There is a decrease in the salivary flow rate (ml) from 0.5±0.2 to 0.4±0.2 through six sessions [4].

The use of chewing gum reduces thirst and xerostomia, significantly lowering the interdialytic weight gain and increasing the flow rate of saliva in the patients [4]. The patients with xerostomia can increase the level of their salivary secretion and it can reduce dry mouth through the use of two flavors of chewing gum [17].

4. Discussion

The findings from the 15 items of literature state that chewing gum effectively reduces the complaint of xerostomia, increases the salivary flow rate and is effective at neutralizing the pH of saliva. The intervention of chewing xylitol gum works through both mechanical and chemical stimuli. The mechanical stimuli obtained from the mastication process causes the muscles in the oral cavity to work so then the chemoreceptors and pressure receptors in the mouth respond. These receptors begin implusions in the nerve fibers that carry information to the saliva center in the medulla oblongata. The saliva center then sends implications through the extrinsic autonomic nerves to increase the salivary secretion. The chemical stimuli are obtained from the taste of gum which will stimulate the parsympathetic nerves from the superior and inferior salivatory nuclei of the brain stem. The nucleus is stimulated by the taste on the tongue and the oral and pharyngeal

cavities according to the salivary needs which increases the rate of saliva. The increased salivary secretions also increase the amount and composition of the salivary content, such as bicarbonates which can increase the salivary pH[18,19]. The purpose of this review was to critically evaluate the effectiveness of chewing gum against xerostomia. Ten out of the 11 literary reviews examined to see if chewing gum can effectively reduce the complaints of xerostomia, increase the saliva flow rate and neutralize the pH of the saliva. One item of literature did not state that there was an effect on xerostomia or the flow rate of saliva[2,3,1,4,17,20,21,22,23,9]. The difference in the findings of this study and other studies is associated with the method, duration, frequency and the number of different candies used in the research [2]. The research conducted by Duruk et al. stated there was a significant difference ($P < 0.05$) between chewing gum and no gum chewing against pH saliva but that it does not increase the flow rate of saliva and that it does not control the dry mouth symptoms. However, it was also reported that most of the patients (68.9%) have a positive opinion about chewing gum, which is likely to be related to its ability to refresh the mouth. In this study, the patients were asked to chew gum every hour for 15 minutes during a session of hemodialysis while the other study patients were asked to chew gum 6 times a day for at least 10 minutes [2]. In addition, a study conducted by Jagodzi et al. stated that the use of chewing gum for 3 months did not cause significant changes in xerostomia and thirst. In addition, the regular use of chewing gum does not improve the parameters of hydration status in chronic HD patients. This is attributed to the non-compliance of the patients in carrying out interventions and the patients felt bored at the intervention [9].

Our review has several limitations. First, the potential incompleteness of the evidence that we reviewed might have limited the validity of the results. Second, the publication bias and location can also influence the results of the systematic review. Third, the number of trials included in our review and analysis and the total sample size was too small to allow for a definite assessment. Fourth, statistical collection was not possible because of the heterogeneity of the studies included and the lack of adequate reporting of the raw data.

5. Conclusion

Chewing gum is an effective way that is simple, inexpensive and that can be well tolerated to change xerostomia, increase the flow rate of saliva and neutralize the pH of saliva in patients who undergo hemodialysis.

[3]Department of Medical Surgical Nursing, Faculty of Nursing, Airlangga University, Surabaya
E-mail: bunda_safa03@yahoo.com

ABSTRACT

To review previous studies of non-pharmacological interventions, namely relaxation and distraction, pain and anxiety disorders in post-fracture surgery and weaknesses of these interventions **.** The literature search was carried out using the terms "pain" "non- pharmacological intervensions" and "Fracture " in Scopus, Google Scholar, and Pubmed from 1990 to March 2018. Studies were reviewed and categorized based on progressive muscle relaxation [PMR], autogenic training, deep breathing relaxation, benson relaxation, guided imagery, finger gripping, music therapy, classical music, murrotal, Dhikr, hypnosis therapy, education and coping mechanisms), and summarized in relation to various research characteristics and results. The researchers support for non-pharmacological interventions, namely a maximum of 6 journals from 15 journals reviewed. The most common distraction techniques are supported by listening to the verses of the Qur'an, especially for pain and anxiety of Patients postoperative fracture. Researchers report total therapy is very supportive therapy in addition to relaxation and music. Little evidence is found for the use of cold packs, aromatherapy and coping, and there is no support for progressive muscle relaxation. Most reviewed studies have weaknesses in the methodology, which limits the ability to draw conclusions about intervention.

Keywords: Pain, non-pharmacological intervention , fracture

1. Introduction

Fractures are defined as fractures caused by physical trauma. They can occur due to excessive pressure versus the ability of the bone to withstand pressure. Various efforts and actions are needed to restore the bone structure and function to as it was before. Actions that are often chosen in fracture patients are surgical procedures commonly known as orthopedic surgery [1]. Pain management can use pharmacological therapy and non-pharmacological therapy. Pharmacological therapy is often carried out but it cannot always be done because of the contraindications within the drug administration, while non-pharmacological therapies such as distraction techniques in the form of the transfer of attention and menden garkan music are still in the process of undergoing continuous research [2]. Pain in a fracture patient, if not treated immediately, can interfere with physiological processes. Pain is the fifth vital sign and pain interferes with hemodynamics. Pain can cause stressors and anxiety, which can ultimately disrupt the healing process of the disease. Therefore the pain needs to be overcome so then further complications do not occur and interfere with patients. This can help

their healing process [3]. The aim of this systematic review was to summarize non-pharmacological interventions used with the intention of reducing the scale of pain by synthesizing the existing qualitative studies to inform of the hemodialysis facilitators and clinical research.

2. Methods

2.1 Design

The design of this study was a systematic review of quantitative study approaches which were formulated to review a handful of relevant studies to allow them to undergo comprehensive analysis. This systematic goal was developed based on the PICO model (Patient, Intervention, Comparison, and Outcome). The reporting was done through the systematic use of PRISMA *(Preferred Reporting Items for Systematic Reviews and Meta-Analysis).*

2.2 Inclusion and Exclusion Criteria

This systematic review established the inclusion and exclusion criteria that focus on both quantitative and quasi-experimental studies. A feasibility study was conducted to identify non-pharmacological interventions to reduce the pain scale in post=operative patients with fracture with the language eligibility criteria being that they used English. The publications had to be from 2012 - 2018. The further inclusion group criteria were studies with post=operative adult fracture patients and the exclusion criteria were post-operative fracture patients who were children.

2.3 Search Strategy

The systematic search used the PICO electronic data framework (Xiaoli Huang., Jimmy Lin., 2006). In the first step, we looked in the Scopus, Google Scholar and Pubmed electronic databases to identify key articles and to identify the keywords by adjusting the key concepts: 1. Patients' post-operative fracture, 2. Pain, 3. Non-pharmacological interventions and 4. Quantitative study. Our keywords were used to look for quotes and full articles, including the title, abstract, text and reference information. The second step was translating keywords in English to find the relevant articles in the selected electronic databases. The third step was to filter using the PICO framework to determine which articles passed for further review according to the topic.

Table 1. Reliability criteria

Criteria	Inclusion	Exclusion
Study Design	RCT Quasi-experimental Pre-experiment	Qualitative
Concept		
Population	People with post-operative fractures	Fracture from multiple traumas Health worker associated with hemodialysis (e.g. nurse, doctor, nutritionist) Family Caregiver
Context	Adults in the Health Services / Community	Children
Language	English (* min. Abstract)	Full text without an abstract in English
Date range	≥ 2012 - 2018	< 2012

2.4 Research design

In this systematic review, most of the research designs used were quasi-experimental (11 articles), and pre-experimental (4 articles). The most widely used research design was quasi-experimental with the largest number of samples being 50 respondents.

2.5 Characteristics of the Respondents

The number of samples ranged from 10 to 50 patients. In 14 journals, the respondents were patients with post-operative fractures. The measuring device for evaluating pain was the Visual Analog Scale (VAS) used in 8 journals and the Numeratic Rating Scale (NR S) used in 5 journals. Vital Signs (TTV) and adaptive coping were each used in 1 journal.

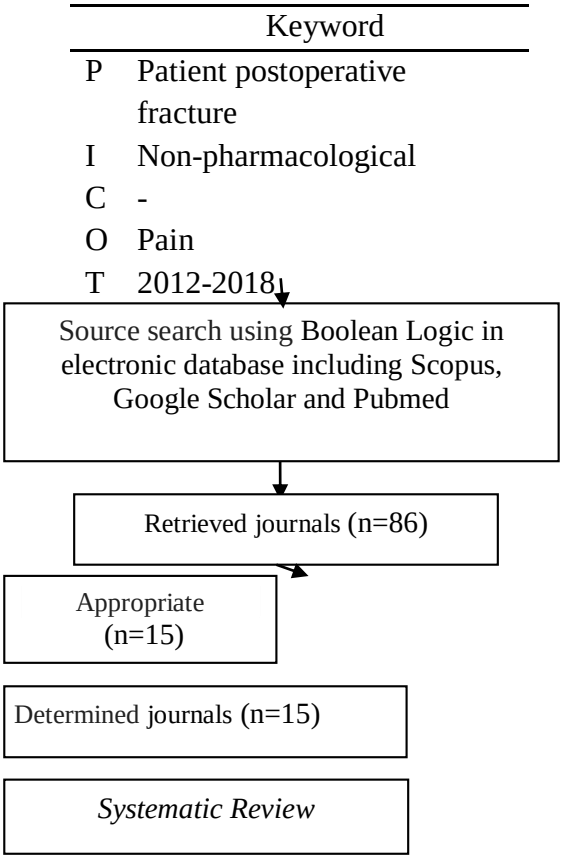

Figure 1: PICOT strategy and Booelan logic source search in the electronic databases

3. Results

3.1 Music therapy

Music has been shown to lower the blood pressure and change the perception of time. Nurse need to be able to use music creatively in various clinical situations. The patients are generally performing the activity by playing the instrument, singing songs or listening to music. Music from the beginning is always according to the mood of the individual, and this is the best option. Music produces a change in status of the consciousness through sound, silence, space, and time. Music must be heard for at least 15 minutes to have a positive therapeutic effect. In the state of acute care, listening to music can have very effective results when it comes to reducing pain in a post-surgery patient.

Four research articles stated that music therapy interventions were used in treating post-fracture surgery patients. In total, 4 of the articles used a quasi-experimental research design. The research conducted by [9] states that music therapy greatly affects the vital signs of the patients who experience pain. The research design was a one group pre-post test with a pre-experimental approach. The population studied were all of the postoperative fracture patients in RSUD Dr. Harjono Ponorogo. Using accidental sampling techniques, the researcher obtained a sample of 26 respondents. The instrument used was an observation. The results were analyzed using the Wilcoxon test ($\alpha = 0$, 05). The results showed the effect of music therapy on blood pressure with a significant p value (0.002), pulse with a p value (0.025), respiration with a p value (0.014), and a non-significant

body temperature with a p value (0.180). This is because music therapy can stimulate serotonin production. Research by Yanuar (2015) states that music therapy causes a decrease in pain intensity. This type of research is quasi-experimental with a Non-Equivalent Control Group Design, and a feature of this study was using a control. The number of samples was 20 respondents; 10 people in the experimental group and 10 in the control group. The sampling method used was the accidental sampling technique. The data was retrieved using interviews and tagging using a pain scale NRS (Numerical Rating Scale) before and after the music therapy for 10 minutes in the experimental group. Based on the Mann-Whitney statistical test, the p value = 0.007 showed that the language p value < 0.05, which means there was a difference in pain intensity in the patients with post-operative fractures between the experimental group and the control group. For the third study by Djamal, Rompas and Bawotong (2015), it stated that there was an effect from music therapy on the scale of pain in the fracture patients at Irina A RSUP Prof. Dr. RD Kandou Manado. The study was quasi-experimental with a pretest-post-test design approach with a control group. The sample taken totaled 50 patients. The data collection was done using a questionnaire. The results were examined using a t test (P value = 0.000; α = 0.05). The latest research by Farida (2019) combines two methods of non-pharmacological interventions, namely music therapy with aromatherapy. The study was quasi-experimental with the study design involving a non-equivalent control group pre- and post-test. The sample totaled 30 respondents; 15 for the intervention and 15 for the control group.

3.2 Murrotal therapy

Murottal therapy, or the recitation of Qur'anic verses, was mentioned as having the same effect as pharmacological therapy. In the study, 36 respondents indicated that there was a difference between murottal therapy and music therapy in reducing their pain levels. The mean reduction in pain in the murottal therapy group was greater than the decrease in pain in the music therapy group (Rilla, Ropi and Sriati, 2014). Research conducted by Khashinah and Candra (2015) stated that there was a significant effect of Juz 'Amma murottal therapy on pain reduction in the post-ORIF patients at PKU Muhammadiyah Hospital in Yogyakarta and Suyanto (2013). Research says that Al Quran (Murotal) reading can stimulate delta waves, so the listener becomes calm and comfortable. The effect is expected to reduce the pain intensity experienced by the fracture patients.

3.3 Asmaul husna therapy

Listen to readings from Beautiful Names can be used for arbitrary anxiety or pain lessening in the treatment of disease. The application of listening to Asmaul Husna is easy to do and quickly implemented. This non-pharmacological intervention can be used as a complementary therapy to pharmacological therapy. Medical therapy is not good enough without being accompanied by religious factors (religion and dzikir) and vice versa. Religious therapy is also incomplete without medical therapy (Wulandini, Roza and Safitri, 2018). Another study states that Asmaul Husna therapy is effective att reducing the pain in fractured patients. Past research that has been conducted by Masrvia, Sulitiyani and Hidayanti (2018) shows that listening to the reading of the Asmaul Husna can be effectively used to reduce the pain in fractured patients both preoperatively and post-operatively in RSUD Dr. R Soedjono Selong. It was given to 26 respondents where the Wilcoxon signed rank test results obtained a p value <α (0,000 <0,05). Ha was accepted and H0 was rejected.

3.4 Other non-pharmacological interventions to reduce pain

In the previous study, that by Aji, Armiyati and Sn (2015), they said that autogenic relaxation was more effective than slow deep breathing relaxation at reducing the pain in post -ORIF patients in Ambarawa Hospital. The study of Novia and Respati (2018) also said that guided imagery therapy has an influence on pain in post-fracture surgery. Guided imagery therapy can be applied by the health workers, especially nurses, in hospitals as a non-pharmacological therapy to reduce pain.

The research by Ayu Puspita (2018) provided two therapies, namely lavender and finger hand aromatherapy to 30 respondents divided into two groups; 15 respondents as an experimental group and 15 control group respondents. There was an influence from the lavender and hand-held aromatherapy on decreasing the pain intensity in post-fracture surgery patients in the hospital. This study involved 48 people divided into 24 in the treatment group and 24 in the control group and the researcher produced a combination of pain education and dhikr meditation to reduce pain intensity and to stabilize the blood pressure, pulse and respiration in the patients after fracture surgery [11]. The research by Kristanto and Arofiati (2016) proved that giving a cold pack had a greater effectiveness than the delivery of deep breath relaxation, so the researchers suggest that the use of cold pack is recommended to be used as an independent nursing implementation but to still consider the patient's physical condition.

4. Discussion

Significant effects from the non-pharmacological interventions related to the pain of the post-operative fracture patients has been described in the 15 studies reviewed. The researcher reported pain relief for the post-fracture surgery patients using music therapy (Lopes, Alimansur and Santoso, 2012; Djamal, Rompas and Bawotong, 2015; Yanuar, 2015; Nurul Farida, 2019), Qur'anic total therapy (Suyanto, 2013; Vava Rilla, Ropi and Sriati, 2014), Asmaul Husna therapy (Masrvia, Sulitiyani and Manhidayanti, 2018; Wulandini, Roza and Safitri, 2018) and other effective interventions such as a combination of 2 autogenic relaxation interventions and deep breathing, lavender and hand-held aromatherapy, education and remembrance, cold pack use and deep breath relaxation (Nasriati, Suryani and Afandi, 2014; Aji, Armiyati and Sn, 2015; Kristanto and Arofiati, 2016; Ayu Puspita, 2018). The use of murrotal therapy is recommended to get more samples and to consider the factors of gender, age and the experience of pain by the patients.

Most of the sympathizers were given a non-pharmacological intervention at a frequency of several times over several days or weeks, providing the sample with a sufficient number of opportunities to learn and practice the technique. Non- pharmacological interventions were documented in 15 studies, in which the patients using the non-pharmacological interventions produced significant improvements in terms of reducing their post-fracture pain.

Apart from the advantages and disadvantages in non- pharmacological intervention studies, some can be used to explain the mixed results. Small sample sizes (n <50) were used in 15 of the research studies. The authors rarely discuss strength or justify their sample size. Although the proportion of the studies show as having beneficial effects, studies with small samples may be underpowered and the results may thus be inaccurate. Relaxation techniques are often practiced independently by the research participants without the researcher monitoring the frequency, duration or if they are doing it according to the standard procedure.

5. Conclusion

Given the variations in the methodology and quality of the involved studies, the conclusions about the non-pharmacological interventions need to be further investigated regarding if they can provide effective treatment for post-fracture surgery patients.

ABSTRACT

Handling in stroke patients is still a polemic in developing countries. There is evidence that shows the importance of caregiver education on improving self-efficacy and recovery in stroke patients. The literature review aims to analyze the effectiveness of giving caregivers to the improvement of self-efficacy self and recovery in stroke patients. Literary studies in a systematic study published in the period 2008-2018, indexed Scopus, Medline, Psychinfo, and Embase with keywords: stroke, caregiver, educations, and self efficacy. Of the 126 quotes there are only 15 quotes that match the inclusion criteria. The results of these studies indicate that there is a significant influence on providing education to caregivers on improving self-efficacy and disease recovery experienced by stroke patients. It can be concluded that providing education to caregivers can help stroke patients to achieve health recovery and improve self-efficacy to restore good social life.

Keywords: stroke, caregiver, education, self efficacy, recovery

1. Introduction

Stroke is a critical public health problem around the world. Every year, around 5.5 million people die from stroke and 44 million people have lost years of their life from adjusting to disability (1) In Thailand, stroke is the fourth cause of death and disability and the number of stroke patients increases every year with an incidence of 352.3 per 100,000 population in 2014. Nearly 50% of stroke patients have moderate to severe disorders and even paralysis, where they are unable to take care of themselves (2). In a previous long-term study, it was reported that 25% -74% of stroke victims needed assistance to carry out their daily living activities (ADL) including feeding, self-care and mobility (3).

Considering the prevalence of cerebrovascular and residual disabilities, comprehensive interdisciplinary rehabilitation interventions are considered to be the main management modality for post-stroke care. This type of intervention is increasingly being requested. Previous reviews have reported that additional program training by therapists on weekends can increase the level of functional recovery after a stroke event. Thus, additional rehabilitation therapy based on caregiver education programs can improve functional recovery after stroke (4). Self-effectiveness refers to an individual's confidence in his ability to perform certain tasks or to meet certain demands. This may explain the reasons for the various levels of performance in people with equal skills. Stroke sufferers

who approach functional activities with confidence have been reported as being more likely to improve after rehabilitation than their counterparts who have less self-confidence. Furthermore, independence and positive influences correlate with motor function, functional activities and the quality of life of stroke patients and it can function as a compensation mechanism for the psychological improvement of adaptation and recovery after stroke (5).

Support for stroke patients globally has been prepared informal and namely done by caregivers. Informal caregivers are defined as those who provide unpaid assistance to other people, usually their family members or friends after the onset of chronic illness or disability (6). According to estimates, 62% of stroke patients will become dependent on others (7). Family caregivers are a major part of the care provision for stroke patients. A family carer is considered to be a friend or family member who offers free assistance to the patients who are chronically ill (8). Strength-oriented psychoeducation also applies to the families of caregivers with low educational attainment because families can demonstrate the ability to learn and to apply problem-solving skills without a long period of training (9). Additional rehabilitation therapy based on the caregiver education program can improve the functional recovery of stroke patients (4).

The systematic review (10) related to self-efficacy and its influence on the recovery of patients with strokes was reviewed, which showed the result that stroke patients with high self-efficacy function better in their daily activities than patients with low self-efficacy. Evidence about the determinants influencing self-efficacy and self-efficacy interventions make it clear how nurses can develop and adapt self-efficacy interventions for the clinical practice of people with stroke. The purpose of this systematic review was to determine the effect of caregiver education on self-efficacy and the recovery of stroke patients.

2. Material and Methods

Using electronic databases such as Scopus, PubMed and Science Direct, searches are carried out with "education", "caregiver", "self-efficacy" "recovery", "stroke" as the main keywords. This SR used the following PRISMA consisting of literature search strategies, inclusion and exclusion criteria, Randomized Controlled Trials (RCT) consisting of 7 articles, randomized controlled clinical trials consisting of 1 article, randomized trials consisting of 1 article, randomized experiments consisting of 1 article, randomized studies consisting of 1 article, an experiment consisting of 1 article, a prospective study consisting of 1 article and 1 cross-sectional article.

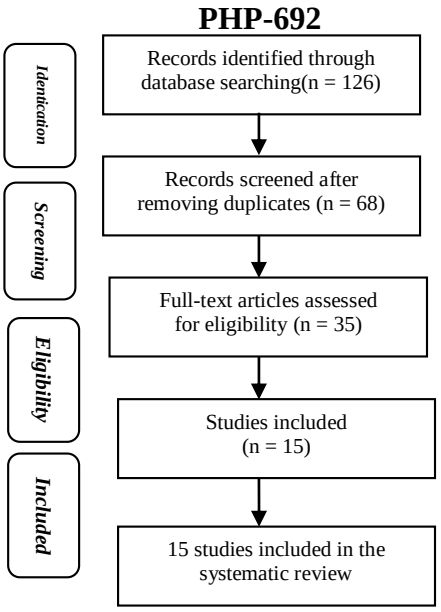

Figure 1 Flow Diagram

3. Result

3.1 Literature search and study selection

A total of 126 articles were found using the selected keywords.

3.2 Study Characteristic

The total number of respondents in the literature selected consisted of the caregivers making up 958 respondents and stroke patients making 1018 respondents in the range of 25 to 128 respondents per study. The respondents were between the ages of 19 - 70 years. The PICOT table shows the characteristics and interventions carried out in the four articles about the effect of a caregiver's education (4, 9, 11, 12) and concerning the programs for family caregivers (2, 13, 14, 15, 16, 17, 18, 2). The focus was also on stroke self-management support improving self effectiveness (19, 20, 21).

3.3 Results of the individual studies

Three articles mentioned that the education had a significant effect on the recovery of stroke patients (4, 9, 12). In this article, the effect of caregiver education programs for the stroke patients had positive results on the patient's functional improvement and on caregiver satisfaction. The author believes that additional rehabilitation therapies with educational programs can help the patients to achieve functional improvement for their return to an optimal social life. (11) It is recommended that the caregivers of stroke patients be given an instructional program to advocate increasing their understanding of the risks and challenges of the dependence of the stroke patients.

Disability can be assessed as a perceived threat (PT) in various activities or as a level of dependence on personal help. Therefore the ranking of PT difficulties in carrying out various activities can be considered to be the main assessment of disability (22). In this case, helping caregivers with educational interventions at PT to regulate the appropriate care and to overcome negative physical and psychological changes might be a priority (23). The effect of education on outcomes after education increases the knowledge of stroke for both the patients and caregivers (24). Patients who are informed and supported are treated well and they often experience successful

discharge from the hospital (25). The provision of information and education interventions also positively influence the patients' physical integration and psychological well-being (26). Education and support also increase their social activities and improve their quality of life (27).

(13, 14, 15, 16, 17, 18, 2); these seven articles describe post-stroke care programs that can improve the post-caregiver family care skills resulting in increasing the functional status and reducing the complications among post-stroke patients. They also increased the skills of the family carers in the group experiments as a part of developing interventions that focus on information, motivation, and skills practice in post-stroke care. First, providing specific information about caring for patients during their recovery after a stroke results in an increased awareness of the family caregivers and this leads to a better understanding of patient care and rehabilitation for the patients experiencing their first stroke.

This finding supports the existing literature that shows education and information on the nature of stroke, recovery and secondary prevention are the key components of skills development. This is the first study that examined whether an increase in limb over function can be predicted by involving caregiver support during the treatment. Both increasing the time taken to exercise and the caregiver's involvement in rehabilitation showed a positive relationship with improvement in upper limb function. This is a factor that changes during therapy (18), involving the relationship between the self-assessment ability to solve psychological problems and stresses, burden and the social support felt by the informal stroke caregivers (28).

A systematic review of Bandura’s construction of self-efficacy is the most common underlying theoretical premise. The expectation of the results of a construct that is closely related to self-efficacy also has an important influence on the behavior of stroke management. However, several studies have examined the role of the expected outcomes or one's judgment about the possible outcomes that occur when they perform a self-management behavior (19).

Newer research has begun to evaluate the role of self-efficacy in terms of activity and participation. Self-efficacy is the individual's own beliefs in their ability to do things and it is related to their self-confidence, motivation, behavior and environment. Understanding the different relationships between the different types of outcome measures, activities and participation after stroke will help therapists in designing optimal rehabilitation interventions to target recovery and to track the progress of stroke patients (20).

Patients with high self-efficacy function better in their daily activities than patients with low self-efficacy. Evidence regarding the determinants that affect self-efficacy and self-efficacy interventions make it clear how nurses can develop and adapt self-efficacy interventions for the clinical practice of people with stroke. Therefore, it is necessary to emphasize the role of self-efficacy in the care of stroke patients in the nursing curriculum (10). In this study, a significant increase in neurological damage was observed but not in functional performance. It was previously reported that an increase in muscle strength did not directly lead to an increase in functional performance and that functional independence can be achieved when a patient has a certain level of muscle strength (29).

4. Discussion

This systematic review investigated the effectiveness of the education of the caregiver related to the self-efficacy and recovery of stroke patients. Most caregiver training programs for patients with acute or sub-acute stroke are performed in hospitals or rehabilitation settings and the program teaches the

participants about stroke-related problems, the skills to help the patients in their daily activities, how to play a supervisory role and how to prevent the complications of the disease (14).

Bandura Theory (30) defines self-efficacy as a person's belief in his ability to achieve set goals or tasks that have an influence on the lives of individuals. The fact that self-efficacy can be obtained through verbal persuasion and the experience of representation is very important in stroke rehabilitation. For example, verbal persuasion such as positive feedback and motivation from rehabilitation professionals can serve to stimulate the stroke patients to be obedient and to share in carrying out tasks and rehabilitation activities that lead to increased functional abilities. Likewise, representative experience by observing their peers can be obtained through group training in rehabilitation and t is likely to spur on the stroke patients to maximize their potential (5).

Non-pharmacological therapy is one of the independent nursing actions of a health worker for the family and clients, namely providing education to families on the recovery of stroke patients. Family caregivers indirectly function as the main component of the care system. Family care provides support and motivation to the families who have experienced stroke through instructional programs to improve the patient health's, the knowledge of the family caregivers and to promote patient independence in ADL (11). There is a relationship between family support and self-efficacy in stroke patients (31).

5. Limitations of the study

The limitations of this study were the period of sampling and the recurrence of stroke. Another limitation was the high level of anxiety of the family caregivers related to a fear of loss or the inability of the patients when hospital, which somewhat reduced their focus when studying the topic of education.

6. Conclusion

This systematic review confirms the importance of the caregivers' families having the important skills needed to care for post-stroke patients at home. The results showed that family caregivers who participated in post-stroke care intervention programs could improve their post-stroke care skills, thereby increasing the Activities of Daily Living and reducing complications in the post-stroke patients. Caregiving assistance can be improved by providing education in the form of instructing the family caregivers and encouraging the need to develop rehabilitation therapy and support from the relevant organizations to assist patients in their recovery. Self-efficacy is an important aspect to be considered in the daily care and rehabilitation of patients post-stroke. Self-efficacy is positively related to mobility, ADL and quality of life related to health (HRQL). This is negatively associated with depression in patients with a stroke, and so interventions and self-efficacy programs need to be developed. Further studies are needed to assess the effectiveness of caregiver education on the self-efficacy of stroke patients. In particular, the research must have an adequate sample size and use validated outcome measures. The reporting of this research must be such that the results can be replicated independently.

ABSTRACT

Caring for critically ill patients in intensive care unit (ICU) is essensial and need capability to influent complex health care need, deliver save. Using the methodology of Whittemore and Knafl, an integrative review of the literature was conducted . The question directed to how is the nature of caring in intensive care and nurses experince about caring on publised literatur. This review analysed 25 articles obtained from electronic databases. Domains theme were caring patient with ventilator, end of life care, care of dying patient, pain control, wound care, infection, complexities of nurse-patient interaction, psychological problems and Caring behaviors of the nurses were. An integrative review was conducted to explore experiences of intensive care nurse as presented in 25 articles. The themes that emerged most frequently about caring behavior were Providing Information, Providing reassurance, Demonstrating Proficiency, Being present, Giving guidance, voice tone.

Keywords: nurse experince caring, intensive care nurse and caring behaviors

1. Introduction

Caring for critically ill patients requires competent nurses to help save and secure the lives of the patients, using technological developments while maintaining humanistic care [1]. The care of a mechanically ventilated patient is at the core of a nurse's clinical practice in the Intensive Care Unit (ICU) [2].

Mechanical ventilation is a major supportive treatment in intensive care and a patient receiving mechanical ventilation require close observation and the continuous monitoring of their vital signs. The nurses can help to make these patients more comfortable by ensuring that they receive a high standard of care in the following areas; the clearance of secretions, ventilated patients who have an endotracheal tube are frequently treated with sedatives and analgesics to ensure tube tolerance, patient comfort and reducing anxiety, oral care, nutritional support, communication and psychological support, humidification, eye care and attention to any safety issues [3].

The aim of this study was to present an integrative literature review of the caring processes as identified by Swanson focused toward mechanically ventilated patients in ICU to improve the nursing care using the methodology of Whittemore and Knafl [4].

2. Methods

To guide this review, we used the integrative review methodology by Whittemore and Knafl [4] with a five step process: problem identification, literature search, data evaluation, data analysis and the presentation of the results. Integrative reviews are the broadest type of research review method allowing for the simultaneous inclusion of experimental and non-experimental research in order to more fully understand a phenomenon of concern, which is congruent with the purpose of understanding the nurses' caring experience of mechanically ventilated patients to improve nursing care. The varied sampling frame of integrative reviews in conjunction with the multiplicity of purposes has the potential to result in comprehensive concepts, theories, or health care problems that are of importance to nursing [4].

2.1. Problem identification

Caring has traditionally been used to define the care of patients and their family members. The caring theory by Swanson outlines five caring processes: knowing, being with, doing for, enabling, and maintaining belief. Published work relating to the numerous nursing issues involved in the care of mechanically ventilated patients in the ICU is growing significantly. The literature focuses on the patient assessment and management strategies for patient stressors, pain and sedation. However, this literature is fragmentary by nature [2]. The literature has not been collectively and critically reviewed. The purpose of this integrative review is to expose the caring processes of a mechanically ventilated patient in the ICU. The research question was: 'What are the caring processes for a patient with a mechanical ventilator and the nurses' experience according to the published literature?' The aim of this integrative literature review was to understand and to examine the nurses' experience of caring for a mechanical ventilator patient, to encourage better understanding among both intensive and critical care nurses and providing information on the caring issues for further research and investigation.

2.2. Search method

The integrative review search should begin with the identification of the variables of interest in the relevant literature, of which the problem or topic of interest has been included in the review [4]. The final search terms were decided based on the databases' thesaurus or MeSH heading as outlined in Table 1. This was based on a preliminary search, a brief review of the abstracts, the use of keywords and the topic of review interest.

Table 1. Search strategy

Databases	Thesaurus or MeSH Headings & other searching terms
PubMed	Caring for a ventilated patient Nurse's experience of caring for a ventilated patient
NCBI	Caring for a ventilated patient Nurse's experience of caring for a ventilated patient Nurse's experience of caring in the ICU
Sopus	Caring for a ventilated patient

Databases	Thesaurus or MeSH Headings & other searching terms
	Nurse's experience of caring for a ventilated patient Nurse's experience of caring in the ICU
Science Direct	Caring for a ventilated patient Nurse's experience of caring for a ventilated patient Nurse's experience of caring in the ICU

2.3. Analysis

To get an understanding of the data, the analysis started by examining and reading the whole text. The data was extracted from the primary sources concerning the sample characteristics and method (if empirical), as well as any reference to the concept of integration. In an integrative review, data reduction occurs during the extraction and subsequent coding [4]. The data was reduced via entry into Excel with the following columns: study design, purpose or research question, abbreviated and detailed findings, gaps that the study filled, gaps remaining, strengths and weaknesses, sample characteristics and instruments and location and setting. Trends across the findings in the Excel spreadsheet were highlighted and further reduced via concept mapping. For example, articles referring to the domains of caring were highlighted using Excel. Commonalities were mapped into a data display via a concept map. The data comparison was conducted using the table data display. The data was examined and the categories were thus developed. The initial thematic categories were the domains of the nurses' caring behavior, the factors influencing the experience of the nurses' care of patient on mechanical ventilation and a category initially labeled 'other'.

3. Result

3.1. Study selection

The number of titles and abstracts found totaled 128 results, with the duplicates removed, which were read through and reviewed based on the inclusion and exclusion criteria. The inclusion criteria were studies conducted between the years 2010 - 2019, peer-reviewed original research articles relating to the nurses' experience of a mechanical ventilator patient and studies in the English language. The exclusion criteria were a specialty setting outside of the ICU and emergency. Studies were excluded if they focused on any other nursing process other than the aspect of caring. Review audits, study protocols, case reports and routine descriptions were excluded. The secondary review involved reading the article content for its relevance to the variables of interest. In total, 17 articles were selected for a full-text review. They were read in full by the first author and discussed with the two other authors. The discussion between the authors resulted in repeated and extended searches in order to cover the topic as well as possible. It was of importance to include articles covering the context of the nurses' caring experience related to ventilated patients. All discussions between the authors were resolved in a consensus solution. Finally, all 17 articles were retained for inclusion and they were found to be appropriate for an in-depth qualitative review (see Figure 1).

3.2. Study characteristic

The final sample of the integrative review included 17 articles; 14 were qualitative, 2 were quantitative and there was 1 qualitative meta-synthesis. All articles critically appraised for quality. As directed by Whittemore and Knafl (2), the empirical reports included a wide variety of methods: case study, cross-sectional, grounded theory, phenomenology and instrument development designs. Due to this diverse representation of primary sources, the reports were coded according to two criteria. No report was excluded based on this data evaluation rating system. However, the score was included as a variable in the data analysis stage.

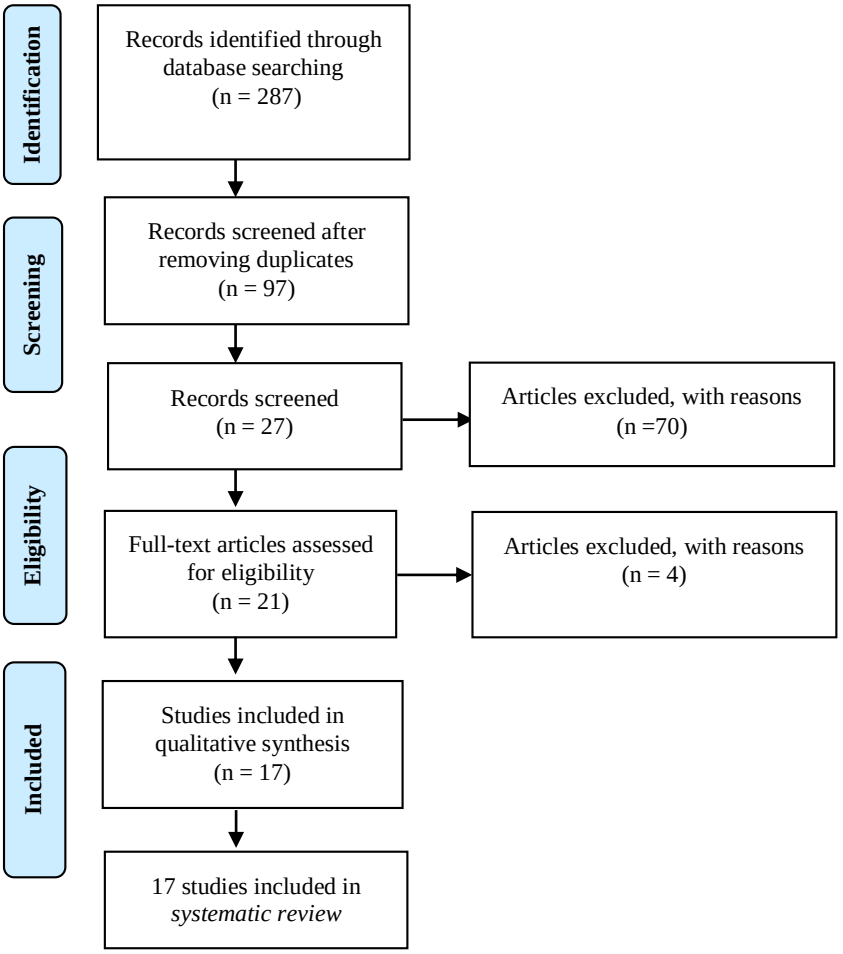

Figure 1. Flow Diagram

3.3. Summary of studies

The number of articles included in the integrative review totaled 17 articles. Articles related to the nurses' experience of caring for mechanical ventilated patients in the ICU described the domain of experience of caring for MV patients, the factors influencing the caring and communication tools of the MV patient and the other nurses' perception of the MV patient caring process (see Appendix A).

3.3.1. Domain aspect of caring. The domain experience of caring across the literature was about providing information and reassurance, demonstrating proficiency, being present, giving guidance, managing frustration, alleviating discomfort and negotiating reality. Eight studies reported that providing the information described as a way of explaining the rationale for the nursing, giving direct information and explaining what was being done and why [5]. Attempting dialogue describes the

interactions involving functional two-way communication based on the principle of dialogue as an ideal in nursing [6]. Talking to the patients, communicating and using communication tools are also involved [5,7–10]. The nurses' actions involve perceptual attention, embodied understanding and calm communication [11]. Four studies found that the nurses provided reassurance. Provide reassurance that makes clients relax and trust them [5], particularly in terms of comprehensive supervision and the time spent building trust [7]. The nurses want to demonstrate a mutual relationship of trust [8] with empathy [9].

Eight studies described demonstrating proficiency. Proficiency is identified as the skill and adeptness of the nursing practice that can influence the patients' and their families' perception of nursing care[5]. Experiential perceptiveness and more experience in patient care are also pertinent [7]. The nurses performed their tasks [12] in the form of immediate and prompt interventions to maintain life [13]. The nurses provided experience and integrated clinical, technical and ethical issues in their problem solving [11]. The nurse has confidence in the management of the ventilated patients by maintaining physiological signs [14,15]. The nurses are responsible for doing their best for the patients and they work dutifully [8].

Table 2. Domain aspect of caring across the articles

Doman	Article
Providing information	[5–11,14]
Providing reassurance,	[5,7–11,14,15]
Demonstrating Proficiency	[5,7,10,11,14,15]
Being present.	[5,7,8,10–12,14,15]
Giving guidance	[5,8,14]
Managing frustration,	[6,7,10–12]
Negotiating reality	[6]
Alleviating discomfort	[6,10]

Seven studies reported the importance of the physical presence of nurses. Being present meant the physical availability of the nurse, demeanor and attitude (Weyant et al 2017). The importance of physical presence and continuous face-to-face contact [7]. Conscious patients demanded more physical presence of the nurse [6,12]. Reacting to body language and maintaining eye contact with the patients [8]. When nurses were able to relationally connect with patients, they would spend extended time [10] and an attentive response to the patients [11].

Giving guidance is described as the nurses not only answering questions but also helping to instruct on what a patient or family member needs to do to restore their health [16]. Managing frustration was identified as what the nurses described as an attentive response [11], where they had a constant awareness of the patients' condition, expressions, actions and needs while trying to comfort and manage their care to handle the situation in the best interests of the patient [12]. Alleviating discomfort means that all patients have a fundamental need for comfort and rest, both of which are important for healing (Minton et al,2017). The nurses have a sense of compassion and duty to reduce suffering [6].

3.3.2. Domain factors influence caring. Three studies found factors that influence caring, namely good technical skills, intelligent management, good interdisciplinary collaboration with physicians, years of experience [7,12] and the need for a more appropriate staffing ratio [6].

3.3.3. Communication tools of the MV patient. Both the nurses and patients have to rely on non-verbal communication, such as body language, lip reading and eye contact. They wanted access to better communication tools to obtain functional communication [6].

4. Discussion

The purpose of this integrative review was to explore the literature about the nurses' caring experience regarding mechanical ventilator patients because the domains and related factors of the caring experience have not been collectively or critically reviewed. The aspect of caring trends across the literature were about providing information, providing reassurance, demonstrating proficiency, being present, giving guidance, managing frustration, alleviating discomfort and negotiating reality. The domains are interrelated and dependent upon one another. Providing information is described as explaining the rationale for the nursing care being provided, interpreting what was happening and providing explanations [5].

Being present means the physical availability of the nurse, their demeanor and their attitude [5]. The importance of a physical presence and continuous face-to-face contact is emphasized [7]. The continuous presence provides more time for the patient and encouraged communication, touch and empathy. The nurses were attentive and responsive to the patients' wishes [12].

Nurses with five or more years of critical care experience stressed the importance of technical proficiency in order to communicate with the patient while performing other tasks. Surprisingly, the less experienced nurses perceived the ability to perform simultaneous but diverse care activities as merely a practical issue [12]. Nurses with more experience will enhance their ability to pay attention to the key factors and to gain a deep understanding of the patient's condition during the weaning process [7]. They wanted access to better communication tools to obtain functional communication [6]. The participants pointed out the role of the ICU management in maintaining the continuity of care. Effective organization of human resources, the close monitoring of staff reporting, nurse support as well as controlled sedation during the night shift were mentioned as important aspects of care.

However, unlike the ICU clinical setting where a 1:1 or 1:2 nurse- patient ratio is generally maintained for ventilated patients (both invasive ventilation and NIV [15], the nurse-patient ratios while caring for a patient receiving mechanical ventilation was 1:1. The nurse-patient ratio was reported by 38% of respondents for invasively ventilated patients but it was infrequent for patients requiring NIV. Out of the respondents, 18 (7%) (invasive) and 51 (21%) (NIV) reported providing care to 4 or more patients at the same time as managing a ventilated patient [15].

5. Conclusions

An integrative review was conducted to explore the nurses' experience of caring for mechanical ventilation as presented in 17 peer-reviewed articles. The three domains of caring experience were the aspect of caring, the factors influencing caring and the communication tools of the MV patient.

This integrative review on the caring experience of nurses practicing in adult ICUs needs further study including domain-based theoretical work and interventions toward caring behavior development among practicing ICU nurses.

6. Appendix A

Table A1. Summary of findings

Articles	Design	Purpose/Question	Domain of Nurse Experience
[5]	Qualitative	To explore the perceptions of the nurses' caring behaviors among intubated patients and their family members	Providing information, Providing reassurance, Demonstrating proficiency Being present. Nurses giving guidance Using a soothing tone of voice. Behavior that was contrary to the perception of caring: - Negative attitude - Interrupting sleep, - Not receiving information - Poor pain management.
[6]	Qualitative	To compare the perspectives of expert and competent nurses regarding their interactions with non-sedated mechanically ventilated ICU patients	Managing frustration, Attempting dialogue, Negotiating reality Alleviating discomfort.
[7]	Qualitative	To describe the continuous care process during weaning	Time spent with the Patient Continuous communication Long, face-to-face contact Time spent in building trust Comprehensive supervision Continuous response to fluctuating indicators, Holism Comprehensive objective-subjective view, Experiential perceptiveness Maintenance of the quality of care during shifts Effective communication between shifts Overnight stop Intelligent management
[12]	Qualitative	To explore nurses' experiences of caring for non-sedated, critically ill patients requiring mechanical ventilation	Caring for and with the patient Negotiating relational and Instrumental care Managing physical and emotional closeness
[8]	Qualitative	To explore the ICU nurses' experiences of caring for non-sedated, critically ill mechanically ventilated patients when following a study protocol as part of a clinical trial	Cautious optimism (positive experiences but with a negative undertone): 1) Excitement and uncertainty 2) Inspiring but demanding nurse-patient relationship, 3) Teamwork or working against the tide
[9]	Qualitative	To explore non-sedated mechanically ventilated patients' communication with nurses in the intensive care unit	Overall nurse–patient communication is a movement between the two opposite feelings of comprehension and frustration Comprehension: Easy to interpret the patient's message, Communication is unequivocal, Communication about basic and/or informative subjects The nurse and patient have a common objective in communication, The patient is awake and participating,

Articles	Design	Purpose/Question	Domain of Nurse Experience
			The patient can use communication tools, Continuity in nursing care, Patience, Calmness Time to prioritize Communication, The nurse shows empathy. Frustration: Difficult to interpret the patient's message, Communication is equivocal, Communication is about complex subjects, Pressure of busyness, noise and disturbances, the nurse shows indifference.
[17]	Qualitative	To describe the intensive care unit experiences of people undergoing mechanical ventilation	Being dependent for survival on other people and technical medical equipment. Being vulnerable in an anxious situation and a feeling of uncertainty about one's own capacity to breathe. Having lines and tubes in one's body was stressful. Being given a diary and follow-up visit
[10]	Qualitative	To explore the patients', families', and health professionals' experiences of a long-stay patient in an intensive care unit	Prioritizing tasks and technology -Devaluing relational and comfort work. -Fundamental psychosocial needs such as family presence, comfort, relationships and communication -Provide fundamental, patient and family centered care -Satisfaction when seeing patients' positive responses
[14]	Qualitative	To describe the registered and enrolled intensive care nurses' perceptions of the feelings of thirst in mechanically ventilated patients	Identified: reasons for thirst, signs of thirst Preventing or reducing thirst The perception that patients had no feelings of thirst. Relieving thirst is a human need that must be recognized in nursing education and on intensive care units
[11]	Qualitative	To describe the reasoning and actions of experienced nurses caring for patients with non-invasive ventilation	The experienced nurses exhibited 'practical wisdom', three interrelated components: 1. Achieving non-invasive adaptation, 2. Ensuring effective ventilation 3.Responding attentively to patients' perceptions of non-invasive ventilation
[15]	Qualitative	To examine the exposure of emergency nurses to patients requiring mechanical ventilation, as well as their responsibilities and education on ventilation received	Respiratory therapists (RTs) remained in the emergency department until patients' condition stabilized and patient transfer RT was on call, no RT was available. Few nurses responsibility for initial ventilator setting and titration of ventilation , nurse responsibility was influenced by RT availability Nurses responsibility for monitoring patient response to ventilation, alarm troubleshooting, and oxygenation management.

PRIMARY SEXUAL ABUSE PREVENTION IN SCHOOL AGE CHILDREN: A SYSTEMATIC REVIEW

Dwi Indah Lestari
Master Student, Faculty of Nursing, Universitas Airlangga, Surabaya
Email:dwiindah343@gmail.com

ABSTRACT

Sexual Abuse is a condition that needs to be considered in recent years. Sexual abuse has become a public health issue because of the various health effects it causes. So it is necessary to make primary prevention efforts on behavior sexual abuse, specifically for school age children. The purpose of this study is to find out how effective health education as a primary prevention effort for sexual abuse in school-age children.This papers uses a systematic review design. Data was taken from the ProQuest, Scopus, and ScienceDirect databases with the period 2000-2018. Search was carried out for journals, articles and literature review using keywords of sexual abuse, prevention and psychoeducation. The results of the analysis looked for articles, analysis of 19 articles according to the Required requirements. namely health education as a form of preventive efforts to prevent sexual abuse in the form of games. The results of the study show that health education was effort to prevent sexual abuse that occurs a lot in the school and family, health education rovided to school-age children can reduce the occurrence of sexual abuse. Health education is provided in the form of games so that it is easily understood by school-age children

Keyword: Sexual Abuse, Preventive and Education

1. Introduction

Sexual abuse is a condition that needs to be considered in recent years. Sexual harassment has become a public health issue because of the various health effects that it causes [1]. Sexual abuse does not only occur in adults; it also occurs in children. Various research evidence states that child sexual abuse (KSA) negatively impacts both their short and long term physical and emotional health, cognitive abilities and educational attainment, as well as their social and behavioral development [2]. The sexual abuse of children and adolescents can cause physical and psychological vulnerability in children[3]. A child who is abused cannot react or oppose the authority carried out by the perpetrator and although he does not agree, he feels that he cannot prevent this occurrence. In the face of threats, children often keep hidden the fact that they have been abused[3].

In the United States, 1 in 5 women (18.3%) and 1 in 71 men (1.4%) reported having experienced rape in their lives (Black et al., 2011). In addition, 44.6% of women and 22.2% of men reported experiencing another form of sexual harassment in their lives (Black et al., 2011). Given the prevalence of sexual violence, as well as the increased public attention to sex crimes against children, there is strong support for federal, state and local governments to develop policies to protect people from sexual acts.

Sexual abuse is the child's involvement in sexual activity. The child does not understand what is happening[4]. Sexual activity includes touching the sensual parts, showing pornographic videos, sexual intercourse and the showing of the genitals [5]. Sexual abuse is a serious problem because if it is not handled, the children who are the victims of sexual abuse will experience depression and post-traumatic stress disorder[6].

The epidemiological data shows that the global average prevalence of sexual abuse in children is 11.8-13.8%, with higher rates among girls (18-19.7%). Africa showed the highest rate of child sexual abuse (around 34 %), while the lowest appears in Asia (around 10%) and Europe [7]. According to the data from CSA (Child Sexual Abuse) in Southeast Asia it varies greatly, with 40 cases of child abuse in 14 countries in the region concluding that around 10% of boys and 15% of girls have experienced at least one form of sexual abuse[8].

This complex public health problem requires prevention strategies at various ecological levels [2]. One ecological level includes the school. Primary prevention is a broader approach that occurs before sexual abuse has occurred to prevent the initial action (for example, by educating the parents and conducting health education in schools). Secondary prevention is a targeted approach to the population "at risk". Tertiary prevention is an immediate response after sexual harassment occurs to deal with the immediate consequences of violence (for example, targeting offenders detected through treatment groups) [9]. School-based sexual harassment prevention programs have positive results. However, little is known about how these programs are disseminated. The deployment model use a main trainer to equip others to implement the program, allowing more adults to teach and then more children to receive the program [10].

School-based programs are created to help children to avoid sexual abuse [11]. Schools evolve as a clear choice for teaching children about people's safety. This is because the school's main goal is to easily educate children. The objectives of the school-based KSA prevention program include five things: (a) helping children recognize the potential abusive situation or potential offender, (b) encouraging the children to reject sexual requests by saying "No", (c) teaching the children to refuse and try and get away from the perpetrator, (d) to encourage children to report in advance or to report ongoing abuse, and (e) to explain that contact with others is not for granted [12].

The family also has an important role in preventing the sexual abuse of children. In principle, the family has great potential when it comes to providing instructions on how to deal with violence against children [13]. The parents need to be involved in the prevention of sexual abuse because the education relayed by the parents to the children as an effort related to self-safety programs, shows an improvement compared to the education that is only done by the teachers in schools. In the program of providing education in schools, it is not running optimally without the contribution of the parents. In this study, the researchers sought to involve the participating parents in terms of preventing sexual abuse behavior in children[14].

The efforts taken to prevent sexual harassment in children are carried out in schools in the form of health education in the form of games. This is so then children are able to understand easily about what is meant by sexual harassment. Health education is very important as a primary effort related to the sexual abuse of children.

2. Research methods

2.1 Data Sources and Search

The journal search strategy began by asking the following research question, namely "Does psychoeducation have an influence on behavior change as one of the primary prevention efforts of sexual abuse in school-age children?" This writing used a systematic review design. The databases used for the journal searches were Proquest, Science Direct, and Scopus. The keywords used are sexual violence, preventive and psychoeducation. The journal was limited to the 2011 - 2018 publication years within the areas of nursing, medicine and psychology as well as journals in English.

2.2 Study options and criteria

The inclusion criteria specified were 1) quantitative or qualitative studies, both observation and experimental; 2) maximum time span of 10 years ago; 3) the subjects in this SR were children at school age and 4) interventions provided in the form of the primary prevention of sexual abuse in school-age children in the form of games. The journals were selected using the PRISMA method.

3. Results

3.1 Study Results and Selection

In relation to the selection of the journals to be used in the systematic reviews of journals, they must have the same characteristics and feasibility in terms of the study. This was assessed using the PICOT approach so then it was easier to understand in writing. They were selected using the systematic review PRISMA method. The population used in this study was school-age children who are at risk of sexual abuse. The primary prevention of sexual abuse needs to be given. The interventions are carried out by providing both standard education and health education. This is good to execute in schools. Health education is provided in the form of games so that it is easily accepted by school-age children because it uses the Comparison Game method. Some journals that carried out the PICOT process were divided into 2 groups, namely control groups and treatment groups. Several journals conducted structured interviews to obtain the desired results. The interventions were carried out in the form of the primary prevention of the sexual harassment of school-age children by conducting health education by playing games. The output was the data before and after the intervention. The results are measured using a questionnaire sheet [15]. The research designs used were both qualitative and quantitative.

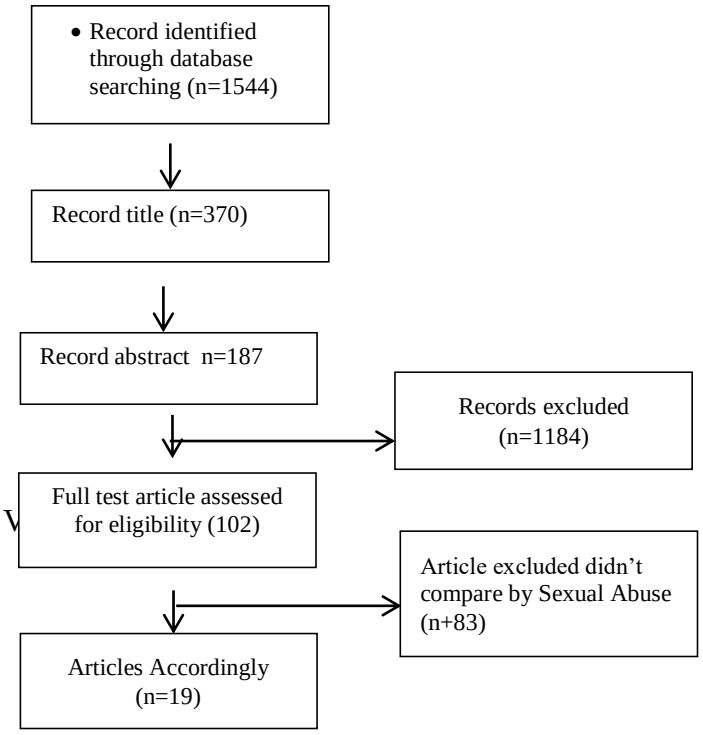

Figure 1. PRISMA Flow Diagram for 'Primary Sexual Abuse Prevention in School Age Children: A Systematic Review'

3.2 Study characteristics

The characteristics of the study are explained in the PRISMA chart. All of the journals obtained from the results of the study involve interventions that are carried out as an effort to prevent the sexual abuse of school-age children with the method of health education through games. This is an approach undertaken by schools commonly.

3.3 Results of the Review Study

The results of the scientific study conducted by the authors were obtained from the search of the Proquest, Medline, and Science Direct and Scopus databases. The total number of participants from all studies was 940 with the theme of violent behavior and the risk of violent behavior both in the school, in the family and in the community. In the current SR writing, the author used 19 journals that are appropriate and that involve different interventions. The interventions given included multiple components including education and cognitive techniques as well as educational games that are expected to be able to change behavior. With different duration averages in all of the studies, most of them used the same measurement tools, namely psychoeducation using Child Sexual Abuse Prevention Education (C-SAPE)[15]. The questionnaire contains items designed to measure CSA knowledge[16] using a questionnaire (WITS) and the *"Body Safety Training Program* (BST)[10].

Post-treatment effect

From a number of the literature journals that have been carried out on PICOT, there are significant

effects found statistically from the various interventions given such as providing education, educational games about the prevention of sexual abuse, parental support related to the prevention of sexual violence behavior as well as the correct ways of care related to education and health regarding to the prevention of sexual harassment behavior in school-age children. After routine and scheduled treatment, the measurement was done using a standardized measuring instrument. The results obtained in the intervention given to the treatment group had a significant impact on the provision of interventions in the form of related education about the prevention of sexual harassment behavior both in the school, by the family and within the community, as well as good forms of care. It was expected to increase the knowledge of school-aged children in terms of the prevention of sexual abuse behavior.

4. Discussion

In making this systematic review, the author selected 19 journals. The author chose to look into the effectiveness of sexual abuse prevention efforts in school-age children in the form of games [17] From the review, several studies have shown that the application of education carried out in schools has a very important role because it is sustainable between the health education that is done at home and that in school [18]. The measuring instrument used in terms of seeing changes in behavior and the knowledge in children was the Child Sexual Abuse Prevention Education (C-SAPE) [15]. The questionnaire contains items designed to measure CSA knowledge [16], using a questionnaire (WITS) and the “Body Safety Training Program (BST) [10]. The in-depth semi-structured nature of all the results is in line with the various efforts made to improve the primary prevention of sexual abuse in school-age children.

Child sexual abuse (CSA) is a serious public health problem. The recent approach to treating the victims and punishing offenders is not enough to overcome this big problem. Rigorous development and the evaluation of CSA prevention strategies is very important. We propose that CSA prevention efforts should target the parents of young children. Parents have been ignored as the focus of the prevention of CSA. They deserve attention because of their potential to improve their children's safety through effective communication and monitoring[19]. Childhood sexual abuse is a significant public health problem that negatively affects the victims, their families, organizations and society[2].

Sexual health education programs with a focus on postponing sexual debuts among children and adolescents should also consider handling ACE, such as neglect, physical, psychological and sexual violence, witnessing parent violence, and parental detention and psychopathology [20] Knowledge about sex in children can prevent sexual deviations in children. This is because they are taught about the role of sex, how to behave as a boy or even a girl and how to get along with the opposite sex. Sex education in children can also prevent the children from becoming victims of sexual abuse. Ideally, sex education for children is given first time by parents at home or family. However, not all parents want to behave openly with their children when discussing sexual issues [21]. Active involvement by the parents can contribute substantially to the success of school-based programs to prevent child sexual abuse (CSA). In China, little is known about the parents' understanding of CSA[22].

Psychoeducation can increase the knowledge of sexual abuse in children because psychoeducation is a process used to develop knowledge, teach, educate and provide important

information related to sexual harassment and the forms and methods of its prevention in school children. Effective education in school-age children in the form of games that are filled with knowledge of sexual abuse [11] can improve the preventive efforts undertaken at school. This is expected to improve behavior change in school-age children.

The findings from the review of this article will have implications for nursing and research practices. In nursing practices, the findings of this review will provide basic information for nurses in terms of providing preventive nursing care that it can be done by the parents of teachers and the children to make efforts to prevent sexual abuse. Providing appropriate interventions will improve their abilities and prompt behavior changes in the children of school age to encourage them to defend themselves against and to act in preventing sexual abuse.[23] Effective interventions are done for the school-age children through game-based health education that is easily understood.

There were no significant differences in the CSA levels between poor and non-poor families. Poor CSA victims were significantly more likely to have a repeat report for abuse. Children with multiple reports are more likely to have negative results overall. Interventions for CSA survivors should focus on preventing the recurrence of persecution in general and not ignoring the needs of male victims[24].Further research is expected to be able to find out other sources that can reduce the burden of care, such as the use of social support, especially in Eastern countries that are still minimal in relation to social support.

5. Conclusion

In conclusion, this review shows that education in the form of games is a good prevention and that it is best done in a family and community school environment. Parents also have an important role in relation to the primary prevention of the sexual abuse of school-age children. This can be used as a guideline and become a reference for further research that is tailored to the characteristics of the respondents. Sexual prevention training in children can increase their knowledge and self-confidence, in addition to the preventive behavior of the children. This is expected to increase the level of behavior change in children.

WORK RELATED MUSCULOSKELETAL DISORDERS AND THE RISK FACTORS IN NURSE: A SYSTEMATIC REVIEW

D N F H Bunga[1], J Haryanto[2], and A Bakar[2]
[1]Magister of Nursing, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
[2]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
E-mail: dinda.nur.fajri-2017@fkp.unair.ac.id

ABSTRACT

Nursing has been identified as the most risk profession experiencing work-related musculoskeletal disorders (WRMDs). Work-related musculoskeletal disorders (WMSDs) are the most important common cause of lost work days, increased costs and human injuries and the main cause of disability. This review study was conducted to determine the risk factor of work related musculoskeletal disorders in nurses. The present study was conducted on the basis of the PRISMA checklist for systematic review. To access eligible articles, domestic and foreign databases such as Scopus, Science Direct, PUBMED, ProQuest, and the Google scholar search engine and keywords of low back pain and nurse and ergonomic. Capping the results journals that do is the year of publication of the journal are restricted to start 2011- 2019 and article in English. The results of the review of 10 eligible articles showed that the risk factor of musculoskeletal disorders and low back pain in nurses. The results showed that predisposing risk factors of lower back pain are gender (female), working time and Working in the same positions for long periods.

Keywords: work-related musculoskeletal disorders, low back pain, nurse, associated factor, prevalence

1. Introduction

Work-related Musculoskeletal disorders (WMSDs) are widespread and an increasing occupational health problem, reported as an important risk for health and safety in the workplace worldwide [1,2]. It is a serious risk factor and a common cause of morbidity affecting occupations such as health professionals [3,4]. Nurses are reportedly at a high risk of WMSDs with the population that constitutes about 33% of the hospital workforce at particularly high risk accounting for 60% of the reported occupational injuries [4–6]. The term musculoskeletal disorders refers to inflammatory and degenerative conditions that affect the muscles, tendons, ligaments, joints, peripheral nerves and supporting blood vessels with consequent ache, pain or discomfort [6–8]. Previous studies also reported that the lower back, shoulders, neck, forearms and hands were the regions most affected by musculoskeletal disorders [3,9]. WMSDs usually occur in workers who have excessive repetition, awkward postures and heavy lifting, poor patient transfer techniques, physical nature of the job, increased patient load and workplace activities such as strenuous action, manual handling and job stress [1,4,6,10–12]. WMSDs are the most important common cause of lost work time or absenteeism, increased work restriction, transfer to another job, human injuries and it is the main cause of disability with a considerable increased cost for the individual, the organization and society

as a whole. It has an impact on quality of life [9,12,21,13–20]. The present study intended to investigate the risk factor of work-related musculoskeletal disorders in nurses using a systematic review.

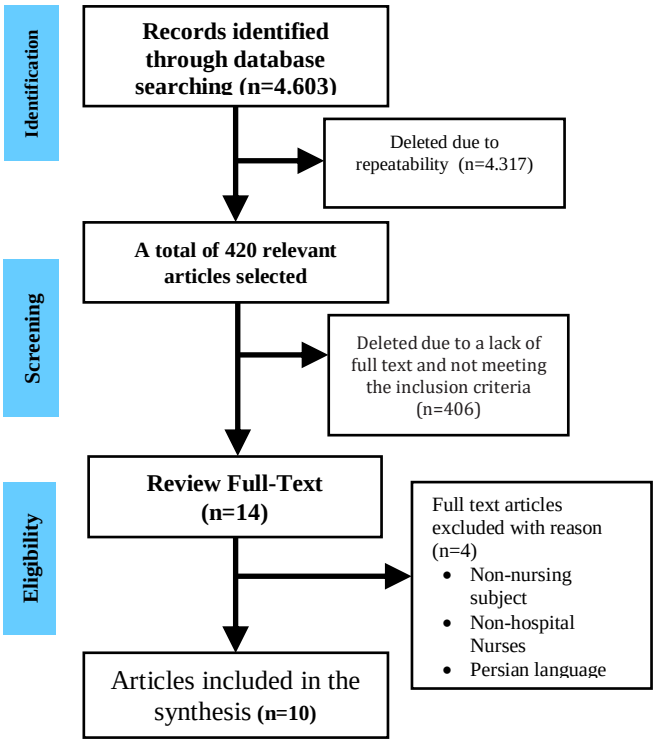
2. Methods

The present study was a systematic review based on a reporting system for systematic review studies (PRISMA). The literature was searched and the selection of peer-reviewed and professional journal publications was conducted through the following search engines; Scopus, PubMed, ProQuest and Science Direct. A literature review was conducted using "Work-related musculoskeletal disorders", "Low back pain", "Nurse", and "Associated Factor" as the keywords. The selection of articles were published between 2010 - 2019.

This systematic review included studies that looked at the prevalence and/or associated risks and contributing factors of WRMDs among the nurses working in hospital. The studies selected for analysis were required to meet the following inclusion criteria: (i) reported evaluation between the associated risks, contributing factors and prevalence of WRMDs; (ii) fully published articles and (iii) a cross-sectional study. Studies were excluded based on the following criteria: (i) population studies that included non-hospital nurses and (ii) papers that were not peer-reviewed or that were only abstracted.

3. Result

In the present systematic review, 4.603 articles were identified, 4317 of which were deleted due to repeatability. Following this, 406 articles were deleted due to a lack of full text and not meeting the



inclusion criteria after a preliminary review. Additionally, 4 articles were excluded due to being on a non-nursing subject, the nurses worked in a non-hospital setting and they were in the Persian language after reviewing the full text. With this done, 10 articles were selected in synthesis (Fig 1). The sum of all nurses involved in these investigations was 3592 nurses who worked in various wards

in hospitals in various countries such as Vietnam, Iran, Greece, China, Pakistan, Nigeria, Iran, Zimbabwe, Turkey and New Zealand.

Figure 1. The inclusion stages of the studies in the systematic reviews

Table 1. Summary of the included studies.

Author, Year [Ref]	Title	Findings
Arsalani, Masou, Malin & Monica (2014) [22]	Musculoskeletal Disorders and Working Conditions Among Iranian Nursing Personnel	The three most prevalent body regions were the lower back (65.3%), knees (56.2%) and neck (49.8%). The participants reported an inflexible work schedule, poor quality of devices for transferring patients, overexertion and job dissatisfaction.
Chiwaridz, Makotore, Dambi, Munambah, and Mhlanga (2018) [4]	Work-related musculoskeletal disorders among registered general nurses: a case of a large central hospital in Harare, Zimbabwe	The most prevalent body region was the back 84%, especially the lower back (lumbar) 67,9%. Repeatedly performing nursing tasks, the perception of treating a large number of patients, the perception of repeatedly bending/twisting the back and the perception of lifting/transferring dependent patients and materials were identified as the significant risk factors.
Celik, Tasdemir, Oksuzoglu, Dirimese, Kocasli (2018) [3]	Critical-Care Nurses' Pain Experiences and the Prognostic Factors	The critical-care nurses were found to experience pain mostly in the lower back (88.3%), upper backs (77.5%), right (76.6%) and left (78.4%) feet, neck (73.9%) and most infrequently in the right (28.8%) and left (28.8%) lower arms. Changing the bed linens while the patient remained in bed and lifting, pulling or pushing heavy materials caused the nurses who felt despondent and tired to feel significant pain.
Luan, Hai, Xanh, Giang, Thuc, Hong, Khue (2018) [1]	Musculoskeletal Disorders: Prevalence and Associated Factors among District Hospital Nurses in Haiphong, Vietnam	A very high prevalence of MSDs in the past 12 months (74.7%) and during the last 7 days (41.1%), with the two most common sites being the lower back (44.4%) and neck (44.1%). When analyzing the factors related to MSDs, the results showed that gender (women), a history of MSDs, psychological distress and frequent absenteeism are the associated factors.
Passali, Maniopoulou, Apostolakis, Varlamis (2018) [2]	Work-related musculoskeletal disorders among Greek hospital nursing professionals: A cross-sectional observational study	The prevalence of musculoskeletal disorders, in general, was 98%, with symptoms reported for the waist (85.3%), neck (71.2%) and back (70.7%). The risk of WMSD was higher for specific RN groups: gender (female), 11-20 years of work experience, strain on the waist and lifting loads. Shift work, age and the body mass index also lead to an increased risk.
Yan, Li, Zhang, Yang, Huang,	Prevalence of Work-Related Musculoskeletal Disorders in the	The most common regions affected by WMSDs were the lower back (62,71%),

Author, Year [Ref]	Title	Findings
Wang, Yao (2017) [9]	Nurses Working in Hospitals of Xinjiang Uygur Autonomous Region	neck (59,77%), shoulder (49,6%) and back (39,5%) The results indicated a working time of ≥6 years, working in the Emergency Department, working in the Department of Anesthesia, working in the Department of Supply Room, working in shifts, working on the night shift for more than once a week, a working time of ≥40 hours per week, poor health conditions and fatigue were the risk factors for WMSDs.
Rathore, Attique, Asmaa (2017) [7]	Prevalence and Perceptions of Musculoskeletal Disorders Among Hospital Nurses in Pakistan: A Cross-sectional Survey	The prevalence of musculoskeletal disorders over a 12-month period was 31.6%, with the most common site being the lower back (32%) followed by the shoulders (20%), upper back, and knees (10%). Working in the same positions for long periods (93.1%), attending an excessive number of patients in one day (81.2%) and working in awkward and cramped positions (78.6%) were the most common perceived risk factors for WRMDs.
Tinubu, Mbada, Oyeyemi, Fabunmi (2018) [6]	Work-Related Musculoskeletal Disorders among Nurses in Ibadan, South-west Nigeria: a cross-sectional survey	The most common regions affected by WMSDs were the lower back (44.1%), neck (28.0%) and knees (22.4%). Working in the same position for a long periods (55.1%), lifting or transferring dependent patients (50.8%) and treating an excessive number of patients in one day (44.9%) were the most commonly perceived job risk factors for WMSDs.
Yang, Liu, Zeng, Wang, Li (2018) [23]	Prevalence and Risk Factors of Work-Related Musculoskeletal Disorders Among Intensive Care Unit Nurses in China	Lower back pain was the most commonly reported musculoskeletal disorder (80.1%), followed by neck (78.6%) and shoulder pain (70.4%). Female gender, unmarried status, a greater perception of risk and a lack of a safe work environment are the significant factors.

4. Discussion

The results will be discussed under the following headings; the most prevalent body region affected by WMSD and the risk factors predisposing nurses to WMSD.

The most prevalent body region is the lower back, followed by the neck, shoulders, knees, waist and arm. Further stratification concerning the prevalence within the vertebral column revealed the lower back to be the most susceptible to WMSD, followed by the neck, shoulders and knees. This result was consistent with that of the previous research findings, as the prevalence of hospital nurses in Iran who experience low back pain is 30-60% [24]. A study conducted in Switzerland found that the prevalence of low back pain over 1 year among health workers was 67.3% of which nurses amounted to 75.6% [25] while in Korea, 90.3% of nurses were intensive units with LBP increases at least once and where only about 18.3% of nurses went for treatment [26]. The nurses' prevalence that

increased the Jordanian nurses' lower back pain was 83.6% and as much as 40% agreed that lower back pain increased absenteeism at work. Meanwhile, 58.7% stated that lower back pain could increase their work productivity by 9% [27] and this gave rise to the theory that the nurses' moods and fatigue triggered somatic complaints. Moreover, it was observed that the nurses who were tired and felt pain did so as a result of decreased opportunities for relaxation at home. This was due to working in shifts, having short or infrequent break times, not using appropriate body mechanics and remaining in a stationary position for extended periods during work [3].

Gender: Females are more at risk than males. This can be understood as women have lower adaptive status than men in terms of patient-related activities, such as patient transport and infusion. A history of musculoskeletal diseases in the past has been a factor in the development of MSDs. When an individual has suffered from previous musculoskeletal diseases, the adaptive capacity of the musculoskeletal system related to the activity will be reduced. Combined with inappropriate manipulations and postures when working, these conditions will motivate and generate the manifestations of MSDs.

Working time: The working time of 50 hours per week and a daily working time of 8.5 hours were considered to be a risk factor for WMSDs. The working time of the nurses [9] was in the range of 30 – 65 hours and the weekly time was 46.87 ± 4.42. According to the multivariate analysis, adequate rest was a protective factor against WMSDs. In a previous study, Wang et al. revealed that a rest time of 15 min could guarantee the recovery of the erector muscle of the spine and the heart rate could settle into the normal range. Therefore, adequate rest is recommended for those involved in the nursing profession [28], in order to attenuate the stress and relax the muscle tissues, as well as to eliminate fatigue.

Working in the same position for a long period: Working in the same position for a long periods, lifting or transferring dependent patients and treating an excessive number of patients in one day were the most perceived job risk factors precipitating WMSDs among the nurses in this study. These findings are consistent with the previous reports indicating that manual patient handling and transferring or moving patients are the important predictors of musculoskeletal disorders and low back pain among nurses [2–4,6,7,22]. From this study, getting assistance or support staff involved in handling heavy patients, the modification of the nursing procedures in order to avoid re-injury or stressing an injury, and the modification of patient's/nurse position were the top three coping strategies in ameliorating the risk of WMSDs. These coping strategies used among the Nigerian nurses seem similar to the previous findings. The worker's performing strenuous work are often advised to prevent problems and to cope with musculoskeletal symptoms by changing their working technique, using lifting equipment, taking breaks and avoiding strenuous work tasks [29–32].

5. Conclusion

This systematic review has identified that nurses are vulnerable to WMSD, especially lower back pain. The predisposing risk factors of lower back pain are gender (female), working time and working in the same position for a long period.

ABSTRACT

Diabetic foot ulcer (DFU) is one of the most common complications in diabetic patients and associated with high morbidity, mortality and health cost. Optimal foot care prevents the DFU reached 85%. Identification of factors related to foot care behavior is important and may help health care providers in designing interventions to improve patient behavior. This systematic review was performed to identify factors that affect foot care behavior in diabetic patients. The literature search used predefined keywords such as foot care behavior and foot self-care through several electronic databases such as Scopus, ProQuest, Ebsco (CINAHL) and Science Direct. All quantitative and qualitative studies from 2014 to 2019 were included. There were 10 studies reviewed. Results showed that there were various factors such as predisposing factors (level of education, socioeconomic status, social support, past experience, information) and precipitating factors (communication with health workers, psychological condition) related to foot care behavior. Information, social support, communication can facilitate positive foot care behaviors. Education for health care providers, patients, and their family is needed for good foot care practices.

Keywords: foot care, diabetic, systematic review

Introduction

Diabetes mellitus is one of the biggest health problems worldwide and it has become one of the leading causes of death globally due to non-communicable disease [1]. Diabetic foot ulcers (DFU) are one of the most common complications that often occur in diabetic patients. DFU is associated with the incidence of amputation, high morbidity, mortality and health costs[2,3]. Globally, there were 425 million diabetics in 2017. The lifetime risk for a diabetic of developing foot ulcers is up to 25 %. DFU occurs in 15-25 % of all diabetics by more than 2% every year and between 5-7,5 % of patients with neuropathy [2].

Foot ulcers are preventable through foot care such as a daily foot inspection, foot hygiene, foot moisture, injury prevention, appropriate footwear and with the toenails cut[4,5]. Optimal foot care activities are proven to reduce the foot ulcers by 85 %[2]. Chin et al. found that foot care (applying moisturizer on dry foot skin) was associated with the incidence rate of diabetic foot ulcers[6].

To improve the foot care behavior among diabetics, understanding some factors affecting good foot care behavior is important. A previous review highlights the psychosocial factors as both barriers and enablers to the foot care in older adults diagnosed with type 1 or type 2 diabetes[7]. Research shows that the level of education and the patient's knowledge of diabetes are important factors that

influence the foot care behavior in patients with diabetes mellitus[5]. In addition to the internal factors, it is important to explore the external factors that influence foot care behavior in diabetics. Therefore, this systematic review aims to identify the factors influencing foot care behavior in diabetics based on the perspective of both the patient and the health care provider.

Methods

This systematic review was conducted using the guidelines of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). This systematic review was conducted to identify the factors related to the foot care behavior in patients with diabetes mellitus, referring to both the internal factors from the patient and the external factors.

Search strategy

The articles were searched for from within several electronic databases i.e Scopus, Proquest, Science direct and EBSCO (CINAHL) published between 2014 and 2019. There were several specific keywords used such as foot care behavior, foot self-care, diabetes mellitus and diabetic foot ulcer.

Inclusion and exclusion criteria

The inclusion criteria for this systematic review included English-language journals where the research subject was adults with diabetes mellitus type 1 or 2 and the health care providers who deliver the care for diabetics. Cross-sectional studies, cohort studies and qualitative studies were included in this review. Systematic and literature reviews were excluded. In this systematic review, first all of the titles and abstracts were reviewed to see if they met the inclusion criteria. After that, the studies that were considered to be included in the review were read in full. Articles with unavailable full papers were excluded.

Data synthesis

All of the studies included in this review were read in full. All of the findings were grouped and then the factors were summarized related to foot care behavior in patients with diabetes mellitus.

Results

Literature search and study selection

From the search results found by using the specified keywords, 983 articles were found and then screening was conducted by looking at the title and abstract. The search first obtained 80 journals. Lastly, there were 10 journals that meet the inclusion criteria (Figure 1).

Study characteristic

There were 8 cross-sectional studies, 1 longitudinal study and 1 qualitative study. The type of participants involved in the systematic review were adults who were type 1 and type 2 DM patients and the health care providers who cared for diabetic patients.

Findings

The summary of the study characteristics and findings have been presented in Table 1. There were several factors related to foot care behavior in diabetics. Six studies found that education level was

associated with diabetic foot care behavior[5,8–12]. Five studies found that socioeconomic status had a significant impact on the patient's foot care behavior[1,3,4,6,7**].** One study showed that social support was an enabling factor of proper good foot care [12]. Three studies found that understanding DM and its management can facilitate good foot care behavior[5,14,15**].** Three studies showed that foot care and DM complication education offered by the health care provider can facilitate the patient's in having good foot care behavior[8,13,16**].** Two studies found that poor communication between the patients and health care providers was a barrier factor for the patient's foot care behavior[12,15**].**

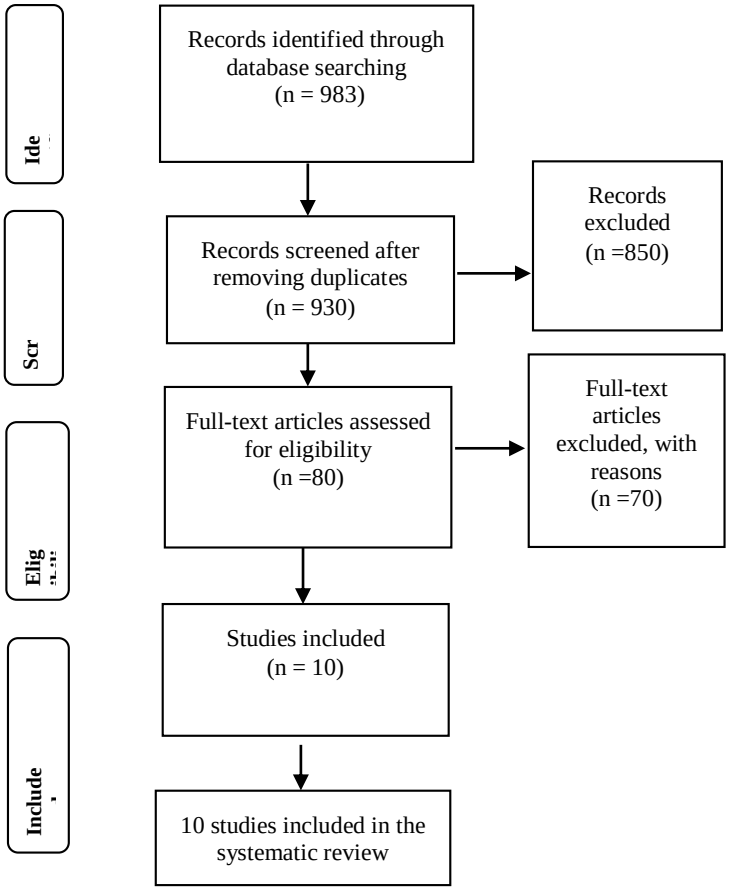

Figure 2. Flow Diagram

Table 1. Study characteristics and findings.

Authors	Study Design	Sample/Participants	Sample Size	Findings
D'souza et al. [5]	Cross-sectional study	T2DM patients	160	*1) Education level* Patients with a high education level (Bachelor's/Master's) had good foot care behavior (p = 0,012) *2) Knowledge* Understanding DM and its management was related

					with good foot care behavior (p = 0,040) *3) Income* Income was associated with foot care education (p = 0,050)
Syed et al. [8]	Cross-sectional study	DM patients	400	*1)* *2)* *3)*	*Community background* A rural or urban background was associated with foot care behavior (p = 0,001) *Income* The individual's monthly income was related with foot care behavior (p < 0,0001) *Foot-care education provided* Foot care education provided by the health care workers influenced the patient's foot care behaviors (p < 0,0001)
Li et al. [9]	Cross-sectional study	T2DM patients	5961	*1)* *2)*	*Education level* Education level was associated with foot care behavior (p < 0,001) *DM complications education* Education about DM complications by the health care workers influenced the patient's foot care behavior (p < 0,001)
Zafar et al.[10]	Cross-sectional study	T2DM patients	220	*1)* *2)*	*Education level* Patients with poor education had a lower foot care behavior score. *Socioeconomic status* Lower socioeconomic status was associated with a lower foot care behavior score.
Darshan et al. [11]	Cross-sectional study	T2DM patients	133	*1)* *2)*	*Education level* Education level had a significant impact on diabetic foot self-care. *Socioeconomic status* Lower socioeconomic status was associated with a lower foot care behavior score.
Chiwanga and Njelekela[12]	Cross-sectional study	T2DM patients	404	*1)*	*Foot-care education provided* Patient who had received foot care education from the health care provider

				had good foot care behaviors.
Pereira, Pedras and Ferreira[13]	Longitudinal study	T2DM patients	271	*1) Knowledge* Understanding DM was associated with good foot self-care.
Mogre et al.[14]	Cross-sectional study	T2DM patients	201	*1) Education level* Education level was associated with good foot care behavior (p = 0,037).
Seid and Tsige, [15]	Cross-sectional study	DM patients	313	*1) Knowledge* A lack of adequate knowledge was associated with poor foot self-care. 2) *Communication between the patient and health care provider*. Poor communication between the patient and the health care workers (nurses/physicians) was associated with poor foot care behavior.
Sayampathan, Cuttilan and Pearce[16]	Qualitative study	Health care providers	17	1) *Predisposing factors* (education level, socioeconomic status, social support, past experience) were related to foot care behavior 2) *Precipitating factors* (psychological factor, health care providers). A low degree of psychological barriers and poor communication between the patient and health care workers were both associated with diabetic foot care practices.

Discussion

The review showed that there were various factors related to foot care behavior. Education level, socioeconomic status, social support, the patient's knowledge, the education provided and the communication between the patients and the health care workers were associated with foot care practices. Education level was a determinant factor of foot self-care. Poor education status was related to poor foot care. People with a low level of education had less access to healthcare facilities and often wore inappropriate footwear[5]. Patients with a higher education level were more likely to understand how to perform good foot care and the benefits of foot care behavior. They were more able to read and obtain information about foot care. Socioeconomic status was related to foot care

practices. People with low socieconomic status have low foot care knowledge and consequently, they have poor foot care [5].

Knowledge is one of the important factors in foot care behavior. Patients with good knowledge about DM management and foot care behavior had good foot care behavior. Level of knowledge was influenced by education level, the duration of diabetes and their education on foot care. Patients who received advice on foot care and DM management from the health care providers performed good foot care behavior [8,9]. When the diabetic patients know about foot care and the benefits therein, they will find it easy to do foot care in their daily activities. Patients who have good knowledge of foot care have a high awareness concerning preventing diabetic ulcers through regular foot care.

The education provided and the communication between the patients and the health care provider were also identified as a determinant factor related to foot care behavior. DM management and foot care education provided by the health care workers could improve foot care [16]. One study showed that patients who received information from the health workers about diabetic foot care had better foot behaviors than those who did not [17]. Seid and Tsige (2015) showed that poor communication between the patients and the health care workers was as a barrier factor for foot self-care [15]. Poor communication between the health workers and patients due to the patient's language skills and the availability of resources in foot care education also played a part [11].

One study showed that social support was associated with foot care practices. A lower level of social support (family or other forms of caregivers) could act as a barrier factor for foot care [12]. Family members play an important role as a supervisor in the patient's regular foot care. The limitation of this systematic review is that it didn't use a quality assessment.

Conclusion

This systematic review provided an overview of the determinant factors of foot care behavior. Good foot care behaviors were influenced by education, social support structure and the health care providers. Therefore, education for the health care providers, the patients and their family is needed for the promotion of good foot care practices. Before planning the intervention, health care providers need to consider the various factors such as level of education and the patient's social support that can facilitate good foot care behaviors. For further research, it is important to modify the educational program based on the patient and the health care resources available for the patient, family or their caregivers and the health care providers.

DOES HYPERTENSIVE ASIAN ELDERLY REQUIRE SPECIFIC CARE IN BLOOD PRESSURE CONTROL?

T P Dewi[1], B Utomo[2], S N Kholifah[3]
[1] Faculty of Nursing, Universitas Airlangga, Surabaya [2] Faculty of Medicine, Universitas Airlangga, Surabaya [3] Polytechnic of Health, Ministry of Health, Surabaya Email: triyana.puspa.dewi-2017@fkp.unair.ac.id

ABSTRACT

The prevalence of uncontrolled blood pressure, hypertension, is the leading of the global risk of mortality among Asian countries. Hypertension caused by arterial stiffness that increase by the age and sedentary lifestyle. However, hypertension still preventable and possible to control, thereby it does not rise in sudden cardiovascular death. The systematic review aimed to identify and synthesize the available evidences about blood pressure control strategies specifically among the Asian elderly. This review conducted database in Medline, Scopus, PubMed and Cochrane Library with inclusions are randomized trial study determined from 2013 to 2019 and related to hypertension that assessed using the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) Statement. Six eligible studies were included with outcome was the blood pressure measurement. One study reported that mechanism of low salt-diet and potassium significantly reduced blood pressure. Others two studies reveals the effect of nutritional intervention to blood pressure and the other provides self-management and supporting intervention in the group. These studies conclude that blood pressure control for Asian elderly based on three main aspects of nutrition, medication and management support.

Keywords: blood pressure control, elderly, hypertension and Asia

1. Introduction

Hypertension in Asia contributes to the increase in cardiovascular disease and death. Uncontrolled blood pressure with low obedience for hypertension management, especially in South East Asia, is reported as a factor that is leading the rise in deaths. Hypertension is a worldwide issue due to the disobedience of patients to the medication program, which has only reached half of the total number[1]. Research was conducted in China in 2017 and it reported that the degradation of medication proportions and blood pressure control needs patient compliance to control hypertension[2]. Vascular aging in the elderly, namely arterial stiffness, is expected to become the dominant phenotype of hypertension, especially in Asia[3].

Virdis et al. described the aging process as involving arterial stiffness and the changing of the inner wall of the arteries, mainly of the aorta and proximal branches. The thickening of the intima causes a loosening of elasticity and this has an effect on the hemodynamics. When stiffness

attacks the large arteries, the cushioning function is damaged. The ejection function of ventricle and recoil elasticity will decline. The continuity of this situation potentially increases the risk of stroke and heart failure[4].

Hypertension in the age group of 65 or more, mostly in women, is known as one of the trigger factors of worldwide premature death[5]. Many studies have reported about hypertension among the hypertensive Asian elderly. The countries with the highest prevalence of essential hypertension in Asia were Singapore (73,9%, aged ≥60years) and Korea (68,7%, aged ≥65 years), and it was indicated that only two thirds received anti-hypertension medication. The number of hypertensive individuals in the most populated countries, namely India and China, was predicted to potentially rise in 2025 to 95,3 million and 117,6 million people respectively[6]. Sinclair et al. conducted *The Systolic Hypertension in the Elderly Program pilot project* in 2012 which revealed that smoking in the elderly was the first predictor of cardiovascular disease and myocardial infarction that caused sudden death[7]. The Indonesian Ministry of Health reported that this amounted to 69,5% of the elderly (aged >75 years) with hypertension as the highest percentage in 2018[8]. A web-based report in 2016 in Primary Health Care showed that hypertension was the first reported case with the total patient admissions amounting to 238.695, dominated by men[9].

Based on all of the studies, hypertensive Asian elderly have had many interventions applied to control their blood pressure with the aim of lowering the risk of complications. Pharmacological intervention programs, dietary management and other types of management to support high quality of life mainly in the Asia region. Therefore, this systematic review aimed to identify the kinds of interventions that successfully help the hypertensive Asian elderly.

2. Methods

This systematic review was reported in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) Statement[10].

2.4 Data Sources and Searches

The databases searched included Medline, Scopus, Pubmed and Cochrane Library. They provided the studies related to the clinical trials of hypertension management in Asia determined from 2013 to 2019 by the following keywords: blood pressure control, elderly, hypertension and Asia.

2.5 Study Selection

Only interventional randomized trials conducted on older adults and the elderly with hypertension were included in this review. The studies selected by the inclusion criteria were open access randomized trial studies within full-text articles in the English language conducted in the Asia region. We excluded studies with a non-clinical trial design focused on non-elderly participants and with unrelated study protocols.

2.6 Data extraction and quality assessment

All of the citations retrieved from the electronic databases were imported into the Mendeley Program. Two reviewers (BU, SNK) independently analyzed the titles and abstracts of every study retrieved from the literature search to identify potentially eligible studies. The full text of the remaining studies was obtained for further examination. The last review was conducted by the first reviewer (TPD).

The data of the included studies were independently extracted by the same two reviewers by including the first author's name, the year of publication, the sample size, the study design, the duration of the trial, the general characteristics of the participants (age, hypertension or high blood pressure, gender) and the main outcome of interest (blood pressure measurements). A detailed description of the nutritional intervention, medication program and supporting management was documented for both the intervention and control group.

We used blood pressure measurement as the main outcome of this systematic review, which changed after the intervention according to a variation of duration. The methodological quality of the studies was measured according to Cochrane Collaboration's tool for assessing the risk of bias in randomized trials. The biases were classified into six domains: selection, performance, detection, attrition, reporting and other[11]. The risk of bias was independently analyzed by two reviewers for each domain and it was classified as high, low or unclear. Regarding the lowering of the blood pressure, the risk was classified as "low" if the study described the changing process of the intervention.

3. Results

3.6 Literature Search

We conducted an identification of 620 studies through the database searches. Seven duplicate studies were excluded, followed by 572 studies due to non-elderly participants, non-RCT, irrelevant studies and poor study protocols. The 41 eligible studies were assessed and 35 of them were excluded because they were from outside of an Asian country and the outcome was not blood pressure monitoring. The six remaining studies were included in the current systematic review.

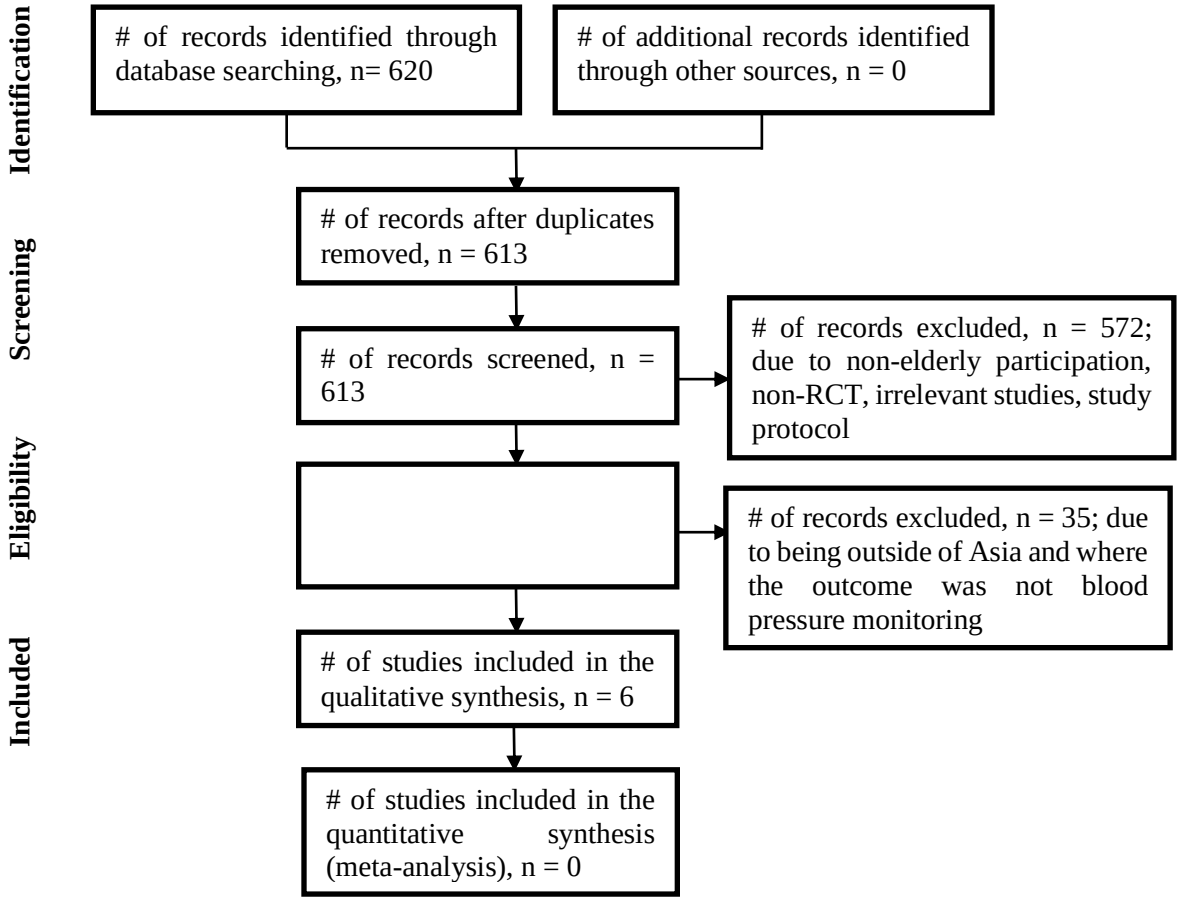

Figure 3. The flow diagram of the literature search used to identify the randomized trials used for evaluating the interventions that successfully lowered the blood pressure of the hypertensive Asian elderly

3.7 Study Characteristics

The total number of participants from the six eligible studies was 537 older adults and elderly with hypertension. Most of the trials were conducted in Asia with one of the outcomes being their blood pressure measurement. Three trials included nutritional interventions, in the form of 300 mg of Nigella sativa seed extract, tomato juice and a low salt diet with potassium. They were conducted for less than 1 month for the hypertensive elderly with a systolic blood pressure >140 mmHg and diastolic >90mmHg. Tomato juice has been effectively proven to lower blood pressure[12]. The dietary intervention of a low salt diet with potassium was also effective at regulating the blood pressure, which is beneficial to enhancing arterial compliance and preventing arterial stiffness. The other studies provided educational and supporting programs to improve the elder's capability of self-reliance in terms of blood pressure management. Table 1 reveals the complete description of the included studies.

Table 2. Characteristics of the studies evaluating the different kinds of intervention that successfully helped the hypertensive elderly

Author, year, location	Design	Duration of trial	Inclusion criteria	Participant	Intervention	Result
Wang, He, Liu, Lin, & Hong, 2017 **China**	A randomized trial	21 days supplementation	Mean systolic BP (SBP) of ≥140 mmHg and/or a mean diastolic BP (DBP) of ≥90 mmHg, or taking one or more antihypertensive medications	44 subjects (38-65 years old) In one group intervention	One group intervention: low-salt diet for 7 days (3.0 g/day of NaCl), a high-salt diet for 7 days (18.0 g/day of NaCl), and then a high-salt diet supplemented with potassium for another 7 days (18.0 g/day of NaCl + 4.5 g/day of KCl)	Potassium consumption combined with a low salt diet is effective at regulating blood pressure and reducing the cardiovascular risk by enhancing arterial compliance
Songthai, Subgranon, Kangchai, & Rosenberg, 2014 **Thailand**	A randomized controlled trial	6 weeks intervention with evaluation in the 4th and 16th weeks	1) Age 60 or older 2) Diagnosed with essential hypertension for at least a year 3) Blood pressure of Grade 1 or 2 4) Understood Thai 5) Possessed normal perceptions of date, time, place and person 6) Able to undertake activities by themselves (based on the Mini-Mental State Examination	81 elderly with hypertension (27 elderly for each group)	Intervention group 1: attended a program of peer-support, self-management led by six of their elderly peers with hypertension Intervention group 2: peer-support, self-	Both interventions resulted in a blood pressure reduction and self-management behavior improvement in the hypertensive older adults which was measured at week 16.

			Thai Version 2002: MMSE-Thai 2002) 7) No persistent disease or disorder that hindered participation in the program (based on Modified Barthel ADL Index: BAI)		management led by six VHVs Control group: none	
Wu et al., 2019 **Taiwan**	A randomized controlled trial	1 month	1) Systolic blood pressure 120–139mmHg or diastolic blood pressure 80–89mmHg 2) HDL-C<40mg/dL for men and<50mg/dL for women 3) Low-density lipoprotein cholesterol (LDL-C) 130–159mg/Dl 4) Triglycerides 150–219mg/dL 5) Cholesterol total200–239mg/dL	84 participants aged > 50 years (43 elderly in the intervention group, 41 elderly in the control group)	Intervention: 2-hour health promotion sessions within 1 month Control: conventional health education	Significant improvements were found in body mass index, systolic and diastolic blood pressure, blood glucose and also HDL-C. Moreover, the improvement of self-efficacy in managing hypertension was also maintained until six months after the intervention
Sabilu, Fachlevi, Saptaputra, &Hidayanty, 2017 **Indonesia**	A randomized controlled feeding design	7 days intervention for each group	1) Elderly hypertension patients who were 60 years of age and older 2) With a systolic BP >140 mmHg or a diastolic BP >90mmHg 3) Were not receiving any antihypertensive drugs 4) Resided in the Kulisusu Public Health Center	28 elderly patients (14 elderly for each group)	Intervention: consumed 1 glass of tomato juice for 7 days Control: nutrition education on a balanced diet for 7 days	The tomato juice taken over 7 days positively affected both the systolic and diastolic blood pressure in the hypertensive elderly

			working area at the time of the study 5) Were willing to participate in the study by providing informed consent 6) Had no co-morbidities.			
Charoensuk, Tansirisithikul, Sakulpipat, Suriyawongpaisal, &Aekplakorn, 2015 **China**	A randomized controlled trial	6 months intervention with an evaluation at 6 and 12months	Patients with systolic BP (SBP) ≥140 mmHg or diastolic BP (DBP) ≥90 mm Hg based on the average of the prior 12 months	224 participants (111 participants in the intervention group and 113 in the control group)	Intervention: self blood pressure monitoring (SBMP) Control: usual care	The SBMP group had a lower blood pressure compared with the usual care group for those aged >60 years. Conversely, no significant effect was found in those aged <60 years
Rizka, Setiati, Lydia, &Dewiasty, 2017 **Indonesia**	A randomized controlled trial	28 days	Patients aged ≥60 years with hypertension (SBP>140 mmHg and or DBP>90 mmHg	76 elderly patients with hypertension (38 participants for each group)	Intervention: capsule consumption containing a dose of 300 mg Nigella sativa extract Control: received a placebo capsule that was the same color	The blood pressure level tended to decrease, but Nigella sativa extract is not yet statistically proven to lower blood pressure

The studies were organized into three types of intervention: nutritional intervention, medication and a management program. Only one study, which was conducted by Wang et al (2017) was not an involved control group. Research by Rizka, Setiati, Lydia, & Dewiasty conducted in 2017 resulted in a blood pressure reduction but this was not statistically significant proven[13].

3.8 Nutritional interventions resulting in blood pressure reduction

The first assessed study involved 21 days of supplementation through a diet combination. This revealed that a low-salt diet (3.0 g/day of NaCl) for the first 7 days of the intervention tended to lower the patient's blood pressure. Furthermore, their blood pressure levels showed a significant incline when the next high-salt diet assessment was performed. Otherwise, it continued to decrease after the intervention changed to a high-salt + potassium supplementation ($p<0.05$). The biochemical result proved that the salt intake affects the serum gastrin levels that are positively correlated with 24 hours of urinary sodium excretion. Gastrin acts as a regulator of the body's sodium balance and blood pressure. On the other hand, a decent potassium intake remarkably alleviates the blood pressure increase that is induced by the high level of dietary salt through inhibiting the sympathetic nerve excitability, salt-induced insulin resistance and oxygen reactive free radical generation. A long duration of potassium supplementation is beneficial concerning arterial stiffness and compliance. The intake of serum gastrin in a high-salt diet was successfully reduced by potassium supplementation[14].

A daily routine involving tomato juice consumption might be one solution as a part of their daily nutrition, easily processed and delicate, aimed to maintain blood pressure in normal range. This non-pharmacological treatment has minimum adverse effects and it contains many natural nutrients such as bioflavonoids, potassium, calcium and fiber. The vulnerable population of the elderly sometimes prefer to choose herbal treatments and to avoid medication. Maintaining essential nutrition in the elderly can help them to maintain their health and prevent complications.

Both of these interventions have proven that potassium is effective at reducing a high blood pressure level in the hypertensive elderly. High potassium consumption is beneficial for lowering the systolic and diastolic blood pressure through the increased concentration of the intracellular fluid which tends to draw fluid from the extracellular compartments. Potassium taken in through the vasodilator action reduces the peripheral resistance which can help to reach normotension. Moreover, it might increase the cardiac output by inhibiting the release of renin[12]. A similar study was conducted in Poland for 4 weeks. It proved that the standardized tomato extract treatment for hypertension has the effect of significant blood pressure reduction and reducing the mean arterial pressure over 24 hours. In addition, pulse pressure also declined in the day time and over 24 hours[15].

The World Health Organization has a promotion program focused on population-level salt reduction which contains three pillars. This includes the reformulation of processed food, consumer awareness and environmental changes in order to increase the availability and affordability of healthy food. The health risks that come from the habitual consumption of excessive salt causes millions of premature deaths annually and this seems to now be a challenge for public health. The lowering salt consumption is an action that is used to save more lives practically with the aim of preventing related diseases, resulting in lower healthcare costs[16]. The World Health Organization also recommends a potassium intake of at least 90mmol/day (3,5g/day) from food in order for adults to reduce their BP

and their risk of cardiovascular disease, cerebrovascular events and coronary heart disease. A regular potassium intake may help people who find it difficult to reduce their sodium intake[17].

3.9 Peer-support in a self-management program resulting in the enhancing of self-management behavior and blood pressure control

The efforts undertaken to enhance the abilities of the elderly through a self-management program has many benefits. The elderly management program for hypertension requires them to have the ability to monitor their blood pressure regularly by themselves. The consensus document, the Improving of Hypertension Management in Asian Patients, was published in AHA journals in 2018. It reported that mask hypertension and mask uncontrolled hypertension were more likely to be diagnosed in Asia than in any other region. Morning blood pressure measurements will hopefully help us to focus on the out-of-office management of hypertension in Asians. The need for home-blood pressure monitoring for hypertensive Asian elderly individuals becomes important because Asians often are associated with a high sodium intake and salt sensitivity[3].

Based on that report, a variety of self-management supports and programs were developed. Several programs have tried to provide knowledge of the illness and problem-solving skills for hypertensive patients. Songthai (2014) tried to prove the effect of peer-support in a self management program which combined the support from the external environment of the elderly and their internal ability to control their blood pressure. The interventions were led by elderly volunteers or by the village health volunteers (VHV's) who were recruited and trained before the intervention. A significant improvement in self-management behavior and blood pressure were proven statistically in the group with elderly volunteers. This proves that support is an antecedent of self-management which corresponds to the conceptual analysis of Udlis (2011). Social and emotional support is needed to succeed in chronic illness management[18].

The first phase of the program was peer-led training which helped the volunteers to get an understanding of the information and emotional support for hypertension management. This phase then continued by exchanging knowledge and behavior (practiced self-management skills) regarding hypertension. After that in weeks 2 to 6, the chance was given to practice self-management by using the hypertension medication, reducing their weight, reducing their alcohol consumption and smoking, increasing their physical activity, relieving stress, adopting the diet recommendations and writing a journal on their home self-management. The last phase was a group visit by the leaders to the group member to exchange knowledge and behaviors, before completing the evaluation[18]. A longitudinal study in 2012 using a multi-component proactive nursing program also proved that a group discussion as part of a home visit as a form of nursing care support can help the elderly to enhance the ability of blood pressure control and a healthy lifestyle[19].

3.10Self-blood pressure monitoring resulting in blood pressure reduction

The skill of self-blood pressure monitoring is required due to the morning hypertension. The morning blood pressure control should be improved with the use of long-acting antihypertensive drugs in appropriate, often full, dosages in the proper combination. In the morning, both ischemic stroke and coronary events often occur. Moreover, the daily blood pressure usually peaks in the morning[3]. Most people do not feel or present with any signs or symptoms. According to the Updated 2014 Eight Joint National Committee (JNC-8) guidelines on hypertension, the recommendation for blood

pressure for the age group >60 years old is less than 150/90 mmHg. The initiation of anti-hypertensive drugs is required if the blood pressure is to remain ≥150/90 mmHg[20].

The effectiveness of self-blood pressure monitoring was proven to lower blood pressure in the elderly. The SBMP group had lower blood pressure compared with the usual care group for ages >60 years. Conversely, no significant effect was found in those aged <60 years. The elderly were trained and observed during the six months of the intervention about how to use a monitor and how to record and interpret their blood pressure result twice a day (concerning their morning and evening blood pressure). For individuals aged ≥60 years, the proportion of those with uncontrolled blood pressure decreased from 90,0% to 38,2% at month 12[21]. The effectiveness of this intervention was also evidenced in the systematic review that revealed that it worked best when combined with more intensive interventions (self-management, systematic medication titration or lifestyle counseling). In addition, it was most effective in those taking less antihypertensive medication and who had a higher baseline systolic blood pressure up to 170mmHg[22].

3.11Health promotion intervention resulting in blood pressure reduction and self-efficacy enhancement

The experimental group received 2-hour health promotion sessions within 1 month that included learning health promotion skills, watching a 30-minute video about hypertension prevention and receiving a booklet to record their blood pressure and other activities. According to The International Partnership in Self-Management and Empowerment, it covered practicing the recommended behaviors, vicarious experiences, verbal persuasion, psychological and emotional self-evaluation. In this study, the participants in the experimental group were empowered to measure their blood pressure by themselves and to maintain their BMI within the ideal range. This was done by choosing healthier foods at home and following their diet plan when they ate out. They believed that medication could control their blood pressure and cholesterol and reduce the likelihood of complications from disease, which increased their level of mastery[23].

This evidence was supported by Haricharan (2017), who proved that health promotions for hypertension using different methods, including via SMS, were also effective at improving knowledge and facilitating healthy living even in deaf hypertensive South Africans[24]. Another article reported that nursing has an important role in health promotion interventions concerning the strategies used to enhance quality of life, health and the participation of hypertensive people in blood pressure control[25]. From the literature review of Asian nursing research, we learned that the areas of health promotion through nursing include the 7 areas of JNC VII which are blood pressure control, weight control, alcohol consumption, physical activity, smoking consumption, adherence to the medication regimen and diet[26].

3.12Methodological Quality Assessment of Studies

Cochrane Collaboration's tool for assessing risk of bias in randomized trials was used to assess the risk of bias of both studies[11]. Six studies were assessed to judge the studies based on their bias characteristics. The complete assessment of the studies is in Table 2.

Table 3. Assessment of the methodological quality or risk of bias item for each included study

Three out of the six included studies meet all of the criteria of bias[13,18,23]. Only one study presented with a high risk of bias in the blinding aspects[21] and two studies showed as having unclear criteria[12,14]. All of the studies were successfully assessed according to the results of the blood pressure measurement after the interventions were given.

	Selection bias		**Performance bias**	**Detection bias**	**Attrition bias**	**Reporting bias**	**Other bias**
	Random sequence generation	Allocation concealment	Blinding of the participant and personnel	Blinding of the outcome assessment	Incomplete outcome data	Selective reporting	Blood pressure

4. Discussion

Major interventions of hypertension highlight the interventions used to reduce blood pressure. The Joint National Committee (JNC) has updated guideline (JNC-8) recommendations concerning hypertension. It is known as the silent killer because it typically has no warning signs or symptoms even when hypertensive people have a dangerously high blood pressure level. It may result in brain damage as a predictor of aneurysm or stroke. Based on this situation, JNC have first and second- line treatment when it comes to medication utilization. Malfunctions in angiotensin and aldosterone, as well as disturbances in the electrolytes, may be controlled by applying a well-balanced diet, exercising and maintaining a healthy weight[5]. In the elderly with many dysfunctions and complications, it may help them to achieve their blood pressure goals with minimum medical intervention.

Based on the consensus of Asian hypertension, the characteristic of the Asian population is that it is aging rapidly. They have a larger diameter and thinner media of the proximal aorta that modulates the interaction between ventricular ejection and arterial load. Moreover, they have a smaller stature and may have greater wall stress and stiffness in the proximal aorta. Consequently, these conditions may have a greater significance on the hypertension outcomes of Asian patients than in other regions[3]. Especially in the senior population, an analysis in Japan revealed that the use of antihypertensive medication and a certain level of compliance is necessary when seeking to achieve the target blood pressure even when there is another risk condition (i.e. chronic kidney disease)[27].

4.3 Summary of findings

Three aspects which play an important role in blood pressure reduction are nutrition management, medication adherence and supporting management. Nutritional management includes salt restriction and potassium supplementation to balance the nutrition and to control the blood pressure[12,14]. Not only diet management, but the natural nutrition also needs to support the elderly with less medication program compliance. The consumption of tomato juice which contains many important nutrients may help them to regulate their blood pressure using natural ingredients.

Hypertensive Asian elderly have a lot of physical impairments that may affect their ability to self-manage their blood pressure. Therefore, the support of a peer group or health care provider is needed

to help them to solve the physical or psychological problems and limitations. Their impairments need evaluation and prevention to reduce the risk of complications without any prejudice regarding their basic ability in terms of hypertension management. The elderly have the potential to act as an active person by applying self-monitoring blood pressure as an effort to prevent hypertension even without signs and symptoms appearing. It may benefit if they received appropriate training and health education[18,21,23].

4.4 Implication for research

Nutrition management, adherence to the medication recommendations and management support have an essential role in maintaining quality of life and a healthy lifestyle, resulting in the lowering of the cardiovascular risk. As far as we know, an excess of salt/sodium consumption increases the blood pressure by fluid retention. Hypertension is a modifiable cause of mortality worldwide due to poor blood pressure control. The control will get hard and the prevalence will increase with age. Optimal blood pressure needs the role of system, physician and patient together to achieve blood pressure goals[28].

Several factors contribute to the current hypertension burden in Asia, such as a high salt intake with high salt sensitivity and an epidemic of obesity. Therefore, home blood pressure monitoring (HBPM) is required to obtain reliable blood pressure recording resulting in better blood pressure control. The review of the HOPE Asia (Hypertension, Cardiovascular outcome Prevention and Evidence in Asia) Network has been reviewed, presenting data about the current utilization of HBPM in Asia. The success of HBPM application among hypertensive Asians is challenging due to limitations such as cost constraints, a lack of understanding and training on how to use the devices by patients and the absence of formal recommendations on HBPM in the national guidelines[29].

4.5 Limitations of the findings

Both of the studies reveal the outcome of the assessed blood pressure level, which mostly declined after the interventions despite the method and tools being different in each study. This may cause there to be different standards of assessment in the blood pressure report and monitoring, resulting in making it difficult to classify them into the same result category.

5. Conclusion

This systematic review has found there to be limited evidence from randomized trials that have categorized one kind of specific interventions. Further research is needed to assess the specific proven interventions by using a qualitative method to explore the benefits and difficulties related to applying the intervention based on the preferences of the elderly, especially in Asia.

ABSTRACT

Cervical cancer often occurs in developing countries. Early detection is one of the prevention efforts to reduce the incidence of cervical cancer. Intention is related to the behaviour of early detection of cervical cancer. This study aims to identify factors that influence women's intention to detect cervical cancer through the integration of the theory of planned behaviour and protection motivation theory. This research was cross sectional study and the sample was obtained from two working areas of community health center in Jember City, Indonesia, with 200 women aged 30-50 years. The sampling technique was simple random sampling. The result showed that attitude variables have a significance value (p=0.003), subjective norm (p=0.0019), perceived behavioral control (p=0.000), perceived vulnerability (p=0.000), perceived severity (p=0.004) and perceived reward (p=0.001). The most dominant factor of influence was the perceived vulnerability with t value is 3.865 and beta coefficient 0.212. The study showed that attitudes, subjective norms, perceived behavioural control, perceived vulnerability, perceived severity, perceived reward have a positive influence on intention. Continuing efforts are needed by women, especially interventions that aim to increase the factors that shape women's intention to make early detection of cervical cancer

Keywords: intention, early detection, cervical cancer

1. Introduction

Cervical cancer is a disease that attacks women. It is the highest cause of death among women [2]. The International Agency for Research on Cancer (IARC) at the WHO (World Health Organization) in 2014 found as many as 14 million new cancer cases and 9% of them were cervical cancer. The WHO issued a resolution in 2005 that asked for priority in the cooperation related to developing cancer control programs. This program aimed to reduce the incidence and mortality of cancer patients [3]. One of them was performing the early detection of cervical cancer [4]. The early detection of cervical cancer has been improved in several developing countries over the recent decades. This experience indicates that good planning and the good organization of the early detection of cervical cancer will decrease the incidence of new cervical cancer. It is associated with a decrease in the mortality rate of women with cervical cancer.

Indonesia is one of the developing countries with the number of cervical cancer sufferers in 2013 being many as 98,692 people with the biggest total number of sufferers of cervical cancer after China [5]. East Java is the province in Indonesia with the highest number of cervical cancer sufferers, reaching 21,313 people[1]. Jember Regency is one of the districts in the East Java Province that has experienced an increase in the number of cervical cancer patients from 2015 to 2017. The Indonesian

government established a program named "The Acceleration of Community Participation in the Prevention and Early Detection of Cancer in Indonesian Women for the period 2015-2019". This program had a target consisting of women aged 30-50 years old [6]. The coverage of the early detection of cervical cancer in 2017 reached 2.98%. This needs to be improved considering that the achievement of the national target is 10% of women aged 30-50 years old performing the early detection of cervical cancer every year.

Improving the behavior of the early detection of cervical cancer in a community is an important strategy to control the incidence of cervical cancer. Therefore we need to understand the factors that are related to performing the early detection of cervical cancer. One of the factors that is related to performing the early detection of cervical cancer is intention [3]. The intention to perform cervical cancer screening by women in Uganda is associated with income, knowledge and cervical screening status before[20]. The Theory of Planned Behavior (TPB) and Protection Motivation Theory (PMT) are social theories of cognition that discuss intention [7]. The study used TPB and as a result, attitude and perceived behavioral control from TPB were found to be significant predictors of the intention to screen for human papillomavirus related to cervical cancer screening with an extended interval[21]. PMT also identified, through another study, that perceived vulnerability and perceived severity were significantly associated with screening intention in rural Chinese women. There has been no study previously that has identified the factors related to the women's intention to perform the early detection of cervical cancer based on TPB and PMT in Indonesia. Therefore, this study aims to identify the factors that are related to the women's intention to perform the early detection of cervical cancer based on the Theory of Planned Behavior and Protection Motivation theory.

2. Research Method

2.1 Research Design

This research was a cross-sectional study using primary data. The data collection was during February 2019. The independent variables in this research were attitudes, subjective norms, perceived behavioral control, perceived vulnerability, perceived severity and perceived rewards. The dependent variable was the intention to perform the early detection of cervical cancer.

2.2 Populations and Sample

The population consisted of women aged 30-50 years registered in two community health center working areas in Jember Regency, East Java, Indonesia. The simple random sampling technique was used to find the respondents in two community health center working areas. The sample size of this study was 200 women. The inclusion criteria was (1) women who had been married or who had ever married for more than 3 years, (2) women who can communicate with oral and written, (3) women who can understand Indonesian. Exclusion criteria are (1) women diagnosed with cervical cancer (2) women with mental disorders.

2.3 Research Instrument

The research instrument used a questionnaire consisting of attitude, subjective norms, perceived behavioral control, perceived vulnerability, perceived severity, perceived rewards and the intention to perform the early detection of cervical cancer. The questionnaire was modified from Kim's cervical cancer TPB questionnaire [8]. The researcher made modifications in the form of adding question

items based on TPB [7] and translating it into Indonesian. The questionnaire about perceived vulnerability, perceived severity and perceived rewards was arranged based on Protection Motivation Theory[7]. The questionnaire consisted of 48 questions in total. There were favorable and unfavorable questions. The choice of answers used a Likert scale (strongly agree, agree, disagree and strongly disagree). All of the variable were derived from one of two categories; good and deficient. It could be in the good category if T≥T mean for the data and it was in the deficient category if T<T mean data. The scale of the data used was an interval.

The attitude questionnaire consisted of 6 questions, while subjective norms had 6 questions, perceived behavioral control had 16 questions, perceived vulnerability had 6 questions, perceived severity had 5 questions, perceived reward had 4 questions and the intention to perform the early detection of cervical cancer had 5 questions. The validity and reliability tests were conducted on 25 respondents. The test was carried out in the working area of the community health center that had similar characteristics with the place of research. The respondents of the validity and reliability test were women who were not the subjects of the main research. The analysis of the validity test used Pearson's product moment with a ρ value of 0.05 and r = 0.396 for N=25. All of the items were found to be valid questions because the r value was more than 0.396. The reliability test used Cronbach's alpha. The question was reliable if Cronbach's alpha was more than 0.65. The value of Cronbach's alpha of the attitude variable was 0.883, while subjective norms was 0.949, perceived behavioral control was 0.883, perceived vulnerability was 0.855, perceived severity was 0.949, perceived reward was 0.683 and intention was 0.880. It can be concluded that all of the items are reliable.

2.4 Data Analysis

Multiple linear regression analysis was used in this research to identify the factors related to the women's intention to perform the early detection of cervical cancer. The results can be concluded if ρ<0.05, which means that there is relation between two variables. The t test was used to determine the most dominant factor related to the women's intention to perform the early detection of cervical cancer. The results can be concluded using the biggest T statistic. All of the data was analyzed using SPSS 16.0

2.5 Ethical approval

All of the procedures of this study received a certificate of approval from the Health Research Ethics Commission (KEPK) of Airlangga University Surabaya registration number NO. 1295-KEPK.

3. Result

The data in this research was normally distributed. The normality test used the one sample Kolmogorov-Smirnov test on the unstandardized residuals with a significance value (ρ = 0.556). Table 1 describes the respondent's characteristic in this research. Most of the respondents were ages 30-39 years old (61%), had an income less than the regional minimum wage (54.5%) and were Javan (50.5%). Table 2 describes the results of the distribution frequency of the independent and dependent variables. Most of the respondent had a deficient attitude (61%), deficient subjective norm (53%), deficient perceived behavioral control (59%), deficient perceived vulnerability (60.5%), deficient perceived severity (53.5%) and good perceived reward (59%). The intention to perform the early detection of cervical cancer was in the good category by 58% and deficient category by 42%.

Table 1. Distribution Frequency of the Respondent's Characteristic

Characteristic	Frequency	Percent
Ages		
30-39	122	61%
40-50	78	39%
Income		
<Regional minimum wage	109	54.5%
> Regional minimum wage	91	45.5%
Ethnicity		
Java	101	50.5%
Madura	99	49.5%

Table 2. Distribution Frequency of Independent and Dependent Variables

Variable	Category	Frequency	Percent
Attitude	Good	78	39%
	Deficient	122	61%
Subjective norm	Good	94	47%
	Deficient	106	53%
Perceived behavioral control	Good	82	41%
	Deficient	118	59%
Perceived vulnerability	Good	79	39.5%
	Deficient	121	60.5%
Perceived severity	Good	93	46.5%
	Deficient	107	53.5%
Perceived reward	Good	118	59%
	Deficient	82	41%
Intention	Good	116	58%
	Deficient	84	42%

Table 3. The Summary of the Multiple Linear Regression Analysis

Variable	Correlation value	Coefficient Beta	T Statistic (*N*=200, *df*=193)	Sig.
Intention [a]				
Attitude	0.565	.205	2.994	.003
Perceived behavioral control	0.515	.198	3.110	.002
Perceived vulnerability	0.429	.212	3.865	.000
Subjective norm	0.468	.143	2.358	.019
Perceived severity	0.431	.166	2.956	.004
Perceived reward	0.379	.174	3.257	.001

[a] Dependent Variable: intention

The results of the multiple linear regressions analysis have been captured in Table 3. All of the variables have a positive correlation to the women's intention to perform the early detection of

cervical cancer. The attitude variable has a correlation value of 0.565, while subjective norm is 0.468, perceived behavioral control is 0.515, perceived vulnerability is 0.429, perceived severity is 0.431 and perceived reward is 0.379. All of the variables are significant. This can be seen from the ρ value being less than 0.05: the attitude variable (ρ = 0.003), subjective norm (ρ = 0.019), perceived behavioral control (ρ = 0.002), perceived vulnerability (ρ = 0.000), perceived severity (ρ = 0.004) and perceived reward (0.001) all indicate this. Table 3 shows that all of the variables have a T statistic greater than the T table. The value of the T table for df 193 is 1,653. The biggest value for the T statistics was perceived vulnerability at 3.865 with a β coefficient of 0.212. This shows that perceived vulnerability is the dominant factor related to the women's intention to perform the early detection of cervical cancer.

4. Discussion

The Theory of Planned Behavior explains that intention was influenced by three aspects: attitude toward behavior, subjective norms and perceived behavioral control [9][10]. This research showed that attitude toward behavior, subjective norms and perceived behavioral control are related to the women's intention to perform detection cervical cancer early. There are three aspects related to the individual beliefs: behavioral beliefs, normative beliefs and behavioral control beliefs. This is in accordance with the previous research explaining that one's beliefs about their health make the individuals participate in more in the early detection of disease [11]. The same study explained that strong subjective norms encourage individuals to perform early detection regularly [9]. The behavior of the early detection of cervical cancer was not already being done, but it was also related to regularity in performing the early detection of cervical cancer. Family, peer and health care support has a significant influence on women's regularity in terms of the early detection of cervical cancer. A positive attitude towards the early detection of cervical cancer was one aspect of a woman's early detection of cervical cancer [12]. A positive attitude can be shown when the women have beliefs about the benefits of the early detection that has been done. The early detection of cervical cancer can provide an earlier picture of the arrival of cancer cells so then action can be taken immediately before the cancer cells expand throughout the body [13].

Perceived behavioral control showed the presence of both inhibiting factors and driving factors as felt by individuals when it came to performing the early detection of cervical cancer. This is in accordance with the previous research which explained that cost is a limiting factor for women in Hong Kong when it comes to the HPV vaccines and the early detection of cervical cancer [13]. The male sex of the examiner was one of the inhibiting factors in terms of conducting the early detection of cervical cancer. Previous research on female inhibiting factors in terms of the early detection of cervical cancer explained that culture and religion are the barriers to the early detection of cervical cancer [14], especially when the early detection is carried out by male doctors [15]. The driving factors included feeling comfortable and finding it easy to consult regarding the health of their reproductive organs with the health workers, convenient access to the health services, self-confidence in the early detection of cervical cancer and the women's concern for the health of their reproductive organs. The previous research explained that one's self-confidence in the early detection of cervical cancer is an important factor when building the intention to detect cervical cancer early [11]

Protection Motivation theory is a social theory of cognition formulated by Roger in 1975 [7]. This theory explains that intention is formed by a threat appraisal which consisted of perceived vulnerability, perceived severity and perceived reward. This research explained that the three factors

had an effect on the women's intention to perform the early detection of cervical cancer. The perceived vulnerability factor was the most dominant factor besides attitude, subjective norms, perceived behavioral control, perceived severity and perceived reward. This was in accordance with the previous research which explained that perceived vulnerability shaped fear, so it encouraged them to take self-protection measures by performing the early detection of cervical cancer[16]. Research on women in Iran also explained that the women's perceptions of cancer shaped them when it came to taking protective measures [17]. This is in accordance with the previous studies indicating that the women's perceptions of the risk of cervical cancer affects the behavior related to the early detection of cervical cancer [19]. The perception of reward was also related to the women's intention to perform detection cervical cancer early. The perception of reward intends to induce an intrinsic reward and an extrinsic reward was obtained when they did not perform the early detection of cervical cancer. Based on the results of the research, it can be seen that the perception of reward was mostly in the good category. This showed that the reward when not perform the early detection of cervical cancer was lacking.

5. Conclusion

This research clearly illustrates that women with a positive attitudes towards the early detection of cervical cancer, the subjective norms, perceived behavioral control, perceived vulnerability, perceived severity and perceived reward will have good intentions when it comes to performing the early detection of cervical cancer. Continuing this line of research is needed with more respondents in order to identify the factors that influence the formation of attitudes, subjective norms, perceived behavioral control, perceived severity, perceived vulnerability and perceived reward. The women also need an intervention to increase the intention to perform the early detection of cervical cancer. The limitations of this study were related to collecting the data. The data taken was primary data based on a cross-sectional study so the relations between the variables were not clearly illustrated and the results thus need to be interpreted with caution.

ABSTRACT

Suicidal behavior is one of the health problems for all of age groups of humans. Depression therapy can be used to prevent the emergence of suicidal ideas and reduce risk of suicide. This objective of this review was to explain the effectiveness of depressive therapy to decrease of suicidal ideas based on various studies. This systematic review in line with PRISMA guidelines. Data retrieved from the ProQuest, Scopus, ScienceDirect, EBSCO, and PubMed databases. Articles pre-identified by using relevant keywords. Tweleve of about 240 articles both meet inclusion and exclusion criteria and were reviewed. The selection of articles using the following criteria: (1) Published between the years 2012-2018; (2) nursing journal area and Psychology; (3) Article using English language; (4) Randomized Control Trial. The depresive therapies that found in these studies were CBT, IPT, DBT, CBFT, MBCT, and ACT The results of this review indicate that CBT is one of the most effective therapies for dealing with suicidal ideation. CBT consist of counseling therapy discussing negative thoughts and negative distortions, sessions in CBT can reduce the impulsive and destructive stimulation that causes suicide ideas can reduce suicidal ideation.

Keywords: suicidal ideation, self harm, depressive therapy, treatment

1. Introduction

Suicidal ideas are a process that goes through the mind without the person taking action. A person will not reveal their idea of committing suicide if it is suppressed [1]. Suicidal ideas are a major risk factor for suicidal behavior in depressed individuals [2,5]. The relationship between depression, suicidal behavior and suicidal ideas is strongly related. More than half of the patients with Major Depressive Disorder (MDD) have suicidal desires and persistent suicidal thoughts. This is supported by the different psychological factors of each individual who is depressed [5].

Depression is involved in 59-87% of suicidal ideas and it is associated with an increase in the risk of suicide by 20 times. Suicide is estimated to have reached a rate of 800,000 cases every year. If depression is handled well, then there will be a 50-80% reduction in suicidal ideas[10]. In other studies, they said that suicide has continued to be a continuing public health problem around the world. More than one million people die of suicide every year and rates have increased by 60% in several countries over the past 45 years [16].

To reduce the risk of the idea of suicide and to reduce the number of suicides, suicide management based on therapy for depression should be a fundamental component of suicide prevention[10]. The management of suicide can be done through the use of psychopharmaceuticals

and psychotherapy. The aim of this form of management was to suppress the idea of suicide and to avoid suicidal behavior[3]. Psychotherapy consisted of 'treatment' OR 'CBT ' OR 'IPT' OR 'DBT' OR ‘CBFT' OR 'MBCT' OR 'ACT'. Journal searches were carried out on the database, with the limitation on the journal results being the year of publication being restricted from 2013 – 2019. They were focused on the nursing and psychology areas, as well as the journals that were in English. When searching using the keywords above with the restrictions used, 240 relevant journals were obtained and then a selection was made; 16 appropriate journals were decided. The 16 journals were reviewed using a randomized control trial. The RTC design was used to determine the effectiveness of the interventions used in the studies.

2. Method

2.1. Protocol

This systematic review was conducted using the procedures outlined in the Preferred Reporting Items for Systematic-Reviews (PRISMA).

2.2. Eligibility criteria

The journal articles were published in English from January 2013 through to January 2019. The search strategy used the PICOS framework to identify the keywords.

2.3 Search Strategy and selection of studies

The preparation of this systematic review began with the selection of the topics after which the keywords were determined. The keywords used were 'suicidal' OR 'self-harm' OR 'self-injury' AND/OR 'treatment’ OR ‘therapy CBT' OR 'IPT' OR 'DBT' OR ‘CBFT' OR 'MBCT' OR 'ACT’. The journal searches were conducted on the ProQuest, Scopus and ScienceDirect databases. We limited the results of the journals according to the year, with the restricted journal publications being from 2013-2018 focused on nursing journals and psychology in the English language. By searching using the keywords above with the restrictions used, 240 relevant journals were obtained. Following this, a selection was made and 16 appropriate journals were decided. The 16 journals were reviewed using the research design of a Randomized Control Trial.

2.4 Types of studies

This systematic review aims to explain the effectiveness of depressive therapy to decrease suicidal ideas based on various studies. Randomized controlled trial studies (RCTs) were used in this review.

2.5 Inclusion and exclusion criteria

The inclusion criteria for this article were articles that used English and that explained the program or effectiveness of depression therapy for suicidal ideation in depressed patients. Articles were excluded if the study did not use a randomized control trial (RCT).

2.6 Population, Interventions, Comparators, Outcomes and Study design (PICOS)

Population: the study population ranged from children through to adults with mild depression. The interventions were in the form of depression therapy including Cognitive Behavior Therapy (CBT), Interpersonal Therapy (IPT), Dialectical Behavior Therapy (DBT), Cognitive-Behavioral Family

Treatment (CBFT), Mindfulness-Based Cognitive Therapy (MBCT) and Acceptance and commitment therapy (ACT). These were used as suicidal therapies that can suppress the idea of suicide and reduce the risk of suicide as well.

Comparison: the participants were randomized to at least one control group with non-intervention conditions. For example, the wait list control group. For the output, there was both pre-and post-intervention data for the interventions and controls for one or more of the outcomes related to depression, including the main results of suicidal ideation observation and the hopelessness inventory. The study design for all was a Randomized control trial (RCT).

2.7 Meta-analysis

Meta-analysis was not possible as the studies were too heterogeneous in their type of intervention, the type of control group, the outcome measures used and the time of the follow-up.

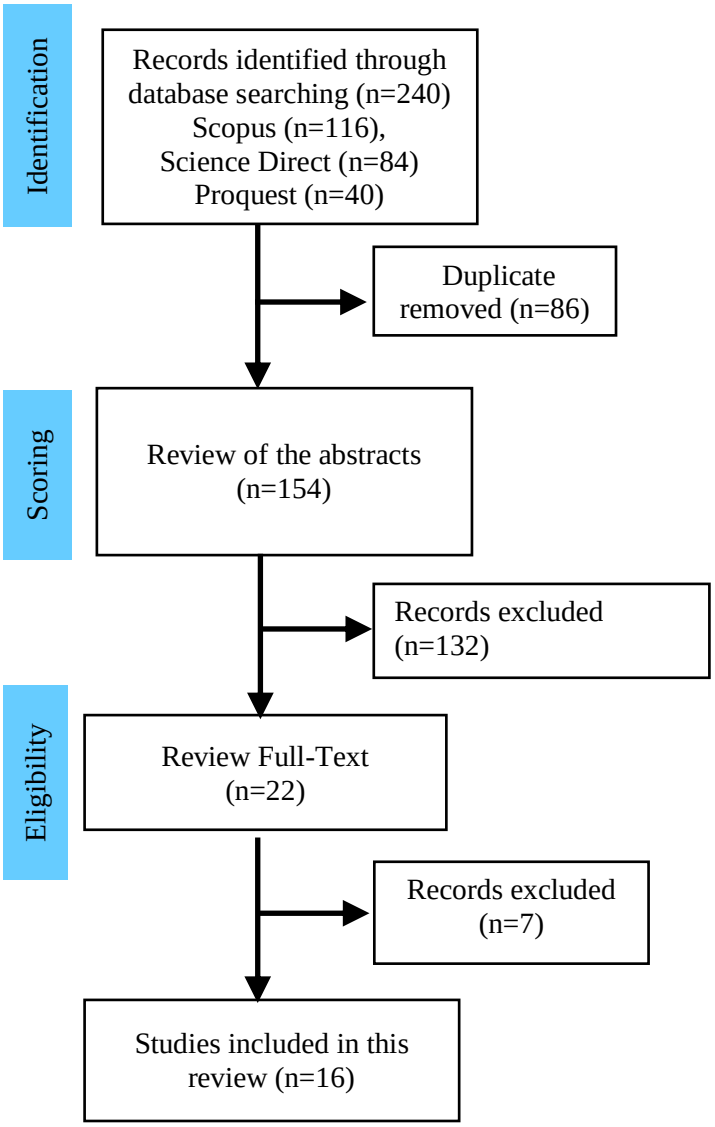

Figure 1. PRISMA flow diagram

3. Result

The total articles collected were 16. After reviewing the results, the total number of participants from

all studies was 2698 from children up to old adults. All had depressive disorders, hopelessness, suicidal ideation disorders and a suicidal history. The interventions used in all studies were multi-component interventions including CBT, IPT, DBT, CBFT, MBCT and ACT. The average duration of therapy was for 6 weeks with an average follow-up of 24 weeks. For all of the studies, most of them used the same measuring instruments, namely Beck's Cognitive Theory of Depression, the Beck Scale of Suicide Ideation and the Beck Scale for Hopelessness Inventory. Significant effects were found to be statistically evidenced from within internet-based CBT-I in terms of the post-intervention results and up until the follow-up. Significant results were found in the provision of CBT-I therapy through internet-based mobile and computerized media.

3.1 Cognitive Behavior Therapy (CBT)

There were seven articles that used Cognitive Behavior Therapy (CBT). Three articles were in the form of pure reviews related to cognitive behavior therapy and four articles were comparative to other depression therapies.

The research conducted by Abdullah & Firmansyah (2012) showed that depressed patients in the Tehran Psychology Clinic in Iran totaled 70 respondents. For those with mild depression, there were 29 respondents and for those with moderate depression, there were 41 respondents. There were three phases carried out for two weeks with the result that CBT can reduce the level of depression, suicidal ideas and increase ADL[1].

The research was carried out by Alavi, Sharifi, Ghanizadeh & Dehbozorgi, (2013) on 30 adolescents (ages 12-18 years) who were depressed with a history of suicide attempts. CBT was conducted once a week for 12 sessions. The CBT component consisted of causal analysis, planning and psychoeducation including developing reasons to hope and stay alive, including case conceptualization. CBT effectively reduces the idea of suicide, depression and hopelessness in adolescents who have a history of suicide attempts[2].

Mewton & Andrews (2015) used an internet-based i-CBT intervention on 484 depressed patients at St. Vincent's Hospital in Sydney. This involved the components of education, behavioral activation, cognitive restructuring, problem solving, graded exposure, relapse prevention and assertiveness skills. The content was presented in the form of illustrated stories where the main characters gained mastery over their symptoms of depression with the help of a therapist [10].

A review of several studies showed that CBT can be used as a successful, acceptable and measurable cost effective alternative and that this can be developed using the internet method. This research shows the usefulness of i-CBT for depression as a tool to reduce suicidal ideas that can be implemented on a large scale without imposing major structural changes at the community level.

3.2 Interpersonal Therapy (IPT)

There were two articles that used Interpersonal Therapy (IPT). According to Weitz, Hollon, Kerkhof & Cuijpers (2014), the management of drugs or pharmacotherapy and a placebo on sensitivity can be used as an alternative to reducing depression severity. This can be used to avoid the possibility of suicidal ideas. Internet-based programs can also be used as an alternative to reduce depression [16].

3.3 Dialectical Behavior Therapy (DBT)

There were four articles related to Dialectical Behavior Therapy (DBT). Research conducted by Priebe et al. (2012) showed that the interventions were carried out according to Linehan's treatment

and training skill instructions. DBT is based on the principles of cognitive behavioral therapy and it is devoted to mindfulness, validation and supportive therapy techniques. The intervention was carried out for 2 hours per week for 12 weeks. DBT is effective at reducing suicidal ideation within a personality disorder but this intervention requires greater costs [11].

Other studies say DBT has a more significant effect on EUC compared to a decrease in self-harm, suicidal ideas and depressive symptoms (Mehlum et al, 2014). Ward-Ciesielski et al. in 2013 and 2017 showed that the two conditions reported significantly reduced rates of suicidal desire, depression and anxiety, although the analysis showed there to be no significant difference between the conditions related to the main outcome measures of suicidal ideation, emotional dysregulation, skill use and depression [9].

3.4 Cognitive-Behavioral Family Treatment (CBFT)

There were two articles related to Cognitive-Behavioral Family Treatment (CBFT). Research by Asarnow, Hughes, Babeva & Sugar (2018) was conducted on 42 adolescents who had a history of suicide attempts and whose parents were interested in the study. SAFETY used the Cognitive Therapy Rating Scale (CTRS) and family / parent sessions were used to conduct MST with the results of the principles using MST Measure-Revised Adherence Therapist (TAM-R). SAFETY is effective at preventing suicidal behavior in adolescents using the Cognitive Behavioral Therapy approach and family approach [3]. Research according to Sandler, Tein, Wolchik & Ayers (2016) shows that the Family Bereavement Program can significantly influence a reduction in the emergence of suicidal ideas [12].

3.5 Mindfulness-Based Cognitive Therapy (MBCT)

There were two articles about MBCT that can be used in synergy to suppress the emergence of suicidal ideas caused by depression. A study by Barnhofer et al. (2015) said that in patients with minimal to moderate symptoms at the time of assessment, there was a correlation between depressive symptoms and suicidal cognition, thus indicating there to be a significant difference between the groups. Although suicide cognition was significantly related to the level of symptoms in the two control groups, there was no such relationship in the MBCT group. The findings indicate that in patients with a history of suicidal depression, training with a focus on awareness can help to weaken the relationship between depression symptoms and suicidal thoughts, thus reducing the important vulnerability to relapse in suicidal depression [4].

Research by Forkmann, Brakemeier, Teismann, Schramm & Michalak (2016) was aimed at treating clients with chronic depression. The interventions were divided into 3 intervention groups, namely: (a) Treatment as Usual (TAU) or usual treatment, where 35 patients were used as the samples. The patients are encouraged to continue treatment at this time and to have a meeting with their psychiatrist / psychotherapist. (b) MBCT; this program consists of individual pre-class interviews and 8 group sessions for 2.5 hours weekly. The group size was limited to 6 patients per class in this trial with the same group size in both psychotherapy and psychiatry. (c) The CBASP program consists of 2 individual treatment sessions and 8 group sessions for 2.5 hours weekly. With the results of MBCT and CBASP, it can be a successful psycho-therapy approach for group-based suicidal ideation treatment in chronic depressed patients [6]

3.6 Acceptance and commitment therapy (ACT)

There were 2 articles about Acceptance and Commitment Therapy (ACT). Research by Zettle (2015) shows that ACT can be used as an intervention in dealing with depression and the emergence of suicidal ideas. Research by Walser et al. (2015) shows that ACT-D causes a decrease in the level of depression and an increase in the value of acceptance and public awareness which is associated with a decrease in the severity of depression.

From the literature review above, the management of depression within the CBT model is the most effective and efficient therapy used as an alternative to reducing the severity of depression and to suppress the emergence of suicidal ideas [13]

4. Discussion

This systematic review provides evidence based on the effectiveness of depression therapy on decreasing suicidal ideas in depressed patients. There are six types of therapy that can be used to reduce suicidal ideas, namely CBT, IPT, DBT, CBFT, MBCT and ACT. The results of this review are certainly useful for nurses, both clinical nurses and community mental health nurses. Nurses can apply one of these health interventions as a form of preventing someone from developing depression. Clinical nurses can intervene and provide the appropriate innovations related to the development of information and technology in an effort to prevent and reduce the symptoms of depression.

Some studies explained that good mental health greatly determines a person's quality of life both physically and psychologically. It also contributes to their welfare. However, this study cannot be fully generalized. Bias can occur. This could be due to the various types of interventions available and the conditions of the study sample are less homogeneous.

The results of a review of various studies can be implicated in the area of mental nursing. Which cognitive behavioral therapy is one of the skills possessed by a specialist nurse. The existence of internet-based CBT-I through various types of technology can be used as an ***innovation in nursing interventions, especially mental health nursing. For its application in Indonesia, further research is needed by adjusting the characteristics of the clients to those commonly found in Indonesia.***

6. Conclusion

Research shows that internet-based CBT-I therapy through various types of technology has a significant influence on depressive symptoms which will lead to the emergence of suicidal ideas and a reduction of the risk of suicide. It is more effective and efficient compared to CBT-I therapy delivered directly by the therapist. This can be used as a reference for further research that is appropriate to the characteristics of the clients in Indonesia.

7. Acknowledgments

The authors would like to acknowledge Allah SWT, my family (especially my parents) and the Faculty of Nursing of Universitas Airlangga (especially the Master’s of Nursing program team).

ABSTRACT

Post-traumatic stress disorder (PTSD) is an experience of someone who experiences a traumatic event that can cause disruption to an individual's personal integrity so that individuals are fearful, helpless and traumatized. Traumatic events that can trigger post- traumatic stress disorder include cruel personal attacks, natural disasters caused by humans, accidents and battles. Databases are used to identify articles that are potentially obtained from Scopus, Direct Science, Proquest is limited to publishing in the last 5 years from 2014-2019. The literature review uses the CBT keyword, PTSD in the search for articles using AND only 12 journals that meet the inclusion criteria. Based on research data that some of the articles reviewed show that CBT interventions are effective for individuals with PTSD. that CBT intervention is a therapy that uses a problem-solving approach by learning how to control the mind through changing perceptions of people or certain situations so that it is recommended to be applied to patients with posttraumatic stress disorder.

Keywords: CBT, PTSD, systematic review

1. Introduction

Post Traumatic Stress Disorder (PTSD), according to the American of Psychology Association (APA), is experienced by someone who experiences or witnesses a traumatic event that can cause disruption to an individual's personal integrity. The individuals become fearful, helpless and traumatized. PTSD is the result of a disaster or accident such as war, natural disasters, terminal disease and violence that occurs suddenly, takes place quickly and causes deep trauma to individuals of all ages. People with PTSD have frightening and persistent thoughts and memories. They may experience sleep problems, feel detached or numb or they are easily shocked. The proper and effective handling of PTSD is needed so then the disorder does not worsen or become a mental disorder. The management and treatment needs to be correct and appropriate in accordance with the results of recent research, one of which is cognitive behavior therapy (CBT). Cognitive behavioral therapy is a form of psychotherapy that emphasizes the importance of the process of thinking and acting. CBT focuses on the feelings of distress. These thoughts and behavior will later lead to positive change. Individuals who receive CBT are ultimately expected to have positive thoughts so then they will learn positive behavior while living their lives.

The prevalence of PTSD in the United States is estimated to be 1 to 14 percent of the population, while the data from the WHO states that patients with PTSD range from 10-20 percent of the population. In a survey conducted in 2007 about 3 years after the tsunami in Aceh, the data found showed that 35 percent experienced depression, 10 percent experienced PTSD and 39 percent experienced anxiety symptoms. It is estimated that 50 percent of the population in the affected areas experienced a significant psychological impact; around 10-30 percent of those who experience traumatic events will suffer from PTSD. Traumatic events that are not resolved in a healthy manner

can cause psychological trauma, but if it can be dealt with in a healthy and effective psychological way, then it is also possible for there to be an increase in individual abilities and a reduction of the adverse effects of a disaster. Therefore the proper handling of the victims of PTSD is needed. If it is not immediately treated, then PTSD may develop into a mental disorder. Psychotherapy can be used to treat Post Traumatic Stress Disorder (PTSD), one of which is cognitive behavior therapy (CBT) [1].

2.Method

2.1 Data sources and search

The journal search strategy began by asking the research questions, namely "How can CBT be effective in post traumatic stress disorder (PTSD)? The databases used for journal searches were Scopus, Science Direct and Proquest. The keywords used were “CBT for PTSD” And "CBT" and "PTSD." The journals were limited to 2014 - 2019 publications within the fields of nursing and medicine. They were English-language journals only.

2.2 Article criteria

The selection of the feasibility of the study was assessed using the Pico Population approach. The study population consisted of PTSD patients. The intervention used was the provision of CBT and the comparison output was the rate of reduction in the PTSD symptoms and the factors that discussed the patients with PTSD published before 2014.

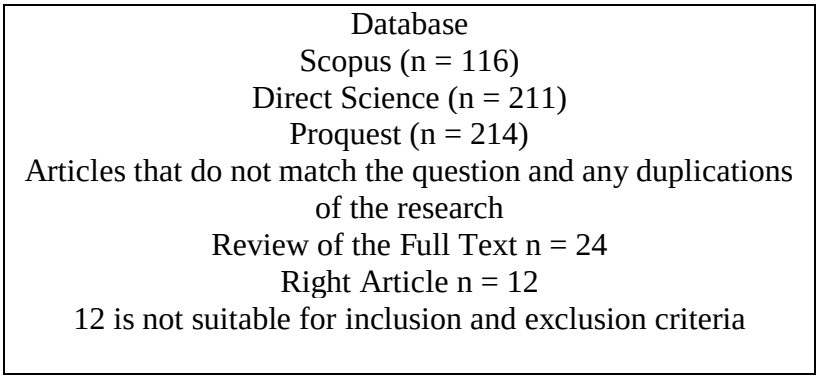

Figure 1. Study flow chart

2.3 Research design

Of the 12 articles chosen, most of them used an RCT design. Randomized controlled trials (RCTs) are a common method known in health science. This method is a controlled experimental comparative study where the researcher provides two or more inventions to the patients who are a part of the study sample. RCTs are commonly used to test the success or effectiveness of the medical actions undertaken. RCTs are required to use actual human / patient samples and they should not be replaced with experimental animals.

3. Results

This systematic review examined the 12 selected articles that met the inclusion criteria which came from communities and hospitals. We obtained several types of CBT intervention combined with other therapies. Some of these studies explain in detail how the intervention procedure was carried out and how long it was given for. The measuring instruments used were CAPS and UCLA.

3.1 Characteristics of Respondents

The number of respondents in the selected articles varied from 24 respondents and up to 1158 respondents. There were even respondents who were not specified. All of the respondents were individuals who experienced PTSD either in the hospital, or in the public area.

The following are the results of the analysis of the existing journals in the review:

Table 2. Article analysis

STUDY	POPULATION	INSTRUMENT	COMPARISON	OUTCOME	TIME
Changes in the trauma narrative of adolescents who receive cognitive behavioral therapy that focuses on trauma in connection with stress symptoms	The sample consisted of 12 non-respondents and 12 maximum-respondents who had reported for treatment (M = 14.3, SD = 2.35, range = 10-17; 75% women).	The adolescents were assessed by the Clinical PTSD Scale for Children and Adolescents both before and after treatment. Their first and last narratives were coded according to the standard coding manual.	Adolescents who received the TF-CBT developed narratives that contained more organized thinking and greater internal focus, both of which are considered to be beneficial for traumatized adolescents. However, a more coherent and organized trauma narrative is not related to the reduction of PTSS.	There were no significant differences found in the pre-treatment PTSS scores between the non-respondent and the maximum group. Furthermore, in line with our classification of the two groups, there was a significant difference in the PTSD change scores from before through to post-treatment between the groups, t (22) = 5.55, p = 0.029. More specifically, the participants in the max-responder group showed a significant decrease in PTSS during therapy, t (11) = 21.5, p <0.001, while participants in the non-respondent group did not, t (11) = - 0.76, p = 0.465. The majority of the sample was made up of women (75%). The non-respondent group had fewer boys (8%) than the max-responder group (42%), and the participants in the non-respondent group were slightly older (M = 15, SD = 1.81) compared to those at the maximum; M = 13.7, SD = 2.71).	
Pilot study comparing telephone	Regarding eligibility, 24 veterans were referred to in the study and 6 (25%) were found to be	Veterans with insomnia diagnosed with PTSD (n1212) or who had significant sub-threshold PTSD	It is not clear why the veterans respond more directly than in telephone	1. This study shows that using CBT-I to reach rural veterans, who might go without treatment, might be	Time is not determined but the

s with the provision of cognitive-behavioral therapy for trauma-related insomnia for rural veterans	ineligible because they did not have PTSD / PTSD (n1 sub-threshold 2 2), CAPS-rated insomnia (n41 ⁄1), or they had been positively screened for psychosis (n1⁄41) and substance dependence (n1⁄42) on SCID. Thus, 50% (16/24) completed a three-month follow-up assessment out of the 24 assessed for eligibility, 75% (18/24) fulfilled the requirements, 100% of which were registered; 67% (16/24) received allocated care; and 50% (12/24) completed all assessments. Two patients left after several sessions	symptoms (n1 n6) on a clinically managed PTSD scale were randomly assigned to receive CBT-I directly (n1 747) or by telephone (n1⁄411). This was to test the potential effectiveness, acceptance, and feasibility of giving CBT-I to the rural veterans. The six-week CBT-I protocol was given, and the veteran's insomnia was assessed at the post-treatment and follow-up.	groups. We required that six weeks of psychotherapy be completed in eight weeks, but we did not track how many weeks the participants needed to complete the protocol. It may be that those who receive CBT-I calls do not complete a lot of the homework or they take longer to complete the therapy than those who receive CBT-I directly.	effective. 2. We found that on average, the veterans reported being satisfied with care, regardless of the group assignments. While all of the veterans will recommend the treatment to others, regardless of their condition, fewer individuals in the telephone group felt the benefits. Acceptance ratings were assessed immediately after treatment, which is the point in time when the telephone group did not see an increase in treatment related to the symptom reduction. If we question usability three months after the treatment, then the findings may be more consistent across groups.	design of this study used an RCT (randomized controlled trial).
Treatment therapy uses an experimental case formulation for cognitive enhancement for PTSD	The nursing meant that 19 out of 23 participants who started the therapy completed it	The Clinically Managed PTSD Scale for DSM-5 (CAPS-5; Weathers, Blake, et al., 2013) and the MINI Neuropsychiatric Interview (MINI; Sheehan et al., 1997, for DSM-IV) were used to determine PTSD status and co-morbidity. The interviewers were trained by the first author and practiced by encoding.	Given that these findings are based on small-scale pilot studies without control groups or only with CPT comparisons, it cannot be concluded definitively that the client outcomes can be solely linked to the CF process, especially given that this process	The results showed a significant reduction in PTSD and depression severity and it did not help PTSD-related beliefs from pre to post-treatment (ds between 1.10-1.92). Treatment gains were maintained at 3 months follow-up.	

		The participants who met the inclusion criteria began weekly therapy sessions. A post-treatment assessment was completed within 2 weeks after treatment was stopped and again at 3 months.	is different for each client (as required by Real CF).	
IMPROVEMENT OF SYMPTOMS DURING EVERY TRAUMA CBT PHASE FOR PTSD	We recruited adolescents (ages 9-17 years) who had experienced interpersonal trauma and who sought treatment for PTSD symptoms. TF-CBT was given to the participants (N 145) at a local clinic (Child Clarity Guidance Center)	Licensed therapists trained in TF-CBT by certification. The symptom severity was measured by the UCLA PTSD Reaction Index before and after each TF-CBT phase. The total symptom severity and symptom subscale were analyzed using SPSS software by comparing the increase in symptoms between the phases.	Symptom change analysis at each phase showed a total trend of symptom improvement during the skill phase (p 1/4 0.058). There was no change during the narrative phase, and there was a significant improvement during the consolidation phase (p 1/4 0.009). Symptom change analysis for each subscale showed that negative thoughts and feelings (p 1/4 0.040) and hyperarousal (p 1/4 0.037) increased significantly during the skill phase, while avoidance (p 1/4 0.025) and hyperarousal (p 1/4 0.013) indicates a significant improvement during the	The total symptom score (and all symptom subscales) increased significantly from pretreatment through to the end of the treatment (p 1/4 0.002).

			consolidation phase		
A Brief, Early Cognitive-Behavioral Program for Cancer-Related PTSD, Anxiety, and Comorbid Depression	35 patients with PTSD were associated with acute cancer, anxiety and depression for the depressed HNC patients	The manual HNC-CBT program was managed individually and consisted of six weekly sessions for 90 minutes plus additional driving sessions conducted 1 month later	This program was developed to run in conjunction with patient care radiotherapy to help the patients to manage their distress during their medical care and through to the initial stages of recovery. We conducted a randomized controlled trial (RCT) to test the efficacy of our HNC-CBT program, which was compared with a nondirective supportive (SC) counseling program in a small sample of 35 HNC patients who were depressed. Both interventions were found to have the same effect in significantly reducing PTSD, anxiety and depression	Regarding the clinical significance, a higher proportion of patients completing the CBT program (67%) no longer met the criteria for anxiety and depression compared with 25% of patients who completed the SC program at 12 months follow-up (Kangas et al., 2013). The latest results have clinical importance because they highlight that the HNC-CBT program can treat acute psychological problems and prevent chronic psychopathology in newly diagnosed HNC patients.	Time is not specified but the study design uses an RCT
Comparison of Repeating Veterans vs. Non-Repeating Cognitive Behavior Therapy and Manuals	US military veterans who participated in single courses (n = 711) or on two separate courses (n = 87) CBT for PTSD through the Veterans Affairs	- CAPS was used to determine the diagnosis of DSM-IV PTSD. CAPS involves a structured clinical interview designed to assess DSM-IV	Veterans who repeated the CBT courses for PTSD did not show a significant degree of increase in PTSD symptom severity during their first	It was demonstrated that the reduction in PTSD symptoms during treatment was no different between those who completed the second and single CBT course for PTSD. However, for those who participated in two CBT programs for PTSD, a	Between June 2005 and June 2014

for Post-traumatic Stress Disorders	outpatient PTSD care program	PTSD symptoms - PCL-S is a 17-item self-report measure designed to assess the symptoms of DSM-IV PTSD. PCL-S was used to assess the severity of PTSD symptoms related to the trauma of each individual index - BDI-II is a 21-item self-report size of depressive symptoms – All of the data was collected as a part of the routine clinical care at PTSD VA outpatient clinics. This type of treatment is coded based on the veteran's electronic medical record review. The CBT treatment protocol ranges from around 9 to 15 sessions and the sessions are usually delivered every week. The CBT treatment protocol includes CPT.	therapy compared to the veterans who only completed one CBT course for PTSD. During the initial therapy, repeaters and non-repeaters showed significant and clinically significant improvements in their PTSD symptoms. However, the results showed that the veterans who repeated the treatments were more likely to leave prematurely.	recurrence of PTSD symptoms was observed between the first and second courses. This finding suggests that a second CBT sequence might be possible for those who experience PTSD symptoms	
Is CBT for disorders related to anxiety changing suicidal ideas? Findings	The participants (n = 355) were adults who sought treatment at the Center Of [X]. All of the participants	The diagnostic steps at the beginning, mid-treatment, and post-treatment by the principal, secondary, and tertiary diagnosis were	Patients with a diagnosis of either PTSD or SAD-supported SI are more often compared with patients with a diagnosis of a specific	Two weeks. BDI-II has very good internal consistency (α = 0.91) and this correlates well with other depression measures (Beck et al., 1996). For the rate of supporting suicidal ideas at the baseline with the	Betwe en Decem ber 2014 and Januar y 2017

from naturalistic samples	had completed the intake evaluation, 164 completed the publication of manuals for CBT that were empirically supported (Dugas&Robichaud) the assessment of middle care, 144 completed post-treatment in 2007; Roemer &Orsillo, 2010). All therapists emphasized exposure and 113 participants completed all three assessments. Finally Out of the 355 participants, 65.1% completed treatment, 15.2% dropped out of the treatment and 20.2% completed the intake assessments.	used to determine and confirm the diagnosis. During the initial evaluation, we used the Neuropsychiatric Mini-International scale. A multilevel mix of effects logistic regression models ran the Interview (MINI; Sheehan et al., 1998), which was short and structured with nesting observations in the Stata participants v. 14 (StataCorp, agnostic interview for DSM-IV and ICD-10 psychiatric disorders with 2015) use-to-treat analysis including all available psychometric properties (intention of Lindrier et al., 1997). After the compass, time was focused on post-treatment. The participants completed MINI. Many of the participants evaluated with additional assessments were mid-treatment for	phobia. These findings are consistent with the previous studies showing risk of elements for SI in PTSD (Brownet al., 2016) and SAD (Cougleet al., 2009). With hypothesis 1, individuals with PD did not report an initial increase in SI compared with other major anxiety disorders, but about a quarter (26.9%) of those with major panic disorder supported the idea of suicide. One possible reason is that groups of panic disorder do not increase relative to other anxiety disorders which may be due to the severity of the sample. Previous research has explored the relationship between PD and suicide in more severe samples, including psychiatric inpatients (Brown et al., 2010)	primary diagnosis of this study, only suicide items (BDI-II) were included, which ranged from 26.9% (for panic disorder) to 48.9% (for PTSD), not including questions about SI at 0- (I have no thoughts of suicide) for 3- (I specific phobias (4.4%) and the level of support for the basic ideology of suicide would be suicide if I had the opportunity) measured using a Likert scale point. This differed according to the main diagnosis [$\chi 2 = 17.57$, $p < 0.01$

		around 14 weeks (SD = 3.8) after taking the steps to confirm their diagnosis, including the Yale-Brown ob-assessment. They completed a post-treatment assessment of about 24 Compulsive Goodman, Price & Rasmussen Scale tests, weeks (SD (YBOCS; = 4.7) after time intake assessment was coded to reflect 1989), Posttraumatic stress Scale-Interview (PSS-I; Foa et al., 2016)		
Amygdala functional connectivity changes during cognitive reassessment predict a reduction in symptoms during cognitive focused-on coverage of adolescent girls with post traumatic stress disorder	Teenage girls with PTSD associated with physical or sexual assault (n = 34) were enrolled in TF-CBT	Delivered in a format of around 12 sessions in an open trial. Before and after the treatment, they were involved in the task of cognitive reassessment, investigating the neural mechanisms of the regulation of explicit emotions for 3 functional magnetic resonance imaging.	It was shown that a significant reduction in PTSD symptoms was caused by the skills development and childcare modules (i.e. in the module there was no development and processing of trauma narratives). As such, it might expand on the skills training module (e.g. doubling the number of sessions, training for some objective criteria, generalization	The current results indicate the possibility of targeting behavioral correlations and emotion regulation nerves. Specific behavioral data and imaging findings indicate that the suppression of the FC amygdalains during reassessment and the suspected downstream effect on emotional regulation ability is a reasonable target for augmentation strategies to improve the clinical response to TF-CBT.

			training etc) which might involve stronger targeted neurocircuitry. This leads to further better clinical improvements.		
Randomized Controlled Trial Group Cognitive Behavioral Therapy for Post-Traumatic Stress Disorder in Children and Adolescents Affected by Tsunamis in Thailand	Thirty-six children and adolescents (aged 10-15 years) and 10 men and 26 women who had been diagnosed with PSTD 4 years after the tsunami. They were allocated randomly to CBT or a waiting list	The participants were assigned to CBT and they were tested pre and post-treatment, as well as at 1 month in the follow-up with two actions. These steps are the Thai version of the Revised Impact Scale (CRIES) and the UCLA PTSD Reaction Index (PTSD-RI) which were completed at each time point of the assessment. CRIES is a 13-item self-reporting scale designed to be used by children aged 8 years and over to assess the symptoms of PTSD in three domains (Intrusion, Avoidance, and Arousal).	The participants who were randomly assigned to CBT showed a greater improvement in the standard measures than those that assessed themselves and their PTSD symptoms compared to those on the waiting list. The increase was not statistically significant in the CBT group for children with PTSD after the tsunami In the post-treatment. After a period of one month, the children were encouraged to monitor their symptoms and to use the relevant techniques to fight them as homework. A significant increase is observed. The size of the effect of increasing the measured score on post-treatment was in the small range (0.21-0.24), while the effect size at the 1-month follow-up was in the small to medium range (0.41-0.69).	The participants who received CBT showed a significant increase in PTSD symptoms at 1 month	This study was conducted from August to October 2009, more than 4 years after the tsunami RCT.

Adaptation of CBT to Traumatized South African Native Group: An example of Multiplex CBT for PTSD	A native of South Africa who had been traumatized	- Normalization and creating positive expectations about treatment - Mindfulness teaching techniques related to attention control.	Although there is evidence of the efficacy of CBT in English-speaking non-ethnic populations (for example, Blanchard et al., 2003; Cohen, Mannarino, & Murray, 2011), to date there has been no culturally sensitive treatment for CBT for African indigenous groups The south is a traumatized group that adheres to a blend of Christianity and traditional beliefs.	Multiplex CBT sessions increases acceptance and positive expectations by trying to create a culture that fits all of the techniques used. For example, by presenting treatment with metaphors and culturally appropriate cultural examples.	
Cognitive behavioral therapy that focuses on trauma with adolescents with illegal sexual behavior in safe housing care facilities	The participants totaled 107 men who were tried for committing a criminal offense and who were referred to care for a residential care program in a safe facility in the southeastern state. Approval was obtained for the 83 original participants	The TF-CBT Practice Concise Checklist was designed to evaluate the absorption of the therapists from the treatment components. TF-CBT can be summarized by the acronym PRACTICE: psychoeducation the trauma, the skill of parenting, relaxation skills, affective modulation skills, cognitive coping skills, trauma narration and the	The current study is among the first to examine the feasibility of implementing TF-CBT, which is an evidence-based trauma-based treatment for juvenile children in RTF arrangements for AISB. Overall, the efforts to implement TF-CBT were successful. That is, the TF-CBT therapists successfully completed the trauma screening,	The current studies show the results of positive feasibility for the successful implementation of TF-CBT with the AISB decided in RTF settings.	The training was between February 2015 and July 2017.

		cognitive processing of traumatic events. There were also trauma mastery in-vivo reminders and desensitization, parental sessions and improving the safety and trajectory of future developments.		facilitated treatment completion and provided TF-CBT loyalty in challenging RTF settings.
Biofeedback breathing in addition to exposure in Cognitive Behavior Therapy Accelerates Reduction of Symptoms of PTSD: Pioneer Study of Aura Symptoms	Eight (6 women and 2 men) were included. The participants had experienced a traumatic event which related to their breathing frequency. When the patient experiences a motor vehicle accident, sexual or physical abuse then they will decrease the correct breathing rhythm, with no sound offered. Their average age was 45 years old (with a range of 25-57).	During the actual therapy session, the procedure for the total sessions varied from time to time. Biofeedback devices were implemented in the exposure samples. The average number of sessions was 7.5 (with ranges) regarding the element of TF-CBT. This was used when focusing on the trauma for between 5 and 18 sessions), for all except for one patient. The procedure was similar for all patients. They responded in a range of 8-12 sessions, consistent. Feasibility was assessed based on the ease of the instructions of the CBT guidelines (Creamer et al. 2004).	By adding biofeedback components such as modifying further symptoms by promoting respiratory biofeedback, exposure treatment may be better disturbances or disturbances during exposure. This was based on the previous research (Zucker et al. 2009; Lande engagement. Especially during the first session, when et al. 2010), we hypothesized that both biofeed breathing and the transient symptoms can increase. Adding this breathing and conducting the treatment as usual will cause a significant decrease in the	Biofeedback has the additional effect of breathing exercises, showing that while it does not prevent the patient from clinically (although statistically borderline) being affected, it is significantly faster than direct exposure to traumatic events. There is a decrease in the PTSD symptoms compared to the treatment because they can experience high anxiety decreases (TF-CBT). Interestingly, the symptoms diminished during the session. This shows that breathing biofeedback is feasible and that it can be easily supplemented with TF-CBT. Although the PTSD symptoms decreased significantly from before through to post-treatment in both conditions, there was a clear tendency towards a faster symptom reduction ($p = 0.051$) in the biofeedback compared to ordinary TF-CBT. The most important limitation was the small sample size.

			components during exposure to reduce the pressure and to lessen the increase of the PTSD symptoms when compared with before the treatment. This results in habituation.	Rapid clinical improvement on the biofeedback conditions supports the idea that biofeedback breathing may be an effective complementary component for exposure in PTSD patients.
Constructive and Non-productive Processing of Traumatic Experiences in Trauma Focused Cognitive-Behavior for Youth	We examined the variables that were thought to be related to unproductive and constructive traumatic processes in a sample of 81 adolescents with increased symptoms of PTSD who received Trauma Focused Cognitive Behavior (TF-CBT) because of traumatic interpersonal abuse or loss.	TF-CBT consists of evidence-based care within 12 sessions for children, adolescents and their caregivers designed to treat PTSD, depression, and other trauma-related behavioral difficulties. TF-CBT can be divided into three phases. 1. The stabilization and building skills phase (Session 1-4) that focuses on the involvement of the therapists and psychoeducators about the prevalence, impact and trauma treatment, as well as the overcoming skills to manage emotional stress. 2. The trauma narratives and treatment phases of therapy (Sessions 5-10	TF-CBT interventions can be designed to reduce the unproductive processes that can disrupt changes and facilitate decomposition and accommodation.	Significant changes in the internalization symptoms and PTSD at the end of treatment were maintained during follow-up. The externalizing symptoms improved after treatment but worsened after follow-up.

	or 11) focus directly on gradual exposure to the traumatic memories through narrative development. 3. The consolidation and enhancing of the safety treatment phase (1-4 sessions) helps to integrate the learning from the previous sessions through mastery activities in vivo when needed. There are also parent-child conjoint trauma sessions that focus on sharing stories when appropriate. The clinical and personal development of safety skills supports the future development of the children.

4. Discussion

This systematic review provides evidence regarding the effectiveness of health interventions in dealing with and reducing post-traumatic stress disorder. The review results explained that all of the CBT interventions combined with multiplex CBT, CBT by telephone / web and CBT using explicit case formulations had the advantage of reducing PTSD. The results of this review certainly benefit both clinical nurses and community mental nurses. Nurses can apply these interventions to better the conditions in PTSD cases. As found in a number of journals, trauma-focused CBT shows that exposure-based care for post-traumatic stress disorder (PTSD) is effective. Emotional processing has been indexed primarily by reducing the fear in and between the sessions, although the original definition of processing includes cognitive change and emotional change [2]. CBT can also be developed within the HNC-CBT program by adapting and modifying the seven core components of the TF-CBT and BA procedures to create an appropriate care approach for newly diagnosed HNC patients who meet the threshold or full criteria for PTSD related to cancer and anxiety with or without

depression. Our HNC-CBT program, which is comparable to a nondirective supportive (SC) counseling program, was conducted on a small sample of 35 HNC patients who were depressed. Both interventions were found to have the same effect; namely significantly reducing PTSD, anxiety, and depression. However, in terms of their clinical significance, a higher proportion of the patients completing the CBT program (67%) no longer met the criteria for anxiety and depression compared with 25% of patients who completed the SC program at the 12 month follow-up [3]. Clinical improvement in the fast biofeedback conditions supports the idea that biofeedback breathing may be an effective complementary component for exposure in PTSD patients. The mechanism of action for biofeedback breathing may be related to competing [4].

Trauma-focused cognitive-behavioral therapy (TF-CBT) is a 'gold standard' psychological treatment for pediatric PTSD with many randomized clinical trials showing clear efficacy for PTSD symptoms, depression and behavioral problems [5]. In studies of trauma narratives before and after emotionally focused therapy for PTSD in patients exposed to abuse in childhood, the results showed that during therapy, there was a significant increase in positive words, temporal orientation and the exploration of subjective internal experiences. However, it is not consistent with the findings and the level of coherence in the narrative does not change significantly from pre- to post-treatment. There is a significant relationship between increasing temporal orientation and the post-treatment outcomes [6]. Positive results from several randomized controlled trials have demonstrated the efficacy of cognitive behavioral therapy (CBT) delivered individually for children and adolescents with PTSD after sexual abuse and traumatic events related to motor vehicle accidents and exposure to violence [7]. Adolescents who receive TF-CBT develop narratives that contain more organized thinking and greater internal focus, both of which are considered beneficial for traumatized adolescents. However, a more coherent and organized trauma narrative is not related to the reduction of PTSS. Some studies have found that the type and quality of cognitive processing after a traumatic event may have a significant effect on the narrative, which, in turn, is related to mental health and PTSS. For example, studies of traumatized adults show that individuals with PTSD have more narratives that are fragmented and disorganized than those who do not have PTSD [6]. In summary, these findings uphold and extend the previous research. In particular, the current pilot data indicates that CBT-I delivered by telephone may reduce the symptoms of insomnia related to trauma. In future, it is necessary to assess the effectiveness of CBT-I delivered to rural veterans with post-traumatic insomnia. The treatment of PTSD has to overcome the other symptoms. For example, two studies examined insomnia after CBT for PTSD and found that 48% and 70% had significant sleep problems after primary care. Furthermore, a study of insomnia after evidence-based psychotherapy for PTSD found that the symptoms of insomnia decreased but did not transmit [11]. Another study stated that CBT's effectiveness can be extended to the sleep problems related to PTSD which generally indicates that it is effective, even when the insomnia has not healed during the PTSD treatment [8].

Another intervention is CBT Multiplex. CBT is also used to reduce PTSD, and so CBT Multiplex Adapted Culture was developed, which has proven to be effective compared to waiting lists and applied muscle relaxation (AMR) in randomized controlled trials for Latino patients and for Southeast Asian refugee patients from Cambodia and Vietnam. Multiplex CBT for PTSD is based on a multiplex psychopathology model. This is a general model of psychology that was developed working with minorities, refugees and non-Western populations who are traumatized in order to explain the high rates of concomitant PTSD and GAD, worry, panic and somatization in these groups. The validity of this model of psychopathology and its relevance to minority and refugee populations has been explored in various studies. Based on this model, Multiplex CBT emphasizes sensory processing and emotion regulation [9].

The results of the research reviewed critically in this systematic review show that the best strategy for reducing or overcoming the symptoms in PTSD patients is CBT combined with various programs such as HNC CBT, CBTCT, CPTCBT Multiplex and TF-CBT. Although not all studies were significant in all parameters measured, the conclusions can be taken in the majority. The nurses

can optimize the nursing intervention program by modifying the method of giving the intervention and the media used, as well as that of the other parties involved in the intervention. A nurse as an intervention provider has several advantages including 1) the intervention method is relayed and can reduce the treatment time, 2) the media used is varied or it can be combined with other therapies and 3) the application is flexible as needed.

ABSTRACT

Falls could be a cause of unintentional injury in patient in hospital. Falls might also be a risk factor for women admitted in hospital, especially during their pregnancy and postpartum. Falls risk assessment is needed to prevent the falls in hospital using a risk assessment tools such as Johns Hopkins Fall Risk Assessment Tools (JHFRAT). This study aimed to compare women patients at risk of fall between pregnancy women, postpartum vaginal delivery and postpartum with cesarean section using JHFRAT. This study was a comparative study. Total of fifty seven respondents recruited in the study. The respondents consisted of fourteen pregnancy women, thirteen postpartum women with vaginal delivery and thirty postpartum women with cesarean section. A Kruskall-Wallis test analysis revealed that there was a significant different of fall risk score between pregnancy women, postpartum vaginal delivery and postpartum with cesarean section ($H(2)= 36.769$; p value < 0.001). Interestingly, when comparing only two different sample using a Mann-Whitney test analysis, all the result was a significant different (p value <0.001), except fall risk score between the pregnancy women and postpartum women with vaginal delivery (p value 0.672). Further study is needed using larger respondents to support the findings.

Keywords: fall risk

1. Introduction

Assessing the risk of falling in patients is one of the priorities for patient safety [1]. It is noted that the first step to prevent patient fall is by assessing patients at risk of fall within 24 hours of admission, as well as identifying and educating patients in regard to the risk of falls [2].

Fall is the second leading cause of emergency admissions for pregnant and postpartum woman [3]. The death rate is 27 % for pregnant women, which is equal to the fall rate of 25 percent for people aged 70 years. The risk factors of falls in pregnant women include women aged ≤ 30 years, women with a height of ≥160 cm, and primigravida three times at risk of falling compared to multigravida [4]. In addition, stability of body decreases during pregnancy and continues to decrease at 6-8 weeks after delivery [5]. Therefore, special attention is needed for pregnant and postpartum women in the maternity room to prevent the occurrence of falls and injuries.

More than 5% of women report an injury during their pregnancy in which falling is the most common cause of their injury [6]. The injuries are caused by falls during their daily activities [7]. Between 5- 7% of all pregnancies are complicated by injuries and trauma in pregnancy which lead to common cause of fetal death [8]. According to Weiss and colleagues[3], around 5.4 per 1,000 fetal deaths were caused by maternal injury. A population-based study reports that 30% of women fall during pregnancy and 10% experience more than one miscarriage during pregnancy [9].

There are many assessment tools to reduce the incidence of falls in hospitals. One of the tools used

by many hospitals is called the Johns Hopkins Fall Risk (JHFRAT) approach[10]. JHFRAT is an evidence-based tool which is easy to be used by nurses to manage, score and interpret the fall risk in hospitals [10]. The JHFRAT is used to assess the risk of falls in adult hospitalized patients covering seven risk factors including age, fall history, elimination-bowel-urine, medications, patient care equipment, mobility and cognition [10].

Fall risk assessment for patients at maternity wards in hospitals is usually conducted using a common fall risk assessment such as JHFRAT.As mentioned before that the JHFRAT can be used for adult hospitalized patients, thus, it is claimed that JHFRAT can be used for patients at maternity wards. One of the reasons is women who are treated in midwifery units are usually young, healthy and are not considered to have a high risk of falling [11]. In other words, patients at the maternity wards are considered similar with other general patients in hospital.

Data from a private hospital in Indonesia in 2017 shows that there were nine incident falls (0.03%) in the hospital. Some of the causes include patients forcing themselves to carry out their activities, patients' weak conditions and patients feeling that they could do their daily activities without help from the nurse.

This study aims to identify the risk of fall using the JHFRAT at the maternity wards in a private hospital in the central part of Indonesia.

2. Method

This research applied a quantitative method [12], using a Johns Hopkins Fall Risk Assessment Tools (JHFRAT) to examine fall risk in maternity ward. Total of fifty seven respondents were recruited in the study. The respondents consisted of fourteen pregnancy women, thirteen postpartum women with vaginal delivery and thirty postpartum women with cesarean section. A Kruskal-Wallis test and a Mann-Whitney test analysis were conducted to analyze the findings of this study.

Ethics Committee at Faculty of Nursing Universitas Pelita Harapan approved this study ethical clearance. In addition, the private hospital in which the study took place gave permission to conduct this study.

3. Result and Discussion

The results of this study comprised types of in-patient at maternity wards, types of in-patient at maternity wards based on age and level of fall risk based on patients' type. Table 1 shows that most of the respondents were three types of patients at maternity wards including pregnant woman, postpartum woman with vaginal delivery and woman with post cesarean section. Most of the respondents in this study were women with post cesarean section (52.63%).

Table 1 Types of in- patient at maternity wards (n = 57)

Type of patients	n	%
Pregnant woman	14	24.56
Postpartum woman with vaginal delivery	13	22.8
Woman with post cesarean section	30	52.63
Total	57	100

Table 2 further shows that most of pregnant women (42.9%), postpartum women with vaginal delivery (53.8%) and woman with post cesarean section (50%) were between 26-30 years old. In addition, majority of women with age range 31-35 were in the condition of post cesarean section (43.3%).

Table 2. Types of in-patient at maternity wards based on age (n = 57)

Type of patient	Range of Age					Total
	≤ 20	21-25	26-30	31-35	36-40	
Pregnant woman	0	4	6	3	1	14
	0.0%	28.6%	42.9%	21.4%	7.1%	100.0%
Postpartum woman with vaginal delivery	1	3	7	2	0	13
	7.7%	23.1%	53.8%	15.4%	0.0%	100.0%
Woman with post cesarean section	0	1	15	13	1	30
	0.0%	3.3%	50.0%	43.3%	3.3%	100.0%

Table 3 reveals that the majority of pregnant women (92.85%) and postpartum women with vaginal delivery (92.3%) were at the level of low fall risk. Meanwhile, all woman with post cesarean section were at moderate level of fall risk (100%).

Table 3. Level of fall risk based on patients' type (n = 57)

Woman Patient	Level of Fall Risk	n	%	Kruskal-Wallis test results	Mann-Whitney test results
Pregnant woman	Low	13	92.85	H(2)= 36.769 p value < 0.001	Pregnant women- Postpartum with vaginal delivery (U= 82.5; z=-0.423; p value 0.672)
	Moderate	1	7.15		
	High	0	0		
	Total	14	100		
Postpartum woman with vaginal delivery	Low	12	92.3		Pregnant women- Post cesarean section (U=12; z=-5.4; p value <0.0001; r=-0.72)
	Moderate	1	7.7		
	High	0	0		
	Total	13	100		
Woman with post cesarean section	Low	0	0		Postpartum with vaginal delivery- Post cesarean section (U=27.5; z=-4.77; p value <0.0001; r=-0.632)
	Moderate	30	100		
	High	0	0		
	Total	30	100		

The results of this study reveals that patients type who had the highest risk of falling among the three types of patients was women with post caesarean section (52.6%), followed by pregnant woman (22.8%) and women with vaginal delivery (21.1%). The cause of moderate risk fall for women with post caesarean section was because of the effects of epidural anesthesia on patients. This is in line with the

study from Lockwood, & Anderson[13], using JHFRAT, that most postpartum were at moderate level of fall risk.

A number of authors stated that JHFRAT tool was good enough in identifying general adult patients in regard to the fall risk[14], [15]. This is also supported by the validity and reliability test of the tool generated by the authors. However, Heafner and colleagues introduced a new evidence-based fall risk assessment tool that is called 'the Obstetrics Fall Risk Assessment System (OFRAS)[11]. This tool identified fall risk factors for pregnant and postpartum women by assessing six categories of risk factors such as history of falls, cardiovascular, bleeding, neuro/anesthesia function, motoric/activity, and medications.

As mentioned in the introduction, the JHFRAT consisted of seven categories in assessing patients' fall risk such as age, fall history, elimination-bowel-urine, medications, patient care equipment, mobility and cognition [10]. Each category of the tool will be discussed further in the following paragraph.

Based on 57 respondents, most of the respondents were <60 years old with the highest age of 38 years. The respondents age were <60 years due to women age of reproduction. The age of menopause woman in Indonesia is relatively around 50 years[16].

The results of the assessment also revealed that 10% of patients had fall experience over the last one-year. A study argued that patients with history of previous falls will likely to have risk fall [17]. The assessment also revealed that 82% patients were assisted in regard to their daily activities. As noted by previous study, post-partum or post caesarean section patients have risk fall related to their first try to stand up and walk [13]. Thus, patients should be assisted in their activities such as sitting beside the bed, personal hygiene, and toilet.

In regard to the elimination pattern, the results of this current study showed that post caesarean section patients need to use a urinary catheter. A survey reported that for post caesarean section patients who were under regional anesthesia, most of them (82%) used urine catheters for both procedures and postoperatively, with minorities used only catheters for procedures or in-out catheters [18].

The assessment also provided findings related to sensory deficit, 7% of patients used bifocal glasses, so they were considered to have falls risk. The coordination of the musculoskeletal, neurological, and visual system can affect individuals' balance which could cause patients' falls [19].

In the category of patient care treatment, the findings showed that 70% of respondents were epidural patients and 56% were postoperative between 0-24 hours. As stated in the JHFRAT, patients with sedatives, epidurals or narcotics, were scored as three. Postpartum and postoperative patients <0-24 hours are still under the influence of analgesia that could lead to less sensation in the extremities, and side effects of drugs [13]. These patients condition can be categorized as having fall risk.

The results of mobility and cognition, the overall respondents had good orientation and were able to do the mobility independently. For patients with good orientation and mobility, the scores were zero. Adult or elderly patients with impaired cognitive status and balance disorders will have fall risk (Shin et al. 2011).

4. Conclusion

Women hospitalized in maternity wards are at risk for falls and this can be examined using a significant tool that guides nurses to identify those at risk and provide appropriate interventions. There is a need to develop a specific risk assessment tool for women in the maternity wards. The implementation of a standardized evidence-based nursing fall assessment tool for pregnant and postpartum woman will improve care in several ways.

HEALTH STATUS OF PATIENTS WITH CORONARY HEART DISEASE

Nur Atiqah Binti Mohd Mossadeq
Department of Nursing Science, Faculty of Medicine
University of Malaya
Kuala Lumpur

CHAPTER 1: INTRODUCTION

1.1 Background

Coronary heart disease (CHD) also called coronary artery disease (CAD), heart disease or ischemic heart disease (IHD). It is a results from hardening and narrowing of the artery walls in the heart where fatty deposits of cholesterol and other cellular waste. (The New York Times, 2013) This condition cause blockage of arteries (ischemia) and prevents oxygen-rich blood from reaching the heart. (The New York Times, 2013)

When a person did not get enough blood supply throughout the body, they easily get chest pain and discomfort which called angina. (Control of Disease Centre, 2015) Prolonged and untreated CHD lead to heart failure where a serious condition because of the heart muscle weaken. (Control of Disease Centre, 2015)

This condition can be diagnosed through electrocardiogram (ECG), echocardiogram, chest X-ray (CXR), coronary angiogram and cardiac catheterization. Someone can reduce the risk of getting CHD by changing their lifestyle, compliance to the medications and surgical procedures. This is where measuring health status of CHD patient takes place.

Health status is an individual's relative level of wellness and illness, taking into account the presence of biological or physiological dysfunction, symptoms, and functional impairment (American Thoracic Society, 2007). US National Library of Medicine defined health status is the level of health of the individual, group, or population as subjectively assessed by the individual or by more objective measures.

1.2 Problem Statements

Coronary heart disease (CHD) or ischaemic heart disease (IHD) is the leading cause of death worldwide in both lower-middle income countries and high income countries. The World Health Organization (WHO), 2016 reported 56.9 million deaths worldwide in 2016, in which 15.2 million deaths is accounted by ischaemic heart disease and stroke. CHD have remained the leading causes of death globally in the last 15 years. In developed and developing countries heart disease is the leading cause of death in men and women. In Europe CHD accounts for an estimated 1.95 million deaths each year ("Health Knowledge", 2006).

According to Department of Statistics Malaysia (2014), CHD remains the principal cause of deaths from 2005 to 2014 at 13.5% (10,432 out of 77,365). The National Cardiovascular Disease-Acute Coronary Syndrome (NCVD-ACS) Registries reported that Malays formed 49.2%, Chinese formed 20.6% and Indians 18.4% of the patients who presented with ACS between 2014 and 2015 (W.A Wan Ahmad, 2017). The WHO mortality estimates (2016) reported that CHD is the common cause of deaths accounted for 98.9 deaths per 100,000 population in Malaysia in 2012, or 29,400 deaths (20.1% of all deaths). The Ministry of Health Malaysia report documented that CHD accounted for 6.99% of total hospital admissions and 23.34% of all hospital deaths in government hospitals.

Contributing factors to the high mortality and morbidity among patients with CHD could be explained by the state of health status which includes cardiovascular risk factors such as hypertension, diabetic mellitus, smoking, high body mass index, hyperlipidaemia and others that still persist. It is estimated that 80-90% of people dying from CHD have one or more major risk factors that are influenced by lifestyle (Health

Knowledge, 2006). High blood pressure is one of the major risk factor for heart disease.

In people aged up to 50 years, both diastolic blood pressure (DBP) and systolic blood pressure (SBP) are associated with cardiovascular risk. In persons aged over 50 years

SBP is a far more important predictor of risk (Mackay & Mensah, 2004). Based on the Annual Report of NCVD-ACS Registry (2015), there are 5,671 out of 9,313 having hypertension which is 64.7%.

Smoking is a major risk factor for CHD. Cigarette smoking promotes atherosclerosis and increases the levels of blood clotting factors such as fibrinogen. Nicotine also accelerates heart rate and raises blood pressure. In Europe, smoking causes an estimated 32% of deaths from cardiovascular disease (CVD) in men aged 3569 years and 6% of CVD deaths in women of the same age (Health Knowledge, 2006). Based on the Annual Report of NCVD-ACS Registry (2015), there are 1,748 out of 9,313 quit smoking more than 30 days which is 19% and 3,423 out of 9,313 still smoking which is 37.3%.

Diabetes substantially increases the risk of CHD. Men with type 2 diabetes have a 2-4 fold greater annual risk of CHD, while women have an annual 3-5 fold greater risk of CHD. Diabetes also magnifies the effect of other risk factors including, raised cholesterol levels, raised blood pressure, smoking and obesity (Health Knowledge, 2006). Based on the Annual Report of NCVD-ACS Registry (2015), there are 3,991 out of 9,313 having diabetes which is 45.9%.

In addition to cardiovascular risk factors, health status indicators such as health –related quality of life (HRQoL) is an important parameter to explain the high comorbidities among patients with CHD. A previous study on general population using

Korean National Health and Nutrition Examination Survey (KNHANES) conducted by

Hyung et al. (2015) had shown that CHD had a significant impact on the reduction in HRQoL. The authors found overall HRQoL in CHD was impaired; and the impairment of HRQoL was relatively larger in the older age and female groups. To our best knowledge, there is lack of current data (e.g. less than 2 years) on HRQoL to reflect health status among patients with CHD in Malaysia.

Measuring health status is important to know the effectiveness of current treatment and health programme implemented for patient with CHD. If the health status show undesirable findings, it could indicates that current strategies are not sufficiently effective. In recent clinical posting, researcher had observed many patients readmitted due to disease recurrence or complications, still actively smoke, poor control of hypertension and other cardiovascular (CV) risk factors. Therefore, there is a need to assess health status that take account of CV risk factors and HRQoL among patients with CHD in Malaysia, specifically in Klang valley, to gauge the extent of disease prevalence and effectiveness of disease management.

1.3 Significance of Study

Patient

Study findings reflect the current health status of patients with CHD. Indirectly, patients who answered the survey were made aware of their cardiovascular health, specifically to aspects of physical health, psychological health, social relationship health and environment health. With such awareness, further action can be mapped out to improve health status at individual level.

Nursing practice

Nurses are first-liner and the closest person to the patient who delivered care to the patients. Nurses are involved in all stages of the disease, which h from prevention to end-of life-care. Findings from of this study will guide nurses when handling the patients with CHD. For example, if the patient population, in general, is poor in their physical health compared to other health domains, the nurses can give more focus on the nursing

care that improve physical health while not neglected the other aspects. The finding helps in prioritizing delivery of care. Similarly, nurses need to give more effort to address risk factor that is more prevalent in order to improve health status among patient population under their care. Measuring health status is important because it helps nurses to prioritize and to improve quality of care given to the patients with CHD.
Organisation

Organisation is the one who provides services and organisation must monitor the quality of services given to all patients. It will improve the level of satisfaction and got positive feedback from the patients and the nurses. Based on study findings, the Ministry of Health Malaysia or specifically the clinical setting involved in this study can improve CHD patients' health status by organising programmes or campaigns which focusing on awareness of CHD and CV risk factors. For hospital's organization, they may evaluate the effectiveness of the treatment given and improve the services such as providing proper equipment, conducive environment and make sure the staffs give treatment equally. Moreover, results revealed from this study will provide better-defined health care outcomes which will benefit the patients ultimately.

1.4 Objective

In this study, the objective is classified into general objective and specific objectives.

1.4.1 General objective

To determine health status among patient with coronary heart disease (CHD).

1.4.2 Specific objectives

In order to achieve the general objective, the specific objectives are determined as follows:

a. To assess health status in relation to risk factors profile and four health domains i.e. physical, psychological, social relationship and environment health)
b. To examine four health domains in relation to sociodemographic characteristics.
c. To determine correlation between physical, psychological, social relationship and environment health.

1.4.3 Research questions

a. What is health status in relation to risk factors profile and four health domains (i.e. physical, psychological, social relationship and environment health)?

b. What are the relationships or associations between the four health domains and sociodemographic characteristics?

c. What are the correlations between physical, psychological, social relationship and environment health?

1.5 Operational Definitions

Health Status

Health status defined as an individual's relative level of wellness and illness, taking into account the presence of biological or physiological dysfunction, symptoms, and functional impairment ("Health Status", 2007). This study referred biological or physiological dysfunction to the presence of cardiovascular risk factors, namely, hypertension, diabetic mellitus, high body mass index, dyslipidaemia and smoking. The individual's relative level of wellness and illness was referred to the concept of health related quality of life (HRQoL).
Risk factors profile

According to WHO (2004), risk factors profile is referred to any attribute, characteristic or exposure of an individual that increases the likelihood of developing a disease or injury. In this study, hypertension, diabetic mellitus, body mass index, dyslipidaemia and smoking are as the risk factors profile of interest.
Health related quality of life (HRQoL).

Health-related quality of life (HRQoL) is a multi-dimensional concept that encompass those aspects of overall quality of life that can be clearly shown to affect health—either physical or mental. On the individual level, HRQOL includes physical and mental health perceptions (e.g., energy level, mood) and their correlates—including health risks and conditions, functional status, social support, and socioeconomic status ("HRQoL Concepts", 2018). In this study, HRQoL was measured using 26-item WHOQOL-BREF questionnaire that consist of four health domains related to physical, psychological, social relationship and environment health.

Physical health domains of QoL

According to WHOQOL-BREF questionnaire, physical health are referred to following aspects:

i. Pain – it is the unpleasant physical sensations experienced by an individual.

ii. Energy - it is the enthusiasm and endurance that a person has in order to perform the necessary tasks of daily living, as well as other chosen activities such as recreation. iii. Sleep - It is sleep pattern, rest and problems in this area, affect the person's quality of life.

iv. Mobility - The mobility is the person's general ability to go wherever he/she wants to go without the help of others regardless of the means used to do so.

v. Activities – it is an individual's ability to carry out activities of daily living.

vi. Working – it is an individual's use of his or her energy for work, which is the major activity in which the person is engaged.

vii. Medication - it is an individual's dependence on medication or alternative medicines (such as acupuncture and herbal remedies) for supporting his/her physical and psychological well-being.

Psychological health domains of QoL

According to WHOQOL-BREF questionnaire, psychological health are referred to following aspects:

i. Positive feeling – it consist contentment, balance, peace, happiness, hopefulness, joy and enjoyment of the good things in life.

ii. Thinking – it is alert, aware or awake, even though these underlie thinking, memory and concentration.

iii. Self-esteem – it is feeling of self-efficacy, satisfaction with oneself and control is also included in the focus of this item iv. Body image – it is satisfaction with the way he/she looks and the effect it has on his/her self-concept.

v. Negative feeling – it consists of despondency, guilt, sadness, tearfulness, despair, nervousness, anxiety and a lack of pleasure in life.

vi. Spirituality – it is personal beliefs and how spiritual affect quality of life.

Social relationship health domains of QoL

According to WHOQOL-BREF questionnaire, social relationship health are referred to following aspects:
i. Relationship – it is people feel the companionship, love and support they desire from the intimate relationship(s) in their life ii. Social support – it is when an individual feels the commitment, approval, and availability of practical assistance from family and friends.
iii. Sex life – it is an individual's urge and desire for sex, and the extent to which the individual is able to express and enjoy his/her sexual desire appropriately.
Environment health domains of QoL

According to WHOQOL-BREF questionnaire, environment health are referred to following aspects:
i. Safety – it is an individual's sense of safety and security from physical harm ii. Home environment – principal place where a person lives (and, at a minimum, sleeps and keeps most of his/her possessions), and the way that this impacts on the individual's life.
iii. Finance – an individual's financial resources (and other exchangeable resources) and which these resources meet the needs for a healthy and comfortable life style iv. Services – it is health and social care availability and quality is focusing on the individual's view of the health and social services.
v. Information – it is an individual's opportunity and desire to learn new skills, acquire new knowledge, and feel in touch with what is going on.
vi. Leisure – it is individual's ability, opportunities and inclination to participate in leisure, pastimes and relaxation.
vii. Physical environment – it is includes the noise, pollution, climate and general aesthetic of the environment and whether this serves to improve or adversely affect quality of life.
viii. Transportation – it is availability of transport for the individual to get around which allows the person to perform the necessary tasks of daily life as well as the freedom to perform chosen activities.

Coronary Heart Disease (CHD)

Coronary heart disease is an availability of transport for the individual to get around which allows the person to perform the necessary tasks of daily life as well as the freedom to perform chosen activities ("Definition of Coronary Heart Disease", 2017). In this study, the respondents for the survey done among patients with CHD.
Summary

In chapter 1, the researcher described the operational definition of this study, objectives specifically and generally, significance of the study and some of the background. Further understanding done throughout the literature in the next chapter,

Chapter 2.

CHAPTER 2: LITERATURE REVIEW

2.1 Introduction

A literature review is discussing published information in a particular subject area and sometimes in particular subject area within certain time of period. Besides, it is another effective way in evaluate of selected documents on research based on the researcher's topic.

According to Dena Taylor, literature review is an account on what has been published of the topic by accredited scholars and researchers. The purpose of literature review is to convey reader on knowledge and ideas have been established on a topic.

Literature review also known as guiding concept.

There are many purposes literature review is important in research study. Literature review able to attain good knowledge of the field inquiry such as facts and others. Literature review itself helps to narrow a problem which from generally to specifically. So, researcher able to research more on the topic. Furthermore, it helps in generate hypothesis, research questions and others.

Literature review act as reference of previous studies to understand more of the topic. It is also able to know the technique they used for identifying the key issues and on how they done the research.

2.2 Search strategies

A literature review in the area of a survey on perceived of health status in patient with coronary heart disease published from year 2008 to 2018. Search strategies researcher used are electronic databases that subscribed by University of Malaya digital library: CINAHL, MEDLINE, SAGE Journals, ScienceDirect and Web of Science. Key words researcher used in databases are health related quality of life, health status, HRQoL, ischaemic heart disease, coronary heart disease and WHOQOL-BREF.

To be more precise in searching, the researcher filtered out irrelevant articles by keyed in inclusive criteria. There are including:

- English language articles
- Full text only
- Year 2006 to 2018

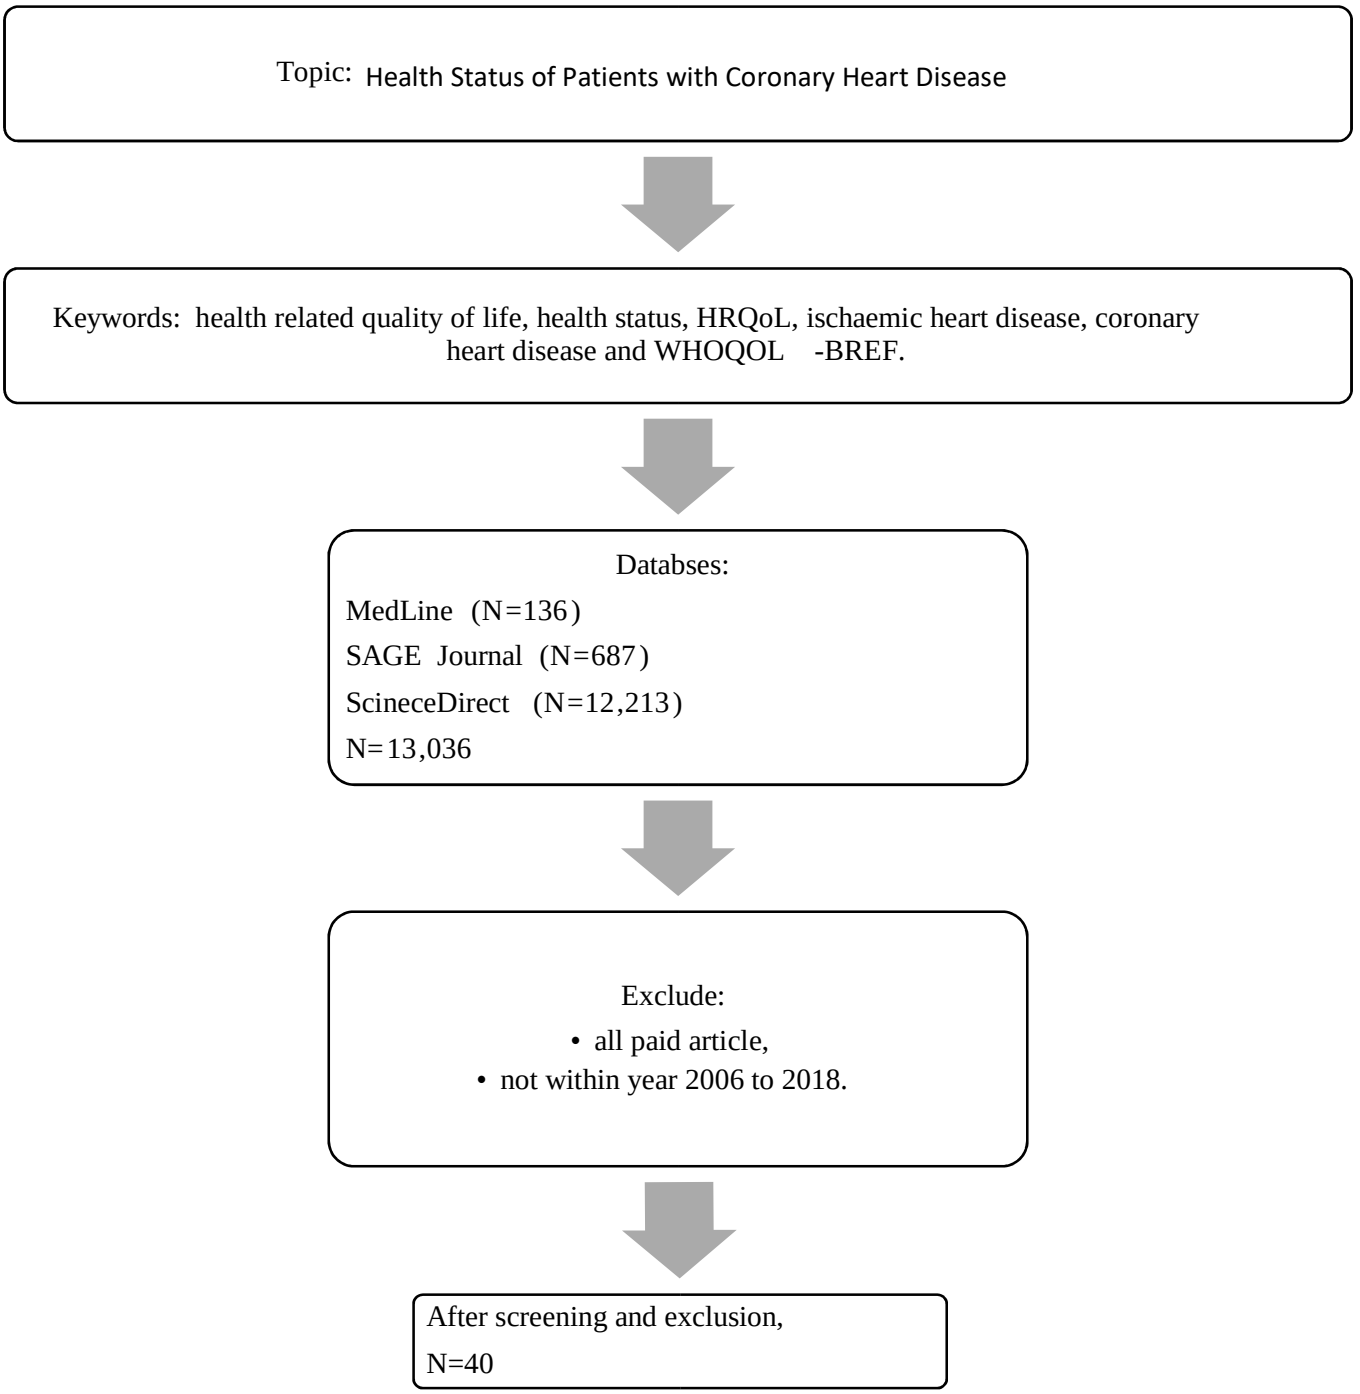

Figure 1: Flow chart of literature search

2.3 Burden of Coronary Heart Disease

The World Health Organization (2016), reported 56.9 million deaths worldwide in 2016, in which 15.2 million deaths is accounted by ischaemic heart disease and stroke. CHD have remained the leading causes of death globally in the last 15 years. In developed and developing countries heart disease is the leading cause of death in men and women. In Europe CHD accounts for an estimated 1.95 million deaths each year ("Coronary heart disease", 2006). Coronary heart disease (CHD) continues to be a leading cause of morbidity and mortality among adults worldwide (Gough, 2011)

Heart diseases and circulatory system (cardiovascular disease or CVD) are the major cause of death in the UK and accounted for almost 180,000 deaths in 2010. Almost half (45%) of all CVD deaths are from CHD and over a quarter (28%) are from stroke. Within England, North West showed the highest premature CHD death rates meanwhile South East and South West showed the lowest premature CHD death rates.

However, there were some fluctuations in death rates between 1998 and 2008, overall

Russia and Ukraine both experienced an increase in CHD mortality. At 2010 in United Kingdom, there are 396 men and 148 women deaths due to CHD. The death rates declined from 2009 which are 397 for men and 149 for women (Townsend et al, 2012).

However in Singapore, CHD is the second leading cause of death (Health Fact

Singapore, 2013). In addition, it has been reported that the proportional mortality from CAD is higher for Canadian men and women of South Asian descent (42% and 29%, respectively) than those of European (29% and 19%, respectively) or Chinese (18% and 11%, respectively) ancestry (Kevin et al, 2011). CHD responsible for one out of five lives, thus, it is remains as a major health problem in European countries (Delphine, Smedt & Clays, 2013). Even though, CHD has been decline in the past decades, the number of individuals with CHD increased in low and middle income country (Roth et al 2015).

According to World Health Organization (2015), CHD accounted for 98.9 deaths per 100,000 population in Malaysia in 2012, or 29,400 deaths (20.1% of all deaths); it is the most common cause of deaths in Malaysia. In year of 2016, WHO stated that in Malaysia there are 154,000 deaths out of 31,187,000 population. It is 35% of the deaths is due to cardiovascular diseases which is included the CHD. Therefore, there are increasing in the number of deaths due to CHD.

Study on CHD has done worldwide including Malaysia but it is already outdated. So, it is important to review the research done in Malaysia to have better understanding of the disease and the impact on clinical practice locally. However, in every study have their own limitation. In previous study, they have to go through several limitations such as that study might result in the underestimation of disease prevalence and selection bias. Besides, unable to adjust or change the cardiac function, number of heart attack or revascularization method. So, all these limitations have the possibilities in effecting the result of health status of patients with CHD (Hyung, 2014).

2.4 Health status among patients with CHD

Health status defined as an individual's relative level of wellness and illness, taking into account the presence of biological or physiological dysfunction, symptoms, and functional impairment ("Health Status", 2007).

Most of the patients consider the quality of the additional life years gained equally important as the length of life. This is because pain, physical and social restrictions, anxiety or depression, cardiovascular patients are particularly vulnerable to have an impaired self-perceived health status, often resulting in a reduced health-related quality of life (HRQoL). A few types of measurement tools being used to assess the importance of disease symptoms and their effect on everyday life as perceived by the patient. (Delphine et al, 2013). Quality of life, along with other health status measures (such as health utility and perceived health status), is useful for assessing the socioeconomic impact of CHD. It is an indicator of the burden of illness, effectiveness of interventions and treatments, and long-term mortality among patients after a cardiac event. (Xie et al, 2008)

World Health Organization Quality of Life – BREF (WHOQOL-BREF) is an instrument that used in several studies to measure health status or known as quality of life. In this instrument, it focused on 4 domains which are physical, psychological, social relationship and environment. (Monika, Garth & Marvin, 2009)

Ian et al. (2013), brief version (WHOQOL-BREF) was used to measure changes in quality of life. This is because it is internationally validated instrument for gynaecologic cancer. In this study it is used to estimate the lifetime gain in the HRQoL from early detection of cervical cancer.

QOL is a multidimensional concept that includes an individual's perception of his or her symptoms, well-being, physical and mental functional capacity, and social aspects of health (Strong et al, 2012).

2.4.1 Risk factors of CHD

Diabetes known as the risk of developing many types of diseases. Diabetes complications are various from acute manifestations such as coronary artery disease, stroke to severe systemic infection. The prevalence of diabetes in Malaysia increase with age in which 83% of population aged over 30 years has diabetes (Wnorlida et al,

2013).

In previous study, the South Asian non responders were significantly more likely to have received medical therapy, have renal disease, have diabetes mellitus type 2, be a current smoker, and have a prior myocardial infarction. They also found high rates of diabetes in the South Asian population. Even though well known as a major risk factor in the development of atherosclerosis. Hypertension and smoking tobacco are major risk factors for CHD, yet South Asians are much less likely to smoke and tend to have lower ambulatory blood pressures (Kevin et al, 2011).

Moreover, risk factors of CHD such as current smoker defined as individuals who reported smoking tobacco or cigarettes include who quit within a year. Meanwhile former smoker defined as smokers who quit more than a year. Obesity defined through ratio between hip and waist. Hypertension and diabetes were defined through selfreport. A previous study found out that risk factors which were more strongly associated with Myocardial Infarction (MI) in women compared to men included hypertension, diabetes, alcohol intake, and physical activity. Only former smoking was more strongly associated with MI in men compared to that in women (Sonia et al, 2008).

According to the World Health Organization, 11.6% of adults in the country have raised blood glucose, 28.8% have raised blood pressure, 10.4% are obese, and 43% of adult males are smokers. The high prevalence of coronary artery disease risk factors hypertension, diabetes mellitus, dyslipidaemia, smoking and obesity are

also consistently reported in the NCVD database registry which publishes annual reports. In terms of risk factor differences, Malays had higher body mass index (BMI), Chinese had higher prevalence of hypertension and hyperlipidemia, while Indians had higher rates of diabetes mellitus and family history of premature CAD (Ang & Chan, 2016). In a case-control study done by Suleiman (2006), and colleagues in Hospital

Kuala Lumpur, out of 102 patients who were admitted to the male medical ward, 44 were diagnosed as CAD and 58 with other diagnosis. Smoking and hypercholesterolemia were significant predictors of CAD diagnosis in this study. However, a study by Chang et al. (2012) in rural Sarawak found lower prevalence of risk factors: 13.5% hypertension, 1.5% diabetes, 15.4% smokers and 22.6% hypercholesterolemia.

2.4.2 HRQoL of Patient with Coronary Heart Disease

Over the past decade, health-related quality of life (HRQoL) has assumed increasing prominence as an important measure of health outcome (Cepeda-Valery, Cheong, Lee, & Yan, 2011). HRQoL is a multifaceted concept that measures the impact of diseases and treatments on the individual's physical, psychological and social wellbeing, such as changes in symptoms, physical functioning and social roles (Stafford, Berk, Reddy, & Jackson, 2007).

Coronary heart disease (CHD) is a major cause of death worldwide. In the past decades, the mortality rate associated with CHD has declined continuously as a result of advancements in disease prevention and treatment. Therefore, the importance of healthrelated quality of life (HRQoL) in survivors of CHD is growing. These days, the purpose of treatment has expanded from reducing morbidity and mortality to improving quality of life. Furthermore, one study suggested that HRQoL is a predictor of longterm mortality in patients with CHD. Accordingly, an understanding of HRQoL in CHD is needed to decide on proper treatment and to determine disease prognosis (Hyung et al, 2014).

In recent years, health-related quality of life (HRQOL) has become an important indicator of health outcome and is of particular interest for treatment strategies in CHD.

The therapeutic aim of any cardiovascular intervention is not only to improve survival but also to alleviate symptoms and improve functional activity (Kevin et al, 2011).

A study has been done in Korea (2014) where data taken from 2007 to 2011 of the Korea National Health and Nutrition Examination Survey. Topic of the study is Health-Related Quality of Life in Coronary Heart Disease in Korea. This study has been done in 2015. This study conducted by the Korean Centers for Disease Control and Prevention (KCDC). In addition, EQ-5D questionnaire used in this study. The result of this study shows that coronary heart disease has a significant impact on the reduction in HRQoL. The impairment of HRQoL occurred in dimensions of mobility, usual activities, pain/discomfort and anxiety/depression and the impairment of HRQoL can be seen more among elderly and female groups (Hyung et al, 2014).

A study has been done on a topic of self-reported health status in coronary heart disease patients and the study has been done in Belgium at 2013. To get the result, researcher need to compare EQ-5D scores in coronary heart disease patients with general population. The result of the study is similar to previous study done among German people. It stated that coronary heart disease patients are having problems on pain/discomfort, usual activities and anxiety/depression. In addition, women reported having symptoms such as angina, pain, nausea, fatigue, syncope, weakness, depression and loss of appetite. This evidence supported with different in physiologically may be the reason why women experience worse outcome. (Delphine et al, 2013)

Poorer health status had been reported compared to population without CHD (Mitchell et al 2015; Imran et al, 2014). Poorer health status caused by different factors, where associated among patient characteristics

and comorbid condition (Dickens, Cherrington, McGowan, 2012). Vascular comorbidities, heart failure and depression are not only effected the outcomes for CHD care but also individuals' health status (Tusek & Petek, 2016). Patients with poor HRQoL, in turn report worsening disease progression and poorer health outcomes (Škodová et al., 2011).

2.5 HRQoL and sociodemographic among patients with CHD

Individuals with higher socioeconomic status, higher education level, who are married and enjoy high levels of social support report better HRQoL (Barbareschi, Sanderman, Kempen, & Ranchor, 2009). On the other hand, females, individuals with a high number of cardiac co-morbidities and those experiencing increased severity of disease, anxiety and depression report poorer HRQoL (Stafford, Soljak, Pledge, & Mindell, 2012; Wang, Thompson, Ski, & Liu, 2012). Age is an inverse predictor with elderly individuals reporting better mental health whilst younger individuals report better physical health (Ford et al., 2008; Kimble et al., 2011; Lee, Choi, Chair, Yu, & Lau, 2012). These predictors would assist healthcare professionals in identifying individuals at risk for poor HRQoL and introducing tailored interventions to mitigate the negative impact of diminished HRQoL (Xie et al., 2008).

A study has done in Korea where impact of CHD on health status and the predictors of health status in Korean population could contribute to knowledge on health status in CHD. Based on Korean population, sample with CHD were generally older than those without CHD. In addition, sample with CHD were more likely to have spouse and lack of education. Sample with CHD had higher prevalence of CHD risk factors and comorbidities except for current smoking and them less likely to be a current smoker. General population in Korea, overall health status of patient with CHD has impaired. Health status adjusted reduction was specially greater in older age and female (Hyung et al, 2014).

CHD is one of the main causes of premature death in the UK (death before the age of 75). 28% of premature deaths in men and 19% of premature deaths in women were from CHD in 2010. (Townsend et al, 2012). Married individuals reported significantly better physical health compared to unmarried ones, possibly due to the presence of a spouse that assists in monitoring the diet and physical activity of the patient (Barry et al., 2006). Higher income individuals reported better physical health, a finding reported elsewhere (Barbareschi et al., 2009). The mechanisms underpinning the observed difference could involve increased access to better healthcare services or even affordability of fitness clubs that could substantially improve physical health outcome (Stafford et al., 2012).

This is because CHD has much bigger impact on younger age due to their productive age compared to older age (Xie et al, 2008). Higher income of individuals also have better physical health which effected their health status (Barbareschi et al, 2009). Better understanding of illness, better education, enhanced behavioural modification and better adherence to management plans lead to improve health status outcomes (Yu et al, 2009). From the study the researcher found out that unemployed individuals reported has better health outcomes especially mental health compared to employed individuals (Skodova et al 2011).

Patients with higher education has better health status and better mobility compared to lower education (Tusek & Petek, 2016). Based on another previous study, CHD effected more on male where 74.1% from 3775 patients with CHD (Delphine et
al, 2015).

There may be varied impact on HRQoL amongst the different ethnic groups that warrants attention given the presence of ethnic differences in CHD in Asian countries such as Singapore; with Indian residents facing higher risk of acute myocardial infarction compared to Chinese and Malay residents (Wong et al., 2012).

2.6 Correlations between domains of HRQoL

However, a study done by Ian, Alan and Carolyn (2013), showed different results where the 6 items of physical health shows mean of 0.61 (SD = 1.95) and it is significant ($p< 0.0001$). Psychological health showed a non-significant result $p>0.05$ ($p = 0.185$). Next, social relationship health showed non-significant which is $p>0.05$ ($p = 0.188$). Environmental health showed non- significant, $p>0.05$ ($p = 0.63$). Mean for psychological, social relationship and environment health is -0.01, 0.42 and 0.19 as respectively. Moreover, this study also showed the result for combination of four health domains which is significant, $p<0.0001$. The total score for the combined scale showed strong correlations with item 1 which assessed patient's perception of overall QoL (Spearman's Rho = 0.64, $p<0.00001$). The scale was very well targeted in the population as none of the patients were found to have a logit value outside of the range of the items.

From the previous study done by Utsav et al. (2017), they found out QOL scores for various domains were obtained with the mean±SD; environmental domain (53.17±15.59), psychological domain (51.23±18.61), social domain (49.86±21.64), and physical domain (45.93±16.90). There were statistically significant correlations among all domains ($p<0.05$ in all cases). Analysis of the strength of correlation among various domains showed moderate inter domain correlation between social and environmental domains (Pearson's $r>0.3$ and <0.5) and strong inter domain correlation among rest of the domains (Pearson's $r>0.5$).

Summary

In this chapter, researcher discussed search strategies done and how it is done to find relevant articles for literature review. The researcher stated the total amount articles in the databases and total amount researcher used after screening and exclusion criteria keyed in. The purpose of literature review is to guide the researcher to have better understanding of the current issue of the research topic and discuss the item content in questionnaire or instrument will be used for this study. It also helps to plan future study methodology after referring to the previous studies done.

CHAPTER 3: METHODOLOGY

3.1 Introduction

In this chapter, researcher will explain the study design, study setting, population and sampling, research instrument, questionnaire, data collection method, validity and reliability. The research design was important to ensure the data collected fair and no bias. Identification of the study setting and population has helped researcher to have a clearer picture in processing data. Identified study design helped in avoiding any irrelevance data, so that it was not included and effected the result. Meanwhile research instrument was help researcher in exact data where answer the research questions and achieved research objectives. Before collecting data, researcher was ethically approved by the respondents and the teaching hospital. Last but not least, data screening is done to process any unrelated data such as incomplete questionnaire or respondent with exclusion criteria.

3.2 Study Design

A cross sectional survey design was chosen when the study was conducted to estimate the prevalence outcome of the interest for a population at the same time. This quantitative design enable researcher to collect a large amount of data in a short time frame which is feasible for researcher. Commonly a cross sectional study was using a survey form. Questionnaire was distributed based on inclusion criteria. Medical records for the period

of February 2018 until September 2018 of selected subjects reviewed and used for data collection form. Self-administered questionnaire used to gather their response.

3.3 Study Setting

This study conducted at University Malaya Medical Centre (UMMC) at Kuala Lumpur. The rationale for selecting this study setting was mainly influenced by available resources. Due to logistical resource, time allowance available was largely influential to selection of the subject hospital because the primary investigator was conducted study with very limited budget. UMMC is the largest university hospital located at southwest corner of Kuala Lumpur. The strategic geographical location, rapidly growing city of over half million inhabitants and near the geographical centre of Peninsular has 1,643 beds which are distributed by 44 wards throughout the medical centre serving a population 1,782,375 for the district of Petaling Jaya. Therefore, patients with chronic diseases like heart disease, diabetes, hypertension or others was easily accessible and to gather enough samples required for this study. The participants will be selected at respective wards.
In UMMC there are 2 places with cardiac problem, namely, Interventional Cardiac Ward (ICW) and Cardiac Ward (4S). ICW consist of 30 beds and patients admitted for cardiac interventional procedures such as angiogram, PCI and stenting.
Meanwhile, 4S located at fourth floor of Menara Selatan consist of 54 beds.

3.4 Population and Sampling

Populations are a complete set of persons or objects that possess some common criteria based on researcher's interest. For target population, it consists of people or objects that meet the designated set of criteria of interest to the researcher. Commonly researcher will use in the study accessible population or study population. However, the data obtained from accessible population.
Samples are elements or members of populations are selected from sampling frame which involve all the elements of a population. Sampling frame is a document or record which contains a list of population or subjects of analysis that can be drawn as respondent or subjects of research. Convenience sampling was used to select sample for this study. All eligible cardiac patients who had voluntarily participated in the survey.
3.4.1 Sample Calculation

Sample size was calculated by using G*Power Software, a statistical power analysis software with ability to calculate power for a wide variety of statistical tests including t-tests, F-tests, and chi-square-tests, among others. A minimum sample of 280 was needed to run one way ANOVA test based on effect size = 0.25, α = 0.05, power = 0.95 and degree of freedom =3. No additional samples were added as survey was interview-administered.
3.4.2 Inclusion and Exclusion Criteria

Sample is selection of the total population or universe that one desired to study. The followings were the inclusion and exclusion criteria for the respondent.
Inclusion criteria

i. Indexed hospital diagnosis of CHD or IHD; ii. Adult aged more than 18 years old.
iii. Clinically stable and physically fit to answer the questions in the questionnaire forms.
iv. Cognitively intact with orientated to person, place and time and not influence by any drug or alcohol.
v. Able to communicate and read in Malay or English.

Exclusion criteria

i. Lodger patients who were not diagnosed with CHD; ii. Foreigner because study focused on local data to examine health status of local patients with CHD.

3.5 Research instrument

Among several questionnaires measuring health-related quality of life (HRQoL) such as PROMIS-29, WOMAC and others, this study used WHOQOL –BREF questionnaire as it was easily available for free and in both English and Malay version.

3.5.1 Questionnaire

The shorter 26-item WHOQOL-BREF was developed from original longer version of 100-item WHOQOL-100. WHOQOL-BREF was a well-established and widely used HRQoL questionnaire used in research. More than 10 languages had tested the reliability. WHOQOL-BREF focuses upon respondents' "perceived" quality of life. The researcher chose this questionnaire to assess each patient's health status because it is one of the best tools developed for cross-cultural comparisons of QOL. Lastly, this questionnaire is concise and easy to administer.

3.5.1.1 Scoring Algorithm

Table 3.1 shows the scoring algorithm. There is no total score and cut of point in computing scoring of WHOQOL-BREF. First two items (Q1 and Q2) were categorized under global domain to reflect overall quality of life and general health. Remaining 24 out of 26 items were divided into 4 domains which were physical health (Domain 1), psychological health (Domain 2), social relationship health (Domain 3) and environment health (Domain 4). The WHOQOL-BREF has 5 points Likert-like scales.

Table 3.1: Scoring algorithm

	Equations for computing domain scores	Raw score	Transformed scores*	
			4-20	**0-100**
Domain 1	(6-Q3) + (6-Q4) + Q10 + Q15 + Q16 + Q17 + Q18 ☐ + ☐ + ☐ + ☐ + ☐ + ☐ + ☐	=		
Domain 2	Q5 + Q6 + Q7 + Q11 + Q19 + (6-Q26) ☐ + ☐ + ☐ + ☐ + ☐ + ☐	=		
Domain 3	Q20 + Q21 + Q22 ☐ + ☐ + ☐	=		
Domain 4	Q8 + Q9 + Q12 + Q13 + Q14 + Q23 + Q24 + Q25 ☐ + ☐ + ☐ + ☐ + ☐ + ☐ + ☐ + ☐	=		

3.5.1.2 Data collection on patient background information

The sociodemographic section consist of 7 items, namely, age, gender, ethnicity, marital status, highest education, employment status and total household income per month. Information gathered from electronic medical record included height, weight, co-morbidities (smoking, hypertension, diabetes mellitus and dyslipidaemia) and others.

3.5.2 Validity and Reliability

Although previous studies had reported good reliability and validity WHOQOLBREF, this instrument was not used for patients with CHD in Malaysia. Therefore, face validity of WHOQOL-BREF was verified by 2 cardiac consultants, 4 nursing personnel who had post basic in coronary care nursing. All items were deemed relevant and no modifications of items were made.

Internal consistency reliability was checked by administering questionnaire to 30 patients. Cronbach's alpha values (α) were 0.76 for physical health, 0.79 for psychological health, 0.80 for social relationship health and 0.87 for environment health.

3.6 Data collection method

Patients who met the inclusion criteria were approached and informed consent was obtained from all patients after explaining purposes and benefits of study using Patient Information Sheet. The questionnaire took approximately 10 to 15 minutes to complete. Questionnaires were interview-administered once with researcher merely reading out the items.

3.7 Data Analysis

Data collected has been checked thoroughly and problem corrected before entering into computer. The questionnaires were processed and numbered. The response has been filled up according to variables and analysed by using Statistical Package for the Social Sciences (SPSS) version 25. The results were analysed by using Independent T-test, ANOVA and Correlation test to identify the significance between patients' with coronary heart disease and health status.

3.8 Ethical consideration

Ethical clearance was obtained (MRECID.NO: 201814-5932). Questionnaires were coded excluding patient's name and were placed in envelope in order to maintain anonymity and confidentiality. The respondents were given the adequate information from the primary investigator about the aim and procedure of the study. Inform consent taken and respondents were informed that the participation was optional and they can withdraw from the study at any time they wanted too. Respondents also informed that their answers were confidential and respondents' anonymities assured by using only code numbers. The study brought no harm to the respondents and the information mainly used for academic purposes. All the information gathered was strictly confidential and only used to carry out this study. All questionnaires were enclosed with cover letter of researcher's identification and purposes of this study. All the questionnaire were collected and kept in covered box.

3.9 Pilot study

Pilot study was a trial study or small study which represents a bigger one to come. It can predict the outcome of a major study in terms of recruitment success, response rate, and material resources requirement among others. Pilot study had been conducted once ethical approval received to see reliability of the study tools among participants. 10% from the total of sample size which is 30 patients were selected in
UMMC, Kuala Lumpur. Although the questionnaire had been validated in context of Malaysia settings but it is never done among patients with CHD in Malaysia. Pilot study was carried out on the 1st March 2018.

Summary

In this chapter, it explained the study design which answered the objectives constructed where the purpose of planning methodology is to guide the research in proper and correct track. The correct methodology enhances the data collection which interpreted in the next chapter. Population and sampling enables the researcher to

study the population based on the subsets as targeted sample. Researcher used convenience sampling with inclusive criteria in selecting the respondents. G*Power software used in calculation of sample size for this study. Research instrument is crucial to be reliable through pilot study and validation from experts in cardiology. Data collection was done systemically to make sure that all items in questionnaire are answered truthfully with the consent of participants.

CHAPTER 4: DATA ANALYSIS

4.1 Introduction

This chapter describes the analysis of data collected. The findings relate to the research objectives that guided the study. Data were analysed to assess perceived health status among patient with CHD. However, New York Heart Association (NYHA) and Canadian Cardiovascular Society (CCS) were taken but did not analyse due to huge number of missing data.

4.2 Data screening and data management

In the initial stage of data analysis, all the data collected were entered based on identification numbers tagged to the questionnaire with accordance to the respondents' identification to avoid double entry. All the data were screened and no missing values detected. Normality test was done on the dependant variables (domains of health status) as shown in Table 4.1. All health domains were normally distributed.

Table 4.1: Normality test

	Skewness		Kurtosis		Conclusion
	Statistic	Std. error	Statistic	Std. error	
Physical health	-0.594	0.162	-0.767	0.323	Normally
Psychological health	-0.551	0.162	-0.090	0.323	distribution
Social relationship health	-0.055	0.162	-0.217	0.323	
Environment health	-0.022	0.162	-0.314	0.323	

*. Normally distributed when skewness between -2 to 2

4.3 Response rate

A total of 280 questionnaires were distributed and collected. However, only 225 of data were completed. This represented a response rate of 80% (n=225). All of distributed questionnaires were collected on the spot. 55 respondents were incomplete data due to several reasons. For examples, double answered for an item, confusing and others. Moreover, the researcher had time constrained to collect another data.

4.4 Description of demographic data of the respondents

Table 4.2 display the details of demographic characteristics of the respondents. This study recruited a total of 225 respondents. The highest percentage of respondents are among patient age less than 58 years old, male, Malay, married, secondary school as highest education, with RM2001-RM4000 total household income per month and employment with wages.

Mean for age 57.44 with standard deviation of 11.940. Mean for the weight (kg) of respondents is 69.058. Median for the height (cm) of respondents is 67.00 with interquartile range of 48 to 104.

Table 4.2: Demographic data of respondents (N=225)

Characteristics	n (%)
Gender	
Male	161 (71.6)
Female	64 (28.4)
Ethnicity	
Malay	96 (42.7)
Chinese	78 (34.7)
Indian	51 (22.7)
Marital status	
Married	205 (91.1)
Single	13 (5.8)
Others (separated / divorced / widowed)	7 (3.1)
Highest education	
Primary school	8 (3.6)
Secondary school	154 (68.4)
Tertiary (college / institute / university)	63 (28.0)
Total household income per month	
Less than RM2000	39 (17.3)
RM2001-RM4000	140 (62.2)
RM4001-RM6000	43 (19.1)
More than RM6000	3 (1.3)

Employment status	
Employment for wages	70 (31.1)
Self-employed	45 (20.0)
Looking for work	1 (0.4)
Not looking for work	1 (0.4)
Unable to work	25 (11.1)
Retired	57 (25.3)
Homemaker	26 (11.6)

4.5 Health status in relation to risk factors profile and four health domains.

Parameters in this study referring the health status by level which are physical, psychological, social relationship and environment health domains. BMI and risk factors of CHD also included as parameters for health status among patients with CHD.

4.5.1

Items	n (%)				
	Very poor	Poor	Neither poor nor good	Good	Very good
1. How would you rate your quality of life?	0 (0)	7 (3.1)	70 (31.1)	124 (55.1)	24 (10.7)
	Very dissatisfied	Dissatisfied	Neither satisfied nor dissatisfied	Satisfied	Very satisfied
2. How satisfied are you with your health?	0 (0)	32 (14.2)	80 (35.6)	97 (43.1)	16 (7.1)

Description of respondents' scoring to WHOQOL-BREF

As shown in table 4.3, it is description of respondents for every items of instrument used. It is 5 Likert scale and there are 26 items. Item 1 refer as “Perception in overall quality of life” and Item 2 refer as “Perception in health status” of patients with CHD.

Table 4.3: Distribution of score among respective by items.

Table 4.3: Distribution of score among respective by items.

Items	n (%)				
	Not at all	A little	A moderate amount	Very much	An extreme amount
	0 (0)	12 (5.3)	78 (34.7)	103 (45.8)	21 (9.3)
3. To what extent do you feel that physical pain prevents you from doing what you need to do?					
4. How much do you need any medical treatment to function in your daily life?	12 (5.3)	30 (13.3)	161 (71.6)	11 (4.9)	11 (4.9)
5. How much do you enjoy life?	23 (10.2)	20 (8.9)	123 (54.7)	48 (21.3)	11 (4.9)
6. To what extent do you feel your life to be meaningful?	0 (0)	38 (16.9)	81 (36.0)	104 (46.2)	2 (0.9)
7. How well are you able to concentrate?	0 (0)	30 (13.3)	118 (52.4)	77 (34.2)	0 (0)
8. How safe do you feel in your daily life?	16 (7.1)	0 (0)	137 (60.9)	70 (31.1)	2 (0.9)
9. How healthy is your physical environment?	0 (0)	18 (8.0)	133 (59.1)	70 (31.1)	4 (1.8)
	Not at all	A little	Moderately	Very much	Extremely

10. Do you have enough energy for everyday life?	27 (12.0)	42 (18.7)	105 (46.7)	0 (0)	51 (22.7)
11. Are you able to accept your bodily appearance?	24 (10.7)	0 (0)	96 (42.7)	0 (0)	105 (46.7)
12. Have you enough money to meet your needs?	12 (5.3)	34 (15.1)	132 (58.7)	18 (8.0)	29 (12.9)
13. How available to you is the information that you need in your day-to-day life?	0 (0)	44 (19.6)	110 (48.9)	65 (28.9)	6 (2.7)
14. To what extent do you have the opportunity for leisure activities?	12 (5.3)	29 (12.9)	132 (58.7)	0 (0)	52 (23.1)

Table 4.3: Distribution of score among respective by items.

Items	n (%)				
	Very poor	Poor	Neither poor nor good	Good	Very good
15. How well are you able to get around?	0 (0)	31 (13.8)	118 (52.4)	74 (32.9)	2 (0.9)
	Very dissatisfied	Dissatisfied	Neither satisfied nor dissatisfied	Satisfied	Very satisfied
16. How satisfied are you with your sleep?	25 (11.1)	51 (22.7)	65 (28.9)	73 (32.4)	11 (4.9)
17. How satisfied are you with your ability to perform your daily living activities?	16 (7.1)	46 (20.4)	61 (27.1)	102 (45.3)	0 (0)
18. How satisfied are you with your capacity for work?	36 (16.0)	46 (20.4)	43 (19.1)	89 (39.6)	11 (4.9)
19. How satisfied are you with yourself?	34 (15.1)	49 (21.8)	45 (20.0)	57 (25.3)	40 (17.8)

20. How satisfied are you with your personal relationships?	20 (8.9)	33 (14.7)	73 (32.4)	71 (31.6)	28 (12.4)
21. How satisfied are you with your sex life?	4 (1.8)	39 (17.3)	98 (43.6)	73 (32.4)	11 (4.9)
22. How satisfied are you with the support you get from your friends?	0 (0)	13 (5.8)	102 (45.3)	87 (38.7)	23 (10.2)
23. How satisfied are you with the conditions of your living place?	32 (14.2)	22 (9.8)	24 (10.7)	110 (48.9)	37 (16.4)
24. How satisfied are you with your access to health services?	0 (0)	26 (11.6)	65 (28.9)	86 (38.2)	48 (21.3)
25. How satisfied are you with your transport?	12 (5.3)	26 (11.6)	82 (36.4)	63 (28.0)	42 (18.7)
	Never	Seldom	Quite often	Very often	Always
26. How often do you have negative feelings such as blue mood, despair, anxiety, depression?	0 (0)	9 (4.0)	115 (51.1)	83 (36.9)	18 (8.0)

4.5.2 Health status by HRQoL

Table 4.4 shows the summary of result of 4 health domains which are physical, psychological, social relationship and environment health.
Environment health shows the highest mean with 104.94 and social relationship health shows the lowest mean with 39.95.

Table 4.4: Perceived health status across according to WHOQOL-BREF

Health domains	Range	Mean (SD)
Physical health	52 – 108	83.56 (16.129)
Psychological health	44 – 100	73.48 (14.532)
Social relationsip health	24 – 56	39.95 (7.478)
Environment health	64 – 144	104.94 (19.922)

4.5.3 Health status by BMI and risk factors of CHD.

Body mass index (BMI) calculated by dividing weight (kg) with height multiple height (m^2). As shown in table 4.5, more than half of the respondents have normal body mass index. Only 4 respondents have underweight which is 1.8%. The range of BMI as
stated in the table.

Table 4.5: Body Mass Index (N=225)

	Range	n (%)	Mean (SD)
Underweight	<18.5	4 (1.80)	24.33 (0.674)
Normal BMI	18.5-24.9	137 (61.71)	
Overweight	25.0-29.9	62 (27.93)	
Obesity	>30	19 (8.56)	

Table 4.6 shows the frequency of the risk factors of CHD. Most of the respondents shows that they never smoke, with hypertension, diabetes mellitus and no dyslipidaemia. Table 4.6: Risk factors of CHD (N=225)

Risk factors	n (%)	Mean (SD)
Smoking		0.37 (0.484)
No	142 (63.1)	
Yes	83 (36.9)	
Hypertension		0.66 (0.474)
No	76 (33.8)	
Yes	149 (66.2)	
Diabetes mellitus		0.63 (0.485)
No	84 (37.3)	
Yes	141 (62.7)	
Dyslipidaemia		0.27 (0.446)
No	164 (72.9)	
Yes	61 (27.1)	

4.6 Four health domains in relation to sociodemographic characteristics

Sociodemographic characteristics are consist of age, gender, ethnicity, marital status, highest education, employment status and total household income per month.
These characteristics tested using independent T-test and analysis of variances (ANOVA). Sociodemographic characteristics and level of WHOQOL-BREF (physical, psychological, social relationship and environment health) done the test to determine any differences or not.

4.6.1 Differences between Age and WHOQOL-BREF

Independent T-test was used. As table 4.7 shows no differences between all the health domains and age.

Table 4.7: Age and health domains of WHOQOL-BREF

Sociodemographic	Physical health	Psychological health	Social relationship health	Environment health
	r	r	r	r
Age	-0.110	-0.151*	-0.074	-0.067

*. Correlation is significant at the 0.05 level (2-tailed)

4.6.2 Differences between gender and WHOQOL-BREF

As shown in table 4.8, only gender and environment health shows significantly difference in male (M=105.54, SD=18.815) and female (M=103.44, SD=22.558) conditions; t (223) = 0.714, p=0.44. Moreover, other health domains does not show any differences with gender.

Table 4.8: Gender and health domains of WHOQOL-BREF (male; n=161, female; n=64)

	Gender		t	p
	Male M (SD)	Female M (SD)		
Physical health	85.17 (15.650)	79.50 (16.722)	2.403	0.582
Psychological health	74.48 (14.071)	70.94 (15.455)	1.658	0.196
Social relationship health	40.30 (7.557)	39.06 (7.259)	1.119	0.816
Environment health	105.54 (18.815)	103.44 (22.558)	0.714	0.044

*. M=mean, SD=standard deviation, t=t-value, p=p value
*. Significant when $p < 0.05$

4.6.3 Differences between selected sociodemographic and level of WHOQOL-

BREF

One Way Analysis of Variances (ANOVA) was carried out to analyse sociodemographic (i.e ethnicity, marital status, highest education, total household income per month and employment status) and health domains of WHOQOL-BREF. As shown in table 4.9, only ethnicity between psychological health and social relationship health were statistically significant.

Participants were classified into three groups: Malay (n = 96), Chinese (n = 78) and India (n = 51). Psychological health increased from the Malay (M = 77.04, SD = 13.097), Chinese (M = 69.59, SD = 15.887) and India (M = 72.71, SD = 13.522) ethnicity groups. Psychological health was statistically significantly different between different ethnicity groups, F (2, 222) = 6.008, W^2 = 0.002. Post hoc test showed there is statistically significant higher psychological health mean score in Malay compare to Chinese.

Participants were classified into three groups: Malay (n = 96), Chinese (n = 78) and India (n = 51). Social relationship health increased from the Malay (M = 41.33, SD = 6.932), Chinese (M = 39.38, SD = 7.976) and India (M = 38.20, SD = 7.346) ethnicity groups. Social relationship health was statistically significantly different between different ethnicity groups, F (2, 222) = 3.336, W^2 = 0.04. Post hoc test showed there is statistically significant higher social relationship health mean score in Malay compare to Indian.

Table 4.9: WHOQOL-BREF health domains according to sociodemographic characteristics (N = 225)

4.7 Correlation between domains of WHOQOL-BREF

Table 4.10 shows the results of correlation between physical, psychological, social relationship and environment health. Spearman's Rho Correlation test was done. Result for correlation between physical and psychological health as shown. The r value is 0.350. The p value is 0.000 ($p<0.05$). Thus, there is moderate positive significant. The higher the physical health, the higher the psychological health.

The r value is 0.688. The p value is 0.000 ($p<0.05$). Thus, there is strong positive significant correlation between physical and social relationship health. The higher the physical health, the higher the social relationship health.

The r value is 0.611. The p value is 0.000 ($p<0.05$). Thus, there is strong positive significant correlation between physical and environment health. The higher the physical health, the higher the environment health.

The r value is 0.534. The p value is 0.000 ($p<0.05$). Thus, there is strong positive significant correlation between psychological and social relationship health. So, the higher the psychological health, the higher the social relationship health.

The r value is 0.636 and the p value is 0.000 ($p<0.05$). Thus, there is strong positive significant correlation between psychological health and environment health. So, the higher the psychological health, the higher the environment health.

The r value is 0.741 and p value is 0.000 ($p<0.05$). Thus, there is strong positive significant correlation between social relationship and environment health. So, the higher the social relationship health, the higher the environment health.

Table 4.10: Correlation between domains of WHOQOL-BREF

Health domains	Physical health	Psychological health	Social relationship health	Environment health
	r	r	r	r
Physical health		0.350**	0.688**	0.611**

Psychological health	0.350**		0.534**	0.636**
Social relationship health	0.688**	0.534**		0.741**
Environment health	0.611**	0.636**	0.741**	

**. Correlation is significant at the 0.01 level (2-tailed)

Summary

In this chapter, data that collected in this study was screen and manage. An analysis was done by researcher to answer all the objective to be achieve in this study. Majority of the respondents that participate in this study has higher mean in environment health compared to social relationship health. In addition, physical health has higher median than psychological health. However, Spearman's correlation test show that there was significant relationship between four health domains. ANOVA, Independent T-test and Spearman's correlation were done for association between sociodemographic and four health domains. Next chapter, a discussion on all of the results as compare to the literature or result from other studies will be done. Implication of study result, recommendation and limitation of the study will be included in the next chapter.

CHAPTER 5: DISCUSSION AND CONCLUSION

5.1 Introduction

In this chapter, result of this study was compared with previous study with almost same topic or using the same instrument which are health status of Coronary Heart Disease patient and WHOQOL-BREF respectively. Discussion was separated into
several parts included:

- Demographic data
- Health status in relation to risk factors profile and four health domains (i.e.

physical, psychological, social relationship and environment health)

- Four health domains in relation to sociodemographic characteristics.
- Correlation between physical, psychological, social relationship and environment health.

Additionally, the implication of this study to our nursing profession, nursing education and nursing research would be discussed further in this chapter based on the findings that the researcher obtained through the study periods. There were several limitations happened to this study which caused the findings to be effected the results generalization. Recommendation would be explored further in order to enhance the future study.

5.2 Discussion

5.2.1 Demographic data

Based on this study, male has 71.6% and female has 28.4% from a total of 225 respondents. Most of the respondents are married with 91.1% (n = 205). Moreover, the highest educational level of respondents is secondary education with 68.4% (n = 154) and the lowest is primary education with 3.6% (n=8). 62.2% (n = 140) respondents has monthly income of RM2001-RM4000 and 31.1% (n=70) respondents has employment for wages as their employment status.

Similar result of the respondents shown in previous study done by Tchicaya & Lorentz (2016) which consist of 70.7% male and 29.3% female. This study shows that percentage of male respondents is higher than percentage of female respondents. In Southern Brazil and South Australia, married respondents are the highest and respondents with others (widowed/divorced) is the lowest (Viviane et al, 2018). The majority of the subjects was Malay and married (Wnorlida et al, 2013). For highest education, 54.2% had secondary education, 14.7% had primary education and 6.1% had tertiary education (Monika, Garth & Marvin, 2009). According to Litza et al (2012), the majority of the samples were male (67.5%) and married (75.6%).

According to Monika, Garth and Marvin (2009), opposite results was shown when there is 43% males and 57% females from total of 491 patients participated. Most were 'single' (88%) with only 10% being married. Only 51.5% were employed
currently.

5.2.2 Health status in relation to risk factors profile and four health domains

Based on this study, all four of health domains shows normally distributed. The highest mean scores is environment health and the lowest mean scores is social relationship health. The results are 104.95 and 39.95 as respectively.

However, this previous study shows different result compared to this current study. The mean scores for the physical health and environmental health were lower than the other domain scores (Monika, Garth and Marvin, 2009).

Body mass index (BMI) calculated by dividing weight (kg) with height multiple height (m^2). More than half of the respondents have normal body mass index. Only 4 respondents have underweight which is 1.8%. Most of the respondents shows that they never smoke, with hypertension, diabetes mellitus and no dyslipidaemia.

According to the World Health Organization, 11.6% of adults in the country have raised blood glucose, 28.8% have raised blood pressure, 10.4% are obese, and 43% of adult males are smokers (Choon Seong & Kok Meng, 2016). Compared to this study only blood glucose level and blood pressure showed similar finding.

However, different finding shown through previous study done by Sonia et al,

(2008), risk factors which were more strongly associated with Myocardial Infarction (MI) in women compared to men included hypertension, diabetes, alcohol intake, and physical activity. Only former smoking was more strongly associated with MI in men compared to that in women.

5.2.3 Four health domains in relation to sociodemographic characteristics.

In this study, age is categorized into less than 58 years old and more than 58 years old. After done the test, the results shows that mean for age less than 58 years old has the highest mean in all four health domains. Male has higher mean in all health domains than female. Primary group for educational level shows the highest

mean in physical, psychological, social relationship and environment health. The mean are 86.50, 75.50, 41.50 and 112.00 respectively. Others (separated/divorced/widowed) group for marital status has the highest mean in all health domains.

Similar finding shown in a study done by Emdadul et al, (2012) physical, psychological, social relationship and environment health had the highest mean score among male respondents. The mean score are 55.8, 56.8, 66.9 and 59.0 as respectively.

However, different finding shown in previous study done by Viviane et al, (2018) the physical health in both studies were higher in males, younger individuals with higher educational level or higher family income.

According to Utsac Joshi et al, (2017) age is only significant difference for social relationship health ($p = 0.005$). Moreover, male has higher mean for physical health and psychological health (M = 47.2: 51.7) but female has higher mean for social relationship health and environmental health (M = 50.0: 53.6). For physical health, secondary and tertiary had the same mean which is 48.3. Educational level for psychological, social relationship and environmental health are higher among tertiary level. The mean are 55.4, 53.9 and 55.1 respectively. The same study was found out that unmarried respondents has higher mean in all health domains except environmental health. It is significant difference between income with psychological health and environmental health ($p<0.05$).

A study done by Po-Chin Strong et al. (2012), where they different between the gender of CABG patients and physical, psychological, social relationship and environment health. Female shows that has higher mean compare to male in all health domains. The result for female is (M=57.60, SD = 12.01), (M=73.8, SD = 16.20), (M=72.60, SD = 13.05) and (M=70.20, SD = 7.82) which is physical, psychological, social relationship and environment health, as respectively.

5.2.4 Correlation between physical, psychological, social relationship and environment health

In this study, there is strong positive significant between all health domains except relationship between physical and psychological health which shows moderate positive significant.

However, a study done by Ian, Alan and Carolyn (2013), showed different results where the 6 items of physical health shows mean of 0.61 (SD = 1.95) and it is significant ($p< 0.0001$). Psychological health showed a non-significant result $p>0.05$ ($p = 0.185$). Next, social relationship health showed non-significant which is $p>0.05$ ($p = 0.188$). Environmental health showed non- significant, $p>0.05$ ($p = 0.63$). Mean for psychological, social relationship and environment health is -0.01, 0.42 and 0.19 as respectively. Moreover, this study also showed the result for combination of four health domains which is significant, $p<0.0001$. The total score for the combined scale showed strong correlations with item 1 which assessed patient's perception of overall QoL (Spearman's Rho = 0.64, $p<0.00001$). The scale was very well targeted in the population as none of the patients were found to have a logit value outside of the range of the items.

5.3 Implication of finding

5.3.1 Patient management

Patient management here refers to on how patient care was delivered. Is it cost effective or not? From this study, the researcher found out that there is strong relationship between all health domains except relationship between physical health and psychological health which showed moderate relationship. So, the researcher conclude that when one health domain increase, another health domain will be increase.

Delivery patient care can be improvise since there are relationship between the health domains. This is because the health domains in this study measure the major health domains which are physical health, psychological health, social relationship health and environment health.

Aware of cultural function, belief and practices in the community especially among patients with CHD. The cultural awareness helps in providing cultural care. This study shows the adaptation process among male patients are higher compared to female patients. This is because male is more dependent in seeking the treatment compared to female.

5.3.2 Patient education

From this study, nurses know the risk factors of CHD. So, the nurses might take actions to educate patient on how to prevent the recurrent CHD. This is because CHD can be reoccur due to unhealthy lifestyle and the risk factors are uncontrolled such as diabetes, hypertension, BMI, smoking and lipid level. Moreover, this study can be used in patient education on how to maintain their health status and the risk factors of CHD.

Every patient has different learning ability. Before starting the patients' education, nurses should assess and consider the education level, teaching method, language used, level of knowledge, and others during the assessment. In order to create an environment that is conducive to patient education, nurses should develop a supportive relationship with their patients. Patients equipped with knowledge can make lifestyle changes and remain self-sufficient even if they have a chronic medical condition. Education can increase the likelihood of successful outcomes and improve patient safety and satisfaction (Nurse Journal, 2018).

5.3.3 Nursing education and research

Based on the findings, it was helpful in educate the patients of CHD. Nurses knows what should be educate to patients of CHD. For example, most of them passed the secondary education so, they might lack of information regarding their health condition. Nurses educate the patient based on their education level. Hence, the organization might encourage or plan for health promotion on the coronary heart disease. This study found out that the characteristics of patients the most are Malay, married, total household income per month of RM2001-RM4000 and employment for wages as their employment status. These characteristics shows that these people need to be prioritized for any education or exposure.

There is limited literature review on the health status of patients with coronary heart disease especially using the same tools, WHOQOL-BREF. There are a lot of studies done using same instrument but the study is focus on another chronic disease such as psychiatric, diabetes type 2, chronic kidney disease and others. It is importance for nurses to perform evidence-based practice regarding health status of patients with CHD. There is the needs in enhancing and increasing the number of research regarding health status among the patients. It helps in improving nursing care in the future and the competency.

5.4 Limitation

There were a few of limitation has been identified by the researcher throughout the study periods. First and foremost, limitation identified in this study is the population is too small and conducted only at a single medical center. The participants who took part in this study may not have been a representative sample of the populations examined. It is cross-sectional design, which prohibits definitive conclusion about causality. It is interviewed based survey. Therefore, the researcher might be misinterpreting the respondents' answer. Variety of version was limited only Malay and English. However, there were some patients unable to read or understand both languages.

5.5 Recommendation

Researcher had come out a few of recommendations for future research related to health status among patient with CHD. This study had only involved small group of sample and focusing on only one medical center. Thus, it would be ideal if the study can involve more medical center and conducted large sample. Future study

can be done by involving different medical centre and compare the results.

5.6 Conclusion

In Malaysia, there were many considerable research had been done. The findings continues to show that CHD is the major cause of mortality and morbidity in the country. A high prevalence of risk factors for CHD is present in the population. Greater efforts must be made towards especially educate public to change dietary habits and other at risk lifestyles such as smoking, and to increase awareness of healthy living such as regular exercise, and others, in order to reduce the prevalence of CHD in the country.

Greater efforts at secondary prevention are also needed to improve outcomes once CHD is diagnosed. From this study, the researcher can conclude, the health domains are strongly significant except physical and psychological health. Physical and psychological health are shows positive moderate significant. For the risk factors of CHD, most of the respondent showed non-smoker, having hypertension, diabetes, normal BMI and no dyslipidaemia. The results able to help local authorities to initiate various interventions

to improvise the health status among patients with CHD. Limitations and recommendations of the study had been stated clearly in this chapter which would help the next researcher who interest in the same field to improve future study and ensure the results able to generalize to the population. Measuring health status of patient might help in allows personnel to provide physical, psychological and social support to the affected patients.

ASSOCIATION OF PERSONALITY TYPES AND PERCEIVED LEARNING STYLES OF NURSING STUDENTS IN CLASSROOM LESSONS

FAIZ BIN ASNI
Department of Nursing Science, Faculty of Medicine
University of Malaya
Kuala Lumpur

ABSTRACT

Background: Association between learning styles and personality types has been studied across different student populations with mixed findings being observed. How personality types influence learning styles among nursing student populations lack empirical evidence.
Objectives: This study aimed to examine learning styles preferences during classroom lessons and the personality types among nursing students across different demography and academic background.
Methods: A cross-sectional study conducted in 2018. A total of 160 diploma nursing students and 160 baccalaureate nursing students from three learning institutions had self-administered two questionnaires, namely, the Learning Style Survey and Ten Item Personality Inventory.
Results: Majority of respondents were visual learner (n=207, 64.7%) and have more than one personality type (n=68, 21.2%). Unlike personality types, learning styles was found to be associated with nursing student type (diploma vs baccalaureate). Four significant but weak correlations ($r \approx 0.12$ to 0.16; $p < 0.05$) were observed between the three categories of learning styles and five categories of personality.
Conclusion: The diploma and baccalaureate nursing students have different learning styles; thus, requiring different approach to classroom teaching. Students who predominantly prefer visual learning styles could be more likely to have extraversion, conscientiousness and emotional stability personality types; while students who prefer kinesthetic learning styles tend to have emotional stability personality type. Further study with larger sample size or/and using different instrument measuring learning styles and personality types is recommended.

CHAPTER 1

INTRODUCTION

1.1 Background of Study

Learning styles refers to the preferential way in which the student absorbs, processes, comprehends and retains the information. Learning style also can be described as a factors, behaviors, and attitudes that assist learning for an individual in any situation (Teach.com, 2017). Personality type is a collection of personality traits that are thought to exist together, especially as determined by a certain pattern of responses to a

personality inventory. It also refers to the habits, attitudes as well as physical traits of an individual which are not similar but have vary from group to society, everyone has personality, which may be good or bad, impressive or unimpressive (Umar, 2011).

The quality of students' thoughts is critical to learning which also can be associated with their personality and could potentially determine their academic achievement. Universities students differ in how they process, encode, recall, organize, and apply the information they learned (Meera, 2011).

The majority of previous studies have examined the relationship between personality types and learning styles via the Myers-Briggs Type Indicator (MBTI). One such study by Fallan (2007) said that a student's personality type is related with the most effective form of learning and if this thing ignored, can present a conflict in the process of education.

Another study conducted by Meera Komarraju (2011) also said that personality and learning styles are both likely to play significant roles in influencing academic achievement. College students which is 308 undergraduates completed the Five Factor Inventory and the Inventory of Learning Processes and reported their grade point average. Two of the Big Five traits, conscientiousness and agreeableness, were positively related with all four learning styles which are synthesis analysis, methodical study, fact retention, and elaborative processing. The Big Five together explained 14% of the variance in grade point average (GPA), and learning styles explained an additional 3%, suggesting that both personality traits and learning styles contribute to academic performance.

Fazarro, Pannkuk, and Pavelock (2009) conducted another study, which examined how learning styles can be affected by an individual's personality types. This study specifically focused on how CTES teachers could improve their instruction by diversifying curriculum and pedagogy to accommodate student-learning preferences. A sample of 87 Agricultural students revealed that 'Structure' was the most prevalent learning style. By implementing "Structure" into the classes and laboratories, educators of career and technical students could better prepare their instruction plans to cater to this preferred learning style (Fazarro, et al., 2009).

There are several themes that can be observed by examining the related personality and learning style literature. First, a relationship between personality and learning style has been identified in select educational settings (Fallan, 2007). Second, the majority of studies, which found a relationship between personality and learning style, used the MBTI (Fallan, 2007). Thus, research on the relationship between personality and learning style within an educational setting could yield valuable data regarding how to better meet the educational needs of students in preparation for the world-of work.

1.2 Problem Statement

Differences in learning style and personality for every individual have long been considered a fundamental factor determining individual behavior and performance (Ming Li & Armstrong, 2015). Yet whether or not learning style is a wholly integral part of personality theory remains unclear (Ming Li et. al, 2015). Some studies concluded that learning style is a sub-set of personality based on consistent correlations between the those two whereas other studies have concluded that learning style is distinctive and worthy of investigation separately from personality due to shared variance between the

two constructs being low (Ming Li et. al, 2015). While sample, sample size and analytical methods adopted by different studies, and interpretations by researchers all contribute to different conclusions from previous studies, further investigations that can contribute to this scholarly debate is needed (Chamorro-Premuzic & Furnham, 2009; Ming Li et. al, 2015).

From many studies that have been done, every student has their own unique way in learning and personality types (Zayeed, 2007). They learn by visualizing, hearing, reflecting, acting, logically, intuition and memorizing (Zayeed, 2007). So, because of this unique characteristic, educators cannot assume that students would be able to learn well by depending on what the educator believes to be the best (Zayeed, 2007). When we look at university typical lectures and classroom with many students, it is important for the lecturers to identify the students learning styles (Zayeed, 2007).

Educators tend to teach the way they were taught, and a strong relationship exists between their teaching style and preferred learning style (Hickcox, 2006; Mark, Richard, Danielle, 2013). These critical findings show a problem that need attention as we do not all come from the same mold in regard to our specific learning style or personality type (Hickcox, 2006; Mark et.al, 2013). All learning style research and application efforts must focus on the development of the individual and the whole learner (Hickcox, 2006; Mark et.al, 2013). Learning styles, as well as personality types should be accounted for when considering the topics of curriculum development and instruction (Hickcox, 2006; Mark et.al, 2013). With the overload of curricular assessment demands, and a vast amount of learning style models, teachers and lecturers may find themselves in a state of confusion regarding the use of learning style models during teaching in the classroom (Hickcox, 2006; Mark et.al, 2013).

While several studies have examined the relationship between learning style and personality type, just a few have examined if there any relationship between personality types and the learning styles of nursing students and registered nurses (Fallan, 2006). But all of the studies is being done regarding on learning styles and personality types during clinical practice and there was no studies being done during classroom lessons among nursing students and registered nurses.

Thus, this study sought to determine whether a relationship exists between the perceived learning styles and personality types among nursing students during classroom lessons. This topic was examined for the purpose of providing more information regarding how to better serve the educational needs in preparing this nursing student population for the world-of-work in hospital. Other than that, the importance of this study is to make the students aware with their learning styles and personality types in order to match their learning styles with personality types.

1.3 Significance of Study

1.3.1 Educators

Learning styles indicate an individual's preferential focus on different types of information, the different ways of perceiving information, and the rate of understanding information. Having an understanding of the learning style preferences of students can provide effective learning strategies for teachers to use. Other than that, educators also can promote problem-solving skills by using student's specific learning styles during

classroom lessons. By making students aware of their learning style educators also can encourage them to know the significance of suitable learning styles for different subjects and that such styles may hopefully be changed to suit changing learning situations. After that, by educators providing a learning environment that suitable with the learning styles of students, students can learn better and feel more comfortable in their own learning styles instead of need to adapt themselves to the different of teaching styles of educators. Educator also can become more flexible in knowing their students learning styles due to the fact that educators show their teaching styles and learning environment. In addition, having an educator who can understands the learning style of a student also can minimize problems that may come up during learning session.

1.3.2 Students

By matching a student learning style to their personality types, it can increase student achievement and satisfaction. According to Naimie et al. (2010), "learning style specialists have confirmed the theory that students will learn more and enjoy the class experience and environment when they can use their preferred learning styles" (Naimie et al., 2010). By making the students aware with their learning styles, it can gives students a head start and maximizes their learning potential and also help students customized their techniques to score better on tests and exams. Other than that, it can help the student by showing them how to overcome the limitations of poor instructors, reduces the stress and frustration of learning experiences and expands their existing learning and studying strategies. In addition, when the student aware their learning styles and personality types, it can increases their self-confidence, improves their self-image and gives them insight into their strengths, weaknesses, and habits. Lastly, when the students know their learning styles that suit with their personality types, it will enables them to enjoy any learning process during classroom lessons.

1.4 Objectives

1.4.1 General Objective

To investigate association between perceived learning styles preferences profile and personality types among nursing students during classroom lessons.

1.4.2 Specific Objectives

1. To identify learning styles preferences during classroom lessons among nursing students across different demography and academic background.
2. To examine personality types of nursing students across different demography and academic background.
3. To determine association between learning styles preferences and personality types of nursing students.

1.5 Research Questions

1. What is learning style preferences among nursing students during classroom lessons?
2. What is predominant personality types of nursing students?
3. Is there any relationship between learning style preferences and nursing student's demography and academic background?

4. Is there any relationship between personality types and nursing student's demography and academic background?
5. What is the association of personality types towards learning style preferences among nursing students?

1.6 Operational Definitions

Learning Styles

The word "learning styles" tells that every student learns differently. Technically, learning styles refers to the preferential way in which the student absorbs, processes, comprehends and retains the information. Learning style also can be described as a factors, behaviors, and attitudes that assist learning for an individual in any situation (Teach.com, 2017). In this study, learning styles refers to three types of learning styles which are kinesthetic, visual and auditory.

Personality Types

Personality type is a collection of personality traits that are thought to exist together, especially as determined by a certain pattern of responses to a personality inventory. It also refers to the habits, attitudes as well as physical traits of an individual which are not similar but have vary from group to society, everyone has personality, which may be good or bad, impressive or unimpressive (Umar Farooq, 2011). In this study, personality types refer to five types of personality which are extraversion, agreeableness, conscientiousness, emotional stability and openness to experiences which use the ten item personality measure (TIPI). This TIPI is based on Big Five dimensions.

Nursing Student

Nursing student is a student in a program leading to certification in a form of nursing and usually applied to students in an RN or practical nurse program (Medilexicon, 2017). Nursing student also is someone who is studying or training to be a nurse (Collins Dictionary, 2017). In this study, nursing student refers to diploma nursing and undergraduate nursing students from University Malaya Medical Centre (UMMC), University of Malaya (UM) and MARA University of Technology Malaysia (UITM) from year 1 to year 4. Nursing students also have lessons in classroom and lecture like students from other courses. Hence, they also have different learning style preferences during classroom lessons.

Classroom Lessons

Classroom is a place where classes are taught in a school, college or university (Merriam-Webster, 2018) while lesson is a fixed period of time when people are taught about a particular subject or taught how to do something (Collins Dictionary, 2018). Usually involves one or more students being taught by a teacher or instructor. Lessons are generally taught in a classroom but may also take place in a situated learning environment. For this study, classroom lessons were referred as lessons that related with nursing course or subjects that take place in university or college.

1.7 Summary

Learning styles refers to the preferential way in which the student absorbs, processes, comprehends and retains the information while personality type is a collection of personality traits that are thought to exist together, especially as determined by a certain pattern of responses to a personality inventory. The majority of previous studies have examined the relationship between personality types and learning styles and mostly said that a student's personality type is related with the most effective form of learning and if this thing ignored, can present a conflict in the process of education. Hence, all nursing students are expected to have their own learning style preferences and also their own personality types. From that, the association of both personality types and learning styles can be done.

CHAPTER 2 LITERATURE REVIEW

2.1 Introduction

In research, literature review is a key step in research process. Before starting any

research study, literature review of previous studies related to the proposed research study should be done. Literature review of previous study can contribute to new study, ideas, knowledge and information. Usually quantitative design of research can get many research articles and journals while qualitative design of research may find a little to access the articles or journals even though the phenomena have been studies before.

A literature review is an evaluative report of information found in the literature related to selected area of study. The review should describe, summarise, evaluate and clarify this literature. It should give a theoretical base for the research and help the author determine the nature of research. Works which are irrelevant should be discarded and those which are peripheral should be looked at critically.

To search for literature reviews, a systematic way should be used in order to get the most related literature to the studies. Information and Technology course has taught students to utilize database wisely. In this study, literature review search strategies will be explained.

2.2 Search Strategies

Literature review in the area of Association of among students published over the past 10 years was conducted. The electronic search was performed on the following databases subscribed by the University of Malaya digital library: PubMed, CiNaHL@EBSCO, ScienceDirect, Medline. The keywords used in the databases search included learning styles and personality types.

To search for the precise literatures, relevant keywords should be keyed to filter out irrelevant articles. The inclusion and exclusion criteria were established to guide the search for related articles. The following inclusion criteria were used:

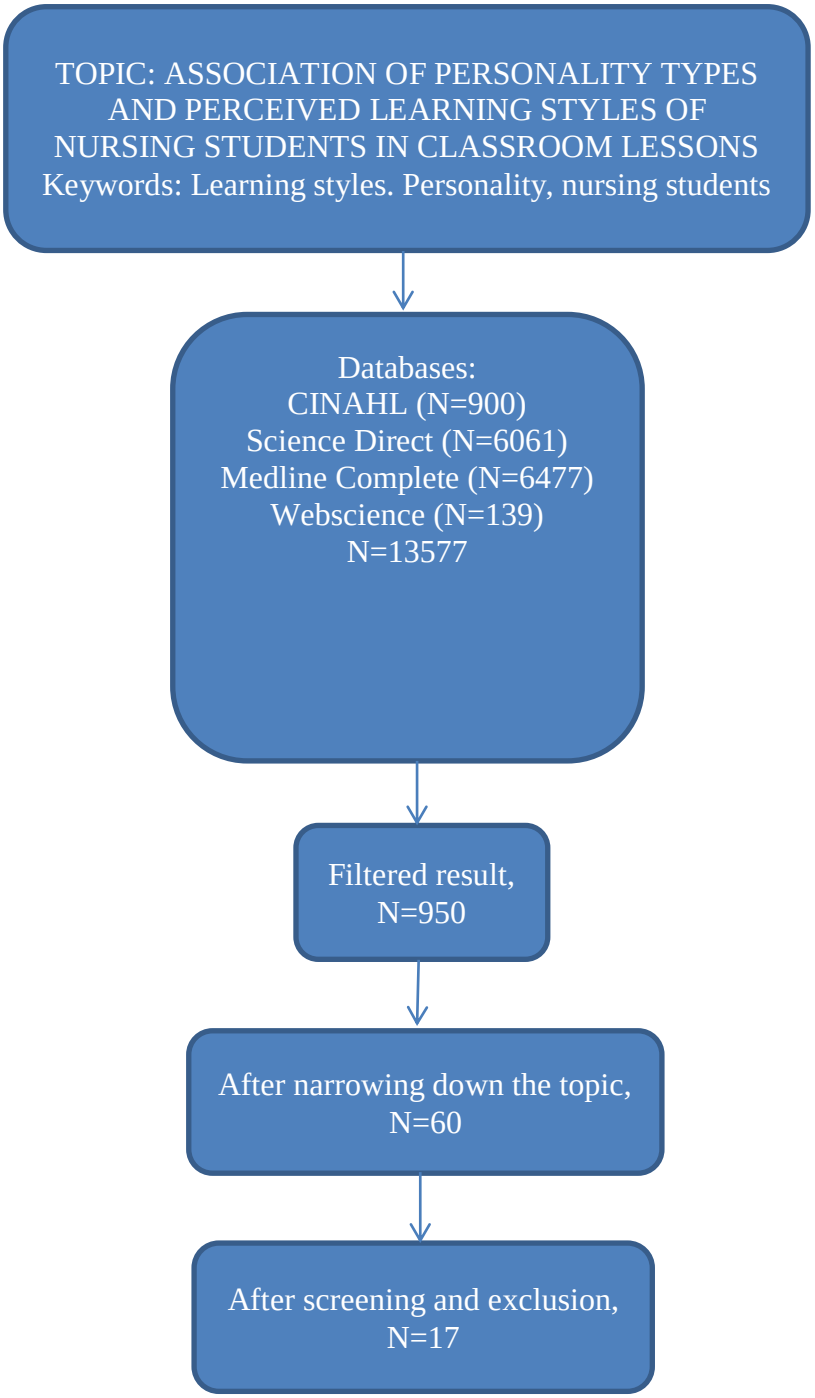
- English language articles
- Primary search articles
- Articles published within year 2007-2017
- Title only

The exclusion criteria were:

- Qualitative research design

As shown in Figure 2.1, the keywords used to search the precise literatures in database were learning styles, personality and nursing. About 13577 literatures were found which consisted from CINAHL, Science Direct, Medline Complete and Webscience. After filtered the literatures, narrowed down it topics, screened and made the exclusion, only about 17 literatures that can be used for literature review in this study.

Figure 2.1: Search Engine



2.3 Learning styles

Learning style refers to how we describe the approach which a person use in acquiring new language or learning. Learning style involves complex manner in processing, storing and recall what they are attempting to learn. The idea of individualized learning styles originated during 1970's and recently has gained popularity. Learning styles are crucial because learning styles are the education relevant expressions of the uniqueness of the person. Some students find that the theory more easier to understand while others may find that practical work more interesting and easy. Learning depends on many factors such as environment, position in class, previous learning and other factors (Shodhganga, 2007).

The term learning style is varied and many researchers have investigated different aspects of learning styles and can be divided into three categories which are cognitive learning styles, learning styles and personality learning styles (Zayeed, 2007). Zayeed Imran (2007) also stated that learning style is a blend of cognitive, affective, and behavioral elements. Most educators agreed that every person learns differently as they have their own learning styles (Zayeed, 2007). Learning styles may simply mean the ways a student prefers to go about learning or the ways each learner starts to focus on, process and retain new and difficult information (Zayeed, 2007).

A study conducted in Sri Aman town by Zayeed Imran (2007) on student's perceptual learning styles preferences. 637 students from three rural secondary schools were selected as respondents. In this study, the researcher classifies the learning styles into six categories and the findings revealed that generally, students were major in all six categories of learning styles (Zayeed, 2007).

Another study conducted by Ryan A.Preece and Alexandra C.Cope on medical students and surgical trainees to compare both their learning styles. The LSI questionnaire was completed by 53 students and 37 trainees. No significant difference for learning styles preference was detected between the two groups with the visual modality being the preferred learning style for both medical students and surgical trainees (Ryan & Alexandra, 2016).

So for my study, it was conducted on nursing student's perceived learning styles during classroom lessons and the respondents involved are about 320 nursing students from diploma and undergraduate. Through this study, it was revealed what major learning styles used by the nursing students.

2.4 Personality Types

Personality has been derived from the Latin word "persona" which means "mask" used by the actors to change their appearance. Personality is the product of social interaction in group life. It refers to the habits, attitudes as well as physical traits of a person which are not same but have vary from group to group and society to society, everyone has personality, which may be good or bad, impressive or unimpressive (Umar, 2011). Personality type is collection of personality traits which are thought to occur together consistently, especially as determined by a certain pattern of responses to a personality inventory.

However, it is clear that personality has a big impact on life. In fact, personality has been found to correlate strongly with life satisfaction (Boyce, Wood, & Powdthavee, 2013). With such a large potential impact on life, it is important to have a reliable way to

conceptualize and measure personality. The most prevalent personality framework is the "Big Five," or the five-factor model of personality. Not only does this theory of personality apply in multiple countries and cultures around the world (Schmitt et al., 2007), there is a valid and reliable assessment scale for measuring the five factors. The five factors identified as primary factors of personality in this Big Five theory are, extroversion, agreeableness, conscientiousness, emotional stability and openness to experience.

A study conducted by Mark D. Threeton, Richard A. Walter and Danielle C. Evanoski (2013) on personality type and learning style: the tie that binds. The target population for this study was postsecondary automotive technology students and method used for measuring the personality types was Holland's theory of vocational personalities. After calculating the results of the SDS, it was determined that the Realistic personality type was the predominant classification of 148 (84.1%) participants within this study (Mark et. al, 2013).

Another study also conducted which by Ming Li and Steven J. Armstrong (2015) on the relationship between learning styles and personality traits in international managers. 269 managers completed the questionnaire and the result showed that the highest mean among five personality types was conscientiousness followed by agreeableness, extraversion, openness to experience and neuroticism respectively.

2.5 Association of Learning Styles and Personality types

A large portion of previous research has focused on identifying learning styles, personality types, intelligence, and adaptive strategies of teaching to meet the learning needs of students. Learning style research has also provided valuable insights regarding the relationship between personality type and learning style. The majority of previous studies have examined the relationship between personality and learning via the Myers-Briggs Type Indicator (MBTI). One such study by Fallan (2007) suggested that a student's personality type relates to the most effective form of learning and, if ignored, can present a conflict in the educational process.

Another study conducted by Meera Komarraju (2011) also said that personality and learning styles are both likely to play significant roles in influencing academic achievement. College students which was 308 undergraduates completed the Five Factor Inventory and the Inventory of Learning Processes and reported their grade point average (Meera, 2011). Two of the Big Five traits, conscientiousness and agreeableness, were positively related with all four learning styles which are synthesis analysis, methodical study, fact retention, and elaborative processing (Meera, 2011).

Another study conducted by Ming Li (2016) on the relationship between Kolb's experiential learning styles and Big Five personality traits in international managers. About 269 managers completed the questionnaire and regression analyses revealed that extraversion was positively related to concrete experience and negatively related to abstract conceptualization (Ming Li et. al, 2016). Extraversion was also positively related to active experiment and negatively related to reflective observation (Ming Li et. al, 2016).

2.6 Association of Demographic Characteristics and Academic Performances with Learning style

Improving student learning and teaching is a key issue in higher education. In order to do so efficiently, it is necessary to have a better understanding of the factors that influence academic performance in the first place. Males and females were found to use different learning styles (Jihan, 2008). Students in different fields of study were also found to have different learning styles (Jihan, 2008).

A study conducted by Bhavna Prajapati, Mark Dunne, Hannah Bartlett and Robert Cubbidge (2011) on the influence of learning styles, enrolment status and gender on academic performance of optometry undergraduates. A total of 270 students consisted of 106 first year students, 89 second year students and 75 final year students gave voluntary informed consent for their data to be analyzed (Bhavna et. al, 2011). Females represented 63% of the sample in all 3 year groups (Bhavna et. al, 2011). There were no statistically significant differences on learning styles across the three year groups (Bhavna et. al, 2011). The majority of students had a balanced learning style (Bhavna et. al, 2011). For gender, there were also no statistically significant differences between the sensing-intuitive and the sequential-global learning styles in males and females (Bhavna et. al, 2011). However, there was a statistically significant difference in the active-reflective and the visual-verbal learning styles (Bhavna et. al, 2011). It showed that females were more likely to have a reflective and visual learning style in comparison to males (Bhavna et. al, 2011). Next for academic performance, there were also no statistically significant variations in the academic performance of students with different learning style profiles (Bhavna et. al, 2011).

Another study conducted by Nor Aniza Ahmad (2011) on the relationship between learning styles and strategies with academic achievement based on gender and type of School (Nor Aniza, 2011). The questionnaires were distributed to 400 students aged 15 years old from single gender and co-educational schools (Nor Aniza, 2011). The finding showed that direct relationship occurred between learning styles, gender and academic achievement (Nor Aniza, 2011).

A study also conducted on learning styles in relation to gender, field of study, and academic achievement for Bahraini University students by Jihan I.A. Alumran (2008). The sample consisted of 877 students which aged between 17 to 30 years (Jihan, 2008). Results revealed that there were significant differences between learning styles with gender and fields of study (Jihan, 2008). Males students were more intuitive learners while females students were more sensing learners (Jihan, 2008). For academic achievement, the results revealed that learning styles were good predictors of student's CGPA were visual/verbal and sequential/global learning styles (Jihan, 2008).

2.7 Association of Demographic Characteristics and Academic Performances with Personality types

Based on previous results, women reported higher Big Five extraversion, agreeableness, and neuroticism scores than men. However, more extensive gender differences were found at the level of the aspects, with significant gender differences appearing in both aspects of every Big Five trait. For extraversion, openness to experience and conscientiousness, the gender differences were found to diverge at the aspect level, rendering them either small or undetectable at the Big Five level. These results show the nature of gender differences in personality and focus on the utility of measuring personality at the aspect level.

Other studies also shown that the personality types of students affect performance on aptitude and achievement examinations. As an example, a study was carried out by Donald J. Sefcik, Frank J. Prerost & Scott E. Arbet (2009) to determine if personality type is associated with performance on aptitude and achievement tests taken by osteopathic medical students. Among the 263 respondents, there is no personality types were associated with high or low scores on the Medical College Admissions Test (Donald et. al, 2009). However, students in the intuition-feeling group had statistically significant lower scores on COMLEX-USA Level 1 (Donald et. al, 2009).

2.8 Summary

Chapter 2 discussed the search strategies and the presentation of relevant literature review. The purpose of doing literature review is to guide the researcher to have better understanding of the current issue of the research topic. It also helps to plan future study methodology after referring to the previous studies done.

CHAPTER 3 METHODOLOGY

3.1 Introduction

Research methodology is the process used to collect information and data for the purpose of making business decisions. The methodology may include publication research, interviews, surveys and other research techniques, and could include both present and historical information. This chapter also provided an overview on the methodology that had used to obtain useful information about the personality types and learning styles of the nursing students. The topic included were study design, study setting, population and sampling, research instrument, data collection method, data analysis, ethical consideration and pilot study.

3.2 Study Design

A quantitative descriptive survey was deemed appropriate and feasible study design to achieve study objectives aiming at determining cross-sectionally the association or relationship between personality types and learning styles of the nursing students during classroom lessons. Descriptive study is the precise measurement of phenomena. Surveys were carried out to provide an accurate portrayal of a group of subjects with specific characteristics. Descriptive designs described what actually exists, determined the frequency with which it occurs, and categorized the information. It was also a cross-sectional study which involved a one-time interaction with groups of people. Among the three types of descriptive study which are observational, case study and cross-sectional survey, cross-sectional survey was used in this study. A set of questionnaire were handed out to targeted population to discuss the related topic in their own opinion.

3.3 Study Setting

The study setting of this study was at University of Malaya (UM), MARA University of Technology Malaysia (UITM) and University Malaya Medical Centre (UMMC). Quota was employed to determine balance ratio of samples from a much larger population of diploma nursing students and a small population of undergraduate nursing students from the three settings. For University of Malaya (UM), Faculty of Medicine became a place to collect the data from the undergraduate nursing students while for University Malaya Medical Centre (UMMC), the nursing college became the setting for collecting the data from the diploma nursing students. For MARA University of Technology Malaysia (UITM), the data collected from diploma and undergraduate nursing students at Faculty of Science Health.

3.4 Population and Sampling

Population is a complete set of persons or objects that possess some common characteristics that is of interest to the researcher. Population composed of two groups which are target population and accessible population. Sample is subset of population or a group of people selected to represent the population. The purpose of sampling is to gather data about the population in order to make an inference that can be generalized to the population.

3.4.1 Target Population

Target population also called the universe composed of the entire group of people or objects to which the researcher wishes to generalize the findings of a study. The target population consists of people or objects that meet the designated set of criteria of interest to the researcher. For this study, the target population were undergraduate and diploma nursing students from University of Malaya, MARA University of Technology Malaysia (UITM) and University Malaya Medical Centre (UMMC). The total of undergraduate of nursing students were 210 students, while for Diploma of nursing students were 800. So the total target population was 1010 of nursing students.

3.4.2 Sampling Method

Due to markedly disproportionate population of diploma and undergraduate populations of nursing students, this study employed disproportional stratified random sampling. Disproportional sampling is a probability sampling technique used to address the difficulty researcher encounter with stratified samples of unequal sizes. This sampling method divides the population into subgroups or strata but employs a sampling fraction that is not similar for all strata; some strata are oversampled relative to others. For this study, the researcher divided the population into subgroup of nursing program which was Diploma of nursing and Bachelor of nursing. The researcher ensured ratio of two subgroups (i.e. diploma and undergraduate nursing students) approximate 1:1.

In order to select respondents in respective subgroup on equal probability, a systematic sampling was employed. Systematic sampling is a probability sampling method where the elements are chosen from a target population by selecting a random starting point and selecting other members after a fixed ‘sampling interval’. Sampling interval is calculated by dividing the entire population size by the desired sample size. In this study, the list name and total of the nursing students from year 1 until year 4 were given to the researcher by the lecturers of each study setting. Then, the total population for each nursing program divided with the total sample size for each nursing program in order to get the sampling interval (k). After that, the researcher selected a random number generated using Microsoft Excel between 1 to k (including k) from the list names given. Then, the researcher added the sampling interval (k) to the chosen random number to add the next respondent to a sample and repeat this procedure to add remaining respondents of the sample.

3.4.3 Sample Calculation

The sample calculation was calculated by using software G Power. Sample calculation using this G Power software was performed based on alpha of 0.05 and power of 95% to detect chi-squared test (DF=5) at modest effect size of 0.25. A minimum sample

size of 317 was estimated. Additional 5% for incomplete to that total sample which is total 330 sets of questionnaire will be distributed to account for potential value and estimate non response.

3.4.4 Inclusion and Exclusion Criteria

The inclusion criteria of this study were undergraduate and diploma nursing students of University of Malaya (UM), MARA University of Technology Malaysia (UITM) and University Malaya Medical Centre (UMMC). The exclusion criteria of this study were undergraduate and diploma students from other courses except nursing course. Other than that, postgraduate university students and international students also have been excluded out as the research was carried out to assess on diploma nursing students, undergraduate nursing students and Malaysian students.

3.5 Research Instrument

Research instrument is the device used to collect data. In this study, questionnaire was used to collect data. The questionnaire consisted of a series of questions and required the respondents to answer all the questions. The questionnaire are modified from the questionnaire of previous study done by Kappler Mikk, Cohen & Paige with title of "Learning style survey: Assessing your own learning styles" and by department of psychology, University of Texas after obtained the approval from the authors/researchers.

3.5.1 Questionnaire

Two publicly available questionnaires were used: Learning Style Inventory by Kappler Mikk, Cohen & Paige (2009) and Ten item personality measure (TIPI) by department of psychology, University of Texas (2014). The TIPI and Learning Style Inventory comprised Part A and B respectively, while the Part c was the demography and academic information. The existing English version of questionnaires was used. It was a simple questionnaire which consists of 48 items.

a) Demographic Background

Respondents were asked on their demographic background including age, gender, highest academic qualification, score in the MUET or any English paper like SPM, current nursing program, current year, latest CGPA and family total household income.

b) Ten item personality measure (TIPI)

Ten items were assessing the student's personality types. This part included all the items for each type of personality types. The answer option are disagree strongly, disagree moderately, disagree a little, neither agree nor disagree, agree a little, agree moderately and agree strongly. Only one answer can be selected and the respondents cannot guess the answer. In this part, score 1 is for disagree strongly, 2 is for disagree moderately, 3 is for disagree a little, 4 is for neither agree nor disagree, 5 is for agree a little, 6 is for agree moderately and 7 is for agree strongly.

To score this TIPI, firstly recode the reverse-scored items (i.e., recode a 7 with a 1, a 6 with a 2, a 5 with a 3, etc.). The reverse scored items are 2, 4, 6, 8, & 10. Then, take the average of the two items (the standard item and the recoded reverse-scored item) that make up each scale. Example using the Extraversion scale: A participant has scores of 5 on item 1 (Extraverted, enthusiastic) and and 2 on item 6 (Reserved, quiet). First, recode the reverse-scored item (i.e., item 6), replacing the 2 with a 6. Second, take the average of the score for item 1 and the (recoded) score for item 6. So the TIPI Extraversion scale score would be: (5 + 6)/2 = 5.5. Then, the highest mark will show the personality type of the respondent. Extraversion: 1, 6R; Agreeableness: 2R, 7; Conscientiousness; 3, 8R; Emotional Stability: 4R, 9; Openness to Experiences: 5, 10R with "R" denotes as reverse-scored items. For more explanation, Table 3.1 showed the scoring of this TIPI instrument as shown below.

Table 3.1: Scoring of TIPI Instrument for Personality Types

Domains of TIPI (Types of Personality)	Item Number	Scoring algorithm (By averaging all Likert-like scale #)
Extraversion	1 & 6R	Mean = (Item 1+ Item 6r)/2
Agreeableness	2R & 7	Mean = (Item 1+ Item 6R)/2
Conscientiousness	3 & 8R	Mean = (Item 1+ Item 6R)/2
Emotional Stability	4R & 9	Mean = (Item 1+ Item 6R)/2
Openness to Experience	5 & 10R	Mean = (Item 1+ Item 6R)/2

Note. * R = Reverse scored; #Likert-like scale were: 1= disagree strongly, 2= disagree moderately, 3 = disagree a little, 4=neither agree nor disagree, 5= agree a little, 6 = agree moderately and 7 = agree strongly; Personality was categorised by the highest mean score e.g. A respondent has Extraversion personality if scored highest mean for extraversion domain.

c) Learning Style Inventory

Thirty items of close ended question in form of multiple choices that were used to assess learning style of the students. This part included all the items for each type of learning styles. Each type of learning styles has ten question that needed to answer by respondents. The answer option are never, rarely, sometimes, often and always. Respondents need to answer all of the items by circling one number among the numbers provided. Only one answer can be selected and the respondents cannot guess the answer. In this part, score 0 is for never, 1 is for rarely, 2 is for sometimes, 3 is for often and 4 which is the highest marks is for always. Then, all the answer for the item in each types of learning styles will be sum to get the highest score. As an example, if a respondent got highest mark in auditory types, it shows that the learning style of that respondent is auditory. For more explanation, Table 3.2 showed the scoring of this Learning Style Survey instrument as shown below.

Table 3.2: Scoring of Learning Style Survey instrument

Domains (Types of Learning Styles)	Item Number	Scoring algorithm (By summation of all Likert-like scale #)
Visual	1 to 10	Sum all the score from item No. 1 until 10

Auditory	11 to 20	Sum all the score from item No. 11 until 20
Kinaesthetic	21 to 30	Sum all the score from item No. 21 until 30

Note. * R = Reverse scored; #Likert-like scale were: 0 = never, 1=rarely, 2= sometimes, 3= often and 4 = always; Learning style was categorised by the highest sum score e.g. A respondent has visual learning style if scored highest sum for visual domain

3.5.2 Reliability and Validity

The questionnaire need to possess validity and reliability to ensure a higher quality of data collected. Reliability of the questionnaire is the degree to which an assessment tool or questionnaire produces stable and consistent result (Colin and Julie, 2005). In this study, internal consistency reliability was assessed using Cronbach's Alpha as the questions had more than more than two response options of Likert-like scales. The instruments of Cronbach's Alpha in SPSS version 25.0 will be used to test for the reliability of questionnaire as the questions were using Likert scale. Good internal reliability was indicated by $\alpha > 0.7$ and < 0.95. But, for heterogenous and small number of items, it is still acceptable if the value of $\alpha > 0.5$. Pilot study was conducted to test the reliability of the questionnaire with duration about one month. The pilot study took about 10% from the total sample size which was 32 nursing students but they are not included in real study as respondents.

Table 3.3: Reliability test using Cronbach's Alpha

Instrument Tool	α
Personality Types	0.697
Visual Learning Style	0.730
Auditory Learning Style	0.728
Kinaesthetic/Tactile Learning Style	0.695

All internal consistency reliability coefficients were acceptable (0.690 to 0.730) Validity can be referred as how well a questionnaire or instrument measures what it purported to measure (Colin and Julie, 2005). Therefore, the questionnaire must be appropriate and related with the objective of the study. The type of validity used in this study was face-to-face validity in which the validity checked by expert and nursing lecturer. In this study, the face validity of the questionnaires had undergo a validity test was verified by Associate Professor from Faculty of Education, University of Malaya and two nursing lecturer from Department of Nursing Science, University of Malaya.

3.6. Data Collection Method

The study had carried out after researcher obtained ethical approval from every each of study setting. The data collected by using self-administered questionnaire at one point to ensure a good response rate. The data collected at University Malaya, MARA University of Technology Malaysia (UITM) and also University Malaya Medical Centre. The researcher approached and attained the respondents which fulfilled the inclusion criteria to participate in the study. The questionnaire was put in an envelope when passed to each respondent to ensure privacy and confidentiality. Consent also taken from the respondent which indicated they agree to fill up the questionnaire. Then, the respondents

were given some time to answer the survey. The researcher waited there until the respondents finish the questionnaire. Time for the respondents to answer the questionnaire was about 10 to 15 minutes. The data started to collect on April 2018 and finished on July 2018.

3.7 Data Analysis

Analysis of data is a process of inspecting, cleaning, transforming, and modeling data with the goal of discovering useful information, suggesting conclusions, and supporting decision making. Data analysis is important in discovering useful information to achieve all the objectives, answer the research questions as well as suggesting conclusion and supporting the decision making. The data collected from this study analysed by Statistical Package Social Sciences (SPSS) Version 25.0. Description data analysis used in analysing the demographic data, parametric test was used to analyse the independent variable and non-parametric test was used to analyse the dependent variable.

3.8 Ethical Consideration

Ethical approval obtained from the University Malaya Medical Centre (UMMC) ethic committee to carry out the research at UMMC. Ethical approval from University of Malaya (UM) and MARA University of Technology Malaysia (UITM) also obtained. Informed consent also given to the respondents as an agreement for their participation in this study. Participants were voluntarily in joining in this study without any force and have right to refuse. Cover letter contained title of study, purpose of study, study objective and other important details were given to the respondents to read before answering the questionnaire. Any clarification of respondents had been made by the researcher before filling the questionnaire.

3.9 Pilot Study

Pilot study is a small-scale, trial run of the actual research study. A group of people similar to the study subjects should be tested in conditions similar to those that will be used in the actual research study. A pilot study should be conducted whenever a new instrument is being develop or when a pre-existing instrument is being used with people who have different characteristics from those for which the instrument was originally developed. The purpose of the pilot study is to help the researcher to determine whether a more substantial study is warranted and the researcher will be able to take a pragmatic view on the main study's potentialities and feasibility (Basavanthappa, 2014). For this study, pilot study carried out after the researcher has got the ethical approval from University Malaya Medical Centre (UMMC), University of Malaya (UM), MARA University of Technology Malaysia (UITM) and also validation of questionnaire by experts. About 10% from the total sample size of this study involved in pilot study. Researcher approached them one by one and obtained the response from them. The respondents from the pilot study were excluded from the actual sample for the research. At the end of the pilot study, the result analysed showed no major modification for questionnaire items and data collection method needed. Furthermore, all questionnaire items must be retained as permission to modify questionnaires were not obtained.

3.10 Summary

This chapter explains the study design use for this study research which answer the objective constructed. The purpose of planning this methodology is to guide the study research in proper way. The right methodology will enhances the data collection which will be interpreted in next chapter. Population and sampling enables the researcher to study the population based on the subset as targeted sample. Sample size was calculated by using G Power software. Research instrument is important to be reliable and valid through validation from experts and pilot study. Data collection also done systematically to make sure that all items in questionnaire were answered honestly with the consent from respondents.

CHAPTER 4: DATA ANALYSIS

4.1 Introduction

This chapter described the analysis of data collected from respondents followed by a discussion of research finding. After coding and entering the data, the researcher analysed the data using the Statistical Package Social Science (SPSS) version 25. Data were analysed by using descriptive statistics and inferential statistics. Descriptive statistics were used to present the overall demographic characteristics of respondents and their satisfaction towards the care provided at a clinic. The researcher also used the Pearson Chi-square test to test the association between two categorical variables. The results also displayed in the form of tables and graphs accompanied with narrative explanation.

The questionnaire comprised of three sections and data generated will be presented as follows. The first section (Section A) comprised of background information or demographic characteristics of respondents while the second section (Section B) comprised of data regarding on personality types of the respondents. In third section (Section C), data obtained from the respondents were regarding the three types of learning styles which is visual, auditory and kinaesthetic or tactile.

4.2 Data Screening and Data Management

In the initial stage of data analysis, all the data collected were entered into the SPSS version 25 based on the identification number tagged to the questionnaire with accordance to the respondents' identity code number like 001, 002, 003 etc. to avoid double entry. All the data was being screened and there was a few missing values detected.

4.3 Data Normality Checking

During the stage of data management, normality test had been done on the dependent variables which were personality types and types of learning styles to determine whether the sample data had been drawn from a normally distributed population. The normality test helped the researcher in selecting the proper statistical test either parametric or non-parametric test to analyse the data. The results of normality test for dependent variables were shown as below.

Table 4.1: Normality test of Students' Personality Types

Variables	Mean (SD)	Median	Std Deviation	Skewness			Kurtosis		
				Statistic	Std Error	Z-scores	Statistic	Std Error	Z-scores
Extraversion	4.48	4.50	0.861	0.198	0.136	1.456	0.549	0.272	2.018
Agreeableness	4.29	4.00	0.976	0.133	0.136	0.978	0.039	0.272	0.143
Conscientiouness	4.60	4.50	0.980	0.076	0.136	0.559	-0.072	0.272	-0.265

Emotional Stability	4.54	4.50	0.965	0.008	0.136	0.059	0.822	0.272	3.022
Openness to Experience	4.53	4.50	0.907	0.116	0.136	0.853	-0.085	0.272	-0.313

According to Table 4.1, the mean value for extraversion personality scores was almost equal with median value and standard deviation smaller than mean. The skewness and kurtosis value were between +2 and -2. Both Z-scores for skewness and kurtosis also were between +3.29 to -3.29. The histogram also presented bell shaped which showed normally distributed. So from that result, it also shows that extraversion personality scores were normally distributed.

Other than that, the mean value for agreeableness personality scores also was almost equal with median value and standard deviation smaller than mean. The skewness and kurtosis value were between +2 and -2. Both Z-scores for skewness and kurtosis also were between +3.29 to -3.29. The histogram also presented bell shaped which showed normally distributed. So from that result, it also shows that agreeableness personality scores were normally distributed.

In addition, the mean value for conscientiouness personality scores was almost equal with median value and standard deviation smaller than mean. The skewness and kurtosis value were between +2 and -2. Both Z-scores for skewness and kurtosis also were between +3.29 to -3.29. The histogram also presented bell shaped which showed normally distributed. So from that result, it also shows that conscientiousness personality scores were normally distributed.

Furthermore, the mean value for emotional stability personality scores was almost equal with median value and standard deviation smaller than mean. The skewness and kurtosis value were between +2 and -2. Both Z-scores for skewness and kurtosis also were between +3.29 to -3.29. The histogram also presented bell shaped which showed normally distributed. So from that result, it also shows that emotional stability personality scores were normally distributed.

Lastly, the mean value for openness to experience personality scores was almost equal with median value and standard deviation smaller than mean. The skewness and kurtosis value were between +2 and -2. Both Z-scores for skewness and kurtosis also were between +3.29 to -3.29. The histogram also presented bell shaped which showed normally distributed. So from that result, it also shows that openness to experience personality scores were normally distributed.

Table 4.2: Normality test of the students' learning styles

Variables	Mean (SD)	Median	Std Deviation	Skewness			Kurtosis		
				Statistic	Std Error	Z-scores	Statistic	Std Error	Z-scores
Visual	27.61	27.00	4.526	0.322	0.136	2.368	-0.264	0.272	-0.971

Auditory	23.58	24.00	4.797	-0.202	0.136	-1.485	-0.375	0.272	1.379
Kinaesthetic	22.27	22.50	5.361	-0.008	0.136	-0.059	-0.321	0.272	-1.180

According to Table 4.2, the mean value for visual learning style scores was almost equal with median value and standard deviation smaller than mean. The skewness and kurtosis value were between +2 and -2. Both Z-scores for skewness and kurtosis also were between +3.29 to -3.29. The histogram also presented bell shaped which showed normally distributed. So from that result, it also shows that visual learning style scores were normally distributed.

Other than that, the mean value for auditory learning style scores was almost equal with median value and standard deviation smaller than mean. The skewness and kurtosis value were between +2 and -2. Both Z-scores for skewness and kurtosis also were between +3.29 to -3.29. The histogram also presented bell shaped which showed normally distributed. So from that result, it also shows that auditory learning style scores were normally distributed.

Furthermore, the mean value for kinaesthetic learning style scores was almost equal with median value and standard deviation smaller than mean. The skewness and kurtosis value were between +2 and -2. Both Z-scores for skewness and kurtosis also were between +3.29 to -3.29. The histogram also presented bell shaped which showed normally distributed. So from that result, it also shows that kinaesthetic learning style scores were normally distributed.

4.4 Response Rate

A total of 330 questionnaires were distributed by researcher through face to face with the respondents and collected back on the same day. Thus, the response rate for this study was 100%. However only 320 questionnaires were can be used for data analysis because 10 sets more the respondents did not complete the questionnaire in one or more subsections.

4.5 Demographic Characteristics of Respondents

Table 4.3: Demographic Characteristics of Respondents (n=320)

Characteristics		Frequency (n)	Percentage (%)	Mean	Standard Deviation (SD)
Gender	Male	47	14.7		
	Female	273	85.3		
Age	18-21 years old	232	72.5	20.92	1.217
	22 years old and above	88	27.5		

Highest academic qualification	SPM	147	45.9		
	STPM	29	9.1		
	Others	144	45.0		
English proficiency	Good	312	97.5		
	Moderate	8	2.5		
Current nursing program	Diploma	160	50.0		
	Bachelor	160	50.0		
Current year	Year 1	89	27.8		
	Year 2	104	32.5		
	Year 3	94	29.4		
	Year 4	33	10.3		
CGPA	2.50 to 2.97	29	9.1	3.3319	.28459
	2.98 to 3.45	173	54.1		
	3.46 and above	118	36.9		
Total household income	<RM3000	161	50.3		
	RM3000 – RM5000	112	35.9		
	>RM5000	47	14.7		

Note. SD= standard deviation

Based on the Table 4.9, the demographic characteristics data including age, gender, highest academic qualification, English proficiency, current nursing program, current year of studies, CGPA and total household income. Among 320 respondents, majority of them were female, 273 (85.3%) while another 47 (14.7%) were male nursing students. Besides that, majority of respondents were between 18 to 21 years old, 232 (72.5%) while another 88 (27.5%) were 22 years old and above. As for highest academic qualification, most of the respondents already qualified from SPM and others (Matriculation and Foundation) while only 29 (9.1%) students qualified from STPM. Furthermore, for English proficiency, majority of the respondents had good English proficiency, 312 (97.5%).

In term of current nursing program, half of the respondents were from Diploma in nursing and another half were from Bachelor in nursing, 160 (50%). In addition, the most respondents came from Year 2 nursing students, 104 (32.5%) while the least came from Year 4 nursing students, 33 (10.3%). For CGPA, most of the respondents had CGPA between 2.98 to 3.45, 173 (54.1%) while least of the respondents had CGPA between 2.50 to 2.97, (29, 9.1%). Lastly, most of the respondents had total household income less than RM3000, (161, 50.3%) while least of them had total household income more than RM5000, (47, 14.7%)

4.6 Distribution of Responses to Questionnaire Items

Table 4.10, Table 4.11, Table 4.12 and Table 4.13 show the distribution of responses across the Likert-like scale for Personality Types and Learning Styles of

respondents in respectively**.**

Table 4.4: Descriptive Frequency for Students' Personality Types. (n=320)

Students' Personality Types	Frequency, n (%)						
	Disagree strongly	**Disagree moderately**	**Disagree a little**	**Neutral**	**Agree a little**	**Agree moderately**	**Agree strongly**
Socially confident	15 (4.7%)	31 (9.7%)	59 (18.4%)	122 (38.1%)	59 (18.4%)	33 (10.3%)	1 (0.3%)
Critical, quarrelsome	2 (0.6%)	4 (1.3%)	22 (6.9%)	119 (37.2%)	78 (24.4%)	80 (25.0%)	15 (4.7%)
Dependable, self-disciplined	0 (0.0%)	5 (1.6%)	24 (7.5%)	91 (28.4%)	96 (30.0%)	82 (25.6%)	22 (6.9%)
Anxious. Easily upset	18 (5.6%)	40 (12.5%)	45 (14.1%)	96 (30.0%)	75 (23.4%)	37 (11.6%)	9 (2.8%)
Open to new experiences, complex	0 (0.0%)	4 (1.3%)	11 (3.4%)	75 (23.4%)	111 (34.7%)	89 (27.8%)	30 (9.4%)
Reserved, quiet	13 (4.1%)	27 (8.4%)	51 (15.9%)	91 (28.4%)	77 (24.1%)	52 (16.3%)	9 (2.8%)
Sympathetic. Warm	0 (0.0%)	8 (2.5%)	23 (7.2%)	96 (30.0%)	92 (28.7%)	88 (27.5%)	13 (4.1%)
Disorganized, careless	23 (7.2%)	48 (15.0%)	64 (20.0%)	93 (29.1%)	54 (169%)	30 (9.4%)	8 (2.5%)
Calm, emotionally stable	1 (0.3%)	8 (2.5%)	26 (8.1%)	97 (30.3%)	83 (25.9%)	84 (26.3%)	21 (6.6%)
Ordinary, uncreative	12 (3.8%)	25 (7.8%)	61 (19.1%)	117 (36.6%)	51 (15.9%)	42 (13.1%)	12 (3.8%)

According to the Table 4.4, more than one-third of the respondents were being neutral in socially confident (122, 38.1%) and critical, quarrelsome (119, 37.2%) while only one respondent answer agree strongly in socially confident, (1, 0.3%). Other than that, thirty percent of the respondents being agreed a little (96, 30.0%) while none of the respondents being disagreed strongly on dependable, self-disciplined. After that, about

thirty percent of the respondents were chose neutral (96, 30.0%) on anxious, easily upset while less than three percent agreed strongly (9, 2.8%) on being anxious, easily upset. After that, for open to new experiences and complex, about one-third of the respondents agreed a little (111, 34.7%) while none of the respondents disagreed strongly. In addition, most of the respondents were neutral on reserved and quiet (91, 28.4%) while only nine respondents agreed strongly on reserved and quiet (9, 2.8%). Furthermore, for sympathetic and warm, most of respondents answered neutral (96, 30.0%) while none of them answered disagree strongly. Next, most respondents answered neutral for disorganized and careless (93, 29.1%) while least of them agreed strongly (8, 2.5%). On the other hand, for calm and emotionally stable, most of respondents also neutral (97, 30.3%) while only one respondents disagreed strongly (1, 0.3%). Lastly, highest number of respondents were chose neutral for ordinary and creative (117, 36.6%).

For Table 4.5, it showed the descriptive frequency for visual learning style. According to it, most of the respondents often remembered something better when they write it down (138, 43.1%) and none of them never remembered something better when they write it down while most of them sometimes take detailed notes during lectures (129, 40.3%) and only two respondents never take detailed notes during lectures. Other than that, more than forty percent of the respondents when they listen, they often visualize pictures, numbers or words in their head (133, 41.6%) but only one respondent never visualize pictures, numbers or words in their head during listening (1, 0.3%). At the same time, more than one third of the respondents prefer to learn with TV or video rather than other media sometimes (115, 35.9%) while only five percent of respondents never prefer to learn with TV or video rather than other media (16, 5.0%). After that, about more than one-third of the respondents also use colour-coding to help them as they learn or work sometimes (112, 35.0%) while least of them never use colour-coding to help during learn or work.

Table 4.5: Descriptive Frequency for Students' Visual Learning Style. (n=320)

Visual Learning Styles	**Frequency, n (%)**				
	Never	**Rarely**	**Sometimes**	**Often**	**Always**
I remember something better if I write it down	0 (0.0%)	8 (2.5%)	73 (22.8%)	138 (43.1%)	101 (31.6%)
I take detailed notes during lectures.	2 (.6%)	26 (8.1%)	129 (40.3%)	110 (34.4%)	53 (16.6%)
When I listen, I visualize pictures, numbers or words in my head.	1 (.3%)	13 (4.1%)	88 (27.5%)	133 (41.6%)	85 (26.6)
I prefer to learn with TV or video rather than other media.	16 (5.0%)	48 (15.0%)	115 (35.9%)	90 (28.1%)	50 (15.6%)

I use colour-coding to help me as I learn or work.	12 (3.8%)	43 (13.4%)	112 (35.0%)	97 (30.3%)	56 (17.5%)
I need written directions for tasks.	4 (1.3%)	18 (5.6%)	124 (38.8%)	122 (38.1%)	52 (16.3%)
I have to look at people to understand what they say.	2 (.6%)	25 (7.8%)	77 (24.1%)	122 (38.1%)	94 (29.4%)
I understand lectures better when professors write on the board	1 (.3%)	11 (3.4%)	106 (33.1%)	114 (35.6%)	88 (27.5%)
Charts, diagrams and maps help me understand what someone says.	3 (.9%)	7 (2.2%)	87 (27.2%)	120 (37.5%)	103 (32.2%)
I remember peoples' faces but not their names.	2 (.6%)	23 (7.2%)	77 (24.1%)	105 (32.8%)	113 (35.3%)

From the Table 4.5 also shown about thirty eight percent of participants often (122, 38.1%) and sometimes (124, 38.8%) need written directions for tasks while only four students never need written directions for tasks (4, 1.3%). In addition, most of the respondents often have to look at people to understand what they say (122, 38.1%) while only two of them never have to look at people to understand what they say (2, 0.6%). Furthermore, highest number of participants often understand lectures better when professors write on the board (114, 35.6%) while lowest number of participants never understand lectures better when professors write on the board. The result also shown that most the students often understand what someone says on charts, diagrams and maps (120, 37.5%) while only three of them never understand what someone says on charts, diagrams and maps (3, 0.9%). Lastly, more than thirty five percent of respondents always remember peoples' faces but not their names (113, 35.3%) but two of them never remember peoples' faces but not their names (2, 0.6%).

Table 4.6: Descriptive Frequency for Students' Auditory Learning Style (n=320)

Auditory Learning Styles	**Frequency, n (%)**				
	Never	**Rarely**	**Sometimes**	**Often**	**Always**
I remember things better if I discuss them with someone.	2 (.6%)	5 (1.6%)	79 (24.7%)	139 (43.4%)	95 (29.7%)
I prefer to learn by listening to a lecture rather than reading.	2 (.6%)	39 (12.2%)	116 (36.3%)	109 (34.1%)	54 (16.9%)

I need oral directions for a task.	4 (1.3%)	27 (8.4%)	143 (44.7%)	111 (34.7%)	35 (10.9%)
Background sound helps me think.	20 (6.3%)	59 (18.4%)	127 (39.7%)	82 (25.6%)	32 (10.0%)
I like to listen to music when I study or work.	21 (6.6%)	49 (15.3%)	95 (29.7%)	97 (30.3%)	58 (18.1%)
I can understand what people say even when I cannot see them.	7 (2.2%)	63 (19.7%)	144 (45.0%)	82 (25.6%)	24 (7.5%)
I remember peoples' names but not their faces.	28 (8.8%)	94 (29.4%)	114 (35.6%)	60 (18.8%)	24 (7.5%)
I easily remember jokes that I hear.	5 (1.6%)	34 (10.6%)	118 (36.9%)	110 (34.4%)	53 (16.6%)
I can identify people by their voices.	3 (.9%)	51 (15.9%)	123 (38.4%)	97 (30.3%)	46 (14.4%)
When I turn on the TV, listen to the sound more than I watch the screen.	24 (7.5%)	76 (23.8%)	102 (31.9%)	90 (28.1%)	28 (8.8%)

According to the Table 4.16 above, more than forty percent of the respondents often remember things better if they discuss them with someone (139, 43.4%) but less than one percent of them never remember things better if they discuss them with someone (2, 0.6%). At the same times, more than thirty five percent of students prefer to learn by listening to a lecture sometimes rather than reading (116, 36.3%) while only two students never prefer to learn by listening to a lecture rather than reading (2, 0.6%). Afterwards, most of the respondents sometimes need oral directions for a task (143, 44.7%) and background sound sometimes help them think (127, 39.7%) while least of them never need oral directions for a task (4, 1.3%) and background sound never help them think (20, 6.3%). Furthermore, more than thirty percent of the respondents often like to listen to music when study or work (97, 30.3%) while less than ten percent of them never like to listen to music when study or work (21, 6.6%) and there were forty five percent of them sometimes can understand what people say even when they cannot see them (144, 45.0%) but only about two percent of them never could understand what people say even when they cannot see them (7, 2.2%). In addition, more than thirty five percent of the respondents sometimes remember peoples' names but not their faces (114, 35.6%) and easily remember jokes that they hear (118, 36.9%) while the least of respondents always remember peoples' names but not their faces (24, 7.5%) and never easily remember jokes that they hear (5, 1.6%). Lastly, most of the respondents sometimes can identify people

by their voices (123, 38.4%) and sometimes when they turn on the TV, they listen to the sound more than they watch the screen (102, 31.9%) while least of participants never could identify people by their voices (3, 0.9%) and when they turn on the TV, they never listen to the sound more than they watch the screen (24, 7.5%).

According to Table 4.7, almost half of the respondents sometimes prefer to start doing things rather than checking the direction first (146, 45.6%) but only eight of them always prefer to start doing things rather than checking the direction first (8, 2.5%) and more than forty percent of the respondents often need frequent breaks when I work or study (140, 43.8%) while only one students never need frequent breaks when I work or study. Other than that, most of the respondents often need to eat something when read or study (117, 36.6%) but least of them never need to eat something when read or study (7, 2.2%). In addition, more than thirty percent of the respondents sometimes if they have a choice between sitting and standing, they rather stand (97, 30.3%) and sometimes get nervous when they sit still too long (101, 31.6%) while at the same time about only seven percent of students always rather stand if they have a choice between sitting and standing (23,7.2%) and always get nervous when they sit still too long (24, 7.5%).

Table 4.7: Descriptive Frequency for Students' Kinaesthetic Learning Style. (n=320)

Kinaesthetic Learning Styles	Frequency, n (%)				
	Never	**Rarely**	**Sometimes**	**Often**	**Always**
I prefer to start doing things rather than checking the direction first.	11 (3.4%)	94 (29.4%)	146 (45.6%)	61 (19.1%)	8 (2.5%)
I need frequent breaks when I work or study.	1 (.3%)	19 (5.9%)	101 (31.6%)	140 (43.8%)	58 (18.1%)
I need to eat something when I read or study.	7 (2.2%)	36 (11.3%)	99 (30.9%)	117 (36.6%)	61 (19.1%)
If I have a choice between sitting and standing, I'd rather stand.	54 (16.9%)	93 (29.1%)	97 (30.3%)	53 (16.6%)	23 (7.2%)
I get nervous when I sit still too long.	47 (14.7%)	87 (27.2%)	101 (31.6%)	61 (19.1%)	24 (7.5%)
I think better when I moved around.	16 (5.0%)	31 (9.7%)	109 (34.1%)	102 (31.9%)	62 (19.4%)
I play with or bite on my pens during lectures.	57 (17.8%)	74 (23.1%)	84 (26.3%)	79 (24.7%)	26 (8.1%)

Manipulating objects help me to remember what someone says.	18 (5.6%)	50 (15.6%)	124 (38.8%)	95 (29.7%)	33 (10.3%)
I move my hands when I speak.	5 (1.6%)	18 (5.6%)	90 (28.1%)	122 (38.1%)	84 (26.3%)
I draw lots of pictures in my notebook during lectures.	24 (7.5%)	77 (24.1%)	85 (26.6%)	78 (24.4%)	56 (17.5%)

From the table 4.7 also shown that more than one third of the respondents sometimes think better when they moved around (109, 34.1%) but a few of them never think better when they moved around (16, 5.0%). Furthermore, more than one fourth of the respondents sometimes play with or bite on my pens during lectures (84, 26.3%) while less than one tenth of them always play with or bite on my pens during lectures (26, 8.1%). Afterwards, most of the respondents also sometimes by manipulating objects, help them to remember what someone says (124, 38.8%) and often move their hands when they speak (122, 38.1%) but least of them never help them to remember what someone says by manipulating object (18, 5.6%) and never move their hands when they speak (5, 1.6%). Lastly, about more than one fourth of the respondents sometimes draw lots of pictures in their notebook during lectures (85, 26.6%) while less than ten percent of students never draw lots of pictures in their notebook during lectures (24, 7.5%).

4.7 Proportion of Dominant Personality Types and Learning Styles

Table 4.8 and 4.9 shows the proportion of dominant personality types and learning styles in respectively. Some respondents had more than one dominant characteristic as they had highest scores in more than one domain of personality and learning styles.

According to the Table 4.8, one fifth of the respondents which is the most possessed more than one personality type (68, 21.2%) which some of them had two or three personality types at the same time through their scores for Personality Types Item in questionnaire while the least were the respondents that possessed extraversion personality (38, 11.9%).

Table 4.8: Frequency of Students' Personality Types (n=320)

Personality Types	Frequency (n)	Percentage (%)
Extraversion	38	11.9
Agreeableness	55	17.2
Conscientioness	52	16.3

Emotional Stability	57	17.8
Openness to Experience	50	15.6
More Than One Personality Type	68	21.2
Total	320	100

Note: Subgrouping was based which personality type domain had the highest mean score.

According to the Table 4.9, most of the respondents possessed visual learning styles (207, 64.7%) while less than ten percent of them possessed more than one learning styles which some of them had two or three different learning styles at the same time.

Table 4.9: Frequency of Students' Learning Styles (n=320)

Learning Styles	Frequency (n)	Percentage (%)
Visual	207	64.7
Auditory	56	17.5
Kinaesthetic	32	10.0
More Than One Learning Style	25	7.9
Total	320	100

Note: Subgrouping were based on which learning styles domain had highest sum scores

4.8 Personality Types of Nursing Students Across Different Demographic and Academic Background

As stated in specific objective #1, the personality types (i.e. 6 subgroups) of nursing students across different demography and academic background were examined as follows:

Independent variables	Dependent variables	Statistical tests
6 subgroupings of personality type (Extraversion, agreeableness, conscientiousness, emotional stability,	Age, CGPA	One-way ANOVA
	Gender, highest academic qualification, current	Chi- square test of independence

openness to experience and more than one personality types)	nursing program, current year of studies and total household income per month	

4.8.1 Mean Difference of Age and CGPA of Respondents Across Personality Type Subgroups

A one-way ANOVA was conducted to determine if respondents' mean age (Table 4.10) and CGPA achievement (Table 4.11) were different across 6 subgroups of personality types. There were no outliers, as assessed by boxplot.

Table 4.10: Differences Between Personality Types and Age of the Respondents (n=320)

Source	Sum of Squares	df	Mean Square	F Ratio	F Probability
Between Groups	13.714	5	2.743	1.876	.098
Within Groups	459.007	314	1.462		
Total	472.722	319			

There was homogeneity of variances, as assessed by Levene's test of homogeneity of variances (p = .098). So, there was no mean differences between age and personality types of respondents, F (5, 314) = 1.876, p > .05, ω2 = 0.014 (see Table 4.26). The personality types had no relationship with age.

Table 4.11: Differences Between Personality Types and CGPA of the Respondents (n=320)

Source	Df	Sum of Squares	Mean Square	F Ratio	*p*-value
Between Groups	5	.486	.097	1.203	.307
Within Groups	314	25.350	.081		
Total	319	25.836			

There was homogeneity of variances, as assessed by Levene's test of homogeneity of variances (p = .307). So, there was no differences between CGPA and personality types of respondents, F (5, 314) = 1.203, p > .05, ω2 = 0.003.

4.8.2 Proportions Difference of Personality Type Subgroups Across Gender, Highest Academic Qualification, Current Nursing Program, Current Year of Studies and Total Household Income Per Month

For sociodemographic variables of categorical data, Chi-square test of independent was employed to determine any significant different proportions of six personality subgroupings across gender, highest academic qualification, current nursing

program, current year of studies and family total household income per month.

Based on the Table 4.12, the Pearson Chi-Square analysed revealed a non-significant relationship existed between personality types of the respondents and their gender, X^2 (5, N=320) = 6.141, p > 0.05. From that table, it showed that most of male and female students were had more than one personality types.

Table 4.12: Association Between Personality Types with Demographic and Academic Background (n=320)

Demographic Characteristics (n)	Personality Types, n (%)								
	Extraversion	Agreeableness	Conscientiousness	Emotional Stability	Openness to Experience	More Than One Personality Types	df	X^2	*p*-value
Gender									
Male (47)	6 (12.8%)	4 (8.5%)	6 (12.8%)	7 (14.9%)	10	14 (29.8%)	5	6.141	0.293
Female (273)	32 (11.7%)	51 (18.7%)	46 (16.8%)	50	(21.3%)	54 (19.8%)			
Total	38 (11.9%)	55 (17.2%)	52 (16.3%)	(18.3%)	40	68 (21.3%)			
				57	(14.7%)				
				(17.8%)	50				
					(15.6%)				
Higher Academic Qualification									
	18 (12.2%)	24 (16.3%)	26 (17.7%)	21	23	35 (23.8%)			
SPM (147)	1 (3.4%)	5 (17.2%)	7 (24.1%)	(14.3%)	(15.6%)	14 (13.8%)			
STPM (29)	19 (13.2%)	26 (18.1%)	19 (13.2%)	7 (24.1%)	5 (17.2%)	29 (20.1%)

Other than that, from the Table 4.12, the Pearson Chi-Square analysed revealed a non-significant relationship existed between personality types of the respondents and their higher academic qualification, X^2 (10, N=320) = 7.684, p > 0.05. Among the 320 respondents, among the students who had SPM as their higher academic qualification, most of them had more than one personality types, (35, 23.8%) which also same with students who had STPM (14, 13.8%) and others (29, 20.1%) as their higher academic qualification. However, among students who had SPM and STPM as their higher academic qualification, least of them had extraversion personality type, (18, 12.2%) and (1, 3.4%) respectively.

Furthermore, based on the Table 4.12 also showed the Pearson Chi-Square analysed revealed a non-significant relationship existed between personality types of the respondents and their current nursing program, X^2 (5, N=320) = 2.782, p > 0.05. Among the nursing students who had diploma as their current nursing program, most of the students had more than one personality types (38, 23.8%) while the least of them were had extraversion personality type (17, 10.6%). At the same time, for baccalaureate nursing students, most of the students were had emotional stability personality type (32, 20.0%) while least of them also had extraversion personality type (21, 13.1%).

In addition, the Pearson Chi-Square analysed also revealed a non-significant relationship existed between personality types of the respondents and their current nursing program, X^2 (15, N=320) = 14.217, p > 0.05. Among the Year 1 nursing students, most of the students had more than one personality types (21, 23.6%) while only eight students had agreeableness personality type (8, 9.0%). However, for Year 2 nursing students, most of them were possessed on agreeableness personality type (21, 20.2%) while the least were openness to experience personality type (14, 13.5%). Different with Year 3 nursing students, most of them had more than personality types which same like Year 1 (24, 25.5%) but least of them had extraversion personality type (10, 10.6%). For the Year 4 nursing students which were final year, most of them had emotional stability personality type (8, 24.2%) while least of them had extraversion personality type (2, 6.1%).

Lastly, based on the Table 4.12, the Pearson Chi-Square analysed revealed a non-significant relationship existed between personality types of the respondents and their family total household income per month, X^2 (15, N=320) = 14.217, p > 0.05. Among the nursing students who had family total household income per month that below than RM3000, most of them were had more than personality types (36, 22.4%) which also same goes with the nursing students who had family total household income per month that between RM3000 to RM5000 (23, 20.5%) while for least of them, both also had extraversion personality type, (18, 11.2%) and (15, 13.4%) respectively. Different with the nursing students who had family total household income per month that more than RM5000, most of them were had agreeableness personality type (11, 23.4%) while least of them were had extraversion and conscientiousness personality type which both were shared same result (5, 10.6%).

4.9 Learning Styles Across Different Demographic and Academic Background

To achieve specific objective #2, learning styles in relation to different demography and academic background were identified as follows:

Independent variables	Dependent variables	Statistical tests
4 subgroupings of learning styles (visual, auditory, kinaesthetic and more than one learning styles	Gender, highest academic qualification, current nursing program, current year of studies and total household income per month	Chi- square test of independence
	Age, CGPA	One-way ANOVA

4.9.1 Proportions Difference of Learning Styles Subgroups Across Gender, Highest Academic Qualification, Current Nursing Program, Current Year of Studies and Total Household Income Per Month

For sociodemographic variables of categorical data, Chi-square test of independent was employed to determine any significant different proportions of 4 learning styles subgroupings across gender, highest academic qualification, current nursing program, current year of studies and total household income per month.

Table 4.13: Association Between Learning Styles with Demographic and Academic Background of the Respondents (n=320)

Demographic Characteristics	Learning Styles, n (%)						
	Visual	Auditory	Kinaesthetic	More than One	df	X^2	*p*-value
Gender							
Male	24 (51.1)	13 (27.7)	6 (12.8)	4 (8.5)			
Female	183 (67.0)	43 (15.8)	26 (9.5)	21 (7.7)	3	5.286	.152
Total	207 (64.7)	56 (17.5)	32 (10.0)	25 (7.8)			
Higher academic qualification	75 (51.0)	37 (25.2)	23 (15.6)	12 (8.2)			
SPM	18 (62.1)	5 (17.2)	3 (10.3)	3 (10.3)			
STPM	114 (79.2)	14 (9.7)	6 (4.2)	10 (6.9)	6	28.853	.001

< RM3000	101 (62.7)	26 (16.1)	16 (9.9)	18 (11.2)			
RM3000 – RM5000	71 (63.4)	24 (21.4)	11 (9.8)	6 (5.4)	6	7.746	.257
> RM5000	35 (74.5)	6 (12.8)	5 (10.6)	1 (2.1)			
Total	207 (64.7)	56 (17.5)	32 (10.0)	25 (7.8)			

According to table 4.13, for the gender, the Pearson Chi-Square analysed revealed a non-

significant relationship existed between learning styles of the respondents and their gender, X2 (3, N=320) =5.286, p > 0.05. Male students usually more possessed on visual learning style (24, 51.1%) while least of them were had more than one learning styles (4, 8.5%). Same goes with female students, they also more possessed on visual learning style (183, 67.0%) while least of them were had more than one learning styles (21, 7.7%).

Other than that, the Pearson Chi-Square analysed revealed a significant association between learning styles of the respondents and their higher academic qualification, X2 (6, N=320) =28.853, p < 0.05. Students who had SPM as their higher academic qualification, most of them were possessed with visual (75, 51.0%) as their learning styles while least of them were had more than one learning styles (12, 8.2%). This result also same towards students who had STPM as their higher academic qualification which were most of them have visual learning styles (18, 62.1%) while least of them have more than one learning styles and also kinaesthetic learning styles, (18, 62.1%). For students with others (matriculation or foundation) as their higher academic qualification, majority of them were had visual learning styles (114, 79.2%) while only about four percent of them were possessed with kinaesthetic learning style (6, 4.2%).

For the current nursing program, the Pearson Chi-Square also analysed revealed a significant relationship existed between learning styles of the respondents and their current nursing program, X^2 (3, N=320) =28.232, p < 0.05. Among the 320 respondents, most of diploma nursing students more possessed on visual learning style (83, 51.9%) which also same with baccalaureate nursing students (124, 77.5%). Meanwhile, least of diploma nursing student were had more than one learning styles (12, 7.5%) while only five percent of baccalaureate nursing students were possessed kinaesthetic learning styles (8, 5.0%).

Furthermore, the Pearson Chi-Square analysed revealed a non-significant relationship existed between learning styles of the respondents and their current year of course, X^2 (9, N=320) =5.342, p > 0.05. Among the 320 respondents, most of Year 1 until Year 4 nursing students more tend to had visual learning styles, (60, 67.4%), (69, 66.3%), (56, 59.6%) and (22, 66.7%) respectively. Meanwhile, among Year 1 nursing students, least of them were kinaesthetic learner (8, 9.0%) but among Year 2 and Year 3 nursing students, least of them were had more than one learning styles, (6, 5.8%) and (7, 7.4%) respectively. For Year 4 nursing students, least of them were kinaesthetic and had more than one learning styles which showed the same result, (3, 9.1%).

Lastly, the Pearson Chi-Square analysed also revealed a non-significant relationship existed between learning styles of the respondents and their family total household income per month, X^2 (6, N=320) =7.746, p > 0.05. Among the 320 respondents, among nursing students who had family total household income per month less than RM3000, they more possessed on visual learning styles (101, 62.7% while least of them were kinaesthetic learner which consisted only less than ten percent among them (16, 9.9%). Same goes with nursing students who had family total household income per month between RM3000 to RM5000 and more than RM5000, most of them also possessed more towards on visual learning styles, (71, 63.4%) and (35, 74.5%) respectively but least of them for both also were had more than one learning styles, (6, 5.4%) and (1, 2.1%) respectively.

4.9.2 Mean Difference of Age and CGPA of Respondents Across Learning Style Subgoups

A one-way ANOVA was conducted to determine if respondents' mean age (Table 4.14) and CGPA achievement (Table 4.15) were different across 4 subgroups of learning styles. There were no outliers, as assessed by boxplot**.**

Table 4.14: Differences Between Learning Styles with Age of the Respondents (n=320)

Source	df	Sum of Squares	Mean Square	F Ratio	F Probability

Between Groups	3	1.113	.371	.249	.862
Within Groups	316	471.609	1.492		
Total	319	472.722			

There was homogeneity of variances, as assessed by Levene's test of homogeneity of variances (p = .862). So, there was no differences between age and learning styles of respondents, F (3, 316) = .249, p > .05, ω2 = -0.007. Learning styles have no relationship with age.

Table 4.15: Differences Between Learning Styles with CGPA of the Respondents (n=320)

Source	df	Sum of Squares	Mean Square	F Ratio	F Probability
Between Groups	3	.203	.068	.832	.477
Within Groups	316	25.633	.081		
Total	319	25.836			

There was homogeneity of variances, as assessed by Levene's test of homogeneity of variances (p = .862). So, there was no differences between CGPA and learning styles of respondents, F (3, 316) = .832, p > .05, ω2 = -0.002. Learning styles have no relationship with CGPA achievement.

4.10 Relationship Between Personality Types and Learning Styles

To achieve specific objective #3, the relationship between learning styles and personality types of nursing students were examined on the extent the distribution of the personality scores correlated with learning styles scores.

Table 4.16: Correlation Between Personality Types and Learning Styles of the Respondents (n=320)

	Visual (r)	Auditory (r)	Kinaesthetic (r)
Extraversion	.160*	.014	.049
Agreeableness	.062	-.044	-.049
Conscientiousness	.122*	-.037	-.053
Emotional Stability	.115*	.041	.132*
Openness to Experience	.099	-.035	.011

*. Correlation is significant at the 0.05 level (p-value < 0.05)

A Pearson's product moment correlation also was run to assess the association between personality types of and their learning styles. Based on the Table 4.16, study conclusions are as follows:

a) A significant weak positive correlation between extraversion and visual, r = .160, p < .05. So, there is small possibility that students who inclined towards extraversion personality maybe also preferred visual learning styles.
b) A significant weak positive correlation between conscientiousness and visual, r = .122, p < .05. So, there is small possibility that students who inclined towards conscientious personality maybe also preferred visual learning styles.

c) A significant weak positive correlation between emotional stability and visual, $r = .115$, $p < .05$. So, there is small possibility that students who had emotional stability personality maybe also preferred visual learning style.

d) A significant weak positive correlation between emotional stability and kinaesthetic, $r = .132$, $p < .05$. So, there is small possibility that students who had emotional stability personality maybe also preferred kinaesthetics learning style.

CHAPTER 5: DISCUSSION, RECOMMENDATION AND CONCLUSION

5.1 Introduction

In this chapter, the researcher discussed the finding of the research in detail and some comparisons were made with the previous studies. Besides that, some limitations that associated to this study were identified. To minimize these limitations in further studies that related to this research topic, some suggestions were recommended.

5.2 Discussion

Discussion of the findings were based on the objective of the study as below:

1. To identify learning styles preferences during classroom lessons among nursing students across different demography and academic background.
2. To examine personality types of nursing students across different demography and academic background.
3. To determine association between learning styles preferences and personality types of nursing students.

5.3 Association Between Personality Types with Demographic and Academic Background

The demographic and academic background that tested in this study were age, gender, higher academic qualification, current nursing program, current year of the course, CGPA and family total household income per month of the respondents. There is no association between personality types with any demographic and academic background in this study. From my study, it shows that demographic characteristics like age, gender and family income did not influence personality of an individual. A quite same study also conducted by Ming Li (2013) and the result showed that some demographic characteristics like age and gender not associated with personality types.

Meanwhile in another study also done which was by Meera Komarraju (2011) with the title of The Big Five Personality Traits, Learning Styles and Academic Achievement. From the study, it is interesting that three personality traits which are openness to exprience, agreeableness, and conscientiousness were positively correlated with CGPA (Meera, 2011). Conscientiousness appears to assist a variety of effective learning strategies and may be an useful trait for attaining high levels of academic achievement (Meera, 2011). Students who are careless and do not study systematically are more likely to see their performance down (Meera, 2011). Both agreeableness and openness also were positively associated with CGPA (Meera, 2011). This suggests that besides being conscientious, students may also benefit from being cooperative and intellectually curious (Meera, 2011).

The association of personality type to academic achievement development is of approximately the same magnitude as the association of home environment, maternal education, or family income to academic achievement development. All of these associations are small, but they are genuinely meaningful for understanding individual differences in development. So, other study showed that personality types were associated with academic background and academic achievement meanwhile this study showed the vice versa. It might be because of some limitations through this study like the respondents used were only from specific setting and the total respondents were not large enough.

5.4 Association Between Learning Styles with Demographic and Academic Background

The demographic and academic background that tested in this study were age, gender, higher academic qualification, current nursing program, current year of the course, CGPA and family total household income per month of the respondents. The findings of this study showed that the learning styles of the nursing students during classroom lessons were significantly associated with higher

academic qualification and current nursing program of the respondents while others were not significantly associated with learning styles.

Nursing students who had SPM as their higher academic qualification possessed more towards auditory and kinaesthetic as their learning styles while students who had STPM as their higher academic qualification more possessed on more than one learning styles. For the visual learning styles, students who had others like matriculation and foundation as their higher academic qualification were more prone to it. It suggested that this may due to different approaches and teaching method used by teachers and lecturers during secondary education and tertiary education. During secondary school, usually teachers tend to give instructions, provide verbal reinforcement, always held some activities which allow students to participate in learning and encourage notetaking. That was suggested why students who had SPM as their higher academic qualification possessed more towards auditory and kinaesthetic as their learning styles. At the same time, during matriculation and foundation, lecturers tend to use video equipment like projector and slide, providing assignments in writing and using charts and pictures during teaching and learning process. That might be the answer why students who had matriculation and foundation as their higher academic qualification more possessed on visual learning style.

For the current nursing program, among the 320 respondents, diploma nursing students more possessed on auditory and kinesthetic as their learning styles while bachelor nursing students more tend to had visual as their learning styles and also had more than one learning styles. This may due to diploma nursing students mostly had SPM as their higher academic qualification while bachelor nursing students mostly had STPM, matriculation and foundation as their higher academic qualification.

But a past study which done by Bhavna Prajapati (2011) on The Influence of Learning Styles, Enrolment Status and Gender on Academic Performance of Optometry undergraduates showed that there were no significant relationship between demographic backgrounds of the students include gender, enrolment status and also their academic performance with learning styles.

Another study also conducted which showed that there is no direct relationship between learning styles and student's academic background and achievement (Nur Aniza, 2011). But according to her, learning styles have significant relationship with learning strategies, which are significantly correlated with achievement (Nur Aniza, 2011). From her study, it can be concluded that learning styles have an indirect relationship with achievement through learning strategies (Nur Aniza, 2011).

However, the effect of learning style preferences on academic performance still needs further investigation. The inappropriate use of learning style inventories make the students confine to one or more group of styles (Murphy et al. 2004). Students also may need to adapt to the real environment, and refrain from adhering to their own preferred styles (Murphy et al. 2004).

Meanwhile, a few studies also examined the relationship between the learning styles and academic achievement of university students. Some of these studies found that learning styles of high achieving students were significantly different from those of the low achieving students (Jihan, 2008). Another body of research in this area found that instructors, if tailored their instructional styles to the students' learning styles, would improve the academic achievement of their students (Jihan, 2008).

5.5 Association Between Personality Types and Learning Styles

Result of this study established a number of interesting linkages between relationship between the personality types and learning styles. Taken as a whole, these findings yield a number of insights with potential practical implications on the dynamic interplay between personality types and learning styles. Three personality types which are extraversion, conscientiousness and emotional stability were positively significant but weak with the visual learning style, while emotional stability also had a significant weak positive correlation with kinaesthetic.

It suggested that students who were socially confident, dependable, self-disciplined, calm and emotionally stable are more likely to use visual learning style while the students who were calm and emotionally stable also more likely to use kinaesthetic learning style in maximizing their learning. Such students are likely to be very thorough, good in presentation, understand quickly what the information that consists from the video and picture, know how to relate what they are learning to previous knowledge and to their own lives, and to study in a systematic way (Meera, 2011). For emotionally stable and kinaesthetic learning style, such students usually calm and know how to handle any project or conducting any experiments well.

On the other hand, a study done which was by Mark D. Threeton (2013) on Personality Types and Learning Styles: The tie that binds. In this study, they used Holland's theory of vocational personalities and environment and Kolb's experiential learning theory (ELT). The results also showed that no significant association between personality types and learning styles. But it is difficult to compare the results of this study to past personality and learning style correlational studies as they utilized different instrumentation such as the Myers - Briggs Type Indicator (MBTI) and Kolb's LSI (Mark D. Threeton, 2013).

Another study also conducted which was by Meera Komarraju (2011) with the title of The Big Five Personality Traits, Learning Styles and Academic Achievement. The results showed that Correlation analyses indicated a number of significant relationships. Specifically, consistent with their predictions, openness was positively related with the two reflective learning styles (synthesis-analysis and elaborative processing), neuroticism was negatively related with all the four learning styles, and agreeableness and conscientiousness were positively related to all the four learning styles (Meera, 2011). Finally, extraversion was positively related with fact retention and elaborative processing (Meera, 2011).

5.6 Implication of Study

Nursing Students

There are a few implication of this study towards the nursing students especially who were became the respondents. After they done answering the questionnaire, it may help them to know what their current learning styles and personality types during classroom lessons. This is important to raise their awareness of their own learning style preferences and personality types. When they already aware what their learning styles and preferences, it will encourage the students to expand their learning style repertoire and explore their own personality types. Other than that, it also will help them get to know each other and foster respect for and awareness of diversity in learning styles and personality types.

Nursing Education

There are also a few implication of this study towards the nursing education. Firstly, when the students already know what their own learning styles and personality types, already expanded and explored and got to know their peers' learning styles and personality types, it might help them on improving their academic achievement which may improve the quality of nursing education. Other than that, lecturers also will get to know what learning styles each of their students possessed which may help them to create and apply new teaching methods to use during classroom lessons. This also may help the students to more improve their academic achievement and CGPA.

Nursing Research

Some implication towards nursing research also could be explored through this study. If most students in every universities already knew their learning styles and personality types, it will be more accurate to gain the results if another future research of the same studies are being done between personality types, learning styles and academic background and achievement. At the same time, a few years onwards, the number of students who have high critical skills could be produced which could help in improving the quality not only nursing education, nursing organization, nursing management but also nursing research.

5.7 Recommendation for the Study

Based on the findings presented, some recommendations are suggested especially to students and also lecturers which may help in future research study and also students itself in term of academic achievement and perhaps clinical performances and working performances.

It is good to have the schools and universities let the students know what their learning styles and personality types. Each style preference offers significant strengths in learning and working which help them to take advantage of ways to learn best. The students also can enhance their learning and working power by being aware of and developing the style areas that they do not normally use. Tasks that do not seem quite as suited to their style preferences will help them stretch beyond their ordinary comfort zone, expanding their learning and working potential.

Other than that, by let them knew what their learning styles and personality types, it may help them to raise their awareness, encourage them to expand their learning style repertoire and explore their own personality types and also help them get to know each other and foster respect for and awareness of diversity in learning styles and personality types. From that, it might influence their academic achievement which also may help the future research to validate more whether there is a huge association between personality types, learning styles and academic achievement.

Strategies for teaching auditory students

Educators need to provide as much auditory stimuli as possible. They should provide verbal reinforcement, hold group activities and class discussions (Zayeed, 2007). Other than that, educators can use drills, have students read aloud, and let them make the information into a rhythmic pattern like poem, song, or rap. Educators also should advise the students to make some tapes of class notes and then listen to them which can help to remember details by trying to hear previous discussions, involving in class discussions, ask questions and volunteer in class and tell themselves new information to when they are alone (Zayeed, 2007).

Strategies for teaching visual students

Educators need to provide as many visual information as possible. Strategies for teaching Visual students include using video equipment, giving assignments in writing and encourage in using charts and pictures (Zayeed, 2007). Educators also should use bright colours, encourage students to take notes and draw pictures in their notes to relate with information that they already learnt (Zayeed, 2007). Students should also occasionally change the colour of ink in pens, observe at all the pictures, charts, and graphs in the textbook, read all of assignment directions, visualize new ideas or information presented, read the class title before it is discussed and visualize the details of what is read (Zayeed, 2007).

Strategies for teaching kinaesthetic students

Educators need to hold many activities to allow students to join in learning process. Educators also need to provide hands-on activities, provide for physical movement in the classroom, and encourage in taking notes (Zayeed, 2007). If possible, educators should provide stories filled with action. Additionally, educators also should advise the students to learn by doing, touching, or practicing, write notes to help remember information, take notes during lectures and discussions,

highlight important information in the textbook, always stand up and having stretch breaks, draw pictures of what is learned and build projects to present the ideas (Zayeed, 2007). Students also should summarize their daily activities in the notes to read later (Zayeed, 2007).

5.8 Limitation of the Study

Although our research sheds some valuable insights into the joint influence of personality traits and learning styles on demographic characteristics, academic background and academic achievement, we must acknowledge that it has some limitations. Most notably, future research could seek participants' permission to obtain grades from the records instead of relying on students' self-reported CGPA because it might be the students lied on their CGPA. The questionnaire also only available in English version which may cause some of the students could not get or understand the meaning of certain words and statement and thus could affect the results. On the other hand, the research participants were only nursing students from University of Malaya, UMMC and UITM and therefore, are not representative of all nursing students across Malaysia. Furthermore, data collection was done during class time which might cause the students rushing in answering the questionnaire due to time constraint. So, it might be some students did not answer the question honestly and properly which may lead in difficulty to gain more accurate results.

So, in the future research, it is more better if the questionnaire available not only in English but also in Malay so that all the students could understand all the items in the questionnaire. Number of respondents also should be more larger to gain more accurate results and at the same time the setting of the study also should be more wider which may cover across the Malaysia. Most notably, future research could seek participants' permission to obtain grades from the records instead of relying on students' self-reported CGPA.

5.9 Conclusion

This study revealed that personality types were not associated with any demographic characteristics, academic background and academic achievement eventhough most of the past studies showed that personality types were significantly associated with academic achievement. This might be because of some limitations of this study which caused inaccurate results. Other than that, this study also revealed that learning styles were not associated with demographic characteristics and academic achievement except higher academic qualification and current nursing program. It showed that learning styles of the diploma nursing students and bachelor nursing students were different. Lastly, for association of personality types and learning styles, correlation analysis were conducted and showed that the students who had extraversion, conscientiousness and emotional stability personality type are positively associated with visual learning style. Meanwhile, the students who had emotional stability as their personality type also are positively associated with kinaesthetic learning style.

HEALTHY LIFESTYLE BEHAVIOURS AMONG NURSING AND MEDICAL SCIENCES STUDENTS

Nurul Farhana Binti Nor Hasni
University of Malaya

ABSTRACT

Background: Healthy lifestyle behaviours are important and depend on the early practice of healthy living habits. Health-related behaviour in early stages of life will affect the illness risk that related to lifestyle in later periods of life. As a future health care provider, nursing and medical sciences students need to be healthy as they will be a person who will provide a care to those in ill for the next generation. This study among nursing and medical sciences students will to be useful and will provide a larger view of younger people's condition towards their health.

Aim/ Objective: The aim of this study is to investigate healthy lifestyle behaviour among nursing and medical sciences students of Faculty of Medicine, University of Malaya. Following specifically to examine the level of healthy lifestyle behaviour, comparing the mean differences in the domain of healthy lifestyle behaviours among students and determine association between the level of healthy lifestyle behaviour with the selected demographic characteristics of the student.

Methodology: This is a Cross-Sectional survey research. Method used is Convenience Sampling. Questionnaire used for data collection for students studying is 1176 students of Bachelor of Nursing Science, MBBS, Bachelor Biomed, and Bachelor of Pharmacy. All science programs will be invited to participate. The questionnaire use is 52-item of Health-Promoting Lifestyle Profile II (HPLP II) (Walker, 1996) which composes of six subscales (spiritual growth, interpersonal relations, nutrition, physical activity, health responsibility, and stress management).

Results: 72.6% of the respondents had moderate healthy lifestyle behaviours. The highest mean score for categories of healthy lifestyle behaviours was spiritual growth. Meanwhile, the lowest mean score was physical activity. Family income and student's academic performance (CGPA) both shown significant association with the level of healthy lifestyle behaviours which are p-value 0.01 and 0.04 respectively.

Conclusion: Healthy lifestyle behaviour in this early life influences later risk for lifestyle that leads to chronic disorders. Thus, it is importance to investigate the healthy lifestyle behaviour among university student especially among medical faculty students.

Keywords: Healthy lifestyle behaviour, nursing and Medical Sciences Students, and Dimensions of Health Promoting Lifestyle Profile II.

1.1 Introduction

In this chapter, researcher explained briefly about the introduction and summary to study that has been conducted. The chapter consists of study background, problem statement, significant of the study, objective which includes general and specific objectives, conceptual definition, and the operational definition.

1.2 Study Background

Malaysia is a multicultural and fast-developing country and in these process of achieve a developed and successful nation status in 2020, all citizen have to take part and must be more aware of the importance of healthy lifestyle behaviour which are closely related with living in order to avoid many chronic illness or disease and non-communicable disease (NCD) like diabetes, hypertension, and other heart problem. Healthy lifestyle behaviours can be refer to general activities that will help to improve and increase self-realization and sense of well-being that include acts that assist individuals in maintaining and getting healthy lifestyles behaviour. Healthy lifestyle behaviour in this early life influences later risk for lifestyle that leads to disorders thus, it is importance to investigate the healthy lifestyle behaviour among university student especially among medical faculty students. World Health Organization has determined the age range for this population is between 15 to 24 as youth (WHO, 2017).

Healthy lifestyle behaviour is important in avoidance of many illness and disease. Research has established a genetic links for disease and found that there is relationship between behaviours and disease whereas environmental will influences and brought in progression of diseases (Al-naggarra, 2017).

It is well stated that a healthy lifestyle behaviour is advantage and beneficial in preventing chronic disease such as cancer hence promotion of well-being. Thus, it is importance for determine lifestyle practice and associated factors among university student in Malaysia specifically (Al-naggarra, 2017).

The investigation about healthy lifestyle behaviour among nursing and medical science students are proved to be very useful and benefited complement and it will provide a larger view of younger people's condition towards their health. According to Bergeron, Sebastian, and Eric (2017), it was stated that there is a poor lifestyle choices associated with an increased risk of developing chronic disease in the general population. Nevertheless, there was limited data regarding lifestyle practices of health care professional students. There was an evidence indicates that better health practices among health care professional has relationship with increased confidence and frequency of person going for counselling regarding lifestyle and diet. There is a research conducted to 145 000 United States (US) physicians and results shown that those with a normal body mass index (BMI) were more confident and more likely to exercise and diet rather than those whom obese or overweight. It also stated that female physicians showed that training and self-confidence in nutrition and diet were act as predictors of weight and nutrition. The healthy lifestyle behaviours of health care professionals have been shown to affect credibility regarding their body weight (Bergeron et all., 2017).

Furthermore, according to Bergeron (2017), most of the findings in health care professional students have focused on exercise and a study conducted on medical students were recommended that it is important for them to spent about 150 minutes per week to do moderate activity or 75 minutes per week of vigorous intensity activity that contribute higher physical activity in their future behaviour. As future health care providers in diverse setting, nutrition provide clear and empowering messages about healthier diet and lifestyle behaviour to their

patient one day. Healthy lifestyle behaviour can improve intermediate risk factors for heart disease (cardiovascular) and diabetes and also contribute to avoid chronic diseases in high risk person (DiMaria-Ghalili, 2014). There is a few health care professional programs adequately practical students on nutrition-related issues so that they feel responsible to counsel their patients about healthy lifestyle (Kris-Etherton, 2014).

Healthy lifestyle can be defined as a way of living that lowers the risk of being a seriously sick and not all illness and disease is preventable. Nevertheless, a large proportion of deaths, particularly those from CHD (Coronary heart disease) and also lung cancer. Healthy lifestyle also is a way of living that will help to enjoy more aspects of life and it mainly not just about avoiding a disease or illness. However, it is about physical, mental, and social well-being too. Moreover, healthy lifestyle is a way of living that helps whole family which is when adopting a healthy lifestyle; a person will provide a more positive role model for other people in their family, particular children as well. Healthy lifestyle will help to create a better environment for individual and community to grow up in by helping them to follow a healthier lifestyle that will be contributing to their wellbeing and enjoyment of life now and in the future. For overall picture, healthy lifestyle is not just about avoiding disease, it is also about physical, mental and social wellbeing (Kznhealthgovza, 2017).

Healthy lifestyle behaviour leaves a person fit, energetic, and also it will help to reduced risk for getting disease based on the choices make about daily habits. Daily exercise, sufficient nutrition, and adequate sleep are the foundations for continuing good health. Thus, managing stress in positive ways, instead of through smoking or drinking alcohol, reduces wear and tear on body at the hormonal level. For a comfortable and longer procedure, to be more lifestyle for a healthy lifestyle and live up to it (Clarke, 2017).

1.3 Problem Statement

In any research studies, there are must be have problem statement because it is essential steps in order to identify the problem occur clearly. According to this researcher which is Hernon & Schwarts (2007), a problem statement must be seen specifically, systematically in arrangement, manageable, and the written was done to stimulate other reader interest to spend their time on reading the research work.

Healthy lifestyle behaviours depends on the early practice of heathy living habits and unhealthy lifestyle among student are strongly linked to unhealthy habits in adulthood. Therefore, health-related behaviour in early stages of life will affected the illness risk that related to lifestyle in later periods of life. This is because they are difficult to change these unhealthy habits that adults have adopted in their youth, many effects of healthy risk factors among adults especially student are avoidable if these behaviour are found and changed at an early phase. That way it is important to increase healthy lifestyle behaviour among young people like university student. (Wang et al.,, 2009).

Healthy lifestyle behaviours are closely related to current and subsequent health status. Health has an important and significant place in the lives of all humans being. Humans need to develop healthy lifestyle behaviour to enhance their quality of life, health status and protect their own health. If they perceive their duty, they will try to avoid risky activities and practice behaviour that protects and increase their health status as well. Health is optimal well-being that will help to contributes to a good quality of life of a person. It is more than freedom or away from illness, diseases, or even sickness, though freedom and away from disease is a vital thing to obtain good health. In addition, an optimal health includes high level mental, social, spiritual,

emotional, and also include physical wellness within the limits of one's heredity and individual abilities.

Besides that, university students was represented a major segment of young adult sample and population of teenager. Previous research study on healthy lifestyle indicate that larger amount of younger university students are minimally engaged in healthy lifestyle behaviours such as tobacco use, substance abuse, improper diet control, alcohol consumption, and other improper physical activity (Wang et al., 2013).

World Health Organization given defined health targets for all in 21st century, and also target four aims in order to enhance the health of young people and improve their social responsibilities in assuming roles in society by the year 2020 (WHO 2017). By referring to the study that had done in our country as well as other countries too, it is found that the students practice healthy lifestyle behaviour only at medium level.

In another studies from Turkey, it was stated that 95.6% of university students wanted to be informed about health-related cases, and 23.5%, 18.1%, and 6.6% needed to be informed about protection from diseases, nutrition and their solution, respectively (Hacihasanoglu, 2011). This investigation shown that health problem experienced by university students were caused by lack of information and practice. Moreover, Savci, Ozturk, Arikan, Ince, and Tokgozoglu (2006) determined in their study that physical activity levels of 68% of university students were very low. It is needed to investigate this problem because of student's healthy lifestyle behaviour because of university student were the person who will constitute a large part of the young population (Savci et al., 2006).

Moreover, the study from Eastern Turkey (Hacihasanoglu et al., 2011) also stated that there are decreases in physical activity and unhealthy eating habits that will lead to an increase in obesity among young people and this usually bring a risk factor for health if these kind of habits or attitude are pursed also in adulthood in future.

As a future health care provider, students of Bachelor of Medicine and Bachelor of Surgery (MBBS), Bachelor of Nursing Science, Bachelor of Biomedical Science (Biomed), and Bachelor of Pharmacy need to be healthy as they will be a person who will provide a care, give health education and be role model to client of the next generation and future. The investigations about healthy lifestyle behaviour among nursing and medical science students were proved to be very useful and benefited complement and it will provide a larger view of younger people's condition towards their health status.

1.4 Significant Of Study

1.1.2 1.4.1 Student of Faculty of Medicine, University of Malaya

This research will be benefited to Faculty of Medicine in University of Malaya student especially Nursing students and Medical Sciences students as well. It main purpose is investigate the level of health among Nursing, Bachelor of Medicine and Bachelor of Surgery (MBBS), Pharmacy, and Biomedical students. In fact, healthy lifestyle behaviour in early phase of life effect the disease risk related to lifestyle in later periods of life. Furthermore, it is crucial that this study finding can be used to enhance or improve healthy lifestyle behaviours among young people. This is because, nursing students and all of these medical science students consist of a part of the young population and it is vital to investigate their healthy lifestyle behaviour. Moreover, student will comprehend the importance of health protection and improvement behaviour and transfer their knowledge into practice in life. The student's awareness on healthy lifestyle can be increased too so that chronic disease can be reduced to the minimal prevalence.

Thus, the prevention of diseases from young are very vital like performing and engaging themselves in their daily activities. Therefore, it also can reduce the cost of medical care treatment either from the student herself/himself or the organization of the whole community.

1.1.3 1.4.2 Nursing Profession

The upcoming result of this research study can be used as a guideline to enhance the nursing practice regarding the healthy lifestyle behaviours among nursing students and medical science students by developing a health programs or health education regarding the important of practicing healthy lifestyle behaviour to community especially to students. Besides that, it also can be used as a foundation or base of further research of this study in the next research. Furthermore, apart from the nurse having to strategies on patients' healthcare plans and to produce programs for healthy lifestyle behaviours among nursing students and also medical science students towards improving wellness, nurses can learn many kind of new things and increase their critical thinking on some practicable ideas for creating student education program in order to be a good nurses both now and for future as this can create a healthy generation from many aspect both in mental and physical health.

1.1.4 1.4.3 Organization

The study also marks an impact on Faculty of Medicine, University of Malaya. From the result, the healthy lifestyle behaviour status in Faculty of Medicine can be undated. By the research study of the problem in depth will help in providing the relevance result which can be used as a guideline in controlling the chronic disease in that area. Therefore, the health status of the population in the Faculty can be improves ideally and can lead to the healthy surrounding. The increase in practicing the healthy lifestyle behaviours will provide many advantage and benefit to the university which will decrease the level of illness and chronic diseases among university student in Faculty of Medicine. It also helps in reducing the treatment cost to who have disease and need expensive medical treatment. At the same time, student will not suffer from high, intolerable costs in medical care unit. This surely shown the understanding and cooperation within the organization itself and can also indirectly improve their professionalism and goodness.

1.5 Research Objectives

1.1.5 1.5.1 General Objective

The general objective of this study is to investigate the healthy lifestyle behaviour among nursing and medical science students of Faculty of Medicine, University of Malaya.

1.1.6 1.5.2 Specific Objectives

There are several specific objectives underlying in this research study which is:

1. To examine the level of healthy lifestyle behaviour perceived by the students.
2. To compare the mean differences in the domain of healthy lifestyle behaviours among students.
3. To determine the association between the level of healthy lifestyle behaviour with the selected demographic characteristics of the students.

1.6 Research Questions

The study is conducted to answer the following research objectives:

1. What is the level of healthy lifestyle behaviour among university student?
2. What is the mean difference in the domain of healthy lifestyle behaviour among students?

3. Does the healthy lifestyle behaviour have any association the demographic characteristics of the students?

1.7 Operational Definition

1.1.7 1.7.1 Healthy Lifestyle behaviour

Healthy is a good physical or mental condition, in good health. Whereas lifestyle is a choice a person makes about how to live and behave, according and based on their attitudes, testes, and values. Therefore, healthy lifestyle is a good condition which is appropriate physical and mental to make a choice on how they live and behave (Oxford Dictionaries, 2017). According to the World Health Organization (WHO), Health encompasses with three dimensions which is a complete state of physical, mental, and social well-being and it is not merely absence of diseases or infirmity (WHO, 2017). According to Clarke (2017), a healthy lifestyle leaves a person fit, energetic and at reduced risk for disease, based on the choices a person make about their daily habits. Good nutrition, daily exercise and adequate sleep are the foundation for good health (Clarke, 2017).

In this study, Healthy Lifestyle Behaviour is the process of empowering the students to improve control over their health and its determinants through health effort and multisector action to improve healthy behaviours. This process include many activities for the students at huge or for populations at increased risk of negative health outcomes. This healthy lifestyle is directed toward individual responsibility for health through 6 domains which health responsibility, physical activity, nutrition, spiritual growth, interpersonal relations and also stress management (Walker, 1995).

1.1.8 1.7.2 Behaviour

Behaviour is defined as the way in which one acts or conducts oneself, especially towards others (Oxford Dictionaries, 2017). While, in this study, behaviour in this study can be defined as an attitude or practice toward a healthy lifestyle in order to know the level of healthy lifestyle of each person. It is also refer to the daily activity on what they do towards achieving a good goal in health lifestyle.

1.7.3 Nursing Students

Nursing students are student in a program that will leading to certification in a form of nursing, usually applied to students in a Registered Nurse or practical nurse program (Medilexicon, 2017). Student nurse also can be defined as a person who is training to be a nurse at a nursing school or hospital (Collin English Dictionary, 2017). In other word, nursing student is someone who is studying or training to be a nurse in the future (Collin English Dictionary, 2017).

In this study, nursing student that will be selected was undergraduate nursing student from Faculty of Medicine, University of Malaya. There are 65 students of nursing that will be participants in this study.

1.1.9 1.7.4 Medical Sciences Students

Medical science can be defined as the branch of science concerned with the study of the diagnosis, treatment, and prevention of disease (Oxford Dictionaries, 2017).

Medical sciences are an art and are concerned with the maintenance of health and the prevention, alleviation, or cure of disease. Meanwhile, the field of medicine as it relates to human health is well known, the medical sciences comprise a wide number of specialties (the sciences | Medical science, 2017). Medical science student is a person who, while gifted in the

art of chemistry, biology, and other bodily issues (Urban Dictionary: Health, 2017). According to Oxford (2017), student is a person who is studying at a university or other place of higher education. Based on Webster's New World (2014), student is a person who studies, or investigates and also a person who enrolled for study at a school, or college. They also define it as someone who is learning at a school, or in any teaching environment. Medical science students also can be defined as a person who learning at a college or university (Oxford Dictionaries, 2017)

The application of knowledge to improve health and patient-centred health care requires basic skills in Health Services Research (HSR). HSR is the multidisciplinary field of scientific investigation that studies how social factors, financing systems, organizational structures and processes, affect access to health care, the quality and cost of health care, and ultimately our health and well-being. HSR has a strong foundation in the social- and management sciences (University of Twente, 2017). In addition, it focuses on the design and evaluation of medical-technological, behavioural and organizational interventions as well as the application of that knowledge to improve health and patient centred health care, and to ultimately improve the quality of life (University of Twente, 2017).

While, in this study, student was referred to the person that involving in healthy lifestyle behaviours which is among university student from Faculty of Medicine, University of Malaya. The student consist of undergraduate students from four different course which Pharmacy, Biomedical and also Medicine and Bachelor of Surgery (MBBS) students. In this study, MBBS student can be defined as medical student from Faculty of Medicine, University of Malaya.

Pharmacy students can be defined as an individual who is enrolled as a student in a school or college of pharmacy approved by the Board or accredited by the Accreditation Council for Pharmacy Education (Code of Maryland, 2018). Whereas in this study, pharmacy student defined as a students who studied in pharmacy in Faculty of Medicine, University of Malaya.

Biomedical science student can be defined as a students who focuses on how cells, organs, and systems function in the human body, an exciting and dynamic area that was highly relevant to the understanding and treatment of human disease (Oxford University, 2018). Whereas in this study, pharmacy student defined as a students who studied in biomedical science in Faculty of Medicine, University of Malaya.

1.8 Summary

The first introduction chapter seeks to explain and give an idea on the researcher's background of the study as to make the direction of this paper clearer, easy to understand and provided more detailed on it. The background of the study explained about healthy lifestyle behaviours among nursing students and medical sciences students that include MBBS, Pharmacy, and Biomedical sciences students. Moreover, in this chapter, the impact of healthy lifestyle behaviour provides a greater because of it can affect the whole population in the faculty in the university. The faculty itself will be also getting affected in term of increase in health status. Fewer studies are conducted to assess the populations on healthy lifestyle behaviours. Mainly, the purpose of this research study is to investigate healthy lifestyle behaviours among nursing and medical sciences students.

CHAPTER 2
LITERATURE REVIEW

2.1 Introduction

The aim of this second chapter of this research study is lies in carrying out a critical review or previous study that related to the 'Healthy Lifestyle Behaviours Among Nursing and Medical Sciences Students'. In fact, literature review can serve a number of important functions in the study process and a high role for nurses to develop an evidence-based practice. The entire searching of materials has been done through the Database which is University of Malaya Library Interactive Database and it is available to all students. Medline, PubMed, Google Scholar, Science Direct, Academic Search Elite @ESBSCOhost, and CINAHL Complete @EBSCOhost were selected as the search materials for the period of 2007 – 2017. This is beneficial for the researcher to know and obtain the latest computer development that has been progressing in nursing education.

Researcher used the keywords "Healthy lifestyle behaviours, physical activity, the dimensions/domains of health lifestyle, university students, the effect of socio-economic status on healthy lifestyle behaviour, and the dimensions of healthy lifestyle behaviour, and relationship between each domain of healthy lifestyle behaviour" to facilitate and accelerate the searching process to be more sufficient. From the literature search, the researcher had extracted 363 articles from PubMed, 322000 from Google Schoolar, 10047 from Science Direct, 3318 from Academic Search Elite @ESBSCOhost, and 2463 from CINAHL Complete @EBSCOhost. However, out of these articles, only 80 articles have been selected, because of those articles have provided full text review and are directly related to this research study and after researcher screening and exclusion more briefly, the researcher found that only 38 related and linked article that can be used in this study.

According to Burns et al., 2011, literature can be defined as a broad, systematic, comprehensive in depth, and a critical review of scholarly publication, unpublished scholarly print materials, personal communication and also audio-visual materials. This 'Scholarly Literature' is representing to published and unpublished database literature and conceptual literature materials found in print and also non-print from database resources are reports as a complete research study. To research for literature review, in order to get the most related and linked literature which is has relationship to the studies, a systemic way must be implied in the study in formation and technology course has taught students to find and search database wisely and easily. Thus, in this chapter, the search strategies and review of any related literature will be explained more and in depth (Burns et al., 2011).

2.1.1 Search Strategies

Search strategy was conducted by using keywords based on the research question. In this research study, the researcher use keywords such as healthy lifestyle behaviours, Association Healthy lifestyle behaviour With Demographic Characteristics, The Effect of Socio-economic Status on Healthy Lifestyle Behaviour, and The Dimensions of Healthy Lifestyle Behaviour, and Relationship between Each Domain of Healthy Lifestyle Behaviour. There are many different database were used in this study which are Medline, PubMed, Google Scholar, Science Direct, Academic Search Elite @ESBSCOhost, and CINAHL Complete @EBSCOhost. All articles are search from a fix year which was between 2007 to 2017 only.

This is because, the researcher would like to know the current status and issues that happen about healthy lifestyle behaviours among the university students.

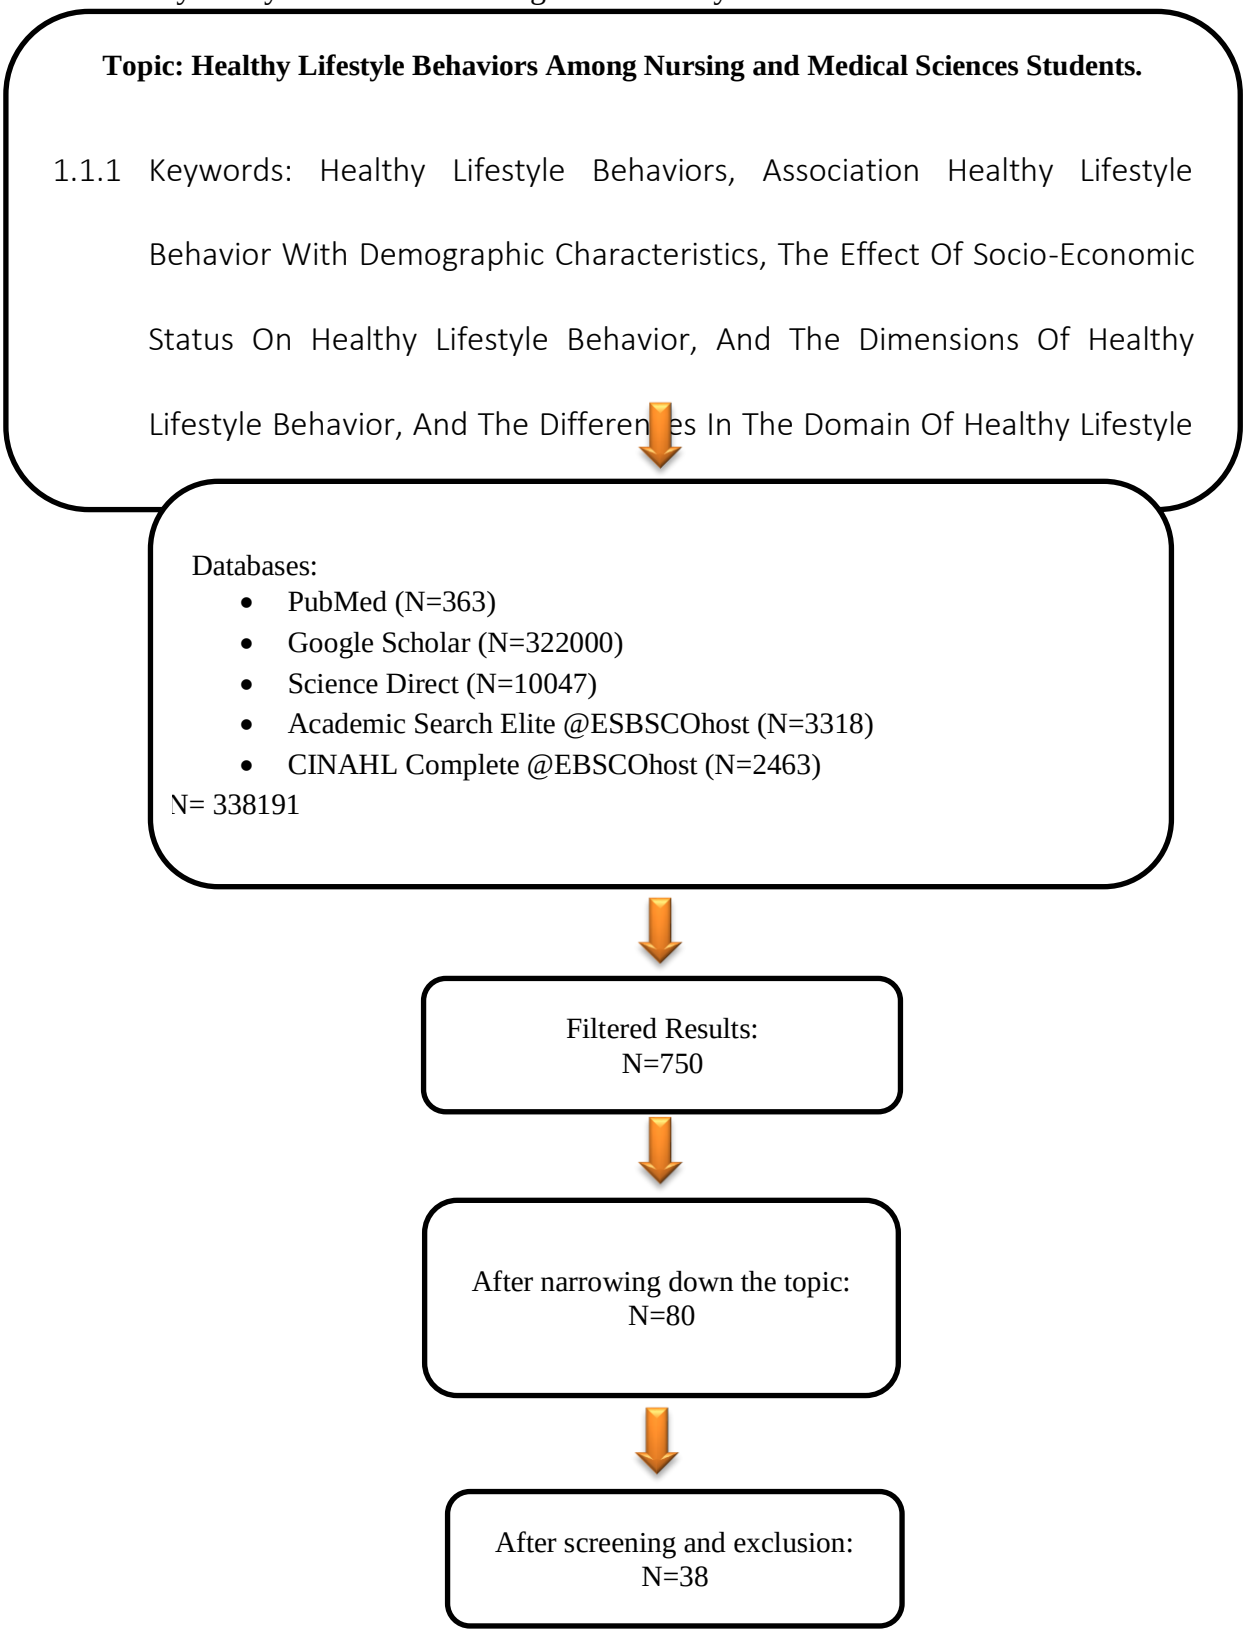

Figure 2.1 Flow Chart of Literature Search

In searching for precise literature, relevant keywords must be highlighted to filter out irrelevant article. The inclusion criteria and characteristics were used to establish a guideline to search for these relevant articles. The following are inclusion criteria were used in this research study:

1. English language articles.
2. Primary search articles (peer-reviewed search, dissertations, evidenced-based practice guidelines)
3. Full text of article only
4. Article that published between year 2007 – 2018

2.2 Result of Key Studies/ Review of the literature

1.1.10 2.2. 1 Healthy Lifestyle Behaviour

Health lifestyle behaviour can be considered as the science and art which will give help to others to change their lifestyle in order to gain an optimal health in life. Health lifestyle behaviour give a person the ability to make a correction and control health, so that it will help to make a person to enjoy health potential and continue to have a healthy lifestyle. Moreover, lifestyle comprises of the decisions on diet, health responsibilities, exercise, stress management and also the action that one takes to achieve those decision making (Paudel, Bhandari, and Arjyal, 2017).

In placing more emphasis to Hancihasanoglu et al., 2011, health related behaviour in early life will provide or produce influences later risks for lifestyle related disorders on a person. Thus, one of these risky groups in society nowadays includes adolescents and young individuals. Therefore, it is crucial to investigate health behaviour among young people since university students is representing a major segment of this population (Hancihasanoglu et al., 2011). Health responsibilities, physical activity, nutrition, interpersonal relationship, stress management and also self-actualization can be include as health improvement behaviours and it act as indicators of an individual's healthy way of life (Hancihasanoglu et al., 2011). So, as a result in many countries, they shown a decrease physical activity and unhealthy eating habits lead to an increase in obesity among young people and this problem distribute a risk for health (Hancihasanoglu et al., 2011).

This claim can also supported by World Health Organization (WHO) (2010), they target for health in the 21st century and they target about four aims to increase health status of young people and their social responsibilities in assuming roles in society by the year of 2020. Furthermore, in an observation-based carried out in Turkey, there are about 95.6% university students who wanted to be informed about health issues, and 23.5%, 18.1% and 6.6% were needed to be informed about protection from diseases, nutrition and psychological problems and their solutions respectively. Thus, due to this study, it shows that health problems experienced by students are caused by lack of information.

There is some review of literature that provided important evidence of increasing unhealthy behaviours among students regarding to dietary, physical activity, drug use, and smoking, there is evidence that students are adopting risky behaviours detrimental to health (Kenny, Holahan, & Taha, 2008). In recent studies, most of the studies found that more female students practice unhealthy behaviours rather than male students especially to physical and dietary habits (Vickers, Patten, Bronars, Lane, Stevens, Croghan, Schroeder, and Clark, 2004). Consequently, the research study were indicated a need for more studies on the health status and lifestyle behaviours of adolescents (especially university students) that represented a vital

group in any nation and country because of education given and leaders for future prospect and model.

The limitation that found in the study of El Ansari (2011) is the population is too small to generalize the results to all university students especially to physical and dietary habit (El Ansari et al., 2011). Therefore, replication of the study with a larger sample and multiple geographic locations may increase the generalizability of the finding. Thus, in my study, researcher will use student from many program which is nursing, MBBS, Pharmacy, and Biomedical Sciences.

According to Gillis (1994), Healthy lifestyle behaviours of individuals are important determinants of health status. In the United States and Canada, about 50% of all health care costs are said to be attributable to unhealthy lifestyle (Gillis, 1994). The International Association for Adolescent Health postulates that the health-compromising behaviours of young people underpin many of their health problems (Tonkin, 2000). Young people represent the future of families, communities, and nations. Unhealthy health practices and behaviours at this stage will continue into adulthood and jeopardize their health status in later life. However, young people are considered to be at a relatively healthy stage of life and, as such, are not viewed as a priority in healthy lifestyle efforts throughout the world (World Health Organization, 1998).

In previous study in Jordan, it is recorded that the total Healthy Lifestyle Behaviours score was 2.5 (SD=0.37) and the result shown that the highest score on the subscales was self-actualization (spiritual growth) which is 2.8 (SD=0.51). Therefore, the score were lower on interpersonal support which is 2.7 (SD= 0.51), nutrition 2.7 (SD=0.58), and health responsibility 2.1 (SD=0.550. Meanwhile, the lowest score was physical activity which is 1.4 (SD= 0.49) (Nassar & Shaheen, 2014).

2.2.2 The Dimensions of Healthy Lifestyle Behavior

1.1.10.1 2.2.2.1 Spiritual Growth

According to Dosse et al., 1989, Spiritual growth focuses on the development of inner resources and is achieved through transcending, developing, and also connecting where transcending puts a person in touch with most balanced selves as it proved with inner peace and opens to possibilities of creating new options for becoming something more by going beyond who and what it is. Whereas connecting is the feeling of harmony, wholeness, and connection with the universe while developing consist of maximizing human potential for wellness through searching for meaning, finding a sense of aim or purpose, and working toward goals in life

1.1.10.2 2.2.2.2 Interpersonal Relations

Interpersonal relations entails utilizing communication to achieve a sense of intimacy and closeness within meaningful, rather than more casual, close and good relationships with others person. Communication involves the sharing of thoughts and feelings through verbal and also nonverbal messages (Travis & Ryan, 1988; Walker et al., 1987). According to Hacihasanoglu (2017), it was stated that score average for female students was higher than male students in this subscale. In this study, there also stated that no significantly difference between gender and interpersonal relations.

2.2.2.3 Nutrition

Based on Ardell (1986), nutrition consists of knowledgeable selection and consumption

of foods essential for sustenance, health, and also well-being. This includes choosing a healthy daily diet consistent with guidelines provided by the Food Guide Pyramid.

According to Thaleia (2015), there was 45% healthy/good health of students considered their diet/nutrition in healthy/good health and it was shown that only 1% having poor healthy lifestyle. According to Bergeron (2017), claims about 59% of pharmacy and medical students were exposed to medium nutrition and 53% of the student have good nutrition (Bergeron, 2017).

Many studies from international were reported on an inadequate consumption of the important foods groups by university students, especially towards dairy products, and also fruits and vegetables. There are only a few South African studies have been conducted on the dietary patterns of Health Science students, and these support some of international trends for example inadequate fruits, vegetables intake and also inactivity. In this previous study, it shown that the dietary intake of Health Science students was not compared with that of other university students. It found that healthier eating and activity patterns in Health Science students were reported in one study, although there are 83% of the sample was found to have an insufficient dairy intake in their life. (Gresse, Steenkamp, & Pietersen, 2015)

1.1.10.3 2.2.2.4 Physical Activity

According to Bouchard, Shepard, Stephens, Sutton, & McPherson, 1990; Dishman, 1988, physical activity were involves regular participation in light, moderate, and/or vigorous activity. Physical activity also may occur within a planned and monitored program for the sake of fitness and health or incidentally as a part of daily life or leisure activities (Bouchard et al., 1990 & Dishman, 1988).

Based on studied from University of Edinburgh, Thaleia Deniozou, June 2015, students was appeared to be overall physically active since majority of the student in the University already met the recommended guidelines for this physical activities. Statistic from this study shown about 42% was categories to be physically active for half an hour or more for 3 to 4 days, for over the past week, whereas about 29% for 5 or more days. In addition, from those student who active in physical activity for 4 days or less, about 62% were indicated that they already active for at least 150 minutes over the course of the past week (Thaleia, 2015). Based on Thaleia's studies, 84% of students self-rated their physical health as good (43%) and poor (3%) only (Thaleia, 2015). There are a guideline that had been published by four UK chief medical officer, Wwwgovuk (2011) recommended that adults should aim to be active daily and over a week. The result comes out about only 29% of students are meeting the recommendation of health for 30 minutes of physical activity most days of the week, encouraging a further 62% are active for 150 minutes. Thus, it shown that majority of students are meeting the time of recommended activity time for adults but not the frequency and this is why it appears to be need to encourage students to be more active that before and always do physical activity more often.

In addition, based on British School (Corder, 2010), not more than half students in British School meet the physical activity guideline and the rest are active students and most of their parent have wrong perception towards their children attending in this physical activity. The purpose of this research is to study student awareness and their parent's perception on the student participation in school activity (Corder, 2010).

Furthermore, other research that aiming university student in Istanbul shows that there are different level of participation on physical activity which are trainer education, physical education and sport teaching. Nevertheless, this research still did not get any result in gender differences of level participation in physical activity (Agopyan, 2015).

1.1.10.4 2.2.2.5 Health Responsibility

Health responsibility involves an active sense of accountability for one's own well-being. It includes paying attention to one's own health, educating oneself about health, and exercising informed consumerism when seeking professional assistance from others (Ardell, 1986).

1.1.10.5 2.2.2.6 Stress Management

According to Antonovsky (1987), stress management entails the identification and mobilization of psychological and physical resources to effectively control or reduce tension. Stress management is valuable for mental health and functioning, include in productive activities and relationship fulfilling (Antonovsky, 1987). According to Krause (1986), they suggest that women seem to be more vulnerable than men to the effects of stressful life events and chronic life stresses, whereas women tend to report more feelings of stress than men despite having larger social network and greater support. In addition, rural women will experience both economic and physical stress due to the distressed farming economy and the high rate of many cases of accidents and injury (Krause, 1986).

2.2.3 The Relationship between Each Domain of the Healthy Lifestyle Behaviour.

According to Pullen et al., 2001, the perceived health status or healthy lifestyle behaviours and the spiritual growth are significantly increased. Therefore, all spiritual has relationship between interpersonal relations, nutrition, physical activity, health responsibilities, and the most significant is stress management. Moreover, for interpersonal relations was explained that it has related which physical activity and nutrition. Interpersonal relation also has related with stress management and both increased significantly. Besides, interpersonal relations also have strong relationship between physical activities. Furthermore, from all of this results, it shown that nutrition have relationship between spiritual, interpersonal relation, nutrition, physical activity, health responsibilities, and also stress management. For physical activity, it was significantly associated or relation between the healthy lifestyle domain except with stress management. According to this study, it shown that health information or health responsibilities was significantly increased with stress management and made a statistically significant independent contribution and related to others domain too. Furthermore, for stress management, it was recorded that all domains have related with each other based on all this results (Pullen et al., 2001).

2.2.4 Association Healthy Lifestyle Behaviour with Demographic Characteristics

2.2.4.1 Age and Gender.

Based on the research study from Eastern Turkey (Hacihasanoglu, 2017) stated that one of the highest risky groups in community includes adolescents and also young individuals. They also found that university student represent a major segment of the young population. According to WHO (1997), the young group is the healthiest person but they also are the most risky one. WHO also has determine that the age range between 10 and 19 years as adolescence and the age range between 15 and 24 as youth as the youth is a period of holistic maturation take part and it is a stage of preparation for their own life. At this stage, youth also a period of transition from childhood to adulthood in which there are many relationship between mental, physical changes, and social relationships. Thus, if each individual get through this period healthy, their chances to be healthy in adult is high. There are many statistics demonstrate that behavioural factors are generally vital and crucial in cases that cause illness or disease in youth as this behavioural are also the indicators of an individual's healthy way of life.

In the study of Eastern Turkey (Hacihasanoglu, 2017), the limitations that been highlighted which is difficult to compare their findings to those from other countries as different measure of healthy lifestyle behaviour were used. Nevertheless, Iran has a 70 million of people that include about 23.7 million of adolescents, therefore this situation contribute a large share of adolescent population in world. Thus, since there are more adolescent in this country, researcher uses university students as participant and sample of study.

According to Sabbah et al., 2013, physical activity is an crucial determinant of quality of life and life satisfaction, among university students (Sabbah et al., 2013). Salami (2010) and Schmidt (2012) were support the results of this study and these studies were provided a collateral explanation for the gender differences in quality of life. For instance, there is an evidence that women are less likely to be physically active than men, and they were found participate in home-based activity like walking (Salami, 2010; & Schmidt, 2012). Overall, men are more likely in vigorous physical activities such as running, or weight lifting rather than women (Huang et al., 2003; Quadros et al., 2009; El Ansari et al., 2011). According to El Ansari et al., 2011, university aged students have high risk of unhealthy lifestyle that might affect their health and also wellbeing (El Ansari et al., 2011).

Based on the research study by Walker et al., 1995, stated that healthy lifestyle behaviour is greater among older people and in the landmark Alameda Country studies that a greater proportion of those older age had good healthy lifestyle behaviour especially concerned with the pattern of nutrition, sleeping, and physical activity than younger age. Later, next studies also have found that older age has significantly higher of healthy lifestyle behaviour especially in nutrition and stress management behaviour. Moreover, regarding to gender, it is reported that female have significant to engage in healthy lifestyle behaviours (Walker et al., 1995).

2.2.4.2 Weight (BMI).

The weight control can escalate to dangerous when a person in other health compromising behaviours while engaging in unhealthy weight control behaviours. A significant relationship between unhealthy weight control behaviour and suicidal ideation in young population was found by Neumark-Sztainer et al., (1998). When linking with gender, previous studies reported that male students are likely to try to lose weight compared to female students (Wardle & Steptoe, 2003). Unfortunately, the desire to be thin creates a pressure on female student to lose their weight continuously and this may be promote unhealthy weight control behaviours for example skipping meals, taking laxatives, diet, pills, food restrictions, or even fasting (Tiggeman, 2006; Pomerleau & Saules, 2007).

Based on the research study from Eastern Turkey (Hacihasanoglu et al., 2011), there are decreases in physical activity and unhealthy eating habits that will lead to an increase in obesity among young people and this usually bring a risk factor for health if these kind of habits or attitude are pursed also in adulthood (Hacihasanoglu et al., 2011).

WHO, 2006 was defined that Body Mass Index (BMI) as the weight in kilograms divided by the square of the height in meters kg/m^2. It is divided into four different categories which is normal weight (BMI 18-2 kg/m^2), underweight (kg/m^2), overweight (kg/m^2), and obesity (BMI >30 kg/m^2). In the study, overweight and obesity are crucial determinants of health and has been associated with adverse metabolic changes for instance increased of blood pressure, cholesterol level, stroke, diabetes mellitus are associated with overweight and obesity (WHO, 2017; Lytie & Black, 2003).

Moreover, some studies shown that BMI is significantly higher among low socio-

economic that middle and high socio-economic groups (Dea, 1999), with lower socio-economic status (SES) being associated with accelerated weight gain during adulthood (Ali & Crowther, 2009; Scully, 2014). According in as study in Eastern Nigeria by Chukwuonye et al., 2013, they shown that the prevalence arises through greater ability of the rich to afford better and excess amount of food sources, and been better educated with higher education, they tend to have office job and rather stay linger in cars (Chukwuonye et al., 2013). Whereas, the person who was poor walk to their class, and this can engaging more in physical activity than the rich was do (Chukwuonye et al., 2013).

1.1.11 2.2.4.3 The Effect of Socio-economic Status.

There are several studies have reported the effect of socio-economic status on healthy lifestyle behaviour. According to Ali and Crowther (2009), they found that the effect of socio-economic status on the prevalence of overweight which is unhealthy health may be mediated by low income which will limit the availability of the more healthy food option and variety type of healthy choices (Ali & Crowther, 2009). There are a study that examined the correlation of mental health and income among students in one of university in Brazil and the result showed a positive relationship between student's income status and mental health (Ali & Crowther, 2009). This is because, income status and social support plays directly and indirectly will affecting health status as well, by restricting the ability to attend hospital and paying for medications and treatment, restricting several lifestyle like consuming healthy food, living in comfort environment, be able to pay for gymnasium for regular exercises and some other luxuries that will makes one live a happy healthy life. However, it stated that most of the respondent had moderate family income (Ali and Crowther, 2009).

2.2.4.4 Academic Performance and Program.

According to Savci et al., (2006), they have determined that in their study physical activity level of 68% of university students were very low. The health problems experienced by students are caused by lack of information (Savci et al., 2006). Based on the educational study that had been carried out by Hsio et al., (2005), there are a significant increases were reported in the total and subscale score averages of healthy lifestyle behaviours. Moreover, Yeh, Chen, Wang, Wen, and Fetzer, (2005) reported that there is positive changes in the healthy lifestyle behaviours of students to increase their healthy lifestyle behaviours (Yeh et al., 2005).

According to Nathalie Bergeron, (2017), clams about 59% of pharmacy and medical students were exposed to medium healthy lifestyle behaviour and 53% of the students have good healthy lifestyle behaviour. Almost majority if the students (74%) were stated to emphasize lifestyle behaviour. Besides, the majority of the students were stated that they have strong healthy lifestyle behaviour especially in nutrition and physical activity (Bergeron et al., 2017). The limitation in their study was the relatively small sample size, originating from Medical students, nursing, pharmacy and biomedical sciences in the state of California. However, the higher healthy lifestyle behaviour are medical students and pharmacy because had meet medium healthy lifestyle behaviour that been recommended (Bergeron et al., 2017). Nevertheless, majority population in faculty of medicine of the students is medical students and pharmacy students (Bergeron et al., 2017).

According to El Ansari et al., 2011, in order to achieve goal of university education, healthy lifestyle would developed to improve the academic performance and avoid ignored health education (El Ansari et al., 2011). From the findings, it shown that uninformed students could lead to inaccurate and incomplete nations regarding health and healthy lifestyle such as

physical activity and fitness as well as weight nutrition consumed (El Ansari et al., 2011). Therefore, as university students are still vulnerable, there is a must to provide research based evidence in order to educate younger students about the lifelong implications that may influenced their healthy lifestyle behaviours (El Ansari et al., 2011).

2.3 Summary

1.1.12 In this chapter, there are many studies which usually discussed about the healthy lifestyle behaviour. Different country have their own result of research study but it is usually depends on the population and the educational level of the people lived in that area. Even the result from every study shown the impressive result, but there is still shows a moderate of healthy lifestyle behaviour among themselves. As a conclusion based on the literature reviewed above, it is well defined that healthy lifestyle can provide effect to the life. This chapter has provided the literature review including introduction of research study, search strategy used are Research Gate, PubMed, Google Scholar, Science Direct, Academic Search Elite @ESBSCOhost, and also CINAHL Complete @EBSCOhost to find research topic related to this study and the use of key term as "healthy lifestyle behaviours", "Association Healthy Lifestyle Behaviour With Demographic Characteristic", and "The Dimensions of Healthy Lifestyle Behaviour", "the differences in the domain of healthy lifestyle behaviours", and "Relationship Between Each Domain Of Healthy Lifestyle Behaviour" to find out more knowledge and understanding about the study being conducted. Furthermore, in this chapter, the researcher more understanding about research topic by dividing it into the subtitles according to study to be conducted. Thus, it will become easier to understand about the study.

CHAPTER 3
METHODOLOGY

3.1 Introduction

In this chapter, the researcher discusses the methodology of the study by explaining in details regarding the study design, study setting, population and sample that were chosen, inclusion and exclusion criteria, research instrument (questionnaires), validity and reliability, ethical considerations, pilot study, data collection method, and data analysis. Furthermore, all the part in methodology is very crucial in order to make sure the study conducted appropriately, properly, and successfully. The ethical and pilot study is also explained. The chosen methodology played an important role in explaining on how the data were obtained and interpreted.

3.2 Study Design

This study is a quantitative study, descriptive cross-sectional surveys design. In quantitative research, it is a formal, rigorous, objective, systematic process to generate numerical information. This study design also were aim to describe new situations, events, or even concepts (Burns & Grove, 2011).

Research design is the process that can help in guiding researchers the ways on how to collect, analyse and also interpret observations. Therefore, in this research study, researcher will use non-experimental, cross-sectional survey and the survey took place at Faculty of Medicine, University of Malaya. Survey was used by researcher to obtain or collect data and any information from the participant that could be involved.

In this study, the researcher will investigate healthy lifestyle behaviour among nursing and medical science students. The researcher gathered objective HLB data directly by using standardized questionnaire. This is because of quantitative study is numeric information that results from some type of formal measurement and that was analysed with statistical procedure (Polit & Beck, 2004). Whereas, descriptive research is the descriptive and exploration of the phenomenon in real life situation or condition. This descriptive research provides an accurate account of characteristic of particular individuals, situation, or groups (Burns & Grove, 2011). The outcomes of this descriptive design research consist of concept, identification of possible relationship between concepts, and development of related hypothesis to the study.

The researcher had chosen this design due to the suitable time consuming. In this study, researcher used Likert Scale questionnaire to discover new information, meaning, and describe what happen in healthy lifestyle behaviour especially among university students. In certain condition, this type of research study design was really helpful and beneficial to the researcher in order to obtain the outcomes of a certain problems occur.

Moreover, this study focused on the healthy lifestyle behaviour among nursing and medical sciences student. Non-experimental research was suitable for the study of student due to several reasons which are: i) human characteristics are inherently not subject to experimental manipulation, for example healthy lifestyle behaviours of the student, ii) non-experimental research are more feasible for researcher that had research constraints on time, personal and type of respondents (nursing and medical sciences students) and the data that being collected at one point in time. Besides, quantitative research approach allowed research to collect data using questionnaire to apply on a large sample size in a shorter period of time and it can be easily analysed using statistical computer programmed (SPSS).

3.3 Study Setting

This research study will be conducted at Faculty of Medicine (FOM), University of Malaya. There are four undergraduate program conducted in the Faculty which is MBBS, Nursing, Biomed and also Pharmacy.

University of Malaya is located in the south-west corner of Kuala Lumpur, the dynamic capital of Malaysia. The name of University of Malaya or 'Universiti Malaya' or UM (in short for both names).

3.4 Population and Sampling

In this section, the researcher explained about the target population and the study sample too which is:

3.4.1 Target Population

Target population can be defined as a survey that the entire set of units for which the survey data to be used to make an inferences (Lavrakas, 2008). Therefore, the target population defines those units for which the findings of the survey are meant to generalize and it is specifically defined as the definition determines whether sampled cases are eligible or ineligible for the survey to carry out (Lavrakas, 2008). Population can be spread into 2 groups which are target population and the other one is accessible population. Target population can be defined as any inferences from a sample refer only to the defined population from which the sample has been properly selected as respondent (Banerjee & Chaudhury, 2010) whereas accessible population can be defined as people from available group that the researcher take into the study. Nevertheless, due to several barrier for example, time, money and personnel, accessible population will be used instead of target population to pursue the study.

Target populations in this study were university students in Faculty of Medicine (FOM), UM. The target population is a large population whom the research study results are to be generalized, so that researcher will select the accessible population of university student from Faculty of Medicine who are currently studying in four undergraduate programs which are Bachelor of Nursing Science, Bachelor of Medicine and Bachelor of Surgery (MBBS), Bachelor of Biomedical Sciences, and Bachelor of Pharmacy. The participant will be filter with inclusion and exclusion criteria.

3.4.2 Sampling Method

Sample is the subset of a population selected as a representative to the population in that area or study setting. While sampling can be defined as the process that been used in a statistical analysis in which a predetermined number of observations are taken from larger population (Investopedia, 2007). Meanwhile, the aim of sampling is to obtain and gather data bout a certain population in order to make an inferences that can be generalized to the population stated.

Meanwhile, the method used in this study is Convenience Sampling. The reason why researcher want to use this convenience sampling as the method of sampling was due to it is the best ways and easy to conduct and inexpensive (Lavrakas, 2008). The researcher will approach and identify the right which is participant who are fulfilling the inclusion and exclusion criteria. The researcher unable to conduct a random sampling method because of the researcher have difficulty to get the participant using sampling frame due to difficulty in distributing the questionnaire to the potential participant of each programs. This is because of the researcher was unable to use probability sampling method due to large sampling frame and having difficulty distributing to student that scattered in various clinical area during data collection period.

The researcher chooses a representative from each program to distribute the questionnaire to students who were available and willing to participate in the study at that particular data collection period. Students from all programs are invited to participate through the program's representative.

1.1.13 3.4.3 Sample Size

In this study, there are about 1245 of undergraduate students in the Faculty of Medicine, University of Malaya in total that include all program of Nursing, MBBS, Biomedical, and Pharmacy. The specific value in their total students for each program was MBBS 800 students, Nursing 63 students, Biomedical 159 students, and for Pharmacy are 223 students.

Researcher using Raosoft calculation to estimate the sample size of the total students and the result from the calculation was 294 samples. It is essential to include attrition rate once the required sample size is calculated. An addition of 10% to 20% from the required sample size will be adequately buffered the attrition bias if there are dropouts or incomplete questionnaires in the study (Rose, Spinks & Canhoto, 2015). Hence, by adding another 10% to 294 participants, the final sample size is 330 participants. The participant was given the questionnaire through representative of each program. All nursing students which are 63 participants were invited in this study (from first year until forth year). Thus, the balance of 330 which is 267 respondents was divided among the three programs through representative. Representative from Pharmacy and Biomedical Sciences have distributed around 90 (from first year until forth year) and 70 respectively (from first year until forth year). Therefore, the balance was given to MBBS students (from first year until fifth year). Postgraduate Master and PhD Student are excluded in this study. Hence, the total amount of the questionnaire that given to each program for this study was; Nursing 56 students, MBBS 114 students, Pharmacy 90 students, and Biomedical Sciences was 70 students. Total respondents were 330 students.

Table 3.1 Calculation of sample size using Raosoft Sample Size Calculator

Description	Calculation
Margin of Error	5%
Confidence Level	95%
Population Size	1245
Response Distribution	50%
Recommend Sample Size	294
Approximate Sample Size	330

1.1.14 3.4.4 Inclusion Criteria

Participants in this study were all students who are currently studying in the four undergraduate programs at Faculty of Medicine, University of Malaya namely Nursing Science, MBBS, Biomed and Pharmacy. The participants who are willing to take part in this research study also the included in this study.

3.5 Research Instrument

The instrument used in this study was questionnaire. The questionnaire was used to collect the data, consisted a series of questions and required the respondents to answer the entire question stated in the questionnaires. Research instrument is a questionnaire used to obtain data. The tool is in English version.

The target populations were university students from Faculty of Medicine, University

of Malaya. All the four programs are conducted in English and the students able to read, write, speak, and understand English language. Therefore, no Malay version needed in the questionnaire for the participants. English language is a requirement to enter this university.

This questionnaire was used to collect and gather the information about healthy lifestyle behaviour of the subject. This questionnaire contains statements about present way of life or personal habits. This research instrument also was adopted from previous research study done by Susan Noble Walker 1995 (Walker et al., 1995).

1.1.15 3.5.1 Questionnaire

In this study, the researcher used questionnaire adapted from Susan Noble Walker (1995) that is previously used in Turkey. The research also has got permission from the respected author. The questionnaire was divided into two section which are Section A and Section B. This set of questionnaire is requiring respondents about 15 to 20 minutes to answer it. This questionnaire contains statement about present way of life or personal habits. Researcher will include 2 sections which are socio-demographic data (7 items), and healthy lifestyle behaviour (52 items).

There are 52-item of Health-Promoting Lifestyle Profile II (HPLP II) questionnaire which is composed of total scale and six subscales to measure behaviours in the theorized dimensions of healthy lifestyle behaviour like spiritual growth, interpersonal relations, nutrition, physical activity, health responsibility, and stress management. All the participants are needed to answer the questions by tick (/) or write the answer at the blank line provided.

1.1.15.1 Part A – Demographic data

The researcher will select demographic variables into 7 items such as age, gender, race or ethnicity, current weight and height (to find their BMI), Program (courses), current academic performance (CGPA) results, and social economic status which include family income. The question of age is used open ended question while the others using multiple choices of question. Demographic is collected to describe the study sample included age, gender, ethnicity, BMI, program (course), family income, and current academic performance of CGPA result.

1.1.15.2 Part B – Health-Promoting Lifestyle Profile II (HPLP II)

There are 52-item of HPLP II that composed of total scale and six subscales to measure behaviours in theorized dimensions of healthy lifestyle behaviours like spiritual growth, interpersonal relations, nutrition, physical activity, health responsibility, and also stress management was included. All the questionnaires used were Likert Scale. This revised tool consists of 52 items, rated on a four-point response format which is never, sometimes, often, and routinely by Walker, Sechrist, and Pender (1995).

The question of the dimension will be separated or divided into each subscales which is consist of 6 items of spiritual growth, 6 items of interpersonal relations, 9 items of nutrition, 9 items of physical activity, 12 items of health responsibility, and there are 10 items of stress management dimension.

The scoring for each level of each domain/subscale for healthy lifestyle behaviour was calculated based on their number of questions (depends on their domain) and it were divided into three categories which are poor, moderate, and good. The calculation was number of questionnaire (times with 4. Because of there were 4 Likert Scale and the maximum number for the Likert Scale was 4) minus with number of questionnaire (times with 1. Because of the minimum number for Likert Scale was 1) then divide by three groups (for scaling them into poor, moderate, and good). The summary calculation for each domain and total HLB as

follows;

Spiritual Growth	(6x4) – (6x1) ÷ 3 = 6 range ∴ 6-12 (poor) 13-19 (moderate) 20 and above (good)
Interpersonal Relations	(6x4) – (6x1) ÷ 3 = 6 range ∴ 6-12 (poor) 13-19 (moderate) 20 and above (good)
Nutrition	(9x4) – (9x1) ÷ 3 = 9 range ∴ 9-18 (poor) 19-28 (moderate) 29 and above (good)
Physical Activity	(9x4) – (9x1) ÷ 3 = 9 range ∴ 9-18 (poor) 19-28 (moderate) 29 and above (good)
Health Responsibility	(12x4) – (12x1) ÷ 3 = 12 range ∴ 12-24 (poor) 25-37 (moderate) 38 and above (good)
Stress Management	(10x4) – (10x1) ÷ 3 = 10 range ∴ 10-20 (poor) 21-31 (moderate) 32 and above (good)
Healthy Lifestyle Behavior	(52x4) – (52x1) ÷ 3 = 52 range ∴ 52-104 (poor) 105-157 (moderate) 158 and above (good)

Figure 3.1 Summary Calculation For Each Domain And Total HLB

The overall healthy lifestyle behaviour score was obtained by calculating the mean of all 52 items which is six subscales measuring the following components of a healthy lifestyle were calculated (health responsibility, physical activity, nutrition, spiritual growth, interpersonal relations, and also stress management). The subscale scores were determined by calculating the mean for the items in the scale and then were divided into number of items for

each domain. This is because, to make sure all the mean was equally divided since each domain contain different number of items. Hence, higher scores indicate a higher level of healthy lifestyle behaviours.

1.1.16 3.5.2 Validity and Reliability

In this study, the face validity was used to measure variable of interest, which can be examined through the use of expected content area. Validity was defines as how well a questionnaire measures what it purported to measure (Colin & Julie, 2005). Therefore, the questionnaire must be appropriate and suit with the objectives of the study. The expert panel were consist of specialists in the field of nursing science, who are 2 lecturers that consist from nursing departments from the Department of Nursing Science of University of Malaya; supervisor (Madam Norsiah Binti Rahmat), other senior (Dr. Chui Ping Lei), and another senior lecturer from other department of Biomedical Sciences (Dr. Nur 'Ain Salehen). For face validity, the experts were asked if all the items in the questionnaires that are relevant to this study.

All the comments and suggestions from the content expert mostly regarding the way of the statement being told as inappropriate word were used. 'I' was added at the beginning of the items to make sentences becomes more appropriate.

While the reliability is the degree to which an assessment tool produces stable and consistent results. Cronbach's Alpha will be used to examine the reliability of the instrument after the pilot study is done since the pilot study will be conducted on March 2018. Reliability must be includes the consistency and stability of the study that will be conducted. The questionnaire had been corrected after evaluation and validation in order to achieve the objectives of the study.

From the validity referral to Susan Nobel Walker (1987). Data from 712 adults aged 18 to 92 were used to assess validity and reliability. Content validity was established by literature review and content experts' evaluation. Construct validity was supported by factor analysis that confirmed a six-dimensional structure of health-promoting lifestyle. Therefore, the alpha coefficient of internal consistency for the total scale was 0.939 by using Cronbach's alpha, alpha coefficients for subscales ranged from 0.824 to 0.892. (Walker et al., 1995).

Reliability of the questionnaire refers to the degree to which an assessment tool (questionnaire) produces stable and consistent result (Colin & Julie, 2005). In this study, the type of reliability used was Cronbach's alpha as the questions had been answer were answer with Likert scale. The instruments of Cronbach's alpha in SPSS version 23.0 and correlation will be used to test for the reliability of questionnaire as the questions were using Likert scale. The acceptable reliability was indicated by a coefficient greater than 0.6 ($r > 0.6$).

The questionnaire tested within the duration of one weeks and pilot study had conducted to test the questionnaire whether it is reliable or not. The pilot study took around 10% from the sample size which was 30 students from Faculty of Medicine, University of Malaya and not used as sample for the real study. From this study for pilot test reliability, the alpha coefficient by using Cronbach's Alpha from the Statistical Package for Social Science (SPSS) version 23 for overall was 0.843. The results is greater than 0.6. Hence, it was reliable for this study. The results of the Cronbach's Alpha for each domain were stated as below:

Table 3.2 Reliability test using Cronbach's Alpha

Instrument Tool	***R***
Spiritual Growth	0.830

Interpersonal Relations	0.797
Physical Activity	0.856
Health Responsibility	0.828
Stress Management	0.895
Overall Healthy Lifestyle Behaviours	0.843

3.6 Ethical Consideration

The study was conducted at the Faculty of Medicine, University of Malaya and the sample populations were the university students of Nursing, MBBS, Biomed and Pharmacy. Hence, the ethical consideration necessary to get permission from 'Student Welfare of University of Malaya' (HEPA), University of Malaya. Thus, a permission letter will be written to HEPA for obtaining a permission to conduct the research study. The researcher provide a letter stating the purpose of this study and to obtain consent from the respondents to participate in this study. The informed consent obtained using cover letter and envelope used to ensure the confidentiality of the data collection.

3.7 Pilot Study

Pilot study is a small scale version, or trial run, and this pilot study was done in preparation for major research study (Lavrakas, 2008). Pilot study was conducted in March 2018. This purpose were test the effectiveness of the questionnaire and it is for the questionnaire fitness to identify any problems that may be arise. The objective of the pilot study was to ensure that the respondent were understood the terminologies, instructions used, questions being asked, and clarity was observed and the instrument used in the study (Lavrakas, 2008).

According to Thabane (2010), pilot study is atrial studies that carry out before a research design is finalized to assist in defining the research question or to test the feasibility, reliability, and validity of the proposed study design (Thabane, 2010). It also can be defined as a small study often done to assist the preparation of a larger and more comprehensive study (Thabane, 2010). The Free Dictionary defines a Pilot Study as a small-scale experiment or set of observations undertaken to decide on how and whether to launch a full-scale project.

In this study, the pilot study was conducted to 10 percent from the total of sample size. Each participant was given about 20 minutes to complete the questionnaire. It is done in March 2018. Therefore, about 30 participants were given the questionnaire. The pilot study took around 10% from the sample size which was 30 students from Faculty of Medicine, University of Malaya and not used as sample for the real study. Therefore, 7 students from Nursing, 7 students from MBBS, 8 students from Pharmacy, and 8 students from Biomedical Sciences were selected in pilot study. Researcher approached the students one by one and obtained the response from them. The participants from the pilot study were excluded from the actual sample for the research. At the end of the pilot study, the result were analysed and some modification had done on the questionnaire before proceed to the collection of data for actual study.

3.8 Data Collection

According to Burns & Grove (2011), data collection is the precise, systematic data gathering of information that relevant to the research purpose or the specific objectives, questions, or even hypotheses of the study (Burns & Grove, 2011). The data collection will be performed on nursing students and medical science students who studying in Faculty of Medicine, University of Malaya that concludes Nursing, MBBS, Pharmacy, and Biomedical

students.

The researcher approaches and identifies the right which is participant who are fulfilling the inclusion and exclusion criteria. A brief and clear explanation of the study and a structured questionnaire were given to the participants. Researcher chooses a representative from each program or courses and provides the question according to the amount of the student for every program. To collect back the questionnaire that had been answered, researcher approached the representative and collects the data.

The data in this study was collected from March until July at Faculty of Medicine, University of Malaya. Respondents' names are not required in the form of questionnaires and all the data collected will be kept confidential and safe. Nevertheless, the participants are allowed to take more time in case of they needed more time to complete the questionnaire. The questionnaires were obtained and envelope will be used to ensure the confidentiality of the data collection. In the questionnaire was attached also with consent form for the participant who indicated they agreed to fill up the questionnaire. Besides, this was a cross-sectional study which examined the subject at one point of time. Therefore, participants were suggested to take 15 to 20 minutes to answer and fill in the questionnaire. The questionnaires recollected by the researcher through the representative after finished answering by the respondents.

3.9 Data Analysis

In this study, the analysis of the data started with the raw data collected from the questionnaire and then was transferred to the computer by using Statistical Package for the social Sciences Version 23.0 (SPSS). Next, the data was analysed using descriptive statistics and it was organized then was summarized the numerical data, gathered from the population and samples. Next, this study was analysed by using inferential statistic which is concerned with population and used sample data to make an inference about the population. The sample is chosen for the study is the representative for the population. The results were presented in percentages (%), means, frequency (*f)* tables, charts, and standard deviation too. In this study, descriptive statistics will be run based on respondent's socio-demographic characteristics and healthy lifestyle behaviour of the students. For inferential statistic, Chi-Square Test was used to analyse and compare the sets of data in the form of frequencies or percentage.

3.10 Gantt Chart

Gantt chart is used in order to help the researcher to plan the work given and finishing time on the accurate and perfect time. Refer Appendix VII.

3.11 Summary

In this chapter, research methodology describes the ways and methods to be implemented in the research survey. The researcher already explained the activity and described the design and method that has been used for this research study. Moreover, this method will give researcher an idea about the implementations of studies to be performed. Questionnaire must be relevant, clear and should be meaningful. For instance, in the demographic data, there is only relevant items specified for each of which will be analysed and linked to other items. Questionnaire should also be compatible with the surrounding community in order to achieve the objectives of the survey. In addition, validity and reliability should also be stated that this of questionnaire stated indicate that can be used for this research project. Besides that, ethical approval for the process is crucial before the study being started. This is vital steps to obtain

permission from the institution and from the participant themselves as well.

CHAPTER 4
DATA ANALYSIS/ RESULT

4.1 Introduction

In this chapter, all the results were analysed to get the research finding and to understand the quantitative information. Data were entered in computer system using Statistical Package for the social Sciences Version 23.0 (SPSS) to analyse the data. Data analysis is a process that involves inspecting, cleaning, and transforming into useful information. In fact, the useful information usually answered the research objective, suggestion hypothesis and conclusion which supporting the decision-making (Farrugia, Petrisor, Farrokhyar, and Bhandari, 2010). This chapter is the main part of research part where all the data will be summarize to know the basic pattern in the data, interpret that data pattern and generalize it. There are two common types of statistical analysis, which is descriptive analysis, and inferential analysis. The descriptive analysis will analyse the demographic characteristic that involve in the research whereas the inferential statistic will elaborate the information that related to association (Chi-Square Test), and relationship (Pearson's Test) (Farrugia et al, 2010).

The data gathered from the samples then were analysed, organized and summarized in a form numerical data. The sample chosen for the study is the representative for the population. Descriptive statistics used were based on respondent's socio-demographic characteristics and healthy lifestyle behaviour of the student. For inferential statistic, Chi-Square test will be used to analyse in order to elaborate the information. The objectives underlying this research is to examine the level of healthy lifestyle behaviour perceived by the students, to compare the mean differences in the domain of healthy lifestyle behaviours among students, and to determine the association between the level of healthy lifestyle behaviour with the demographic characteristics of the students.

4.2 Data Screening

Data screening is very vital and crucial as it will check the correctness and find other potential problems that might occur before analyse the data obtained. The exact goal and aim of this screening and checking data prior to proceeding to final interpretation and testing were to check the correctness of the data and the assumptions were meet.

In the initial stage or phase of the data analysis, all the data that been collected were entered based on the ID number (Questionnaire number) tagged to the questionnaires in accordance to the respondent identification for example, 001, 002, 003 etc. This is performed by the researcher to avoid from double entry of the data. All the data were being screened and no missing value detected. That is why all data entered were checked few times when entered the data in the SPSS 23.0 version to avoid from entered the data wrongly missing data.

4.3 Data Management and Testing the Normality among the Study Variables

For the stage of data management, a normality test had been done on the dependent variables which were the healthy lifestyle behaviours to determine whether the sample data had been drawn from a normality distribution from normality distributed population. Meanwhile, the normality test helped the researcher in selecting the appropriate statistical tests either parametric or non-parametric test in order to analyse the data (Nayak & Hazra, 2011). The results of normality test for dependent variables were shown as below which in Table 4.1.

The test of normality of the healthy lifestyle behaviour among nursing and medical sciences students of Faculty on Medicine, University of Malaya is seen in Table 4.1. All

Skewness and Kurtosis were in range between -2 and 2. The value of mean and median was almost same, and the SD value was less than mean value. Therefore, it was normally distributed.

Table 4.1 Normality test

	Mean (SD)	**Median**	**Variance**	**Skewness**		**Kurtosis**	
				Statistic	**Std. Error**	**Statistic**	**Std. Error**
Spiritual Growth	18.44 (3.09)	18.00	9.565	-0.138	0.140	-0.393	0.279
Interpersonal Relations	18.16 (3.35)	18.00	11.233	-0.056	0.140	-0.632	0.279
Nutrition	20.70 (4.50)	20.00	24.991	0.239	0.140	0.097	0.279
Physical Activity	20.40 (5.68)	20.00	32.337	0.145	0.140	-0.480	0.279
Health Responsibility	30.05 (6.18)	30.00	38.190	0.047	0.140	-0.472	0.279
Stress Management	27.03 (5.37)	27.00	28.857	0.123	0.140	-0.130	0.279
Total HLB	134.78 (20.94)	133.00	438.418	0.109	0.140	-0.753	0.279

4.4 Response Rate

A total of 330 questionnaires were distributed by researcher though representative of each program and collected back on the same day. However, only 317 questionnaires were received with 13 sets were missing as some respondents took the questionnaires and did at another place which at the end went missing. This represented a response rate of 96.06%. Out of 317 questionnaires, 14 respondents did not complete the questionnaire in one or more subsections so that that questionnaire were omitted. Thus, only 303 questionnaires were usable for this study and met the inclusion criteria as discussed in previous chapter. The flow of distribution of questionnaire was displayed in Figure 4.1.

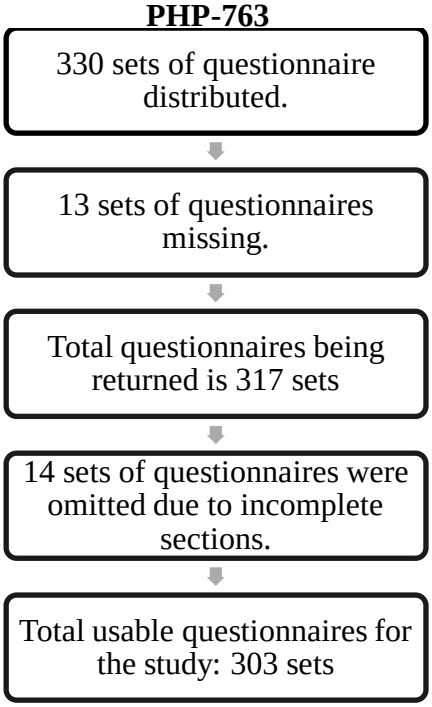

Figure 4.1 Flow of the distribution of questionnaire

4.5 Demographic Analysis

Based on Table 4.2, the demographic characteristics data including age, gender, race/ethnicity, Body Mass Index (BMI), family income, program (course) of the respondents currently studying, and academics performance (CGPA) of the respondents.

Among 303 respondents, there were 73.6% (n=223) were aged between 20 to 22 years old which contributed the highest percentages of the respondents and indicate as younger age, and only 26.4% (n=80) of the respondents were aged 23 and above which contributed the lowest percentage in this study. Besides that, as shown that 65% (n=197) were female respondents which contributed the highest while remaining were male respondents that contribute to 35.0% (n=106).

The ethnicity consists of four ethnics that were Malay, Chinese, Indian and others (Iban, Kadazan, Bajau, and Murut). From the table, it shows that the Malay occupied highest percentage in this study that was 73.6% (n=223), while Indian ethnic contributed only 2.3% (n=7) which was the lowest percentage of the respondents. Meanwhile, Chinese occupied 21.2% (n=64) and the rest was of other ethnicity.

The body mass index (BMI) of the respondents consists of four groups that were underweight, normal, overweight, and obese. Form the table, it shows that the underweight BMI occupied highest percentage in this study that was 65.3% (n=198), while obese BMI contributed only 1.0% (n=3) which was the lowest percentage of the respondents. Meanwhile, normal BMI occupied 30.7% (n=93) and the rest was overweight.

There were 35.6% (n=108) of the respondents had monthly household income range between RM3001 – RM6275 which contributed the highest percentage among the respondents. Meanwhile, only 29.7% (n=90) of the respondents had monthly household income range between RM6276 and above, which contributed the lowest percentage of the respondents. This shows that majority of the respondents were having monthly household income per month between RM3001 – RM6275.

Next, for program (course) aspect, there were 33.0% (n=100) of respondents were

MBBS students, which contributed the highest percentage of the respondents and 18.5% (n=56) of the respondents were Nursing Sciences which contributed the lowest percentage of the respondents. This shows that majority of the respondents in this study were MBBS students.

Lastly, the academic performance (CGPA) of the respondents categorized into three groups: pass, good, and distinction. From the table, it shows that the good CGPA occupied highest percentage in this study that was 71.3% (n=216), while pass CGPA contributed only 9.9% (n=30) which was the lowest percentage of the respondents. Meanwhile, distinction CGPA occupied 18.8% (n=57).

Table 4.2: Demographic characteristic of respondents (n=303)

Demographic characteristic		**Frequency (N)**	**Percent (%)**
Age	20 – 22 years old (younger age)	223	73.6
	23 years old and above (older age)	80	26.4
Gender	Male	106	35.0
	Female	197	65.0
Ethnics	Malay	223	73.6
	Chinese	64	21.2
	Indian	7	2.3
	Other	9	3.0
BMI	Underweight (11.7-18.4)	198	65.3
	Normal (18.5-24.9)	93	30.7
	Overweight (25.0-29.9)	9	3.0
	Obese (30 and above)	3	1.0
Family Income (monthly)	Below than RM3000	105	34.7
	RM3001 – RM6275	108	35.6
	RM6276 and above	90	29.7
Program (Course)	Nursing	56	18.5
	MBBS	100	33.0
	Pharmacy	81	26.7
	Biomedical Science	66	21.8
Student's Academic Performance (CGPA)	Pass (2.50-2.99)	30	9.9
	Good (3.0-3.69)	216	71.3
	Distinction (3.70 and above)	57	18.8
	Total	**303**	**100**

4.6 Descriptive Frequency for Healthy Lifestyle Behaviour

Table 4.3 Frequency table for respondent Healthy Lifestyle Behaviour (N=303)

Statement	Frequency, n (%)				Mean (SD)
	Never	**Sometimes**	**Often**	**Routinely**	
Feel I am growing and changing in positive ways.	7 (2.3)	105 (34.7)	151 (49.8)	40 (13.2)	2.739 (0.710)
I praise other people easily for their achievements	**0 (0.0)**	64 (21.1)	150 (49.5)	89 (29.4)	3.083 (0.707)
I believe that my life has purpose	1 (0.3)	44 (14.5)	123 (40.6)	135 (44.6)	3.294 (0.721)
I accept those things in my life which I cannot change	5 (1.7)	70 (23.1)	146 (48.2)	82 (27.1)	3.001 (0.755)
I look forward to the future	4 (1.3)	61 (20.1)	127 (41.9)	111 (36.6)	3.139 (0.777)
I am aware of what is important to me in life	8 (2.6)	42 (13.9)	140 (46.2)	113 (37.3)	**3.182 (0.766)**
Maintain meaningful and fulfilling relationships with others	3 (1.0)	38 (12.5)	**173 (57.1)**	89 (29.4)	3.149 (0.662)
I spend time with close friends	9 (3.0)	59 (19.7)	129 (43.0)	103 (34.3)	3.092 (0.792)
Touch and I am touched by people I care about	7 (2.3)	59 (19.5)	139 (45.9)	98 (32.3)	3.083 (0.778)
I find ways to meet my needs for a good relationship with others	1 (0.3)	80 (26.4)	146 (48.2)	76 (25.1)	2.980 (0.728)

I feel connected with some force greater than myself	8 (2.6)	97 (32.0)	127 (41.9)	71 (23.4)	2.861 (0.802)

Table 4.3, continued.

Frequency table for respondent Healthy Lifestyle Behaviour (N=303)

Statement	**Never n (%)**	**Sometimes n (%)**	**Often n (%)**	**Routinely n (%)**	**Mean (SD)**
I choose a diet low in fat, saturated fat, and cholesterol	45 (14.9)	157 (51.8)	73 (24.1)	28 (9.2)	2.277 (0.827
I limit use of sugars and food containing sugar (sweets)	46 (15.2)	124 (40.9)	92 (30.4)	41 (13.5)	2.422 (0.909)
I eat about 3 servings of carbohydrate (such as bread, cereal, rice and pasta) each day	29 (9.6)	114 (37.6)	99 (32.7)	61 (20.1)	2.634 (0.910)
I eat 2-4 servings of fruits each day	66 (21.8)	172 (56.8)	46 (15.2)	19 (6.3)	2.052 (0.787)
I eat 3-5 servings of vegetables each day	47 (15.5)	137 (45.2)	86 (28.4)	33 (10.9)	2.347 (0.870)
I eat only 2-3 servings from the meat, poultry, fish, dried beans, eggs, and nuts group each day	18 (5.9)	118 (38.9)	135 (44.6)	32 (10.6)	2.597 (0.757)
I reads labels to identify nutrients, fats, and sodium content in packaged food	65 (21.5)	136 (44.9)	65 (21.5)	37 (12.2)	2.244 (0.928)
Do you aware about calories of food consumption per day?	104 (34.3)	99 (32.7)	66 (21.8)	34 (11.2)	2.099 (1.002)

I exercise vigorously for 20 minutes or more at least three times a week (such as brisk walking, aerobic dancing, using a stair climber)	49 (16.2)	131 (43.2)	81 (26.7)	42 (13.9)	2.383 (0.916)
I take part in light to moderate physical activity (such as sustained walking 30-40 minutes for 5 or more times a week)	31 (10.2)	137 (45.2)	97 (32.0)	38 (12.5)	2.469 (0.841)
I take part in leisure-time (recreational) physical activities (such as swimming, dancing, bicycling)	47 (15.5)	139 (45.9)	88 (29.0)	29 (9.6)	2.327 (0.851)
Get exercise during usual daily activities (such as walking during lunch, using stairs instead of elevators, parking car away from destination and walking)	17 (5.6)	110 (36.3)	128 (42.2)	48 (15.8)	2.683 (0.805)

Table 4.3, continued.

Frequency table for respondent Healthy Lifestyle Behaviour (N=303)

Statement	**Never n (%)**	**Sometimes n (%)**	**Often n (%)**	**Routinely n (%)**	**Mean (SD)**
I check my pulse rate when exercising	102 (33.7)	110 (36.3)	62 (20.5)	29 (9.6)	2.059 (0.961)
I reach my target heart rate when exercising	104 (34.3)	112 (37.0)	65 (21.5)	22 (7.3)	**2.017 (0.922)**
I pace myself to prevent tiredness	62 (20.5)	112 (37.0)	104 (34.3)	25 (8.3)	2.304 (0.888)
Report any unusual signs or symptoms to a physician or other health professional.	47 (15.5)	124 (40.9)	100 (33.0)	32 (10.6)	2.386 (0.872)
Have a good quality of sleep (about 6-8 hours)	27 (8.9)	138 (45.5)	102 (33.7)	36 (11.9)	2.485 (0.817)

I read article or watch media such as TV programs about improving health	10 (3.3)	139 (45.9)	122 (40.3)	32 (10.6)	2.581 (0.723)
I ask detail or further information to health professionals in order to understand their instructions about healthy lifestyle	27 (8.9)	113 (37.3)	137 (45.2)	26 (8.6)	2.535 (0.775)
I get an advice when I have query about my own health status	16 (5.3)	125 (41.3)	136 (44.9)	26 (8.6)	2.568 (0.724)
I discuss my health concerns with health professionals	28 (9.2)	138 (45.5)	113 (37.3)	24 (7.9)	2.439 (0.769)
I aware about long-term goals in my life	11 (3.6)	87 (28.7)	143 (47.2)	62 (20.5)	2.845 (0.784)
I inspect my body once a month for physical changes/danger signs	54 (17.8)	127 (41.9)	91 (30.0)	31 (10.2)	2.327 (0.885)
Balance my time between study and leisure	20 (6.6)	107 (35.3)	151 (49.8)	25 (8.3)	2.597 (0.734)
I ask for information from health professionals about how to take good care of yourself	41 (13.5)	130 (42.9)	119 (39.3)	13 (4.3)	2.343 (0.764)

Table 4.3, continued.

Frequency table for respondent Healthy Lifestyle Behaviour (N=303)

Statement	**Never n (%)**	**Sometimes n (%)**	**Often n (%)**	**Routinely n (%)**	**Mean (SD)**
Expose myself to new experiences and challenges	16 (5.3)	115 (38.9)	129 (42.6)	43 (14.2)	2.657 (0.785)
Discuss my problems and concerns with people close to me.	15	105	128	55	2.736

	(5.0)	(34.7)	(42.2)	(18.2)	(0.812)
I take some time for relaxation each day	7	61	157	78	3.010
	(2.3)	(20.1)	(51.8)	(25.7)	(0.744)
I concentrate on pleasant thoughts at bedtime	20	79	152	52	2.779
	(6.6)	(26.1)	(50.2)	(17.2)	(0.806)
I feel content and at peace with myself	17	89	139	58	2.786
	(5.6)	(29.4)	(45.9)	(19.1)	(0.816)
I find it easy to show concern, love and warmth to others.	10	80	155	58	2.861
	(3.3)	(26.4)	(51.2)	(19.1)	(0.755)
I use specific methods to control my stress	8	87	143	65	2.875
	(2.6)	(28.7)	(47.2)	(21.5)	(0.770)
I find each day interesting and challenging	16	115	132	40	2.647
	(5.3)	(38.0)	(43.6)	(13.2)	(0.775)
I practice relaxation technique or meditation for at least 15-20 minutes daily	76	123	76	28	2.185
	(25.1)	(40.6)	(25.1)	(9.2)	(0.916)
I get support from a network of caring people	20	88	146	49	2.739
	(6.6)	(29.0)	(48.2)	(16.2)	(0.806)
I seek guidance or counselling when necessary	55	104	108	36	2.413
	(18.2)	(34.3)	(35.6)	(11.9)	(0.920)

The overall results of the respondent's HLB are presented in frequency and percentages as displayed in Table 4.3, It is shown that majority of the participants responded "often maintain meaningful and fulfilling relationships with others" were 57.1% (n=173). Besides that, the least of the respondent "never praise other people easily for their achievements" were 0.0% (n=0). The highest mean score for the items is item "I am aware of what is important to me in life" that is 3.294. Meanwhile, the lowest mean score is item "Feel I am growing and changing in positive ways" that is 3.182. This shows that most of the respondents had high healthy lifestyle behaviours in term of aware of what is important to them in life. However, respondent had low healthy lifestyle behaviours with feel growing and changing in positive ways.

4.7 Descriptive Frequency for Domain of Healthy Lifestyle Behaviour (HLB)

4.7.1 Descriptive Frequency for Spiritual Growth Domain of HLB

In Table 4.4, majority of the total respondents chosen the most often practicing that are i) Feel I am growing and changing in positive ways 49.8% (n=151), ii) I praise other people easily for their achievements 49.5% (n=150), iii) I accept those things in my life which I cannot change 48.2% (n=146), iv) I look forward to the future 41.9% (n=127), and v) I am aware of what is important to me in life 46.2% (n=140). Besides, 44.6% (n=135) of total respondents routinely believe that life has purpose.

The least of the respondent never practicing were in the domain of spiritual growth of healthy lifestyle behaviours in feel growing and changing in positive ways 2.3% (n=7), praise other people easily for their achievements 0.0% (n=0), believe that my life has purpose is 0.3% (n=1), accept those things in my life which I cannot change 1.7% (n=5), look forward to the future 1.3% (n=4), and aware of what is important to me in life 2.6% (n=8).

The highest mean score for the items in the domain of spiritual growth is item "I believe that my life has purpose" that is 3.294. Meanwhile, the lowest mean score is item "Feel I am growing and changing in positive ways" that is 2.739. This shows that most of the respondents had high spiritual growth towards healthy lifestyle behaviours in term of believe that their life has purpose. However, respondent had low spiritual growth in statement "feel growing and changing in positive ways".

Table 4.4 Healthy Lifestyle Behaviours: Spiritual Growth (N=303)

Statement	**Frequency, n (%)**				**Mean (SD**
	Never	**Sometimes**	**Often**	**Routinely**

4.7.2 Descriptive Frequency for Interpersonal Relations Domain of HLB

Based on Table 4.5, majority of the respondents often in maintain meaningful and fulfilling relationships with others 57.1% (n=173), spend time with close friends 43.0% (n=129), touch and touched by people care about is 45.9% (n=139), find ways to meet my needs for a good relationship with others 48.2% (n=146), feel connected with some force greater than myself 41.9% (n=127), and settle conflicts with others through discussion and compromise 46.5% (n=141).

The least of the respondent never practicing interpersonal relations towards healthy lifestyle behaviours in maintain meaningful and fulfilling relationships with others 1.0% (n=3), spend time with close friends 3.0% (n=9), touch and touched by people care about is 2.3% (n=7), find ways to meet my needs for a good relationship with others 0.3% (n=1), feel connected with some force greater than myself 2.6% (n=8), and settle conflicts with others through discussion and compromise 0.7% (n=2).

The highest mean score for the items of interpersonal relations towards healthy lifestyle behaviours is item "Maintain meaningful and fulfilling relationships with others" that is 3.149. Meanwhile, the lowest mean score is item "I feel connected with some force greater than myself" that is 2.861. This shows that most of the respondents had high interpersonal relations towards healthy lifestyle behaviours in term of maintaining meaningful and fulfilling relationships with others. However, respondent had low interpersonal relations towards healthy lifestyle behaviours with feel connected with some force greater than them.

Table 4.5 Healthy Lifestyle Behaviours: Interpersonal Relations (N=303)

Statement	**Frequency, n (%)**				**Mean (SD)**
	Never	**Sometimes**	**Often**	**Routinely**	
Maintain meaningful and fulfilling relationships with others	**3 (1.0)**	38 (12.5)	**173 (57.1)**	89 (29.4)	**3.149 (0.662)**
I spend time with close friends	**9 (3.0)**	59 (19.7)	**129 (43.0)**	103 (34.3)	3.092 (0.792)
Touch and I am touched by people I care about	**7 (2.3)**	59 (19.5)	**139 (45.9)**	98 (32.3)	3.083 (0.778)
I find ways to meet my needs for a good relationship with others	**1 (0.3)**	80 (26.4)	**146 (48.2)**	76 (25.1)	2.980 (0.728)
I feel connected with some force greater than myself	**8 (2.6)**	97 (32.0)	**127 (41.9)**	71 (23.4)	**2.861 (0.802)**
Settle conflicts with others through discussion and compromise	**2 (0.7)**	79 (26.1)	**141 (46.5)**	81 (26.7)	2.993 (0.746)

4.7.3 Descriptive Frequency for Nutrition Domain of HLB

In Table 4.6, majority of the total respondents sometimes in taking nutrition for healthy

lifestyle behaviours which are i) I choose a diet low in fat, saturated fat, and cholesterol 51.8% (n=157), ii) I eat 2-4 servings of fruits each day 56.8% (n=172), iii) I eat 2-3 servings of milk, yogurt or cheese each day 53.1% (n=161). Besides, there were 44.6% (n=135) of total respondents often in taking nutrition that it is eat only 2-3 servings from the meat, poultry, fish, dried beans, eggs, and nuts group each day. However, 34.3% (n=104) of the total respondents never aware about calories of food consumption per day.

Apart from that, the least of the respondent is routinely which are choose a diet low in fat, saturated fat, and cholesterol 9.2% (n=28), eat 2-4 servings of fruits each day 6.3% (n=19), and eat 2-3 servings of milk, yogurt or cheese each day 3.6% (n=11). However, 9.6% (n=29) was never eat about 3 servings of carbohydrate each day, 5.9% (n=18) never eat only 2-3 servings from the meat, poultry, fish, dried beans, eggs, and nuts group each day, and 11.2% (n=34) was routinely aware about calories of food consumption per day.

The highest mean score for the items of nutrition domain of healthy lifestyle behaviours is item "I eat about 3 servings of carbohydrate (such as bread, cereal, rice and pasta) each day" that is 2.634. Meanwhile, the lowest mean score is item "I eat 2-3 servings of milk, yogurt or cheese each day" that is 2.023. This shows that most of the respondents had high nutrition towards healthy lifestyle behaviours in term of eat about 3 servings of carbohydrate. However, respondent had low nutrition towards healthy lifestyle behaviours with at 2-3 servings of milk, yogurt or cheese each day.

Table 4.6 Healthy Lifestyle Behaviours: Nutrition (N=303)

Statement	**Frequency, n (%)**				**Mean (SD)**
	Never	**Sometimes**	**Often**	**Routinely**	
I choose a diet low in fat, saturated fat, and cholesterol	45 (14.9)	**157 (51.8)**	73 (24.1)	**28 (9.2)**	2.277 (0.827
I limit use of sugars and food containing sugar (sweets)	46 (15.2)	124 (40.9)	92 (30.4)	41 (13.5)	2.422 (0.909)
I eat about 3 servings of carbohydrate (such as bread, cereal, rice and pasta) each day	**29 (9.6)**	114 (37.6)	99 (32.7)	61 (20.1)	**2.634 (0.910)**
I eat 2-4 servings of fruits each day	66 (21.8)	**172 (56.8)**	46 (15.2)	**19 (6.3)**	2.052 (0.787)
I eat 3-5 servings of vegetables each day	47 (15.5)	137 (45.2)	86 (28.4)	33 (10.9)	2.347 (0.870)
I eat 2-3 servings of milk, yogurt or cheese each day	73 (24.1)	**161 (53.1)**	58 (19.1)	**11 (3.6)**	**2.023 (0.761)**

I reads labels to identify nutrients, fats, and sodium content in packaged food	65 (21.5)	136 (44.9)	65 (21.5)	37 (12.2)	2.244 (0.928)
Do you aware about calories of food consumption per day?	104 (34.3)	99 (32.7)	66 (21.8)	34 (11.2)	2.099 (1.002)

4.7.4 Descriptive Frequency for Physical Activity Domain of HLB

As displayed in Table 4.7, majority of the total respondents sometimes doing physical activity for healthy lifestyle behaviours which are items i) I exercise vigorously for 20 minutes or more at least three times a week (such as brisk walking, aerobic dancing, using a stair climber) 43.2% (n=131), ii) I take part in light to moderate physical activity (such as sustained walking 30-40 minutes for 5 or more times a week) 45.2% (n=137), and iii) I take part in leisure-time (recreational) physical activities (such as swimming, dancing, bicycling) 45.9% (n=139). However most of the students often get exercise during usual daily activities 42.2% (n=128), and never follow a planned exercise program 43.2% (n=131).

Apart from that, the least of the respondent is "routinely" are items: reach target heart rate when exercising 7.3% (n=22), pace self to prevent tiredness 8.3% (n=25), and 5.3% (n=16) are follow a planned exercise program. However, 10.2% (n=31) never take part in light to moderate physical activity (such as sustained walking 30-40 minutes for 5 or more times a week), and 5.6% (n=17) never exercise during usual daily activities.

The highest mean score for the items of physical activity domain of healthy lifestyle behaviours is item "Get exercise during usual daily activities (such as walking during lunch, using stairs instead of elevators, parking car away from destination and walking)" that is 2.683. Meanwhile, the lowest mean score is item "I follow a planned exercise program" that is 1.839. This shows that most of the respondents had high physical activity towards healthy lifestyle behaviours in term of exercise during usual daily activities. However, respondent had low physical activity towards healthy lifestyle behaviours with follow a planned exercise program**.**

Table 4.7 Healthy Lifestyle Behaviours: Physical Activity (N=303)

Statement	**Frequency, n (%)**				**Mean (SD)**

4.7.5 Descriptive Frequency for Health Responsibility Domain of HLB

Table 4.8 shows majority of the total respondents chosen "sometimes" in health responsibility for healthy lifestyle behaviours which are items i) Have a good quality of sleep (about 6-8 hours) 45.5% (n=138), ii) I read article or watch media such as TV programs about improving health 45.9% (n=139), and iii) I discuss my health concerns with health professionals 45.5% (n=138). Besides, there were 45.2% (n=137) of total respondents chosen "often" in asking detail or further information to health professionals in order to understand their instructions about healthy lifestyle, 47.2% (n=143) often aware about long-term goals in life, 49.8% (n=151) often balance time between study and leisure, and 42.6% (n=129) often expose self to new experiences and challenges.

Besides that, the least of the respondent never practicing health responsibility in the domain of HLB were read article or watch media 3.3% (n=10), get an advice when query about own health status 5.3% (n=16), aware about long-term goals in life 3.6% (n=11), expose self to new experiences and challenges 5.3% (n=16). The least chosen "routinely" were 7.9% (n=24) discuss my health concerns with health professionals, 4.3% (n=13) ask for information from health professionals about how to take good care of themselves and 8.3% (n=25) attend educational programs on personal health care.

The highest mean score for the items of health responsibility towards healthy lifestyle behaviours is item "I aware about long-term goals in my life" that is 2.845. Meanwhile, the lowest mean score is item "I attend educational programs on personal health care" that is 2.284. This shows that most of the respondents had high health responsibility towards healthy lifestyle behaviours in term of aware about long-term goals in life. However, respondent had low health responsibility towards healthy lifestyle behaviours is attending educational programs on personal health care**.**

Table 4.8 Healthy Lifestyle Behaviours: Health Responsibility (N=303)

Statement	**Frequency, n (%)**				**Mean (SD)**

I attend educational programs on personal health care	58 (19.1)	**126 (41.6)**	94 (31.0)	**25 (8.3)**	**2.284 (0.868)**
Expose myself to new experiences and challenges	**16 (5.3)**	115 (38.9)	**129 (42.6)**	43 (14.2)	2.657 (0.785)

4.7.6 Descriptive Frequency for Stress Management Domain of HLB

According to Table 4.9, majority of the total respondents were often in stress management for healthy lifestyle behaviours which is i) I take some time for relaxation each day 51.8% (n=157), ii) I concentrate on pleasant thoughts at bedtime 50.2% (n=152), and iii) I find it easy to show concern, love and warmth to others 51.2% (n=155). Besides that, there were 40.6% (n=123) of total respondents practice relaxation technique or meditation for at least 15-20 minutes daily.

The least of the respondent were never managing stress of healthy lifestyle behaviours are 2.3% (n=7) take some time for relaxation each day, find it easy to show concern, love and warmth to others 3.3% (n=10), and use specific methods to control stress 2.6% (n=8). However, there are 9.2% (n=28) and 11.9% (n=36) get support from a network of caring people and seek guidance or counselling when necessary respectively.

Table 4.9 Healthy Lifestyle Behaviours: Stress Management (N=300)

Statement	**Frequency, n (%)**				**Mean (SD)**
	Never	**Sometimes**	**Often**	**Routinely**	
Discuss my problems and concerns with people close to me.	15 (5.0)	105 (34.7)	128 (42.2)	55 (18.2)	2.736 (0.812)
I take some time for relaxation each day	**7 (2.3)**	61 (20.1)	**157 (51.8)**	78 (25.7)	**3.010 (0.744)**
I concentrate on pleasant thoughts at bedtime	20 (6.6)	79 (26.1)	**152 (50.2)**	52 (17.2)	2.779 (0.806)

I feel content and at peace with myself	17 (5.6)	89 (29.4)	139 (45.9)	58 (19.1)	2.786 (0.816)
I find it easy to show concern, love and warmth to others.	**10 (3.3)**	80 (26.4)	**155 (51.2)**	58 (19.1)	2.861 (0.755)
I use specific methods to control my stress	**8 (2.6)**	87 (28.7)	143 (47.2)	65 (21.5)	2.875 (0.770)
I find each day interesting and challenging	16 (5.3)	115 (38.0)	132 (43.6)	40 (13.2)	2.647 (0.775)
I practice relaxation technique or meditation for at least 15-20 minutes daily	76 (25.1)	**123 (40.6)**	76 (25.1)	**28 (9.2)**	**2.185 (0.916)**
I get support from a network of caring people	20 (6.6)	88 (29.0)	146 (48.2)	49 (16.2)	2.739 (0.806)
I seek guidance or counselling when necessary	55 (18.2)	104 (34.3)	108 (35.6)	**36 (11.9)**	2.413 (0.920)

From the table 4.9, the highest mean score for the items of stress management towards healthy lifestyle behaviours is item "I take some time for relaxation each day" that is 3.030 Meanwhile, the lowest mean score is item "I practice relaxation technique or meditation for at least 15-20 minutes daily" that is 2.185. This shows that most of the respondents had high stress management towards healthy lifestyle behaviours in term of take some time for relaxation. However, respondent had low stress management towards healthy lifestyle behaviours is practice relaxation technique or meditation for at least 15-20 minutes daily**.**

4.8 Level of Healthy Lifestyle Behaviours perceived by respondent

4.8.1 Level of Healthy Lifestyle Behaviour: Spiritual Growth

The overall level of spiritual growth perceived by students is 2.38 (0.526). The level of spiritual growth was divided into three categories: poor spiritual growth with the range of score 6 to 12, moderate spiritual growth with the range of score 13 to 19 and good spiritual growth with the range of score 20 and above. As shown in Table 4.10, more than half, 57.8% (n=175) of the respondents had moderate spiritual growth and only 2.0% (n=6) of the respondents had poor spiritual growth of healthy lifestyle behaviour.

Table 4.10 Spiritual *Growth Level (N=303)*

	Range of score	Frequency (n)	Percent (%)
Poor	6 – 12	6	2.0
Moderate	13 – 19	175	57.8
Good	20 & above	122	40.3

4.8.2 Level of Healthy Lifestyle behaviour: Interpersonal Relations

The overall level of interpersonal relations perceived by students is 2.29 (0.558). The level of interpersonal relations was divided into three categories: poor interpersonal relations with the range of score 6 to 12, moderate interpersonal relations with the range of score 13 to 19 and good interpersonal relations with the range of score 20 and above. As shown in Table 4.11, more than half,

60.7% (n=184) of the respondents had moderate interpersonal relations and only 5.3% (n=16) of the respondents had poor interpersonal relations of healthy lifestyle behaviour.

Table 4.11 ***Interpersonal Relations Level (N=303)***

	Range of score	Frequency (n)	Percent (%)
Poor	6 – 12	16	5.3
Moderate	13 – 19	184	60.7
Good	20 & above	103	34.0

4.8.3 Level of Healthy Lifestyle behaviour: Nutrition

The overall level of nutrition perceived by students is 1.74 (0.600). The level of nutrition was divided into three categories: poor nutrition with the range of score 9 to 18, moderate nutrition with the range of score 19 to 28 and good nutrition with the range of score 29 and above. As shown in Table 4.12, more than half, 57.4% (n=174) of the respondents had moderate nutrition and only 8.3% (n=25) of the respondents had good nutrition of healthy lifestyle behaviour.

Table 4.12 ***Nutrition Level (N=303)***

	Range of score	Frequency (n)	Percent (%)
Poor	9 – 18	104	34.3
Moderate	19 – 28	174	57.4
Good	29 & above	25	8.3

4.8.4 Level of Healthy Lifestyle behaviour: Physical Activity

The overall level of physical activity perceived by students is 1.67 (0.606). The level of physical activity was divided into three categories: poor physical activity with the range of score 9 to 18, moderate physical activity with the range of score 19 to 28 and good physical activity with the range of score 29 and above. As shown in Table 4.13, more than half, 52.5% (n=159) of the respondents had moderate physical activity and only 7.3% (n=22) of the respondents had good physical activity of healthy lifestyle behaviour.

Table 4.13 ***Physical Activity Level (N=303)***

	Range of score	Frequency (n)	Percent (%)
Poor	9 – 18	122	40.3
Moderate	19 – 28	159	52.5
Good	29 & above	22	7.3

4.8.5 Level of Healthy Lifestyle behaviour: Health Responsibility

The overall level of health responsibility perceived by students is 1.88 (0.553). The level of health responsibility was divided into three categories: poor health responsibility with the range of score 12 to 24, moderate health responsibility with the range of score 25 to 37 and good health

responsibility with the range of score 38 and above. As shown in Table 4.14, more than half, 68.0% (n=206) of the respondents had moderate health responsibility and only 9.9% (n=30) of the respondents had good health responsibility of healthy lifestyle behaviour.

Table 4.14 ***Health Responsibility Level (N=303)***

	Range of score	Frequency (n)	Percent (%)
Poor	12 - 24	67	22.1
Moderate	25 - 37	206	68.0
Good	38 & above	30	9.9

4.8.6 Level of Healthy Lifestyle behaviour: Stress Management

The overall level of stress management perceived by students is 2.04 (0.547). The level of stress management was divided into three categories: poor stress management with the range of score 10 to 20, moderate stress management with the range of score 21 to 31 and good stress management with the range of score 32 and above. As shown in Table 4.15, more than half, 70.0% (n=212) of the respondents had moderate stress management and only 12.9% (n=39) of the respondents had poor stress management of healthy lifestyle behaviour.

Table 4.15 ***Stress Management Level (N=303)***

	Range of score	Frequency (n)	Percent (%)
Poor	10 – 20	39	12.9
Moderate	21 – 31	212	70.0
Good	32 & above	52	17.2

4.8.7 Level of Overall Healthy Lifestyle Behaviours

The overall level of healthy lifestyle behaviours perceived by students is 2.09 (0.517). The level of healthy lifestyle behaviours was divided into three categories: poor healthy lifestyle behaviours with the range of score 52 to 104, moderate healthy lifestyle behaviours with the range of score 105 to 157 and good healthy lifestyle behaviours with the range of score 158 and above. As shown in Table 4.16, more than half, 72.6% (n=220) of the respondents had moderate healthy lifestyle behaviours and only 9.2% (n=28) of the respondents had poor healthy lifestyle behaviours.

Table 4.16 ***Healthy Lifestyle Behaviours Level (N=303)***

	Range of score	Frequency (n)	Percent (%)
Poor	52 – 104	28	9.2
Moderate	105 – 157	220	72.6
Good	158 & above	55	18.2

4.9 Compare the Mean Differences in the Domain of Healthy Lifestyle Behaviours among Students

Table 4.17 shows the details of the categories of healthy lifestyle behaviours among students and its representative mean score and standard deviation (SD). Overall mean score for healthy lifestyle behaviour among students was 2.59. The highest mean score for categories of healthy lifestyle behaviours was 3.07 which was spiritual growth.. Meanwhile, the lowest mean score was an physical activity that was 2.27. This showed that the most healthy lifestyle behaviour that commonly used among students were spiritual growth. However, the least healthy lifestyle behaviour that commonly used among students was physical activity.

Table 4.17 The means scores of each domain of HLB.

Healthy Lifestyle Behaviours	Mean	Standard Deviation
Spiritual Growth	3.07	3.09
Interpersonal Relations	3.03	3.35
Nutrition	2.30	4.50
Physical Activity	2.27	5.68
Health Responsibility	2.50	6.18
Stress Management	2.70	5.37

4.10 Association between Level of Healthy Lifestyle Behaviours with the Selected Demographic Characteristics of the Students

Table 4.18 shows the chi-square test was conducted between level of healthy lifestyle behaviours and demographic characteristics of the students. The first test is between age and level of healthy lifestyle behaviours. All expected cell frequencies were greater than five. The chi-square analyses reveal no significant difference exist between age and level of healthy lifestyle behaviours, $\chi 2$ (2, N=303) = 1.844, p=.398. Therefore, the result showed that there was no significant association existed between age and level of healthy lifestyle behaviours.

Next, Association between gender and level of healthy lifestyle behaviours also was tested by using chi-square test as shown in the table 4.18. All expected cell frequencies were greater than five. The chi-square analyses reveal no significant difference exist between age and level of healthy lifestyle behaviours, $\chi 2$ (2, N=303) = 3.848, p=.146. Therefore, the result showed that there was no significant association existed between gender and level of healthy lifestyle behaviours.

Association between ethnics and level of healthy lifestyle behaviours also was tested by using chi-square test as shown in the table 4.18. All expected cell frequencies were greater than five. The chi-square analyses reveal no significant difference exist between ethnics and level of healthy lifestyle behaviours, $\chi 2$ (6, N=303) = 6.204, p=.401. Thus, the result showed that there was no significant association existed between ethnics and level of healthy lifestyle behaviours.

Next, for association between Body Mass Index (BMI) and level of healthy lifestyle behaviours also was tested by using chi-square test as shown in the table 4.18. All expected cell frequencies were greater than five. The chi-square analyses reveal no significant difference exist between ethnics and level of healthy lifestyle behaviours, $\chi 2$ (6, N=303) = 5.515, p=.480. Thus, the result showed that there was no significant association existed between BMI and level of healthy lifestyle behaviours.

Table 4.18 Association between level of healthy lifestyle behaviours with the selected demographic characteristics of the students (N=303)

Demographic characteristic	Level of healthy lifestyle behaviours				Chi-square		
	Poor n(%)	Moderate n(%)	Good n(%)	Total n(%)	x^2	df	*p-value*
Age					1.844	2	.398
20-22 (younger)	18 (8.1)	162 (72.6)	43 (19.3)	223 (100)			
23 and above (older)	10 (12.5)	58 (72.5)	12 (15.0)	80 (100)			
Total	28 (9.2)	220 (72.6)	55 (18.2)	303 (100)

Pharmacy	8 (9.9)	60 (74.1)	13 (16.0)	81 (100)			
Biomedical Science	8 (12.1)	47 (71.2)	11 (16.7)	66 (100)			
Total	28 (9.2)	220 (72.6)	55 (18.2)	303 (100)			
Family Income					13.049	4	.011*
Below than RM3000	12 (11.4)	80 (76.2)	13 (12.4)	105 (100)			
RM3001 – RM6275	12 (11.1)	67 (62.0)	29 (26.9)	108 (100)			
RM6276 and above	4 (4.4)	73 (81.1)	13 (14.4)	90 (100)			
Total	28 (9.2)	220 (72.6)	55 (18.2)	303 (100)			
CGPA					9.766	4	.043*
Pass (2.50-2.99)	0 (0.0)	26 (86.7)	4 (13.3)	30 (100)			
Good (3.0-3.69)	23 (10.6)	147 (68.1)	46 (21.3)	216 (100)			
Distinction (3.70 and above)	5 (8.8)	47 (82.5)	5 (8.8)	57 (100)			
Total	28 (9.2)	220 (72.6)	55 (18.2)	303 (100)			

*significant at 0.05 level

For association between program (course) and level of healthy lifestyle behaviours also was tested by using chi-square test as shown in the table 4.18. The chi-square analyses revealed no significant difference exist between program and level of healthy lifestyle behaviours, $\chi 2$ (6, N=303) = 3.442, p=.752. Thus, the result showed that there was no significant association existed between program (course) and level of healthy lifestyle behaviours.

Furthermore, from the table 4.18, it shows that family income have significant association with the level of healthy lifestyle behaviours which is the p-value is less than 0.05. The chi-square analyses reveal that there was a significant difference exist between family income and level of healthy lifestyle behaviours, $\chi 2$ (4, N=303) =13.049, p=.011. Hence, there was association between family income with level of healthy lifestyle behaviours.

Last but not least, from the table 4.18, it shows that Current Academic performance (CGPA) have significant association with the level of HLB which is the p-value is less than 0.05. The chi-square analyses reveal that there was a significant difference exist between CGPA and level HLB, $\chi 2$ (4, N=303) =9.766, p=.043. Hence, there was association between CGPA with level of HLB.

4.11 Summary

Researcher had analysed and interpreted the research findings. Data obtained earlier, were

analysed using SPSS 2.3 Version Software. For the analysis of the data, the researcher had used the descriptive analysis to really look for the relevancy of the findings with the objectives of the research study. In this chapter, in order to describe the characteristic of the study respondent with HLB, student's academic performance, and demographic data of the students, statistical approaches were used to determine any association. The result of the statistical tests were displayed in table and explained in detail through text. Definitive interpretation of the foregoing result will be discussed in the succeeding chapter. Therefore, in this study, it shows that 72.6% of the respondents had moderate HLB. The highest mean score for categories of HLB was health responsibility. Meanwhile, the lowest mean score was an interpersonal relation. Family income and Current Academic Performance (CGPA) has significant association with the level of HLB.

CHAPTER 5
DISCUSSION, RECOMMENDATION, AND CONCLUSION

5.1 Introduction

In this chapter, researcher will interpret the results, analysis and describe all the data finding that have been done in chapter 4 which is data analysis based on the 3 objectives stated earlier in the previous chapter. Thus, in this chapter, researcher discussed detail regarding the level of healthy lifestyle behaviour perceived by the students, the relationship between each domain of healthy lifestyle behaviour, and the association between the level of healthy lifestyle behaviour with the selected demographic characteristics of the students (age, gender, ethnics, BMI, socio-economic status, program, and academic performance (CGPA)). The discussion described in greater detail of the study. Following of the discussion, researcher focused on similarity and comparison of the study findings with others literature review. In order to complete the discussion, researcher discussed the implication, limitation and recommendation to nursing practice as well a conclusion. Therefore, the researcher discussed and elaborates more about the limitation of the research to the research study.

5.2 Discussion of findings

The discussions of the finding were according to the specific objectives that the researcher wanted to achieve which were:

1. To examine the level of healthy lifestyle behaviour perceived by the students.
2. To compare the mean differences in the domain of healthy lifestyle behaviours among students.
3. To determine the association between the level of healthy lifestyle behaviour with the selected demographic characteristics of the students.

5.2.1 Demographic Characteristic Data of the Students

From the total sample of 303 of respondents, most of the students who participate in this study are from younger age which is 20 years old to 22 years old. This finding is similar with the previous study on healthy lifestyle indicates that amount of students, younger university students are higher in population compare to older people (Wang, 2013). Moreover, in this study, mostly all the students involved in this research were female which is same from study conducted in Nebraska (Walker et al., 1995).

From the finding, for ethnicity, Malaysia was having more than one ethnicity, the students' majority were Malay students. Moreover, in the present study shown that most of the respondent is underweight. The result differ from previous study among students in Saudi Arabia which is found that most of the students were reported overweight (Al-Rethaian, Fahmy, & Al-Shwaiyat, 2010). This might because of university students in Malaysia strict large consumption of unhealthy diet for example fat, junk food, fast food, and cholesterol.

In this study, majority of the students had moderate family income (monthly). The result is consistence with the previous result from study by Ali & Crowther (2009). The present study also revealed that MBBS students are the majority among the other courses. It stated that majority population in faculty of medicine of the students is medical students and pharmacy students. The present study shown that the most who in charge at each condition student's academic performance (CGPA) was good result.

5.2.2 Level of Healthy Lifestyle Behaviour among Students.

The result of this study showed that more than half of the respondents were had moderate spiritual growth level, interpersonal relations, nutrition, physical activity, health responsibility, and stress management. The result constant with the result from Hacihasanoglu, the level for all the domains was in moderate level (Hacihasanoglu et al., 2011).

Moreover, for the overall level of healthy lifestyle behaviours in this study showed that majority of the respondents had moderate level of healthy lifestyle behaviour. There is similar finding were reported that students healthy lifestyle behaviours in moderate level (Hacihasanoglu et al., 2011). On the other hand, there is some review of literature that provided important evidence of increasing unhealthy behaviours among students regarding to dietary, physical activity, drug use, and smoking, there is evidence that students are adopting risky behaviours detrimental to health (Kenny et al., 2008). The findings was very worrying as the wrong believe can lead to an ineffective preventive planning and measure in order to apply a correction method to increase the problem.

5.2.3 Comparison in mean difference in the domain of Healthy Lifestyle Behaviours.

In current study, the highest mean score for categories of healthy lifestyle behaviours was spiritual growth. Meanwhile, the lowest mean score was physical activity. This showed that the most healthy lifestyle behaviour that commonly used among students were spiritual growth. However, the least healthy lifestyle behaviour that commonly used among was physical activity.

In a survey by Al Maaitah et all., 1999, it stated that the lowest mean was interpersonal relation and the highest ranking in comparison was stress management subscales (Al Maaitah et all., 1999). It is contradict compare to present study whereby spiritual growth was the highest whereas physical activity was the lowest. This is because of Malaysia students think that they have awareness toward healthy lifestyle more.

Next, current study was similar with other previous study in Jordan where it is recorded that the total Healthy Lifestyle Behaviours score was shown the highest score on the subscales was self-actualization (spiritual growth). Therefore, the score were lower on interpersonal support, nutrition, and health responsibility. Meanwhile, the lowest score was physical activity (Nassar & Shaheen, 2014). Hence, it was similar with previous study whereby spiritual growth was the highest score while the lowest score was physical activity (Nassar & Shaheen, 2014). This is might because of both study was conducted to university students and they usually had same type of knowledge regarding healthy lifestyle behaviour and this might influenced the highest score for domain of healthy lifestyle behaviour.

Moreover, the present study shown a contrast result compared to previous study in Nebraska by Pulen et al. (2001), among the domain of interest, the respondents scored highest result on the nutrition domain and the lowest was physical activity domain. It was reported this is because, the Nebraska's respondents was focus on their diet, meals, and calories in their lifestyle but they prefer to never or sometimes in doing physical activity to increase their healthy lifestyle. Meanwhile, in Malaysia, most of the nursing and medical sciences students more focus on spiritual growth in order to think more focus on their future.

Furthermore, other related study also shown similar result with Pulen et al. (2001) which is the score mean of nutrition domain was the highest and the lowest was physical activity. Hence, the previous study stated that physical activity was the lowest because of lack of feasible exercise

program in order to enhance their healthy lifestyle behaviours (Pullen et al, 2001).

5.2.4 Association between the level of healthy lifestyle behaviour with the selected demographic characteristics of the students (age, gender, ethnics, BMI, socio-economic status, program, and academic performance (CGPA).

Age

In this study, it was noted that younger students had higher level of healthy lifestyle behaviours than older students and it reveal that no significant difference exist between age and level of healthy lifestyle behaviours. Therefore, the result showed that there was no significant association existed between age and level of healthy lifestyle behaviours. This finding is similar with the previous study on healthy lifestyle indicates that amount of students, younger university students are more engaged in healthy lifestyle behaviours (Wang, 2013). This might because of their ability and strengths to do perform a healthy lifestyle was more easier during young age compared to older age and this also might because of older age may had many commitment towards their study, assignments, and works.

Gender

In this study, it was noted that female had higher level of healthy lifestyle behaviours than male and it reveal that no significant difference exist between gender and level of healthy lifestyle behaviours. Therefore, the result showed that there was no significant association existed between gender and level of healthy lifestyle behaviours. Salami (2010) and Schmidt (2012) were support the results of this study and these studies were provided a collateral explanation for the gender differences in quality of life. Contrasly, there is an evidence that women are less likely to be physically active than men, and they were found participate in home-based activity like walking (Salami, 2010; & Schmidt, 2012). Overall, men are more likely in vigorous physical activities such as running, or weight lifting rather than women (Huang, 2003; Quadros, 2009; El Ansari, 2011). Other than that, most of the studies found that more female students practice unhealthy behaviours rather than male students especially to physical and dietary habits (Vickers et al., 2004). From this study, it shown that female has higher level of healthy lifestyle behaviour might because of they have more awareness about their health status and want to achieve good body image as in this faculty, they need to communicate with other person to deliver care.

Ethnics

From the study, it reveals that there was no significant difference exists between ethnics and level of healthy lifestyle behaviours. Besides that, in the present study, ethnics Malay had higher level of healthy lifestyle behaviours than other ethnics. This might because of the population of Malay was higher than the other ethnics. Nevertheless, there is no any evidence to support this finding.

Body Mass Index (BMI)

In this study, it was noted that underweight had higher level of healthy lifestyle behaviours than normal, overweight, and obese and the result reveal that there was no significant difference exist between BMI and level of healthy lifestyle behaviours. There was another similar study support the finding, it shown that student's healthy lifestyle behaviour are lower due to obesity and overweight (Ali & Crowther, 2009). Nevertheless, there was a study stated that inactive people might spend their long hours watching television, surfing internet, eating junk food and snacks, and also might sitting long hours in cars or sleeping long hours daily (Ali & Crowther, 2009; Chukwuonye et al., 2013). This might because of all of these unhealthy behaviours are becoming a common routine among

university students. Despite of busy life and many assignments to be submitted, they might cannot focus on their healthy lifestyle behaviour. Other than that, this might due to their weight that makes them feel lazy to do any physical activities.

Socio-economic status: Family Income (monthly).

In the present study, there shows that family incomes have significant association with the level of healthy lifestyle behaviours. It shown that there was association between family income with level of healthy lifestyle behaviours. Nevertheless, there are a study that examined the association of mental health and income among students in one of university in Brazil and the result showed a positive association between student's income status and health (Ali & Crowther, 2009). This is because, income status will affecting health status as well, by restricting the ability to attend hospital and paying for medications and treatment, restricting several lifestyle like consuming healthy food, living in comfort environment, be able to pay for gymnasium for regular exercises and some other luxuries that will makes one live a happy healthy life.

Academic Performance (CGPA) and Program (courses)

In the present study, it was noted that good result of CGPA had higher level of healthy lifestyle behaviours than pass and distinction and there shows that there was association between CGPA with level of healthy lifestyle behaviours. According to Savci et al., (2006), they have determined that in their study physical activity level of university students were very low and the higher the academic performance, the lower their healthy lifestyle (Savci et al., 2006). This is might because, the health problems experienced by students in the study are caused busy life and due to too much commitment toward study, they cannot focus on their healthy lifestyle. Nevertheless, there is no other any evidence to support this finding.

In this present study, it reveals that there was no significant difference exist between program (course) and level of healthy lifestyle behaviours. Therefore, the result showed that there was no significant association existed between program (course) and level of healthy lifestyle behaviours. According to Nathalie Bergeron, (2017), clams about 59% of pharmacy and medical students were exposed to medium healthy lifestyle behaviour and 53% of the students have good healthy lifestyle behaviour (Bergeron, 2017). It stated that majority population in faculty of medicine of the students is medical students and pharmacy students.

5.3 Implication of the Study

The result from the study indicated that healthy lifestyle behaviours are important in order to reduce disease and illness and could bring a few implications. Generally, the findings from the research give implication to nursing students and medical sciences students, nursing practice, and nursing research.

5.3.1 Nursing and medical sciences students

In medical lines and clinical practice, nursing and medical sciences students need to be taught the advantage and benefits regarding the healthy lifestyle behaviours. As nursing and medical sciences students, it is importance to investigate the healthy lifestyle behaviour among university student especially among medical faculty students. As a health care provider, nursing and medical sciences students need to be healthy as they will be a person who will provide a care to those in ill for the next generation and future. The investigation about healthy lifestyle behaviour among nursing and medical sciences students are proved to be very useful and benefited complement and it will

provide a larger view of younger people's condition towards their health. It is also an individual responsibility to reinforce the knowledge and information that has been given to increases the level of healthy lifestyle behaviours.

As a part of medical team, health education and health motoring care was very important in order to achieve their aim in increasing the level of the healthy lifestyle behaviours. The level of health among Nursing, Bachelor of Medicine and Bachelor of Surgery (MBBS), Pharmacy, and Biomedical Sciences students is enhanced. In fact, healthy lifestyle behaviour in early phase of life effect the disease risk related to lifestyle in later periods of life. Moreover, student will comprehend the importance of health protection and improvement behaviour and transfer their knowledge into practice in life. The student's awareness on healthy lifestyle can be increased too so that chronic disease can be reduced to the minimal prevalence. Next, they will also perform and engage themselves in their daily activities undistracted, if they are not experience illness.

5.3.2 Nursing Practice

Form this study, it shown that nurse has a big role and responsibilities in giving nursing care to those who need a treatment. Nurses are health care providers who also act as a leader, advocator and educator too. Therefore, nurses need to spend time and give health education to the individual who are unhealthy and this could bring a huge challenge to nurses. A proper nursing practice with a very good quality nursing care will give a good image to nursing professional by doing their skills. The health education to public is very crucial as from the findings we knew that future generation especially university students were not in a very good healthy lifestyle behaviours. All the consequences from poor heathy lifestyle behaviours should be included in the health education to the public and community as it can alert and therefore help future generation to detect earlier and gain earlier awareness to prevent further illness. Apart from the nurse having to strategies on patients' healthcare plans and to produce programs for healthy lifestyle behaviours among nursing students and also medical science students towards improving wellness, nurses can learn much kind of new things and increase their critical thinking on some practicable ideas for creating student education program.

Moreover, a good and professional nurses will provide education as it is the crucial part to the teenagers especially university students. Build a team of educational program and provide a proper standard of teaching about healthy lifestyle behaviours to the nursing and medical sciences students as well as university students. They will gain some benefits knowledge and understanding about their condition on their level of healthy specifically. From this study, it is used as a guideline to enhance the nursing practice regarding the healthy lifestyle behaviours among nursing students and medical science students by developing a health programs or health education regarding the important of practicing a healthy lifestyle behaviour to community especially to students.

5.3.3 Nursing Research

This is a study conducted in one setting and only in one faculty. It is a research should be conducted to include other faculty and nationwide to evaluate nursing student in other university in the country to be able to generalize the finding. An experimental study will be conducted in future in order to improve the level of healthy lifestyle behaviour among students.

5.4 Limitation of the Study

The limitation of this study is that, the study only focuses to one faculty only. This is because,

other study were involving other university students and not specific on one faculty. This may result in limitation of the generalization of the final results to the health organization as well. Apart from that, the researcher used Not proportional Sampling Method (Convenience Sampling Method) that may result inaccuracy of the finding data. This is because of researcher could not randomized and generalized the sample size of the respondent. This sampling method had to be used because of the number of nursing student does not many. Moreover, other than that, the literature review on this study from Malaysia limits the ability and accessibility of the research to compare the findings of this research with local setting. Besides than that, the researcher were unable to rule out possibility that social desirability bias affected the results. This is due to all respondent were from Faculty of Medicine and educated. Next, the researcher used Convenience Sampling method that might bring a lot of biases throughout the data collection taken and the study only used quantitative approach that might not focus or observe on the real behaviour of the students.

5.5 Recommendations in Future

According to the results obtained from this research, there are some recommendations and it is suggested that health protection and improvement courses should be included in the curriculum of all departments at the faculty and also university. Furthermore, education programs on health protection and improvement should be offered for university students at a certain intervals. In this way, it is believed that university students will comprehend the importance of healthy lifestyle behaviour, improvement of the healthy lifestyle behaviours, and also transfer their knowledge into practice.

In addition, prevalence of overweight in this university also increases not only obesity. Therefore, students should practice more healthy diet and perform physical activity. Result in present study also shown that students not practice good healthy lifestyle might because of busy life and need to give commitment to their assignments and study. Hence, healthy steps toward healthy lifestyle should be practice and follows all the recommended programs about improving healthy lifestyle.

Moreover, other than that, the study recommends that university authorities and health departments are engaged in a coordinated healthy lifestyle behaviours programs. These programs should include health awareness and health education, which should be tailored towards giving positive lifestyles. The importance of physical activity and healthy diets as stated above must be emphasized to all the students. Furthermore, the present study recommends that governments in this country together with the universities authorities should establish program to encourage healthy diet on the campus area. There should be video shows on overweight and obesity documentaries, including health awareness, and education seminars. For example, there should be also pamphlets, leaflets, and food-based dietary guidelines too. Students should be encouraged to do juggling and other vigorous exercises for at least 3 to 4 times of about 30 minutes duration per week. This is because, physical activity can be used to address preventable lifestyle-related diseases such as obesity, depression and heart problems.

Next, further study could be conducted to examine demographic variables. Comparisons between female and male students from different faculty of medicine in various universities would be an interesting future direction for this research. Socio-economic data, which are known to have an impact on healthy lifestyle behaviours, could also be monitored closely in a future study.

Furthermore, the researcher recommends that an observational study to be done to observe people’s actually healthy lifestyle behaviour towards the prevention of any disease regarding health

status. Although this self-reported study might have response bias, but it helps in access to people real life condition and scenario. The researcher can observe on what the public actually say and do, rather than only focus on what they say and what they do by conducting this study. This is because, people are not willing to write their true view on a questionnaire or tell a person they did not know about what
they really think. Therefore, with the actual condition or scenario, the healthcare personnel can take immediate action to control the healthy lifestyle behaviours from worsening. Hence, an observational study is highly recommended.

5.6 Conclusion

This study was carried out in the Faculty of Medicine. Researcher had achieved all the three objectives in this study. This study suggested a few recommendations that should be used in order to enhance the healthy lifestyle behaviours in the future. The overall Healthy Lifestyle Behaviour of students in medical faculty had moderate healthy lifestyle behaviours. Besides that, Nursing students had moderate healthy lifestyle behaviour.

INFOGRAPHIC MEDIA OF URINE COLOR ON STUDENTS' BEHAVIOR WITH FLUID COMPLIANCE

B F Hidayat[1], Makhfudli[1], D Yasmara[1] and H Arifin[1]
[1]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
Email: hidayat.arifin-2018@fkp.unair.ac.id

ABSTRACT

Fluid was one of basic human needs that often neglected and unfulfilled. The aim was to analyze the influence of infographic media of urine colour to improve students' behavior in fluid compliance. The design was a one-group pre-experimental with pre-posttest. The population was all of student in Nursing Faculty of Airlangga University. Total sample were 250 respondents obtained by clusster sampling. Inclusion criteria in this research were active students and willing to be respondents, while exclusion criteria was student that consumed some medicine include aminopirin, flutamid, niacin, fenitoin riboflavin. Independent variable in this study was infographic media of urine color. The dependent variable in this study were knowledge, attitudes and actions of students in fluid compliance. The data collected by questionnaire and observation sheet and then analyzed by using Wilcoxon signed rank test with significance level of α=0.05. The result shows that infographic media of urine color is effective to increase students' knowledge, attitude, and practice in fluid compliance (p=0.000). Infographic media of urine color is effective to increase students' behavior in fluid fulfillments. Therefore, a similar media expected to be developed to improve awareness in fluid fulfillment.

Keywords: infographic, urine colour, fluid compliance, media

1. Introduction

The balance of fluids in the body plays an important role in maintaining the stability of the body's physiological health. This is influenced by the input and output of fluids. A person's daily needs are between 1500ml - 2000ml of water to maintain the fluid balance that comes out every day through the urine, sweat, breathing and bodily secretions. These needs, if the body cannot fulfill them, will give a response of thirst. The body becomes weak, resulting in dehydration and over a long time, this can cause kidney failure [1]. The high activity of students causes frequent forgetting to drink. A person's fluid intake needs can be determined from the color of their urine and this can be compared to the color on the infographic[2]. However, this media has not been applied in the Faculty of Nursing even though it is a health agent environment.

The results of the Indonesian Regional Hydration Study Team (THIRST) study in 2010 in DKI Jakarta, West Java, East Java and South Sulawesi found that 46.1% of the population experienced mild dehydration. Adolescents had the highest rating for this (49.5%), followed by adults (42.5%). The main cause of this problem is their low knowledge about the function of water for the body, the need for drinking water, the benefits of drinking water for health and access to drinking water [3]. Other studies regarding water consumption conducted by students showed that 61% of students still lack an adequate level of consumption of drinking water [4]. The results of a preliminary study

conducted by the researchers on October 6th 2016 on 10 students showed that 9 people claimed to drink less than 6 glasses of water a day.

Habits mean that a student cannot be aware of the lack of water in the body and they may not have the habit of drinking the right amount of water every day. This can have a negative impact on their health, such as causing the body to weaken up to the point of dehydration. In the long run, this will cause kidney failure [1]. A lack of knowledge is not the only reason. The lack of awareness to immediately obtain drinking water and replace lost fluids is the reason for the disruption of fluid balance in individuals. In other words, water consumption behavior can affect the health status of individuals. A person's behavior influences their health status [5]. The urine color infographics provide information about the adequacy of fluids in the body [2]. The urine color when urinating, when compared with the color of urine in the infographic. will indicate if someone is dehydrated or not. If someone is dehydrated as indicated by the infographic, then they can change their behavior to become more aware. The aim of this study was to analyze the influence of the infographic media on urine color on the students' knowledge, attitudes and practices in terms of fluid compliance.

2. Material and methods

2.1. Research design

The design used was a pre-experiment with a pre-post-test one group design.

2.2. Population and sample

The population in this research consisted of all students in the Faculty of Nursing of Universitas Airlangga. This totaled as many as 715 respondents and the researcher obtained 250 respondents through cluster sampling. This research was conducted in the Faculty of Nursing of Universitas Airlangga between January 6th – 30th 2017. The inclusion criteria in this research were that they were active students and willing to be respondents, while the exclusion criteria were students that were taking medication such as aminopirin, flutamid, niacin and fenitoin riboflavin.

2.3. Variables

The independent variable in this study was an infographic media on urine color. The dependent variables in this study were the knowledge, attitudes and practice of the students in terms of fluid compliance.

- *2.4. Instruments*

The instruments used in the data collection were knowledge questionnaires, attitudes and observation sheets that the researchers developed themselves and tested for validity and reliability.

- *2.5. Research procedures*

The researcher took the respondents from all students at the time of the study. The data collection was done by the researchers by first looking for the respondents. The researchers wrote down numbers on a small scrap of paper that had been rolled up based on the number of students in the class. Then the researcher took the number of scrolls according to the number of respondents desired from each class. The names taken were made into a list submitted to the research assistant in each class. After the research assistant recorded the names of the students from each generation, the

researcher then made a time agreement to explain the purpose of the study and to get informed consent. After the respondents signed the informed consent form, the session was continued by giving a pre-test. After the respondent filled out all the questionnaires that had been distributed, the questionnaire was withdrawn. The infographics were posted in the campus toilets and given to each respondent to be used in their respective residences. One week after attaching and giving the infographics, the post-test is performed.

2.6. Analysis

The data was analyzed using IBM SPSS Statistic 24. The statistical analysis consisted of two stages, namely the descriptive and inferential analysis. The descriptive analysis included the mean and standard deviation. The inferential analysis used the Wilcoxon Signed Ranks Test to determine the difference between the independent and dependent variables. The confidence interval was 95% with alpha (α) = 0.05.

2.7. Ethical Clearance

This research passed the ethical review and obtained an Ethical Approval certificate No. 306-KEPK issued by the Health Research Ethics Committee of the Faculty of Nursing, Universitas Airlangga.

3. Results

The characteristics of the respondents on Table 1 showed that the majority of respondents came from the age group of 18-21 years old, totaling as many as 132 respondents (52.8%). Based on the sex of the respondents, there were more females, totaling as many as 146 respondents (58.4%). According to the highest respondent generation, there were 45 respondents (18%) from the 2015 transfer type.

1. Characteristics of the respondents in the Faculty of Nursing, Universitas Airlangga in January 2017 (n = 250).

Characteristics of the Respondents	n	%)
18 – 21 years	32	2.8
22 – 25 years	79	1.6
> 25 years	39	5.6
	50	.00

Fulfilled	34	3.6	8	7.2	.000
filled	16	6.4	32	2.8	
	50	00	50	00	

The pre-test knowledge of most of the respondents, namely 150 respondents (60.0%), had a good knowledge about meeting their fluid needs. In the post-test, the number of respondents who had a good level of knowledge increased to 190 respondents (76.0%), increasing by 16% from the previous test. The results of the statistical tests conducted using the Wilcoxon signed rank test obtained a value of p=0.000. This shows that there was a significant difference in the respondents' knowledge before and after the intervention. The attitudes of the respondents showed that 128 respondents (51.2%), or half of the total respondents, had a positive attitude toward fulfilling their fluid needs. In the post-test that was conducted after being given the intervention, the number of respondents who had a positive attitude in terms of meeting their fluid needs increased to 154 respondents (61.6%). The results of the statistical tests using the Wilcoxon signed rank test obtained a value of p=0,000. This shows that there were significant differences in the attitudes of the respondents before and after the intervention. A small portion of the total respondents, 34 respondents (13.6%), were those whose daily fluid needs were being met. In the post-test, there was an increase in the number of respondents up to 68 respondents (27.2%) whose daily fluid needs were being met. The results of the statistical tests using the Wilcoxon signed rank test obtained a value of p = 0,000. This shows that there are significant differences in the respondent's practices before and after the intervention (Table 2).

4. Discussion

The results of the study of the knowledge variables showed that before the intervention was given, 60% of the total respondents - 150 respondents - had good knowledge about meeting their fluid needs. After being given the intervention, the number of respondents who had a good level of knowledge increased to 190 respondents (76.0%). However, there were still 2 respondents who lacked knowledge. The results of the statistical tests of the knowledge variables prove the existence of a significant influence from the use of urine color infographic media on the knowledge of the respondents about meeting their fluid needs.

Knowledge is the result of the human sensing of an object. The factors that can affect knowledge includes experience, level of education and a source of information [5]. Someone will have a perception of what he lived which will lead to the perceptions related to the level of knowledge obtained from information. If the information received is less clear, then the learning outcomes obtained are also not optimal. Edgar Dale's cone illustrates that someone who sees photos or illustrations of information can remember the information by up to 30%. Knowledge arises when

someone uses his senses to recognize certain objects or events that have never been seen or felt before. The increase in the value of knowledge is due to the process of studying the messages in the media infographics by the respondents [6]. The research results conducted show the influence of visual media on knowledge [7].

During the pre-test, the number of respondents who had a good knowledge of the body's constituent components, the amount of fluid consumed in a day, the impact of a lack of fluids and how to overcome the lack of fluids was high. As for the questions about urine color in numbers 5 and 6 in the questionnaire, only 70 respondents answered correctly. The question about the amount of fluid that must be consumed a day (no. 2) was answered correctly by all of the respondents and only 8 people answered incorrectly. This can be caused by the respondents who are nursing students who had gotten lectures about fluid intake before. So when given a test, the respondents were able to answer the question correctly. The information obtained from formal and non-formal education can provide short-term effects resulting in changes or increased knowledge [8].

There was an increase in the number of respondents who were well informed after being given an intervention because the information listed in the media infographic is understood by the respondents. This is in line with the research which states that infographics affect the students' memory and reasoning power [9], meaning that the students are able to answer the questions as part of a test. The use of media infographics is something that has just began to be applied in the area of the Faculty of Nursing in Airlangga University, making the respondents interested in seeing, reading and studying the information listed on media infographics.

This is in accordance with the statement that the existence of new information about a matter can provide a new cognitive foundation for the formation of knowledge about something [8]. Infographics are also included in the form of one visual media, making it easier for the reader to understand the information. According to the statement above, the information that is captured visually will be processed faster by the brain, in contrast to the information conveyed via text where the information will be processed linearly (from the beginning of the sentence to the end of the sentence) [10]. In this study, it was found that 2 respondents still lacked knowledge after being given an intervention, such as when someone had a perception of something. In this case, the infographics will mean that the person finds it difficult to clearly understand the contents of the infographic so then the respondents still cannot meet the cognitive domain of knowledge in terms of their level of understanding (comprehension). However, the respondent still answered incorrectly on the post-test.

The results of the attitude variable showed that before being given an intervention, as many as 128 respondents (51.2%) had a positive attitude in reference to meeting their fluid needs. After being given the intervention, the respondents who had a positive attitude increased to 154 (61.6%), while 96 respondents were still negative. The results of the statistical tests showed that there was a significant effect of using the urine color infographic media on the attitudes of the respondents after being given the intervention.

Attitude is the closed reaction of humans from a stimulus [8]. Attitudes can be influenced by several factors, namely personal experience, the influence of important figures, cultural influences, mass media, educational and religious institutions, and emotional factors. Attitudes are not taken from birth. They are formed and studied throughout human development in relation to certain objects [11].

In this study, half of the total respondents (128 respondents) had a positive attitude towards meeting their daily fluid requirements during the pre-test. In statement number 4 about drinking during solid activities, the respondents preferred "Never". Only 73 respondents chose "Sometimes" and 24 respondents chose "Often". This is because the respondents already had a good level of knowledge about fulfilling their fluid needs. The status of the respondents as nursing students meant that they got lecture material on the ways to always keep up with their fluid needs. In this study, the urine color infographic media was a stimulus / object that caused the respondent to behave according to the message / content as stated in the media. The proof is the increasing number of respondents who are positive when doing the post-tests. Attitudes are views, opinions, responses or judgments and they are also a person's feelings for stimuli or objects accompanied by a tendency to act [5].

This is what supported the change in attitude from negative to positive in most of the respondents. The value of the respondent's attitude after being given information through media infographics increased because the respondents were able to capture all of the positive things that they got from the media infographic. After their knowledge is sufficient, their emotions react to the existing stimuli and there is a change in attitude to the positive. The number of respondents who were still negative is caused by their habits. If someone already has a habit, then it is very difficult to change the attitude of the person, be it a negative attitude or a positive attitude. This is in accordance with the theory put forward as stated by Greenaway [12], in that one component forming behavior in terms of attitude is the influence of culture.

The results showed that before the intervention, only 34 respondents (13.6%) had their daily fluid needs met. The respondents whose daily fluid needs were not being met had an average consumption of water amounting to 1200 ml (6 glasses) a day. There were even respondents who consumed only 800 ml (4 glasses) of water. Regarding the urine color of 216 respondents whose daily fluids were not fulfilled, on average they had urine colors of 3, 4 and 5. After being given the intervention, the number of respondents whose daily fluid needs were met increased to 27.2% (68 respondents), which meant that there were 182 respondents whose daily fluid needs were not being met. The results of the statistical tests indicate a significant influence on the use of urine color infographic media on the respondent's practice in meeting their fluid needs.

Action is an attitude manifested in a real reaction [5]. Practice occurs when humans get knowledge in the form of information or stimulus, and then they assess it for the next step to be carried out. Everything must be known and addressed properly. Based on theory, a person's behavior is influenced by three factors: 1) predisposing factors, namely attitudes, knowledge, beliefs, values and norms; 2) supporting factors, namely the availability of facilities and the availability of health facilities and 3) driving factors, namely family, peers, teachers and health workers [12].

This study shows that media infographics can improve the practices related to meeting the respondents' fluids needs. This can be caused by an increase in the knowledge and attitudes that first occur. An increase in action can occur when the respondent absorbs the information contained in the infographic media. The respondent then responds to the information relating to meeting their fluid needs. The respondent is interested in adapting the knowledge obtained by realizing their attitude through the act of fulfilling their fluid needs. As mentioned in [5],new behavior is formed starting from the cognitive domain (knowledge) where the subject knows in advance the stimulus in the form of media infographics. This knowledge raises an inner response in the form of the respondents' attitudes toward meeting their fluid needs. Finally there was a response that was even further along

in the form of their practice of fulfilling their fluid needs. In this study, it was also found that there were still many respondents whose daily fluid needs were not being met. When measuring knowledge and attitudes, a number of respondents were well-informed and had a more positive attitude. Behavior will be formed after going through several processes.

Someone who has good knowledge will tend to be positive. This is because attitude is the application of knowledge. However, many practices are also influenced by environmental factors. As stated, one of the behavioral factors are supporting such as the availability of facilities [12]. Students with heavy activities may not meet their fluid needs. As mentioned, there are five elements of health that can influence someone to do something, one of which is cues to action. This is the view or belief of an individual when making a decision to do or not do a certain form of action [13]. This study also revealed several factors that influence the intention to behave aligned with the Theory of Planned Behavior [14]. Another is the perception of behavioral constraints (Perceived Behavior Control) which are the perceived difficulties when doing a behavior and the things that reflect past experiences. The same is true for the respondents with their daily fluid requirements not being met. This is because at the beginning of the pre-test, the individual is accustomed to not fulfilling their daily fluid requirements so when the post-test was carried out, there was no change in the pattern of meeting their fluid needs.

5. Conclusion

The urine color infographic media influences the student's knowledge of fluid compliance through the information contained in the media infographic. The student attitudes regarding fluid compliance are due to providing stimuli that trigger the students' reaction and practices in meeting the recommended fluid compliance through the adaptation of their knowledge by manifesting attitudes through their practice in meeting their fluid needs. Future researchers are expected to conduct research using different types of respondents, such as the general public, students and others.

6. Acknowledgment

We would like to say thank you so much to all of the respondents. They were really cooperative when it came to joining in the research. I would also like to thank the Dean of the Faculty of Nursing of Universitas Airlangga who supported this research.

QUALITY OF WORKING LIFE AMONG NURSES IN UMMC

Nadzatul Farzanna Binti Razali
University of Malaya

ABSTRACT

Background: Quality of work life has been found to influence the commitment of health professionals including nurses. Quality of work life is defined as "the degree to which registered nurse are able to satisfy important personal needs through their experiences in their work organization while achieving the organization's goals".

Objectives: The objective of this study is to assess the quality of working life among nurses in UMMC and to associate it with the selected socio demographic variables.

Methods: A descriptive and cross-sectional quantitative study performed using questionnaire on RN (N=320) working in UMMC. Data was analyzed by using SPSS. Descriptive, Pearson Chi-square and Fisher's exact analyses used in data analysis.

Results: In general, the results of the study showed that 62.2% of nurses reported had moderate level of quality of work life. A significant relationship was found between variables such as age, ethnicity, educational level, working experiences and monthly income with quality of work life.

Conclusion: Findings from this study showed that nurses in UMMC had moderate quality of work life. Quality of work life can be promoted by providing autonomy, sufficient staffing and with better working conditions. Administrator can also make transparent performance appraisal and conduct training programs for the nurses. For achieving a high level of care, it is essential to have a high quality of work life and the commitment of nurses in the job.

Keywords: "nurses", "quality", "work life", "nursing work life" and "quality of work life"

CHAPTER 1
INTRODUCTION

The general purpose of the study is to determine the quality of working life among nurses. The researcher experience different response by the nurses. Thus, this chapter is to present the background and formulate objectives related to this study as well as research questions.

1.1 Background of the study

The largest and diverse work forces in the health care system are the nurses. Nursing is one of the most valued, noble and honorable profession in the world. It is the profession in which a person does not think or care about the monetary gains and care solely for the benefit of the people who are sick and unwell. Nursing also is a very demanding career, this is because nurses do not only have tons of things to get done, but they also forced to make some decisions (Nizar, 2013). The role of nurses in the health care settings is expanding and changing. Their role is not just limited to institutional care, but they are also involved in the delivery of services at various levels of health care system. Many people believe that nurses are one of the strongest pillars of the health care delivery system in providing safe, affordable and good quality of services to the people (Jayaraman & Chandran, 2010). Nurses play a major role in maintaining health status and trying hard to achieve the health targets of the country.

Most of the nurses have a lot of things they are responsible for, and to make good decisions about patient care and well-being. Before nurses improve quality of care of patients, it is important for them to improve quality of working life of themselves. Quality of working life (QWL) affecting

different aspects of nurses such as their commitment, productivity, patient satisfaction, and quality of their own life (Rai, 2013).

Based on Van Laar, Edwards & Easton (2007), they defined quality of working life as "the part of overall quality of life that is controlled by work, which is the wider context in which an employee would evaluate the influence of work on their life". In nursing outlook, Brooks (2004) defined the QWL as "the degree to which registered nurses are able to satisfy important personal needs through their experiences in their work organization while achieving the organization's goals. QWL is mainly a multidimensional concept, and one of the ways of reasoning about people, work and the organization. It seems that the relationship between QWL and the nurse's involvement in their work, is an important factor in achieving higher levels of quality of care delivery especially to the patients. In health care organizations, such as hospitals, QWL has been described as referring to the strengths and weaknesses in the total work environment (Knox & Irving, 2007).

Based on Shalini & Sunil (2012) quality of life includes an opportunity to realize one's potential and utilize one's talents as well as to excel in challenging situations that require decision making and taking initiative and self-direction. However, quality of life are affected by QWL of that person. Working will provides people the opportunity to use their abilities, skills, and creativity throughout their productivity. In return, they would fulfill and feel satisfy in their life. Health professionals especially nurses are exposed to critical influence and pressures when socialized into a work environment. The QWL sometimes affects quality of life in four areas which are competency, health, time and wealth (Macstravic, 2006). The QWL is a concept that concerns workers' management and emphasizes the outcomes nurses and organizations. Professional nurses have the responsibility for patients' quality of life, so they should have a quality of working life more effectively before they can help patients.

The phrase QWL often used to assess the general well-being of individuals and societies. People should not be confused the term of QWL and the concept of standard of living which is the based primarily on income. Standard indicators of the QWL include not only wealth and employment, but also the built environment, mental health and physical, education, social belonging, recreation and leisure time. Sometimes, nurses own needs and own quality of working life been ignored even though they always trained to give patient's care and improve their quality of life (Mohammadi et al., 2011). QWL is a comprehensive, program designated to boost employee satisfaction, strengthening workplace learning and helping employees to handle change and transition (Sree Devi & Ganapathi, 2014). Based on Barnett, Namasivayam & Narudin (2010), the current shortage of nurses in Malaysia highlights the importance of nurses' to understand their work environment, giving emphasis to the variety features of QWL, so that relevant strategies and policies can be formulated to retain them in the workforce and offer good quality service and care to the patients.

Quality of nursing care are considered as a crucial criteria in evaluating the quality of health care. The quality of nurses and health care is directly interlinked to the levels of job satisfaction and quality of work life. The rapidly changing health care environment has had an impact on the nursing work environment, workload and quality of nursing work life. Job discomfort, burn out, emotional distress and job turnover usually be seen in the nurses who are not satisfy with their work. These elements would in turn affect the quality of care given by nurses (Daubermann & Pamplona, 2012). The organization's success in achieve its goal depends on the quality of human resources especially the nurses. Therefore, close attention should be given to the nurses' physical and emotional needs (Janaabadi & Nastiezaie, 2012).

1.2 Problem statement

Public hospitals are a stressful work environment and shift work places an additional strain on nurses (Lindokuhle et al., 2014). The RNs described that increasing number of patients, staff and skills were not always sufficient to manage the care of the seriously ill, can consequently

led to feelings of frustration (Halm, Peterson & Kandels, 2008). Other than that, the poor support system, advancement in technology, shortage of nurses, dealing with the patient, caring for death and dying are the factors that cause stress for the nurses (Nevidjon & Erickson, 2001).

Besides, hospital is internationally recognized as an appropriate setting for health promotion, deliver of care and disease prevention as it is a place where working individuals could spend up to 60% of their waking hour. Unfortunately, the risk of non-communicable disease (NCDs) and exposure to infectious disease remains a concern to nurses. Employees especially nurses are at higher risk of getting non-communicable diseases such as diabetes, hypertension and coronary heart diseases (Skaal & Pengpid, 2011). The main risks of NCDs are unhealthy eating, disturbance sleeping time, physical inactivity, smoking and alcohol abuse.

Patient care cannot be confined to usual working hours (0800 – 1700 hours), so nurses need to work in shifts. But, shift work also can give a negative impact on the nurses and could lead to job related stress, increased drug use, poor job performance, insomnia, and disrupted social and family life (Abdalkader & Hayajneh, 2008). Night working shift is considered as a kind of challenge among most nurses and can lead to several forms of physical and emotional disorders (Nasrabadi et al., 2009). The high prevalence of health related conditions and risk factors such as obesity, overweight, physical inactivity, and poor eating habits usually always be seen amongst shift and rotational night shift workers.

According to Ashy (2004), some of the nurses in Saudi unable to balance the work-family requirements as they had to work hard to balance the demands of their careers and their family needs. Due to spent a long time at work, many nurses stated that they had little energy that left after work. The usual working hours for primary health care (PHC) nurses, are between 47.5 hours per week until 49 hours that work two shifts per day, compared to 35 hours for other workers in other public sector professions. In UMMC, the working hour are divided into 3 period which are morning shift (0700-1400), evening shift (1400-2100) and night shift (2100-0700). As a result, some of the nurses become unable to balance their work with their family requirements.

Nowadays, even though there are abundant job opportunities available in Malaysia, nursing become no longer popular as it used to be. The nursing shortage is a worldwide phenomenon and Malaysia is no exception. Shortage in the nursing workforce also can affect quality of work life and this problem can places a high load on the nurses who remain in the settings. 'Push' factors that can affect nurses to leave their organization were issues of understaffing and demanding workloads (Hegney et al., 2006). In Malaysia, the shortage of nurses has been identified as a critical problem faced by public hospitals (Manaf, 2005). World Health Organization (WHO) recommended nurse-to-population ratio of 1:200, so, Malaysia would need 130,000 nurses in all specializations by 2020 (Ministry of Health, 2017). Due to work life condition, staffing problem and a high workload is making the nurses to leave the profession itself. Thus, this study intended to know the quality of work life of the nurses working currently with the institution.

1.3 Objectives

1.3.1 General objective

The general objective of this study is to determine the quality of working life among nurses in University Malaya Medical Center (UMMC).

1.3.2 Specific objectives

i. To assess the quality of working life among nurses in UMMC.
ii. To determine the association between socio-demographic and quality of work life among nurses in UMMC.

1.4 Research questions

- What is the quality of working life among nurses in UMMC?

- What is quality of work life or home life among nurses working in ward and clinic at UMMC?
- What is quality of work design among nurses working in ward and clinic at UMMC?
- What is quality of work context among nurses working in ward and clinic at UMMC?
- What is quality of work world among nurses working in ward and clinic at UMMC?
- What is the association between socio demographic and quality of working life among nurses in UMMC?

1.5 Significance of study

1.5.1 Nurses

The results of this investigation can be used to create theory-based and evidence informed strategies to enhance the quality of work life in nursing profession with the potential to support the delivery of quality patient care. The morale of workers especially nurses can be increase by efficient QWL program and at the same time it can enhance the organizational effectiveness.

Nurses with high quality of working life seems to achieve high life satisfaction. They are defined as those who perceived their life conditions as outstanding, leading almost an ideal way of life and are gratified with their life. When nurses are satisfied with their jobs, rates of absenteeism and turnover decrease, staff morale and productivity increase, and work performance as a whole can be improve. Moreover, nurses with high QWL also can appear to be delivering high service quality to patient. They are described as providing empathy services such as understanding patient's feelings, bringing emotional comforts and providing courage and confidences to the patients and families.

1.5.2 Patient

The focus of nurses is the provision of patient-centered care. This is because, nursing care are concentrated on patient self-management and encourage development of health and recovery. Nurses usually become the first points of contact for patients. Nurse is the one who often with the patients and gather information about them. Direct contact with the patient and good quality of care can building and maintaining a relationship of trust.

Benefits of good quality of work life of nurses on patients can be evidenced in higher levels of patient satisfaction and improved quality of care. Patients' perceived ability to manage their health condition after leaving the hospital and the can manage themselves from recurrent health problem.

1.5.3 Organization

This study paper can enhanced the effort of nurses to improve the treatments and care towards patient based on evidenced based practice specifically in the nursing profession. Moreover, with the high standard of quality of nurses work life and standard of care, the prestige of the hospital can be maintained and even can become the role model for the other hospitals around Malaysia.

The study can contribute to the growing body of knowledge regarding effective work environments in hospital settings particularly regarding the link to objective measures of nursing-sensitive patient outcomes. Besides, quality of work life will increase the quality care and patient safety as well as improving the shortage of nurses in hospital. As the result, it will increase the reputation of the organization.

1.6 Operational Definition

1.6.1 Nurses

Nurse is a person who completed a program of basic, generalized nursing education and is authorized by the appropriate regulatory authority to practice nursing. Besides, nurses also carry out health care teaching, participate fully as a member of the health care team, supervise and train nursing and health care auxiliaries and also involved in research (Braveman, 2011). Other than that, American Nurses Association, (2015) define nursing as the protection, promotion, and optimization of health

and abilities, prevention of illness and injury, facilitation of healing, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, groups and communities.

In this study, the researcher focused more on nurses working in the inpatient wards and clinics in UMMC. They are also the person who participate in giving care and treatments to patients.

1.6.2 Quality of working life

Quality of Working Life (QWL) is defined as a term that is used to describe the broader job-related experience an individual has. It also refers to the favorable or unfavorable of a job environment and condition for the people working in an organization. Daubermann & Pamplona (2012), said that quality of working life is a process by which the organizations' employees learn how to work better together to enhance both the staff's quality of life and the organizational effectiveness simultaneously.

Other than that, Sree Devi & Ganapathi (2014) interpret quality of work life (QWL) as an area of study that has attracted and also increase the interest not only in the areas of health, rehabilitation, disabilities and social services but also in medicine, education and others. The ultimate goal of QWL study is to ensure people to lead quality of their lives so that they can lives in both meaningful and enjoyable.

In addition, Brooks and Anderson (2005) describe quality of life as a complex things impact by and interacting with many aspects of work and personal life. In the nursing perspective, Brooks highlighted that the QWL of nursing emphasizes on the "degree to which RNs are able to fulfill important personal needs through their experiences in the work, while accomplishing the organization's goals and to make meaningful contributions to their organization".

Quality of nursing work life (QNWL) focus on identifying opportunities for nurses to improve their work and work environment while achieving the organization's goals. Moreover, some evidence suggests that improvements in work life are needed to improve efficiency and productivity to do work. Therefore, QNWL focus on identifying opportunities for nurses to improve their work and work environment while achieving the organization's goals.

In this study, the researcher focused on the quality of work life among nurses in UMMC. Quality of nursing work life is focused on the degree to which nurses able to satisfy personal needs through experiences in work, and at the same time achieving the organization's goal. There are four aspects that researcher explored in this study which are quality of work life/home life, work design, work context and work world.

1.7 Summary

Nurses are trained to focus on patient's quality of care and life but sometimes they neglect their own needs. Quality of working life is a system of evaluate how people experience to work, how the experience relates to job satisfaction, intent to leave, turnover rate, personality and work stress. It is now almost universally recognized that nursing is one of a stressful occupation. This is due to insufficient staffing so that nurses experience difficulties in meeting patient needs. To endure with any challenges in the health care delivery system and to ensure the quality of care rendered and patients satisfaction on the care received, it is important to know how nurses satisfied with their quality of work life and jobs and what characteristics influence their QWL.

CHAPTER 2
LITERATURE REVIEW

2.1 Introduction

In research, literature review is a key step in research process. Before the researcher starting the study, literature review of previous studies and experiences related to the research is done. Review of literature of past studies can lead to new study ideas, knowledge and insight. Usually, quantitative researches can obtain more research articles compared to qualitative study.

According to Richard (2017), literature review is the process of reading, analyzing, evaluating, and summarizing scholarly materials about a specific topic. Scholarly materials refers to published and unpublished database literature and conceptual literature materials found in print and non-print from 'database resources'. The results of a literature review may be compiled in a report or may be serve as part of research article, thesis or proposal.

The purpose of this chapter was to report on the review of literatures related to the research topic. The chapter told also how the researcher uses several of search engines and databases to look for the previous study related to the topic. Besides, the overview of quality of nursing work life was discussed to help researcher gained information and knowledge about this topic. Previous studies related to the research topics were further reviewed to report the findings and help to support the researcher ideas.

2.2 Search strategies

As shown in Figure 2.1, researcher used various kind of databases in order to find any research articles related to the topic. The electronic search is performed on the following databases subscribed by the University of Malaya digital library which are Ovid, ScienceDirect, CINAHL and PubMed. The research keywords entered were *nurses, quality, work life*, *nursing work life and quality of work life*. CINAHL database showed 8505 results, ScienceDirect showed 231 results, Ovid showed 8876 results and PubMed showed 1693 results. Then, several limitations were used to narrow the result besides to look for the any relevant literature.

To search for the precise literatures, the researcher keyed the relevant keywords to filter out irrelevant articles. The researcher also establish the inclusion and exclusion criteria to guide in filtering the articles. The inclusion criteria are English article, quantitative research, full-text article, publication year was limited from 2008 to 2018 and the journal subset was limited to nursing only. The exclusion criteria are qualitative approaches articles and paid articles.

As the result, CINAHL database showed 158 results, ScienceDirect showed 13 results, Ovid showed 86 results and PubMed showed 7 results. Then, the results were screened by excluded articles that the inclusion criteria not met, duplication article and research instrument not suitable to find relevant articles related to the research topic by reviewing the titles and abstract of each articles. Finally, there were 13 total relevant articles found and retrieved for the purpose of literature review.

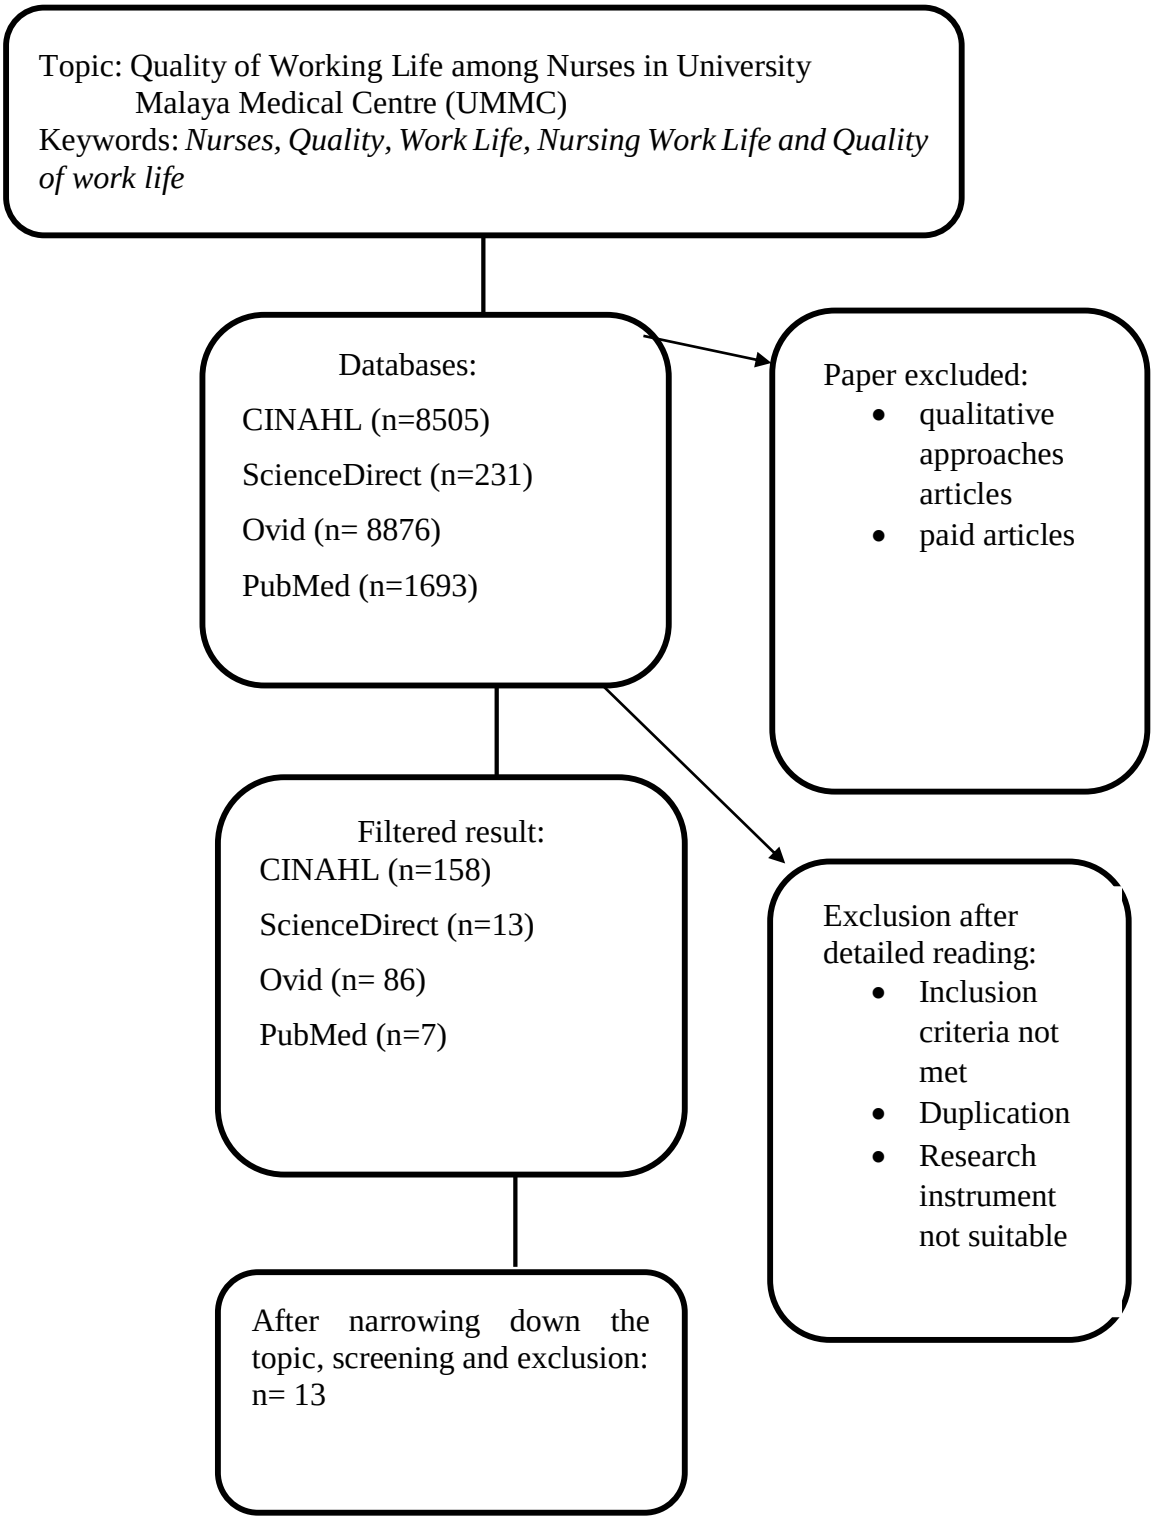

Figure 2.1 Flow Chart on Search Strategies

2.3 Quality of Work Life (QWL)

Quality of Work Life is a concept that was developed in the early 1930's showing its importance in the productivity of workers. This concept has gained interest and importance across the globe. There is also a drastic change in the idea of work life and work culture among the

employees. Employers are considering work life as a critical factor for personal as well as career development (Nanjundeswaraswamy & Swamy, 2012). A healthy work environment can be defined as a work setting in which nurses are able to both achieve the goals of the organization and derive personal satisfaction from their work (Disch, 2002)

The Hawthorne studies by Mayo in 1930 was considered to be the first study that develop the impact of workplace miniature on productivity which specified the importance of QWL on workers' productivity (Lokanadha & Mohan, 2010).

Quality of work life was the idea which gained more acceptance in nursing profession. Some studies have been done to measure the quality of work life among nurses. QWL also refers to strengths and weaknesses in the total work environment (Knox & Irving, 2007). Quality of work life had many of definitions and predictors that influence the nurses' quality of work life. Unfortunately, there was a lack of uniformity in findings related to quality of work life.

2.4 Perception of the quality of work life among nurses

Aspects such as salary, personality, job-related stress, occupational accidents, safety regulations and labor discipline, work setting health conditions, welfare facilities and work prospects are shown to influence the QWL of the nurses. Thus, changes or lack in any of these features may affect the QWL among nurses (Khaghanizadeh et al., 2008)

Besides, the consequences of the work patterns on an employee's ability to achieve work-family balance are clear and formerly demonstrated (Yildirim & Aycan, 2008). When the employees had a negative perception of the shift schedule, it can increase the possibility for the work-family conflict through the perception of the scheduled hours as too irregular, inflexible or excessive. These can increase pressures on the nurse's perception of ability to serve in the family role and fulfill expected demands (Millicent & Richard, 2010).

Based on study by Mona & Samah, (2014), another important issue that appear to give positive impact to the nurses' perception towards QWL is attending of training course and continuous lifelong learning. This is because with the training itself, it can enhance the requirement for self-development and improvement which are the important components of work satisfaction and consequently, it can improve the QWL. However, less than half of the nurses had the opportunity of attending training courses. In congruence with this, the opportunities for professional development were reported by the respondents, in Saudi Arabia as unsatisfactory (Almalki et al., 2012). Similarly, study by Alhusaini (2006) in Riyadh found that 30.3% of nurses were not offered any continuing education programs or training courses.

2.5 Dimensions Quality of Nursing Work Life (QNWL)

The dimensions of quality of work life which are reported in 'Quality of Work Life: A Stance from Nursing Professionals' consist of 10 dimensions. There are health and well-being, job security, job satisfaction, competence development, work life balance, control over work load, nursing leadership, control over nursing practice, innovation and creativity and support and recognition (Jayaraman & Chandran, 2010).

Most of the studies on nurse's quality of work life measured QWL using a variety of combination tools. The tools do have certain concepts in common but often it results in different interpretations by the researchers. This resulted in a lack of consistent conceptualization (Vagharseyyedin, Vanaki & Mohammadi, 2011) .The tools which are used for measuring QWL are qualitative approaches and standardized or developed questionnaires based on the various dimensions of quality of work life.

Dimensions which are captured through Brooks Quality of Nursing Work life (QNWL) are work life/home life, work design, work context, and work world (Brooks & Anderson, 2004):

Work life/home life - Define as interface between the lives experiences of nurses in their place of work and in the home. Routinely shift changes can be related to turnover intention, job frustration,

and work commitment. Allowing nurses to influence shift patterns and accommodating preferred shift pattern, were positively associated with commitment to nursing (Brooks & Swailes, 2002). Based on Hegney et al. (2006), change in working environments and rotating shift are found to be the crucial sources of work dissatisfaction among 130 nurses and midwives in four London hospitals. Shift patterns also have been shown to rise nurse turnover in the organization.

Work design - Known as the composition of nursing work and describes the actual work nurses perform. Hegney et al (2006), conclude based on their study that nurses found that their workload are abundant, and most of them unable to finish their tasks in the time. Major reason that lead the nurses to leave their workplace and occupation were workload and inequality of workforce. Most of the respondents in Hegney et al (2006) study, believed that the registered nurses in their units were not enough and this cause increasing workload to other nurses. Recent research has linked low staffing levels with poor patient welfare and longer patient stay (Needlemann et al., 2002).

Work context - The aspect that comprises the practice settings in which nurses' work and discovers the impact of the work environment to both nurse and patient requirements. Hegney et al. (2006) reported that there were 65% of nurses stated that the managers were not listen and respond to their concerns and opinions. The results propose that enhancement in the management attitudes and perspectives were needed as well as better valuing of nurses' rights. Based on Rout (2009), respondents specified that their work settings are not offer course advancement occasions, and skill upgrading often insufficient. His study also reported that nurses became dissatisfied in their work when they perceived a least of opportunity for job advancement and managers did not recognized their achievement. Lee et al. (2004) conclude that critical motivators in the pursuit for success especially in nursing practice and environment were potential for accomplishment, recognition, and development. To increase the nurse's work satisfaction, approaches in improving the nurse's professional status and individual achievement should be effective. Other than that, nurse's teamwork with other interdisciplinary health care team can also impact their QWL. Cooperation with other health care personnel as well as with colleagues, is vital for their professional growth and improve quality of care for the patients (Johns, 2003).

Work world - Describe as the effects of broad societal influences and change on the practice of nursing (Brooks & Anderson, 2005). Many respondents state that public does not have precise opinions regarding nurses' image and profession. Based on Nasrabadi et al., (2003), another important factor that has contributed to the nursing problem is the poor social position of registered nurses in Iran. People think registered nurses as assistants to the physicians, and many physicians also regard nurses as their helpers and do not consider them as specialists in the art of caring. A poor public image of nursing may affect not only nursing recruitment, but also the nurse's attitudes towards work (Takase, Maude & Manias, 2006).

2.6 Predictors Quality of Nursing Work Life (QNWL)

Some studies have identified various predictors which can influence the quality of work life especially among nurses. The main factors which have direct impact on quality of work life as reported by a systematic review was health and well-being, job security, job satisfaction, competence development work life balance, control over work load, nursing leadership, lack of autonomy, appropriate job performance feedback and opportunities for advancement.

A findings were reported by a study done in clinic in Taiwan among 56 nurses. The study suggested that nurses perceived good quality of work life as maintaining a good balance between work life and home life. However, the nurses reported difficulties in balancing the work as well as the family responsibilities due to longer time of working. In this study the salary for nurses differ in terms of the hospital, the type of their license and nursing grades. The nurses considered salary as a reason to quit the profession (Hsu & Kernohan, 2006)

The study by Xu Zeng et al. (2009) among 811 Singaporean nurses found five factors that affect the quality of work life which are job and career satisfaction, general well-being, homework

interface, stress at work and working conditions. The study also concluded that quality of work life and quality of life are not the same. Social functioning (SF-12) was used as a tool to measure the quality of life in which the general well-being is measured. This also suggested that quality of work influenced the quality of life and it is an aspect of quality of life.

QWL assessment provides an understanding about the often things the nurses have face in relation to the work environment (Flinkman et al., 2008). A systemic study that is done by Vagharseyyedin et al. (2011) examine two concept which are the predictors for quality of work life and defining quality of work life in nursing perspective. This study was done among 14 Iranian nurses and the result was found that shift work schedules negatively affected the personal life of nurses. The factors that contribute to poor quality of work life were workload, role conflicts, lack of autonomy, low salary, lack of opportunities for career advancement, lack of managerial support and insufficient welfare services. The negative attitude and behavior towards nursing also impacted the quality of work life (Vanaki & Vagharseyyedin, 2009).

Another findings from the study that is done in Thailand among 550 nurses shows that the quality of work life was not influenced by the personal factors. The nurses in the study also reported the moderate level of quality of work life (Boonrod, 2009).

Quality of nursing work life is considered to be a critical aspect in increasing the quality of care delivered to the patients. The findings of the study by Almaki et al (2012) among 508 primary health care nurses in Saudi Arabia showed that most of the nurses were dissatisfied with their work life. Amongst the four dimensions work context followed by work design gave the strong contribution to turnover intention. The main variables under work context are management and supervision, co-workers, professional opportunities and work environment. The main work design variables which had an impact of turnover intention are workload, job satisfaction level, lack of workforce, lack of autonomy, perform many non-nursing tasks, having interruptions in working and limited time to do jobs and care for patient (Almalki, FitzGerald & Clark, 2012).

A study done in Malaysia among nurses in public hospitals was also consistent with similar findings. The study suggested that nurses' shortage in Malaysia is strongly related to the work environment. The factors identified to solve nursing shortage in the present study were needs for communication, opportunities for career advancement and work and home life balance. They also suggested an effective work environment is essential to maintain the nursing workforce (Mohamed, 2012).

Study that was done by Brooks and Anderson among nurses in the University of Illinosis Chicago in 2004 reported that the interactions at the work place had affect the quality of nursing work life. The nurses felt that day care facilities for child care, on-site degree programs and rest room separately for nurses are essential (Brooks & Anderson, 2004).

Similar study that is done in Iran by Khani et al (2007) reported a moderate quality of nursing work life among 120 Iranian registered nurses at Isfahan Hospital, University of medical Sciences. The nurses reported that they were incapable of balancing between the work-home lives and were dissatisfied in their job. The findings from the study showed that shift duties, inadequate salaries, workload, autonomy problems and career advancement opportunities are the main factors for poor quality of nursing work life and also result in job dissatisfaction (Khani, Jaafarpour & Dyrekvandmogadam, 2008).

Hence, preliminary evidence suggests that improvement of QWL is a prerequisite to increasing productivity in hospitals. Thus, QWL is in need of scholarly investigation. Identifying the nurse's quality of work life can provide critical information for nursing managers in their efforts to design managerial programs that will enhance retention and work productivity

2.7 Summary

Quality of work life has strong theoretical roots and legitimacy and it has engendered significant interest in the organizational literature. Quality of work life of nurses, job satisfaction and

quality of care to the patients should be the major concern of any organization. The profession of nursing itself is often marginalized. It is important that even though nurses play a key role in saving lives, the quality of life among nurses must not put aside. Findings from many studies shows that nurses still have challenging working conditions, low salary, workplace restrictions, poor work environments, no social acceptance, shortage of nurses and abuse from employers, colleagues, and patients' families. Clearly, there appears to be a basic set of needs and work environment characteristics that are universally important for all nurses, but the importance of any particular need is not well understood.

CHAPTER 3
METHODOLOGY

3.1 Introduction

This chapter discussed about the ways on how the study was conduct to achieve its objectives and answer all the research questions. It includes the study design which explained the method that was use by the researcher to conduct the research besides defining study settings where the data was collect. This chapter also explained the population and sampling which contain target population, sample calculation, sampling method, inclusion and exclusion criteria of the research population. Moreover, the research instrument discuss in what type of instrument was use and its reliability and validity to be use for the purpose of research. Data collection method and its analysis was discuss in order to explain the research approval from the ethics body so that the research conduct in proper ways and manners based on the ethical consideration. In addition, pilot study and its research also was discuss and lastly a summary is include to summarize the whole chapter.

3.2 Study design

A research design is the set of methods and procedures use in collecting and analyzing measures of the variables specified in the research problem research (Ader, Mellenbergh & Hand, 2008). It is a framework that will be creating to find answers for the research questions. The research approach for this study was quantitative and cross-sectional. Quantitative research is a formal, objective, systematic process in which numerical data are used to obtain information about the world (Burns & Groove, 2005). Cross-sectional research design does not have time dimension and only measure difference between or from among a variety of people, subjects or phenomena rather than a process of change (Labaree, 2009), which more suitable to gather information for this study. The cross sectional study involve single examination like a snapshot of cross sectional of population at a given time. In this study, researcher use cross-sectional study to assess the quality of working life among nurses in UMMC.

3.3 Study setting

The setting of this study was a teaching hospital at Klang Valley area which was University of Malaya Medical Centre (UMMC) or formerly known as University Hospital. The hospital located in Pantai Dalam, south-west corner of Kuala Lumpur. The hospital was part of University of Malaya and one of the government-funded medical institution or teaching hospital under the Ministry of Higher Education available in Malaysia. UMMC consists of 4 main buildings which are Menara Utama, Menara Timur, Menara Selatan and Kompleks Wanita dan Kanak-kanak. There are altogether 62 departments with total of 1911 staff nurses. In this study, researcher selected inpatient units (medical-surgical unit and critical care unit) and outpatient units as the study setting.

3.4 Population and sampling

3.4.1 Target population

Population can be divided into 2 groups which are target population and accessible

population. Target population can be defined as any inferences from a sample refer only to the defined population from which the sample has been properly selected (Banerjee & Chaudhury, 2010) while accessible population refers to people from available group that the researcher take into the study. The target population in the study was registered nurses who work in hospital and the accessible population was registered nurses that work in University of Malaya Medical Centre (UMMC). From the records of Nursing Department of UMMC in 2017, there are about 1911 of registered nurses in UMMC. Participants were define as the registered nurses who are working at the outpatient units, medical-surgical units and critical care unit.

3.4.2 Sampling method

Sample is the subset of population selected to represent the population. Sampling is the process used in statistical analysis in which a predetermined number of observations are taken from larger population (Investopedia, 2016). The sampling method use in this research were stratified random sampling and convenience sampling. Researcher used stratified random sampling to in selecting the number of respondents required in every units. Researcher divided the nurses' whole population into sub-populations which were medical unit, surgical unit, critical care unit and outpatient services. Then, researcher applying random sampling to each stratum by using draw lots. This method enable researcher to gather the representative data from each subgroups. After that, the researcher used convenience sampling to distribute the questionnaires to the registered nurses who were available and willing to participate in the study during the period of collecting the data.

For example, for medical-surgical unit, the wards selected using draw lots were 13U, 8U, 6U, WP2, 8TD, 7TD, 6PA, and antenatal ward. For critical care services, 4S/CCU (Cardiology ward), ICU, emergency department and operation theatre had been selected. For outpatient unit, researcher selected RUKA, eye clinic, ENT clinic, pediatric clinic, dialysis daycare, medical clinic and oncology clinic.

3.4.3 Sample calculation

The sample was calculate by using sample size calculator which is Raosoft Sample Calculator. There were 1911 registered nurses working in UMMC. Based on the total population size was 1911, 5% acceptable margin of error, confident level of 95% and 50% of response distribution, the minimum recommended size of the study was 320 of registered nurses work in UMMC.
Example calculation for total sample in each service showed in Table 3.1:

Total nurses in selected unit after draw lots = medical + surgical + critical care (ICU, CCU + Operation theatre + Emergency department) + outpatient

= 116 + 126 + (159+134+127) + 159

= 821

$$\text{Number of respondents} = \frac{\text{Total nurses in each unit}}{\text{Total nurses in selected unit}} \times \text{sample size}$$

Table 3.1: Calculation of sample size

Unit/ service	Calculation	Number of respondents
Medical	**Error!**x 320	45
Surgical	**Error!**x 320	49
Critical care – ICU, 4S/CCU	**Error!**x 320	62
– Operation theatre	**Error!**x 320	52
– Emergency department	**Error!**x 320	50
Outpatient	**Error!**x 320	62
Total		320

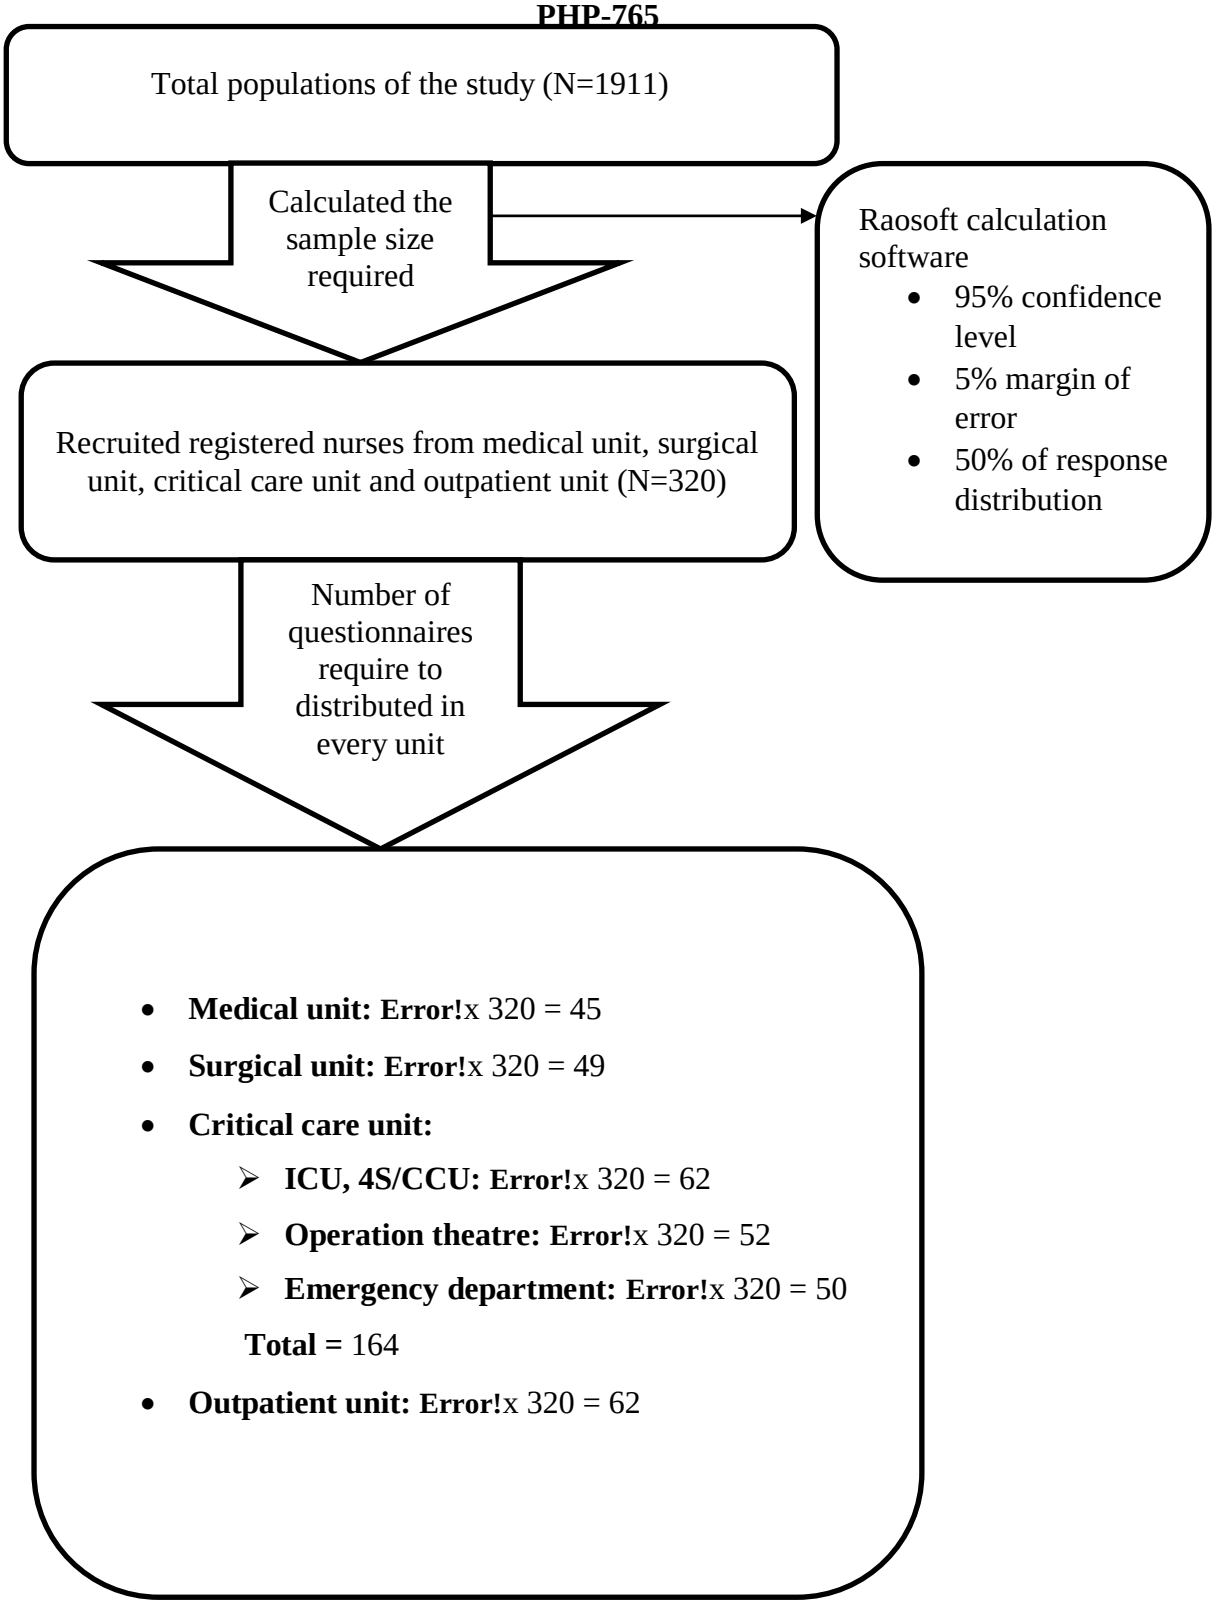

Figure 3.1: Sample calculation method

3.4.4 Inclusion and exclusion criteria

Inclusion criteria are characteristics that the prospective subjects must have if they are to be included in the study. Inclusion criteria, along with exclusion criteria, make up the selection or eligibility criteria used to rule in or out the target population for a research study (Hulley et al., 2007). The inclusion criteria was the nurses registered with minimum one year of working experience.

Exclusion criteria are a set of predefined definitions that is used to identify subjects who will not be included or who will have to withdraw from a research study after being included (Hulley et al., 2007). The exclusion criteria was the nurses who from other hospitals. For example, those who come to UMMC for their post-basic. For those for those who had taken part in the pilot study are excluded from the real survey and who those who away during the study period also been excluded from this study.

3.5 Research instrument

The instruments are device or tools that the researcher tends to use to carry out the study. The instruments can be in the form of survey, questionnaire, test, scale, rating or tools designed to measure the variable of interest. The quantitative data are obtained through closed-ended questionnaire. The researcher used the questionnaire which was one of the instruments categorized in subject-completed instruments and involving the self-checklist method.

3.5.1 Questionnaire

Questionnaires are doubtless one of the primary sources of obtaining data in any research endeavor. However, the critical point is that when designing a questionnaire, the researcher should ensure that it is valid, reliable and unambiguous (Richards & Schmidt, 2002). Questionnaire is a set of designated question given exactly in the same form to a group of people. The questionnaire use by the researcher is Brooks Quality of Nursing Work Life (QNWL) Survey. This questionnaire is adapted from Brooks and Anderson (2004) to measure the QWL among registered nurses. Some modification done in this questionnaire. In addition to the original English format, the questionnaire was converted into Malay using a translating and back-translating technique. This questionnaire also has been validated and suitable to be used.

3.5.1.1 Part A (Socio demographic characteristics)

The first part of the questionnaire was the background information or demographic data developed by the researcher which contain 9 items including age, gender, marital status, ethnicity, educational level, working experiences, type of discipline, working setting and monthly income. Participants needed to answer the questions by tick (/) or write the answer in the box provided.

3.5.1.2 Part B (Quality of Working Life)

The second part consist of 42 items and it has four subscale (Home life/Work life, Work Design, Work Context and Work World). There are 7 questions in quality of work life/home life, 10 questions in quality of work design, 20 questions in quality of work context and 5 questions in quality of work world as shown in Table 3.2. The work life/ home life dimension is defined as the interface between the work and home life of the nurses. The work design dimension is the composition of nursing work and describes the actual work that nurses performed. The work context dimension includes the practice settings in which nurse's work and explores the impact of the work environment on both nurses and patient systems. Finally, the work world dimension is defined as the effect of broad societal influences and changes on the practice among nursing (Brooks & Anderson, 2005). Each item in the original scale is scored in 6-point Likert scale ranging from strongly disagree-1, moderately disagree-2, disagree-3, agree-4, moderately agree-5 and strongly agree-6. By following

the plan used by Brooks and Anderson (2005), the 6-point scale was divided to two categories which are agree and disagree. The agree category contains positive responses (agree, moderately agree and strongly agree), while disagree category contains negative responses (strongly disagree, moderately disagree and disagree). The score of QNWL ranges from 42-252 which indicate low, moderate and high according to the scores. The minimum total score is 42 and the maximum is 252. Higher total scores indicate high quality of working life. The score for the QNWL and its interpretation is given as shown in Table 3.3.

Table 3.2 Quality or working life items

Quality of work life (4 subscale)	
Home life/ work life	7 items
Design	10 items
Context	20 items
World	5 items

Table 3.3: Interpretation of Scores for Brooks' Quality of Nursing Work life Survey

QNWL scale	Scores	QNWL
Total QNWL (range 42-252)	42-112	Low
	113-182	Moderate
	183-252	High
Home life/ Work life	7-18	Low
(Range 7-42)	19-29	Moderate
	30-42	High
Work design (Range 10-60)	10-26	Low
	27-44	Moderate
	45-60	High
Work context (Range 20-120)	20-38	Low
	39-77	Moderate
	78-120	High
Work world (Range 5-30)	5-12	Low
	13-20	Moderate
	21-30	High

3.5.2 Validity & reliability

Validity and reliability are very important criteria in order to approve and validate the study. According to Joppe (2000), validity determines whether the research truly measures that which intended to measure or how truthful the research results are. Remeyi et al (2005) describe validity as a good fit between theory and reality, in the same sense that when a description of a process is evaluated, best fit between theory and reality can be traced. On the other hand, reliability is a similar observations that should be made by researchers on different occasions and the concern is that how replicable the study is (Remeyi et al, 2005).

The research questionnaire checked by the expertise to ensure its validity that can be use among nurses to assess the quality of working life. The researcher forwarded the questionnaire to three expertise who are nursing lecturer at Department of Nursing Science, ward sister and nurse manager (management).

Besides validity, the questionnaire also being tested for its reliability to ensure that the

research instrument was reliable enough to be use as a tool to measure the variables. A pilot study conducted in 1 month to ensure the reliability of the questionnaire. In this pilot study, the researcher chose 32 respondents to be part of the trial and the result analyzed in Statistical Package for Social Sciences (SPSS) software. The reliability coefficient (alpha) is range from 0 to 1, with 0 representing an instrument with full of error and 1 representing total absence of error. If the alpha is >0.70, it is considered acceptable reliability (Esposito, 2002). The result of the Cronbach alpha had shown in Table 3.4.

Table 3.4: Reliability test using Cronbach's Alpha

Instrument Tool	*r*
Quality of work life/home life	0.780
Quality of work design	0.706
Quality of work context	0.761
Quality of work world	0.728
Total Quality of working life	0.797

3.6 Data collection method

The researcher carried out a quantitative study in order to achieve the research objectives. Data was collected using self-administered questionnaire to the respondents to ensure a good response rate. Data collection was after the approval from the Ethics Committee of University Malaya Medical Center (MRECID NO: 201813-16). In this study, researcher went to the selected wards and clinics to distribute the questionnaires. The researcher also obtained permission from respective ward or clinic sister before distribute the survey. After that, the researcher approached nurses, gave a brief explanation regarding the research and obtained voluntarily consents from the participants. Participants also being assured that all data collect would be kept confidential and would be used for the academic purposes only. Participants were suggested to take at least 10-20 minutes to answer all the question. The questionnaires then was kept in a covered box to ensure the confidentiality.

3.7 Data analysis

Data was analyzed by using SPSS version 23. This is an easy software to utilize, code, enter, transform and manipulated the huge amount of data. Data were analyzed by using descriptive statistics and inferential statistics. Descriptive analysis performed on socio-demographic data and quality of working life. Total scores and sub-scores for QNWL items and item summary statistics were computed and reported. Besides, inferential statistic was used to determine the association between demographic factor and quality of working life. For association between socio demographic data and quality of working life, researcher had used non-parametric test which was Chi-square. A p value <0.05 will consider as statistically significant.

3.8 Ethical consideration

Ethical approval obtained from the Ethics Committee of University Malaya Medical Center (MRECID NO: 201813-16) to legally conduct the study. There was no data collected until approval from the Ethics Committee and respective body obtained. .Informed consent given by the respondents as an agreement for their participation in the study. The subject have their freedom to refuse at the outset or even withdraw from the study at any time. The data collected was not be shared at any cost and are used for research purpose only. In addition, several things and rules inside the information sheet provided along with the questionnaire form for participants to understand. The answered questionnaires was kept properly in a covered box. This is to ensure that the feedback on

questionnaires are remain confidential and at the same time, protecting the participants.

3.9 Pilot study

A pilot study is a preliminary small-scale study that researchers conduct in order to help before conduct a large-scale research project (Polit et al., 2001). It is conducted when a new instrument is being develop or when a pre-existing instrument is being used with people who have different characteristics from those for which the instrument was originally developed. The pilot study conducted after the researcher gets the ethical approval from the Ethics Committee of University Malaya Medical Center and validation of experts done. The pilot study was carried out in 12U prior the main research by using 10% of the actual sample size. Thus, an initial pilot study that using the same framework of questionnaire was administered to 32 nurses. Researcher approached the registered nurses one by one and obtained the response from them. The feedback from the pilot study became a baseline for the researcher to test the questionnaire and made some modification before actual research carried out. The respondents from the pilot study was excluded from the actual sample for the research.

3.10 Summary

This chapter summarized about the research design that composed by the study design and setting, population and sampling, research instrument, data collection method, data analysis, ethical consideration and pilot study. All these are study to achieve the objectives of the research. Quantitative design are used for the data collection to answers research questions for the purpose of study.

CHAPTER 4

4.1 Introduction

This chapter described the analysis of data collected from participants followed by a discussion of research finding. The findings related to the specific research questions that guided the study which stated in Chapter 1. After coding and entering the data, the researcher analyzed the data using the Statistical Package Social Science (SPSS) version 23. Data were analyzed by using descriptive statistics and inferential statistics.

Descriptive statistic was used to analyze the distribution and frequency of demographic characteristics and quality of working life among nurses. Besides, inferential statistic was used to determine the association between demographic factor and quality of working life among nurses. Non-parametric test was used to determine association between variables. The researcher used the Pearson Chi-square test to test the association between two categorical variables. If more than 25% of expected cell frequencies <5, Fisher's Exact Test will be used. The result also displayed in the form of tables and graphs accompanied with narrative explanation.

4.2 Data screening and data management

In the initial stage of data analysis, all the data collected were entered into the SPSS. All questionnaire was labelled with a serial number to avoid duplicate or repeated entry of data. All data was being screened and no missing value detected.

Normality test had been done on the dependent variables which was quality of working life among nurses to determine whether the sample data had been drawn from a normally distributed population. The normality test helped the researcher in selecting the proper statistical tests either parametric or non-parametric test to analyze the data. The results of normality test for dependent variables were shown as below in Table 4.1.

Quality of working life is normally distributed as mean was 157.28 and median was 158.0 which almost the same. Standard deviation also smaller than mean. The skewness shows value of -.38 and kurtosis was -.70 which were between +2 and -2. The histogram showed normally distributed. However, both the significant values of Kolmogorov-Smirnov and Shapiro-Wilk were < 0.05. Although the significant values of Kolmogorov-Smirnov and Shapiro-Wilk were less than 0.05, the dependent variable of nurse's quality of working life was still consider normally distributed according to other results.

Table 4.1 Normality test

	Quality of working life among nurses
Mean	157.28 (SE= 1.78)
Median	158.0
SD	31.87
Skewness	-.38 (SE= .14)
Kurtosis	-.70 (SE= .27)

4.3 Response rate

As shown in figure 4.1, a total 320 questionnaires were distributed by researcher through face to face with the respondents. The researcher collected back the questionnaires on the same day to avoid missing somewhere. After collected, researcher received 320 questionnaires from the respondents. This represented a response rate of 100.0%.

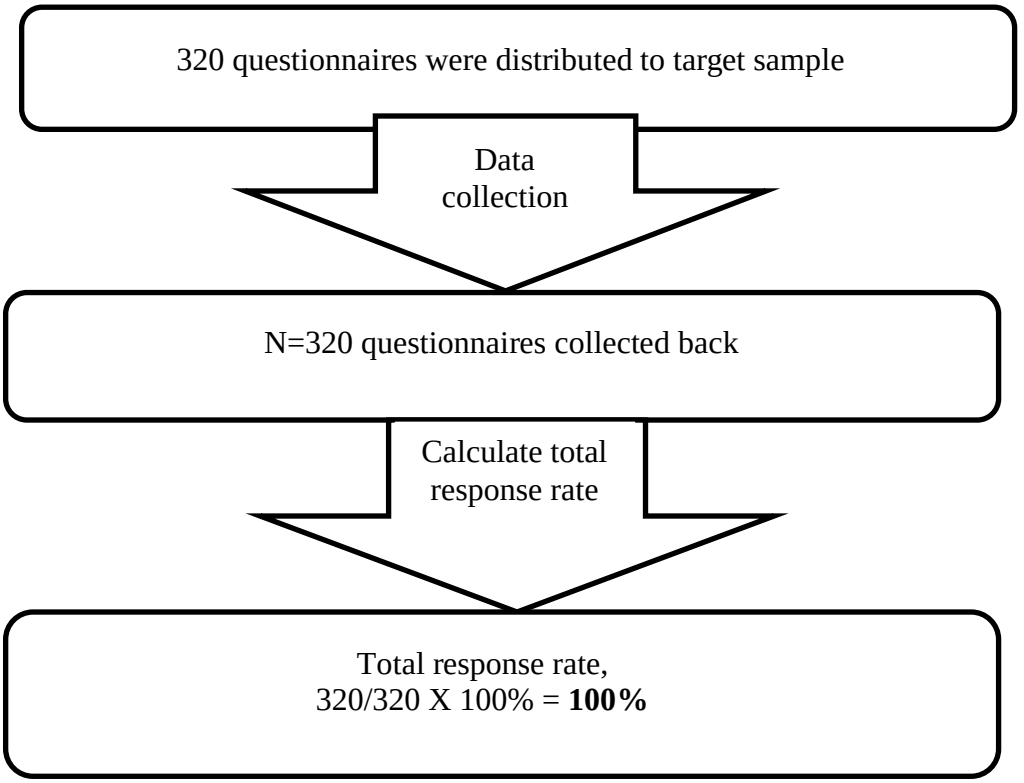

Figure 4.1: Illustrated the total response rate of this study

4.4 Demographic data of the respondents

From the Table 4.2, it showed that respondents with age group of 22 to 31 years occupied the highest percentage which was 45.9% (n=147), while the age of 52 years and above had the lowest percentage in this study which was 0.9% (n=3). The mean and SD for age of the respondents was 33.13 (7.16). Among 320 respondents, there were 78.4% (n=251) female respondents in this study. For marital status, respondents who married shows the highest percentage which were 54.7% (n=175), while divorced had the lowest percentage which were 6.9% (n=22).

Table 4.2: Demographic characteristics of respondents (N=320)

Characteristics	Frequency (n)	Percent (%)	Mean (SD)
Age			33.13 (7.16)
22-31	147	45.9	
32-41	126	39.4	
42 and above	47	14.7	
Gender			
Male	69	21.6	
Female	251	78.4	
Marital status			
Single	123	38.4	
Married	175	54.7	
Divorced	22	6.9	
Ethnicity			

	PHP-765		
Malay	242	75.6	
Chinese	49	15.3	
Indian	29	9.1	
Education level			
Diploma	270	84.4	
Bachelor	20	6.3	
Post basic	30	9.4	
Working experience			11.84 (7.11)
1-10	156	48.8	
11-20	115	35.9	
21 and above	49	15.3	
Working setting			
Ward	258	80.6	
Clinic	62	19.4	
Working discipline			
Medical	45	14.1	
Surgical	49	15.3	
Critical care unit	164	51.3	
Outpatient unit	62	19.4	
Income per month			
Less than RM 2999	167	52.2	
RM3000 and above	153	47.8	

For ethnicity, it shows that Malay respondents occupied highest percentages which were 75.6% (n=242), while Indian has the least percentages that were 9.1% (n=29). Besides, for educational level, 84.4% (n=270) of respondents graduated from diploma level while there were only 6.3% (n=20) respondents graduated from bachelor level. For working experience, most of the respondents 48.8% (n=156) had between 1 to 10 years of working experiences in nursing while respondent with more than 31 years had the lowest percentage which was 0.3% (n=1). The mean and SD for working experiences was 11.84 (7.11). Among 320 respondents, there were 80.6% (n=258) nurses working in ward. As for working discipline, it shows that critical care unit occupied the highest percentage which was 51.3% (n=164) while medical unit had the lowest percentage which was 14.1% (n=45). Other than that, for household income per month, the highest percentage of income of the respondents was less than RM2999 which were 52.2% (n=167), while the lowest income was above RM4000 which had .9% (n=3).

Objective 1: Assess the quality of working life among nurses

4.5.1 Quality of work life/ home life

Table 4.3 shows the details of the items (7 items) for quality of work life/ home life. Among 320 respondents, 53.2% (n= 170) agree that they able to balance work with family needs. 53.7% (n=172) also agree that it is important for a hospital to offer employees on-site childcare services. Besides, most of the respondents, 63.4% (n=203) disagree that they have energy left after work. 51.9% (n=166) of the respondents, agree that shift work schedule negatively affect my life. Other than that, 59.6% (n=191) agree that their organization's policy for family-leave time is adequate and 64% (n=205) also agree that it is important for a hospital to offer employees on-site day care for elderly parents. There are also 62.5% (n=200) of respondents agree that it is important for a hospital

to offer employees on-site ill child care services.

Based on Table 4.3.1, majority of nurse respondents had the moderate quality of work life/ home life with 60.6% (n=194) while there was only 14.1 (n=45) of the respondents that had low quality of work life/ home life.

Table 4.3: Quality of work life/ home life (N=320)

Item	Disagree n (%)	Agree n (%)	Mean (SD)
1. I am able to balance work with my family needs.	150 (46.8)	170 (53.2)	3.58 (1.27)
2. It is important for a hospital to offer employees on-site childcare services.	148 (46.3)	172 (53.7)	3.59 (1.25)
3. * I have energy left after work.	203 (63.4)	117 (36.6)	3.17 (1.26)
4. * Shift work schedules negatively affect my life.	154 (48.1)	166 (51.9)	3.51 (1.22)
5. My organization's policy for family-leave time is adequate.	129 (40.4)	191 (59.6)	3.71 (1.15)
6. It is important for a hospital to offer employees on-site day care for elderly parents.	115 (36.0)	205 (64.0)	3.83 (1.16)
7. It is important for a hospital to offer employees on-site ill child care services.	120 (37.5)	200 (62.5)	3.761.26)

* Reverse code

Table 4.3.1 Level of quality of work life/ home life (N=320)

Quality of work life/ home life level	Range of score	n (%)
Low	7-18	45 (14.1)
Moderate	19-29	194 (60.6)
High	30-42	81 (25.3)

4.5.2 Quality of work design

Table 4.4 shows the details of the items (10 items) for quality of work design. Among 320 respondents, 63.5% (n=203) agree that they receive a sufficient amount of assistance from healthcare providers (dietitian, patient care technicians, and nursing assistants). 61% (n=195) of the respondents agree that they satisfied with their job and 52/6 (n=168) also agree that their workload is too heavy. Besides, 62.2% (n=199) of the respondents agree that they have autonomy to make patient care decisions and 50.9 (n=163) agree that they perform many non-nursing tasks. In addition, 51.9% (n=166) of the respondents agree that they experience many interruption in daily work routine and 60% (n=192) agree that they have enough time to do job well. Other than that, more than half of the respondents, 63.7% (n=204) agree that there are enough RNs in their work setting. 62.1% (n=199) of the respondents agree that they able to provide good quality patient care. There was also 57.7% (n=185) respondents agree that they receive quality assistance from health care providers (dietitian, patient care technicians, and nursing assistants).

Based on Table 4.4.1, majority of the respondents had moderate of quality of work design with 67.2 (n=215) while there was least of the respondents had low quality of work design, 13.4% (n=43)

Table 4.4: Quality of work design (N=320)

Item	Disagree n (%)	Agree n (%)	Mean (SD)
1. I receive a sufficient amount of assistance from healthcare providers (dietitian, patient care technicians, and nursing assistants).	117 (36.5)	203 (63.5)	3.78 (1.11)
2. I am satisfied with my job.	125 (39.0)	195 (61.0)	3.76 (1.18)
3. * My workload is too heavy.	152 (47.4)	168 (52.6)	3.49 (1.19)
4. I have the autonomy to make patient care decisions.	121 (37.8)	199 (62.2)	3.68 (1.18)
5. I perform many non-nursing tasks.	157 (49.1)	163 (50.9)	3.48 (1.15)
6. * I experience many interruptions in my daily work routine.	154 (48.1)	166 (51.9)	3.51 (1.35)
7. I have enough time to do my job well.	128 (40.0)	192 (60.0)	3.73 (1.13)
8. There are enough RNs in my work setting.	116 (36.3)	204 (63.7)	3.89 (1.27)
9. I am able to provide good quality patient care.	121 (37.9)	199 (62.1)	3.90 (1.35)
10. I receive quality assistance from health care providers (dietitian, patient care technicians, and nursing assistants).	135 (42.3)	185 (57.7)	3.751.32)

4.5.3 Quality of work context

Table 4.5 shows the details of the items (20 items) for quality of work context. Among 320 respondents, 64.3% (n=206) agree that they able to communicate well with their nurse manager/supervisor and 61.3% (n=196) agree that they have adequate patient care and equipment. 59.4% (n=190) of the respondents agree that the nurse manager/supervisor provides adequate supervision. Besides, 62.9% (n=201) of the respondents agree that friendship with co-workers are important and 59.4% (n=190) also agree that their work setting provides career advancement opportunities. More than half of the respondents, 61.5% (n=197) agree that there is teamwork in their work setting. In addition, 64.7% (n=204) of the respondents agree that they feel a sense of belonging in their workplace and 64.7% (n=207) also agree that they able to communicate with the other therapists (physiotherapist, occupational, etc.). There was 59.4% (n=190) respondents agree that they receive feedback on their performance from nurse manager/supervisor. 59.9% (n=192) of the

respondents agree that they able to participate in decisions made by their nurse manager/supervisor. Other than that, 58.8% (n=188) agree that they feel respected by physician in thee work setting and 61.2% (n=196) agree that it is important to have a designed, private break area for the nursing staff. 56.6% (n=181) of the respondents agree that it is important to have nursing degree programs available in the hospital. There was 59.4% (n=190) respondents agree that they receive support to attend in services and continuing education programs. Besides, more than half of the respondents, 64.6% (n=207) agree that they communicate well with the physician in the work setting and 58.4% (n=187) also agree that they recognized for their accomplishment by nurse manager/supervisor. There was 59.1% (n=189) agree that the nursing policies and procedures facilitate their work. In addition, 57.8% (n=185) of the respondents agree that the security department provides a secure environment and 64.4% (n=206) also agree that they feel safe from personal harm (physical, emotional, or verbal) at work. There was 60.5% (n=195) of the respondent agree that he upper-level management has respect for nursing.

Based on Table 4.5.1, the majority of the respondents had high quality of work context while there are none of the respondent that had low quality of work context.

4.5.4 Quality of work world

Table 4.6 shows the details of the items (5 items) for quality of work world. Among 320 respondents, there was 54.6% (n=175) agree that the society has an accurate image of nurses. Besides, 53.8% (n=172) of the respondents agree that their salary is adequate for the job, taking into account the market conditions. There was 52.5% (n=168) of the respondents disagree that they would be able to find the same job in another organization with about the same salary and benefits. Other than that, 57.8% (n=185) of the respondents agree that they believe their job is secure and 70.3% (n=225) also agree that their work impacts the lives of patients/families.

Based on Table 4.6.1, majority of the respondents had moderate quality of work world with 50.3% (n=161) while there was only 12.8% (n=41) respondents that had the low quality of work world.

Table 4.6: Quality of work world (N=320)

Item	Disagree n (%)	Agree n (%)	Mean (SD)
1. In general, society has an accurate image of nurses.	145 (45.4)	175 (54.6)	3.56 (1.25)

4.5.5 Total quality of working life

4.5.5.1 Mean and SD for quality of work life items

Table 4.7 below shows the mean and SD for quality of working life among nurses. The overall quality of working life is 157.28 (31.87).

Table 4.7: Total quality of working life (N=320)

	Min	Max	Mean	SD
Quality of work life/home life	11	40	25.14	5.74
Quality of work design	18	51	36.98	7.85
Quality of work context	42	109	76.77	16.97
Quality of work world	10	27	18.39	4.26
Total quality of working life	85	222	157.28	31.87

4.5.5.2 Quality of working life level

The maximum level of nurses' quality of working life is 222 whereas the minimum level is 85. The nurses' quality of working life divided into three levels. Respondents who scored 42 to 112 considered as low level, respondents who scored 113 to 182 considered as moderate level and respondents who scored 183 to 252 considered as high level. It was noticed that most of the respondents have moderate quality of working life with 62.2% (n=199) whereas least respondents have low quality of working life with 12.8% (n=41) as shown in Table 4.8 below.

Table 4.8: Nurses' quality of working life level

Quality of working life level	Range of score	Frequency (n)	Percentage (%)
Low	42-112	41	12.8
Moderate	113-182	199	62.2
High	183-252	80	25.0
Total		320	100.0

Objective 2: Association between socio-demographic data and quality of working life

4.6 Association between socio demographic and quality of working life among nurses

There were 320 respondents involved in this study. The Pearson Chi-Square used to determine the association between socio demographic and the quality of working life among nurses. There was no outliers in the data as assessed by boxplot. Based on Table 4.9, the Pearson Chi-Square was used to determine if there were association between age groups of the respondents and quality of working life. There was statistically significant association between age and quality of working life, $\chi 2$ (4, N=320) = 23.08, p = .001. Majority of the nurses were between age 22-31 years old had moderate QWL with 63.3% (n=93).

Pearson Chi-Square analyses also revealed significant relationship existed between ethnicity and quality of working life, $\chi 2$ (4, N=320) = 10.07, p = .04. Majority of the nurses were Malay had moderate QWL with 58.7% (n=142). Other than that, there was a significant relationship existed between educational level and quality of working life among respondents as shown by Pearson Chi-Square Test, $\chi 2$ (4, N=320) = 20.29, p = 0.01. Majority of the nurses were graduated from diploma level had moderate QWL with 65.2% (n=176).

RM3000 and above						

Remark: # p-value of Fisher's Exact Test & * indicate significant result.

Furthermore, Pearson Chi-Square analyses also revealed a significant relationship between working experiences (year groups) and quality of working life among nurses as $\chi 2$ (4, N=320) = 21.16, p = 0.02. Majority of the nurses had working experiences between 1-10 years had moderate QWL with 64.1% (n=100).

Pearson Chi-Square analyses also revealed a significant relationship existed between monthly income of respondents and quality of working life, $\chi 2$ (2, N=320) = 11.6, $p < .05$. Fisher's Exact analyses also revealed a significant relationship exist between the monthly income of respondents and quality of working life as $p < 0.05$ (p-value = .04). Majority of the nurses had monthly income RM3000 and above had moderate QWL with 66.0% (n=101).

Other than that, there were no significant relationship between gender, marital status, working setting and working discipline with QWL.

4.7 Summary

In conclusion, SPSS version 23 was used to analyze the result. Most of the respondents had moderate quality of working life. Besides, inferential statistic was analyzed by using Chi- Square test. For the association of the quality of working life with selected demographic characteristic, only age, ethnicity, educational level, working experiences and monthly income show the significant result.

CHAPTER 5

5.1 Introduction

This chapter would provide justification and discussion of the findings in each of the objectives of this research study and it would be supported by previous study and literature review. The objectives covered as followed:

- Factor influencing quality of working life among nurses
- Quality of working life among nurses
- Association between socio demographic data and quality of working life among nurses

Additionally, the implications of this study to nursing profession, nursing education and nursing research would be discussed further in this chapter. Some limitations of this study and suggestion to overcome them also had discussed in order to develop a more holistic and comprehensive studies on the research topic in future.

5.2 Discussion based on socio demographic data

In this study, there was more respondents with age group 22 to 31 years old and had working experiences less than 10 years. This may because of the hospital management that always recruit a large number of new nurses every year and the nurses with more years of experiences will either already end their contract or resigned from the position due to family factors or others. It is consistent with that finding of research done by Yaakup, Eng & Shah (2014) which majority of participants were younger nurses (below 40 years old) and more than 70% had worked less than 10 years.

The participants that took part in this study were made up of more female compare to male. It is only in recent years, where gender equity became the norm in the workplace however, the number of female nurses still overwhelmed in the workplace (Evans, 2002). Evans also wrote that nursing is an occupation established by women, it supports the stereotypical "feminine" image with traits of nurturing, caring, and gentleness in contrast to masculine characteristics of strength, aggression, and dominance. It may cause the males to be reluctant to join the nursing profession due to the perception of the society.

Besides, most of the respondents were married. The perceptions and attitudes of the person can also differ by the marital status of the persons because the marriage might make the persons little more responsible and matured in understanding and giving the responses to the questions asked (Panisoara & Serban, 2013).

Most of the respondents in this study were Malay with religion of Muslim as 50.4% of Malaysia population were Malay (CIA World Factbook, 2010) and all the Malaysian Malay are Muslim by law. According to Department of Statistic Malaysia, population projections in 2017 show that the Malays and Bumiputeras comprised a total of 68.8% of the total population, Chinese 23.2% and Indians 7.0%.

Most respondents in this study were having educational level of diploma and nurses with educational level of Bachelor and above were limited which also reported in the study conducted by Yaakup, Eng and Shah (2014). This is because many nursing schools in Malaysia offered diploma courses which only required three years of studies and they received large numbers of students as compared to the college or universities that offered nursing courses in Bachelor which required four years of studies.

In addition, most of the respondents were working in ward. As the researcher tried to obtain the same amount of each discipline, however, it appeared that there were more nurses who from critical care unit participate in this study as the quantity of nurses in ICU, CCU, operation theatre and emergency department were more. Critical care unit are also distinguished from normal hospital wards by a higher staff-to-patient ratio and access to advanced medical resources and equipment that is not routinely available elsewhere because they need to provide total care to the patients (Maria & Jose, 2014).

According to Jackie (2016), nursing salary in Malaysia is paid in malaysian money "Ringgit Malaysia (RM)". The salary standard for staff nurse with level Diploma and 3 years' experience around RM 2,000 - RM 2,500 per month. Bachelor Nurse (BSN) are getting more salary around RM 2,500 - RM 3,500 per month.

5.3 Discussion based on the specific objectives

5.3.1 The quality of working life among nurses

The study showed that the nurses had moderate quality of working life with the percentage 62.2%. This result was similar with the study by Khani et al (2007), reported a moderate quality of nursing work life among 120 Iranian registered nurses at Isfahan Hospitals University of medical Sciences in 2007. The nurses reported that they were incapable of balancing between the work-home lives and were dissatisfied in their job. The findings from the study showed that shift duties, inadequate salaries, workload, lack of autonomy and career advancement opportunities are the main factors for poor quality of nursing work life and also result in job dissatisfaction. Other than that, the study in Thailand also showed that the majority of nurse practitioners had a moderate level of QWL (Patcharee et al, 2017). This may because nurses may had little energy after work due to spend a long time at work and increasing in workload affect their QWL Contrary to the previous study of quality of work life among primary health care nurses in Jazan, Saudi Arabia where the respondent were not satisfied with their QWL (Almaki et al, 2012). Amongst the four dimensions work context followed by work design gave the strong contribution to turnover intention. These were because nurses felt that their relationship with supervisory personnel, co-workers and interdisciplinary health team were not good and there may also non-insufficiency in provision of resources.

In quality of work life/home life, majority of the respondent agree with the factors such as able to balance work with family needs, important to have on-site child care service, important to have support for taking care of elderly parents, policy for vacation is appropriate and important to have on-site ill child care services. The results from the current study are congruent with the findings from a study on acute care nurses in a Midwestern state by Brooks and Anderson (2004). The majority of nurses in this study reported disagree with had energy left after work. Nurses stated that they had little energy after work due to spent a long time at work. As a result, they were unable to balance their work with their family needs (Khani, Jaafarpour & Dyrekvandmogadam, 2008). Other than that, present study show that the shift work schedules negatively affect their life. Previous study also stated that factors lead to turnover intention, job frustration, and work commitment of the nurses was rotating shift patterns (Brooks & Swailes, 2002). According to Newman, Maylor & Chansarker (2002), the most important causes of work dissatisfaction among 130 nurses and midwives in four hospitals in London were routinely shift changes and working conditions.

Besides, for quality of work design, this study show that there were majority of nurses agree that their workload is too heavy and they have enough time to do job. However it is not similar with the study by Hegney et al (2006) that they also concluded nurses' workload was heavy and distribution of workforce was not equal, and these cause nurses cannot finish their work in the period available. Major cause for nurses considering leaving their workplace and their profession was cited as workload. This study also agree that there were enough RN in their setting. This findings was not similar with study by Needlemann et al (2002) where the nurses in their study concluded that there were not enough registered nurses in their workplace and units. Previous study by Aiken et al (2002) found that each additional patient per nurse ratio was associated with a 15% increase in the job turnover and 23% increase in the nurse burnout. Workload and related issues such as understaffing or inappropriate staffing can cause turnover, which then compounds the problem (Hegney et al, 2006). Other than that, Vagharseyyedin, Vanaki & Mohammadi (2010) reported that nurses in their study were given additional non-nursing tasks. This mal-utilization of the nursing workforce may increase the shortage of nurses and affect their nursing skills and experiences.

In addition, for quality of work context, majority nurses in this study concluded that the upper

management respect their role and they were able to participate in the decision making and ideas. However, Hegney et al (2006) concluded that 65% of nurses believed that the administration did not listen or acknowledge to their concerns and opinion. The results suggest that there needs to be some improvements in the management attitudes, with greater valuing of nurses. The present study also show that most of the nurses agree with the management and supervision. Shermont and Krepcio (2006) found that to increase the level of QWL among nurses, they need to focus more on building trust among themselves, develop open communication between managers, staffs and other healthcare providers and encourage involvement in decision making. This study also reported that their setting provides career advancement opportunities. Bodek (2003) claimed that workers want to feel respected in their workplace for who are they and what they do. Above all, they need to be valued for their skills, knowledge, performance and participation in the development process. However, Rout (2000) in his study found that the nurses reported low QWL due to perceive a lack of opportunity for career advancement and training. In order to increase the nurses' QWL, development of strategies to enhance the nurse's professional status and individual achievement should be effective (Lee, Hwang & Kim, 2004). Besides, the nurse's collaboration with other health care personnel can influence their QWL. Johns (2003) stated that to improve the professional development, collaboration with other professionals as well as with colleagues is important and this can increase the quality of care for the patients and form as an important concern for the clinical nurse leadership. The working environment and condition was also one of the concern among nurses. More than half of the nurses stated that the security unit deliver a protected working environment. Some of the previous study highlighted that major factor in nurses' dissatisfaction in workplace was the security of the working environment. (Alhusaini, 2006).

Lastly, for quality of work world, many of the respondents felt that society have a definite image of nurses. The findings of this study are incongruent with studies in Japan that carried out concerning the socio-cultural status of nurses. Poor social position of registered nurses in Iran had become an important factor that contributed to the nursing problem. People think of RNs as assistants to the physicians, and some of physicians also regard nurses as their helpers and do not consider them as specialists in the art of caring for the patients (Nikbakht et al, 2003). If public had poor image toward nursing profession, it can affect the nurses' attitudes towards work and organization may had problem in recruitment of new nurses (Takase, Maude & Manias, 2006). Besides, majority of respondents were disagree that the salary is adequate. This was supported with focus group discussions showed that the nurse's salaries were differ in term of the hospital salary system, and income was a buffer for them to stay in nursing (Hsu & Kernohan, 2006). In another study by Abu Alrub (2007) in Jordan, concluded that major reason for nurses dissatisfaction in work was underpayment and this cause decrease in QWL of the nurses. The majority of the respondents in this study reported that their jobs are secure and they do not expect to lose the job unexpectedly. This result appear similar with the research conducted in Queensland (Day, 2005).

5.3.2 The association between socio-demographic and quality of working life among nurses

In this part of research, the results had obtained the respondents' age, gender, marital status, ethnicity, educational level, working experiences, working setting, working discipline and monthly income. For all socio-demographic data obtained was analyzed with nurses' quality of working life by using Chi-square analysis test and Fisher Exact Test based on the criterion. It show there was significant association between age and QWL. This can because of majority of nurses participated in this study were within age between 22 to 31 years old. Not just that, younger nurse can able to make a better adjustment and can easily adapt to the working condition when compared to the older nurses (Shah et al, 2004). Besides, nurses with working experiences less than 10 years had the higher QWL. This may because of the quantity of the younger nurses were more than older nurses. This findings was incongruence with the study by Shah et al (2004) where in the Arab nation, older and more experienced nurses are more satisfied with their QWL as they accorded greater recognition by

managers.

Result of this study showed a significant association between QWL of nurses and their education level. Study by Sharhraky et al. (2011) concluded that there was no significant association between the nurses QWL and their education level. In this study the researcher found that the QWL of nurses with diploma education level was better than nurses with higher education. Nurses with higher education level seems to had more expectations of their working life and because of this they can easily experience emotional exhaustion when working at place that does not meet their expectation (Dargahi, Gharib & Goodarzi, 2007). Besides, this can also occur due to huge number of diploma educational level of the nurses in UMMC as the majority of nurses were younger nurses.
Besides, there was also significant association between ethnicity and QWL. This also may because of 75% of the nurses participated in this study were Malay and most of them had moderate QWL.

In addition, monthly salary and QWL showed that there were significant differences. According to Almaki et al (2012), the results were consistent with their findings where life satisfaction score was a positive correlation with nurse's income and also found to be a key factor in the dissatisfaction of nurses with their QWL. According to a salary survey conducted however, Malaysian nurses' salary average is RM2000 – RM 2500 per month (Jackie, 2016).
On the other hand, the other socio-demographic data collected such as gender, marital status, working setting and working discipline were not significant association existed with the nurses' QWL.

5.4 Limitation of the study

There were a number of limitations which had been identified by the researcher throughout the study period. One of the limitations being identified was this study conducted at one institution only and it was not able to covering most healthcare institutes in the country.

In addition, the questionnaires would only be distributed to whoever available during the study period and not all of the nurses have the equal chances to participate in this study. Sampling bias may played a part in affecting the findings.

Moreover, the used of structured questionnaire with close ended questions also brought limited outcome and it not always represent the actual occurring in generalized form. There was another possibility that the respondents did not answer the question sincerely as the questionnaires were given as self-administered tool. The use of self-reporting instruments may have decreased the reliability of responses due to misinterpretation of some of the items.

5.5 Implication of the finding

5.5.1 Nursing profession

The study showed that most of the nurses had moderate quality of working life. Hence, nursing institution should develop activities and provide way to enhance the quality of working life among nurses. In collaboration with their colleagues in human resources, nurse manager can develop and implement employee benefit programs that would improve the work life of nurses. Programs that enable nurses to balance work with their family needs, decrease rotating shifts, bonus programs for off-shifts, onsite child care, on-site ill child care, on-site day care for elderly parents, and on-site degree completion programs are important (Brooks, 2001). In the area of practice environment that nurses able to fulfill their expectations and had a good communication between nurse and physician, hence, the quality of work life was high (Campbell, Fowler & Weber, 2004). Other clues gleaned from this concept analysis provide information that could be used to improve the work environment. The focus on healthy work setting began in clinical environments with the goals of improving patient safety, promoting excellence in clinical practice and enhancing the recruitment and retention of nurses. More importantly healthy and supportive work relationships have been shown to be related to increase nurse intention to remain employed. Furthermore, nurse manager may re-examine the utility of job satisfaction surveys in light of the benefits of assessing the quality of nursing work life.

5.5.2 Nursing research

The research on quality of working life among nurses should be enhanced as there were least number of literature review found regarding this study in Malaysia setting. The results can be used as to improve the nurses' quality of work life. The study was conducted using a quantitative research method and data was collected using questionnaires. Therefore, the results of this study were limited to providing numerical descriptions rather than a detailed narrative and generally provide less elaborate accounts of human perception. The development of structured standard questions could lead to false representation, where the data actually reflects the view of the researcher instead of the participating subjects.

5.6 Recommendation

As the quality of work life of nurses working in UMMC was moderate, nursing management in hospitals should take some action to ensure that nurses can increase their QWL. To increase quality of work life/ home life among nurses, nurse managers must to consider the family aspect of their registered nurses. Childcare facilities, convenient working hour, support for nurses who have elderly parents and adequate vacations should be made offered for nurses. These advantages can help nurses to balance work with their family necessities. Besides, in order to increase quality of work design, management should recruit more qualified nurses in the hospital, as well as ensure adequate nursing services for patients, families and community. Other than that, equitable distribution of the work are important to reduce workload so that nurses can focus on their own work and can finish work on time. For work context dimension, management should encourage nurses to involve in decision making, respecting their opinions and viewpoints, develop strategies or policies for promotion of nurses' quality of work life through improvement of environment and develop a friendly, supportive and pleasant working condition for all the staffs. In addition, management can also design a payment system based on the nurses' real function and provide more effective humanistic communication with their staffs. Besides, it is suggested that hospital management should make transparent performance appraisal, conduct training programs that would enhance skills and capabilities of the nurses. The nurses who perform challenging job must be motivated to perform better. Other than that, to increase quality of work world, management can increase the salary of nurses commensurate with the tasks performed. Management also should collaborate with the media to reveal the vital role of nurses in the care of patient, in the provision of health care services and in the development of the health of the population.

5.7 Conclusion

The study was done to determine the quality of nursing work life among nurses working in UMMC. The study findings revealed that there was a moderate QWL reported among nurses. The result of the study can provide a picture whether nurses satisfied with their work or not. The findings also been compared with other studies related to the topic among nurses across worldwide based on the previous study. Finding from this study suggest that nurses did not have energy left after work and they did not able to find same job in another organization. Limitation of the study had been stated clearly in this chapter which would help the next researcher who interest in this issue to improve the future study. Several recommendations also discussed based on the result. This research provides a beginning step in understanding the working life of nurses in UMMC. Besides, there is a need for outcome-driven research examining the effectiveness and efficacy of specific strategies aimed at improving the QWL of the nurses and organizational productivity.

KNOWLEDGE, ATTITUDE AND PREVENTION PRACTICES TOWARDS LEPTOSPIROSIS AMONG SECONDARY SCHOOL CHILDREN

Nor Syafini Binti Ahmad Halmi
Faculty of Medicine University of Malaya
Kuala Lumpur

CHAPTER 1: INTRODUCTION

1.1 Background

Leptospirosis is a widespread zoonotic disease that is recognized as an emerging global public health problem due to its increased incidence in both developed and developing countries (Bharti et al, 2003). There is evidence that Leptospirosis exists as an endemic disease in temperate countries such as China, Korea, Vietnam, Cambodia, Laos, India, Indonesia, Bangladesh, Nepal and Thailand (Mcbride et al, 2005). In recent years there is also high in incident rate in Malaysia.

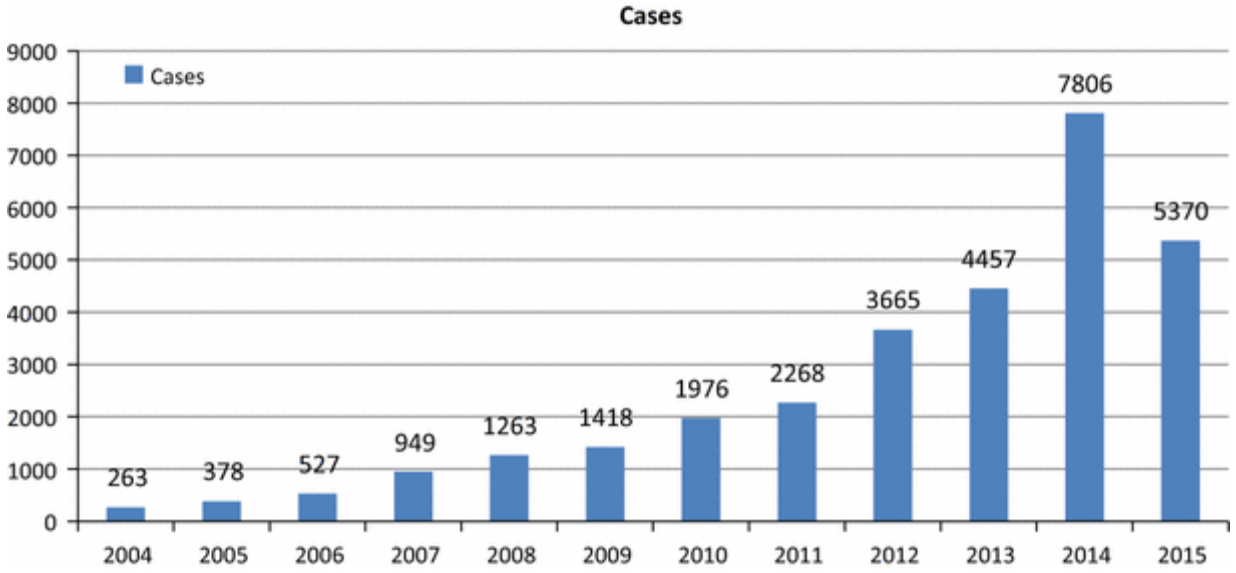

Figure 1: Cases of leptospirosis in Malaysia

Leptospirosis is notified disease and therefore probable and confirmed cases must be notified to relevant health district office since 2010. There were probable and laboratory confirmed Leptospirosis which 3665 in 2013 and 4457 in 2014. In these two years, most common age of patients was 19 years old and less than 19 years old, with male: female ratio of 2.6:1. Students consisted about 16.9% of patients, followed by agriculture-based or plantation workers (14.7%). Overall age-standardized incidence rate of Leptospirosis in Malaysia for 2012 and 2013 was 29.02 per 100,000. Overall case fatality rate was 1.47% for 2 year period and overall age-standardized mortality rate was 0.45 per 100,000. Increase in incident rate year by year may give Malaysia significant health impact and can be burden to the nation if not well controlled. (Tan, 2016)

In February 2018, two children infected with Leptospirosis at Gunung Lumut recreational area in Kluang, Johor Bahru, Malaysia and after that the recreational area was ordered to close. Johor Health, Environment, Education and Information Committee chairman Datuk Ayub Rahmat said Kulai health officers immediately conducted an investigation and found that nine others who have same trip, experience the same sign and symptoms. Some people may experience mild symptoms and some people the sign and symptoms may appear two days , one week or two later. (Loh, 2018). This the reason, the researcher wanted to conducted this study to children as, most of them like to take part in activity related to recreational are and the children usually experience severe complication if infected by Leptospirosis.

In Malaysia there are studies had done to find out the knowledge, attitude and practices of Leptospirosis but it were among Malaysian wet worker seller (Ismail et al, 2015) and also study among Malaysia town service (Rahim et al, 2012). Besides, in Malaysia there is also study to find out the seroprevalence of leptospiral antibodies and knowledge, attitude and practices of Leptospirosis to non-high risk group in Selangor (Sakinah et al, 2015). But there is no study on knowledge, attitude and practices among secondary school students.

Besides, it is important to conduct this study to children as in children, if they get infected, the disease can simulate the infectious diseases, such as viral meningoencephalitis, pharyngitis, urinary tract infection, mononucleosis, and other (Suarez et al, 2016). This is very important especially in the case of hepatitis, for the presence of severe leptospirosis cases with a fatal ending have been documented, and which were initially treated as viral hepatitis (Garcia et al, 2013).

In the study of Leptospirosis prevalence and associated factors in school children in the Mexico, (Espinosa et al, 2017) it stated that contact, the children in Mexico are in addition exposed to frequent and large floods and stagnant waters which are the risk for infection.

1.2 Problem statement

There are studies on knowledge, attitude and practices of Leptospirosis are done in outside country which are Brazil, Philippines and Sri Lanka. Mostly, the study focuses on public and workers. Samarakon and Gunawardena (2013) had done study of Leptospirosis toward secondary school children in Sri Lanka. In other hand, Malaysia also had done this study recently but it is more focus on public. Therefore, the researcher decided to do this study of knowledge, attitude and practices on Leptospirosis among secondary school children.

Although studies have been performed in the general population, and being considered an occupational-type disease (Gamage et al, 2012), children are almost always excluded; in the same way, most of these studies have been performed in diseased persons in acute state, and the infection prevalence in children in unknown and little is known regarding the presence in carriers and/or chronic Leptospira infection in them. Besides, there is little information about the clinical manifestations and complications that happen or the factors associated to the infection in the children group (Espinosa et al, 2017).

Furthermore, human infections primarily results after exposure to the urine of infected animals either directly or indirectly through contact with contaminated water or soil (Ko et al, 2009). In Malaysia, there are a lot of waterfall, river and even swimming pool that most likely be visited by children and also adults. Therefore, the risk for them to get Leptospirosis is high. Besides, there are also high in incidence rate of students infected with Leptospirosis in Malaysia. This is the reason the researcher chooses to make secondary school children because the most common age of patients was 19 years old and less than 19 years old in 2013 and 2014 cases of Leptospirosis.

The fatality rate for this cases was 1.47% for 2 year period and overall age-standardized mortality rate was 0.45 per 100,000. Increase in incident rate year by year may give Malaysia significant health impact and can be burden to the nation if not well controlled (Tan et al, 2016). The study also evaluates the understanding of individual knowledge of the disease and health behaviors plays important role in disease prevention, health and safety (Arbiol et al, 2016).

The main purpose of selecting secondary school children for this study is to promote awareness to health related disease which is Leptospirosis. During secondary school age, they are very active and like involve in activities that have high risk towards Leptospirosis such as swimming in stagnant water, did not take care of their cleanliness and surrounding. This study done for form 1 and 2 because for the exposure regarding Leptospirosis as they involve more on outdoor activities that high risk to be infected such as camping, swimming and hiking. This study is run to assess the knowledge, attitude and prevention practices towards Leptospirosis for future studies and improvement of quality of life. In addition, in February 2018, Hutan Lipur Gunung Belumut, Johor was close after two children being infected by Leptospirosis after went to the waterfall there. They admitted to the nearest hospital after showed the symptom of diarrhea and vomit (Mohamed Amin, 2018). Therefore, this

study is suitable for the research to find out current knowledge, attitude and prevention practices towards Leptospirosis of secondary school children in Malaysia as most severe cases of Leptospirosis in Malaysia involved school age children.

1.3Significant of study

1.3.1 Organization

This study will be benefit to any health organization that want evaluate the secondary school knowledge, attitude and prevention practices towards Leptospirosis. It is significant want to make sure that the public including the students to have knowledge related to Leptospirosis in order to prevent it. By doing this study, evaluation on the secondary school students' level of knowledge, attitude and level of practices of Leptospirosis can be done. Therefore, intervention can be done in order to improve the children and also the public level of knowledge, attitude and level of prevention practices towards Leptospirosis. This is because it is very important as if they have the knowledge on how important to prevent it, their attitude and level of prevention practices also will also improve, therefore the prevalent cases and incident rate will be decreases. The findings of this study also may able to help any organizations to reinforce the knowledge, attitude and prevention practices towards Leptospirosis through articles, journal and advertisement in television.

1.3.2 Secondary school children

This study finding is significant for secondary school students because they able to self-evaluation on their level of knowledge, attitude and prevention practices towards Leptospirosis. The results of study reflect on the students' knowledge, attitude and practices of leptospirosis. Therefore, they should have knowledge on preventing themselves, changing their attitude and practices of their frequent activity and avoid from being infected so that they can prevent it. This study also significant to secondary school students as according to National Center for Biotechnology Information (2016), the most common age of patients infected with Leptospirosis was 19 years old and less than 19 years old in 2013 and 2014 respectively. Leptospirosis is very common in 19 years old and less than 19 years old which these also included secondary school students which the range of age is 13 until 17 years old.

1.3.3 Nursing profession

The findings of this study are able to help nurses in understand and evaluate the current level of knowledge, attitude and prevention practices towards Leptospirosis. Besides, from the findings of this study, the nurses able to create interventions to increase the knowledge, attitude and prevention practices towards Leptospirosis in by making sure they aware the effects of Leptospirosis which if not treated as it can lead to fatal. Therefore, the intervention that nurses should include the awareness of preventive practices towards Leptospirosis.

1.4 Objectives

1.4.1 General Objective

To assess the knowledge, attitude and prevention practices towards Leptospirosis among secondary school children.

1.4.2 Specific Objective

a. To assess the level of knowledge regarding Leptospirosis among secondary school children
b. To assess the attitudes towards Leptospirosis among secondary school children
c. To assess level of prevention practices towards prevention of Leptospirosis among secondary school children
d. To assess association between socio-demographic characteristics and knowledge, attitude and practice towards Leptospirosis among secondary school children.
e. The relationship between knowledge, attitude and practices of Leptospirosis among secondary school children.

1.4.3 Research question

- What is the level of knowledge towards Leptospirosis among secondary school children?
- What is the attitude towards Leptospirosis among secondary school children?
- What is the association between level of prevention practices towards Leptospirosis among secondary school children?
- What is the association between socio-demographic characteristics and knowledge, attitude and practice towards Leptospirosis among secondary school children?
- What is the relationship between knowledge, attitude and prevention practice towards Leptospirosis among secondary school children

1.5 Operational definition

1.5.1 Leptospirosis

Leptospirosis is a zoonotic disease caused by bacteria of the genus Leptospira. It is most commonly spread through water contaminated with urine from infected animals, but contaminated food or soil can be transmission of the disease. The main animal reservoirs are rodents, livestock and dogs (WHO,2017). In this study, Leptospirosis is a disease that transmitted by infected animal which commonly spread through water contaminated with urine from infected animals specifically rat.

1.5.2 Knowledge of leptospirosis

Facts, information and awareness about leptospirosis acquired through experience or education or from the mass media (Meriam-Webster,2017). Facts, information and awareness of the secondary school students about Leptospirosis acquired through experience or education or from the mass media. This study assesses the secondary school children knowledge on the transmission of disease, risk factor, the sign and symptoms and complication of Leptospirosis.

1.5.3 Attitude of leptospirosis

Feeling or thinking that affected a person behavior leptospirosis (Merriam-Webster, 2017). Secondary school students feeling or thinking that affected a person behavior Leptospirosis. In this study the researcher assess the secondary school attitude on what they believe the Leptospirosis is, what they can do to prevent from infected and what other related information that they believe regarding Leptospirosis.

1.5.4 Prevention practices of prevention Leptospirosis

Prevention practices are to do or perform often or habitually and to perform or work at repeatedly so as to become proficient (Merriam-Webster, 2017). This study assess the secondary school students' habitual or expected procedure or way of doing things related to risk to be infected with Leptospirosis and the safety measure taken to avoid Leptospirosis

1.5.5 Secondary school children

A school intermediate between elementary school and college and usually offering general, technical, vocational, or college-preparatory courses (Meriam Webster, 2017). In this study, secondary school refers as form 1 and form 2 from Sekolah Menengah Kebangsaan Bukit Bandaraya, Kuala Lumpur, Malaysia.

1.6 Summary

In this chapter researcher had explained about the background the problem statement, the significant of the study involve organization, secondary school children and the significant in nursing profession. Furthermore, the researcher also explain about the objective of this study include general and specific objective, research question and operational definition of knowledge, attitude, practice, leptospirosis and secondary school children.

CHAPTER 2: LITERATURE REVIEW

2.1 Introduction

Leptospirosis is an infectious disease of humans and animals that is caused by pathogenic spirochetes of the genus Leptospira. It is associated with rodents in settings of poor sanitation, agricultural occupations, and increasingly "adventure" sports or races involving fresh water, mud, or soil

exposure. It is transmitted via the urine of infected rodents. (Gompf, 2018). The risk factors include recreational activities, occupational exposure natural disaster and others but the most common factor in Malaysia is recreational activities (Benacer et al, 2016).

Leptospirosis ranges in severity from a mild illness to a viral infection to a various sign and symptoms includes fever (38-40°C), rigors**,** headache, retro-orbital pain, photophobia, muscle pain localized to the calf and lumbar areas, conjunctiva suffusion, dry cough**,** diarrhea, nausea and vomiting. If the disease is progressive, it can lead to complication of icterus or frank jaundice, renal failure with oliguria, hemorrhagic features and systemic inflammatory syndrome or shock (Gompf, 2018).

For the method of prevention of infection is control the reservoir. Rat is the natural reservoir for this infection. Rodent control by continuing rat trapping, good sanitation and proper garbage disposal is very important to reduce the rat population. In addition, public health awareness is also important in order to prevent the infection. Public should be advice on drinking only purified and boiled water, proper water and food storage, avoiding prolonged immersion in and consumption of river water (Benacer et al, 2016).

There are studies on knowledge, attitude and practices of leptospirosis are done in outside country which are Brazil, Philippines, Sri Lanka and India (Federico et al, 2012; Arbiol et al, 2016; Charmaine et al, 2014; Samarakoon and Gunawardena, 2013; Andres & Dave 2011; Prabhu et al, 2014).

In Malaysia there are studies had done to find out the knowledge, attitude and practices of leptospirosis but it were among Malaysian wet worker seller (Ismail et al, 2015) and also study among Malaysia town service (Rahim et al, 2012). Besides, in Malaysia there is also study to find out the seroprevalence of leptospiral antibodies and knowledge, attitude and practices of leptospirosis to non-high risk group in Selangor (Sakinah et al, 2015). But there is no review of literature in the area of knowledge, attitude and practices of leptospirosis among secondary school students done in Malaysia.

Besides, the researcher also has done this study because although there was increasing incidence rate, leptospirosis remains as a neglected disease that suffers from lack of awareness. In addition, the researcher wants to conduct this study because the understanding of individual knowledge of the disease and health behavior play important role in disease prevention, and in improving health and safety (Arbiol et al, 2016).

The researcher has use the electronic search by using databases in University of Malaya digital library which are Science direct, Pubmed, MEDLINE@EBSCO. In order to get accurate result of literature, relevant keywords are used to sort out related article. There are inclusive and exclusive criteria used.

The inclusive criteria are:

- Year of the article published which are 2007-2017
- Full text given

The exclusive criteria are:

- Other language than English
- Qualitative related article

Keywords: knowledge, attitude, practices, Leptospirosis, secondary school children.

From figure 2, after using the search strategies by insert the keyword, the researcher found out 294 articles. After that the researcher the filter results of that only includes year of the article published which are 2007-2017, full text article, and exclude other language than English and qualitative related article, the researcher found out 123 of article. Then, the researcher screens the article, and includes the article that related knowledge, attitude and practices of Leptospirosis, the researcher found out total of 9 articles.

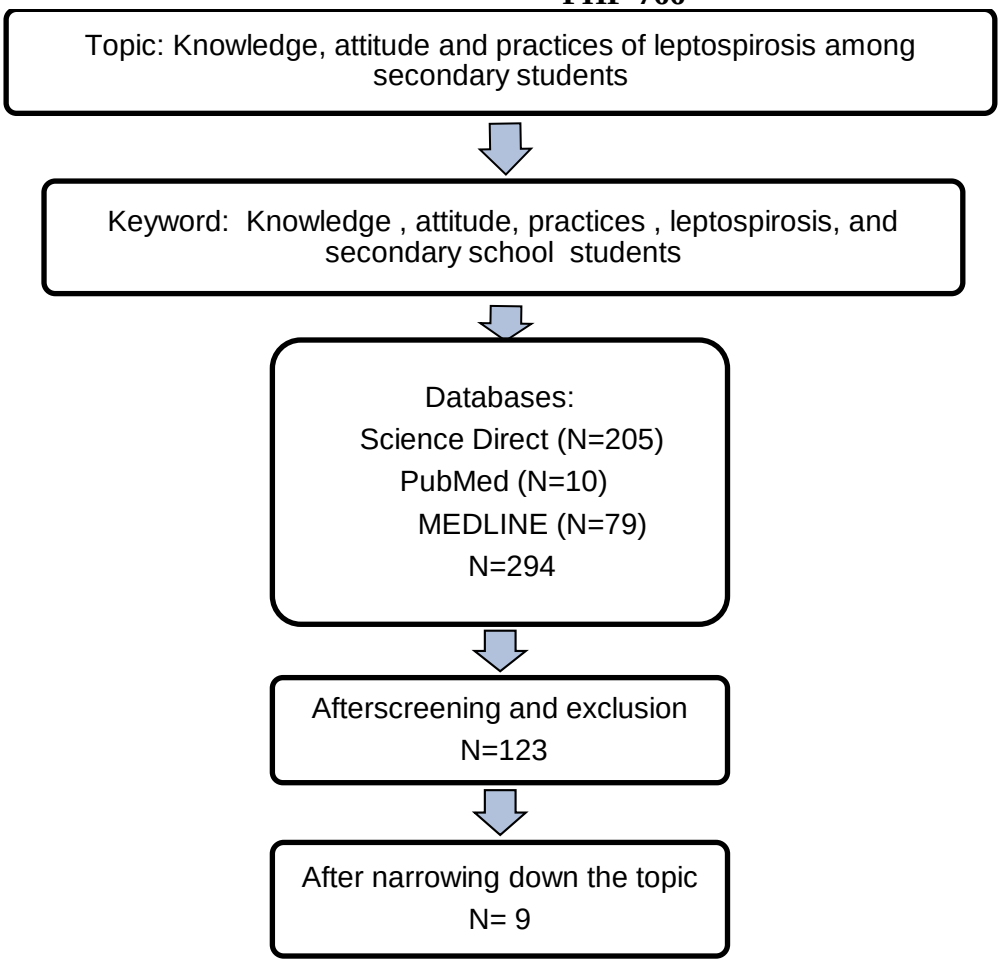

Figure 2: Flow chat of literature review search strategies

2.2 Knowledge of leptospirosis

Based on the study by Samarakoon and Gunawardena (2013) in Sri Lanka, involved 460 respondents, most of them who have good level of knowledge and majority have their parents involved in paddy cultivation which is one of high risk job related to Leptospirosis. The study was only done in endemic rural area in Sri Lanka. Thus, future study should in other area such as urban and suburban.

Furthermore, in the study of Rahim et al. (2012) in Malaysia, of 296 respondents, a large majority never heard of Leptospirosis which is 87.5% respondents. Based on the result from overall respondents, majority of 87.2% of them have poor level of knowledge. The study only done for wet seller worker. Thus, future study should include adults from different job scope.

Based on the study from Sakinah et al. (2015) in Selangor, 98% of the respondents have poor knowledge regarding Leptospirosis. However, this study only done to adult in Selangor. Future study should include other age categories such as the secondary school children and should include respondents from other states.

2.3 Attitude on leptospirosis

Besides, in the study of Rahim et al. (2012) of wet seller market in Malaysia, from 296 respondents, generally the attitude towards Leptospirosis was good. More than half which is 64.9% of the respondents have good attitude. The study was done only at Kelantan. Hence, the result cannot generalize the entire population of wet seller market in Malaysia.

Furthermore, based on the study of Mohamad Azfar et al. (2018) in northeastern Malaysia, more than half which were 52.0% of the respondents have good attitude. Thus, for overall results, the respondents have good attitude towards Leptospirosis. However, this study used simple random and limited data collection from town service worker at northeastern Malaysia. Therefore, it did not represent all town service workers in Malaysia population.

From study of Arbiol et al, (2016), for the overall result, majority of the respondents have good attitude regarding Leptospirosis. However, this study only done to adult. Future study should include children as children also have high risk to be infected by Leptospirosis.

2.4 Prevention practices of leptospirosis

Based on the study of Mohamad Azfar et al. (2018) in northeastern Malaysia, 39.9% of the respondents have good prevention practices regarding Leptospirosis. Thus, for overall result, they have good level of practices as there are more respondents have good prevention practices.

The study of Rahim et al. (2012) in Malaysia, from 296 respondents, 64.5% of the respondents showed them showed unsatisfactory score. Therefore, in this study, it was concluded, for overall result, they have poor level of practices. The study was done only for wet seller market. The other respondents from other job characteristic did not assess in this study, therefore future study should include from different job characteristic.

Besides, the study by Samarakoon and Gunawardena (2013) in Sri Lanka, involved 460 respondents and the finding revealed that the respondents have poor level of prevention practices. In this study, the prevention practices were done obtained through self-report. Ideally, practices need to be evaluated through observation.

2.5 Relationship between level of knowledge, attitude and prevention practices

The study of Ismail et al. (2015) in Malaysia, which related to knowledge, attitude and practices of Leptospirosis among Malaysian wet seller and in the study, the overall result for the respondents are moderate knowledge, unsatisfactory attitude score and satisfactory practice score. Based on this study, there was significant positive low correlation was observed between attitude and practice of Leptospirosis.

Furthermore, the study of Arbiol et al, (2016), from Philippines, there was significant positive low correlation between knowledge and preventive practice. This study states that, knowledge improves individual ability to translate preventive measure into action.

2.6 Association between and demographic characteristics, level of knowledge, attitude and prevention practices.

From the study of Ismail et al. (2015) in Malaysia, there is significant association between level of knowledge and educational level. Most of the respondents that have high score, have the highest completed level of education.

Besides, in the study of Rahim et al. (2012) in Malaysia, the data was collected from 296 respondents, they find out there were no different between knowledge, attitude and practice with educational level, age and duration of employment. However, there was a significant difference between attitude and practice level with job category.

From the previous study from Arbiol et al. (2016) in Philipines, based on result, the higher Leptospirosis prevention practice score have significantly associated with female respondents and obtained health information from the broadcast media. This study did not cover the range of reasons for engaging or not engaging in specific prevention practices. Future study may use open-ended questionnaire to explore the reason for respondents choices.

Based on study from Prabhu et al, (2014) there were no significant difference between knowledge, attitude and practice with education level, age, duration of employment and job category. However, the significant difference between knowledge, attitude and practice level with job category.

2.7 Summary

This chapter discuss about the search strategies which include the selection criteria, exclusion criteria and results of key studies. The purpose of literature review is to make the researcher understand more about this study.

CHAPTER 3: METHODOLOGY

3.1 Introduction

In this chapter, the researcher explain and describe the study design, study setting, population sample (sampling calculation, inclusive and exclusive), the research instrument (questionnaire, validity, and reliability), data collection method, data analysis, ethical consideration and pilot study.

3.2 Study design

In this study, quantitative design and cross-sectional descriptive study is use. Cross-sectional study is use to collect information from a group at one time. Quantitative methods is use to emphasize objective measurements and the statically, mathematical, or numerical analysis of data collected through questionnaires, and surveys, or by manipulating pre-existing statistical data using computational technique. In quantitative research designs, it is focuses on gathering numerical data and generalizing it across groups of people or to explain a particular phenomenon. (Babbie and Muijs, 2010).

Quantitative research designs are either descriptive (subjects usually measured once) or experimental (subjects measured before and after a treatment). A descriptive study establishes only associations between variables, an experimental study establishes causality. (Babbie, 2010). In this study, researcher use quantitative descriptive design.

3.3 Study setting

The study setting is at Sekolah Menengah Kebangsaan Bukit Bandaraya in Bangsar which in the area of Klang Valley. Besides, the researcher only had given permission by the Ministry of Education to do the survey on form that excluded from taking important examination. After taking permission from the headmaster of SMK Bukit Bandaraya, I had done the survey to form 1 and form 2.

3.4 Population & Sampling

There are total of 980 students there. The sampling method use is simple random sampling. Both female and male from the form 1and 2 secondary school children in Sekolah Menengah Kebangsaan Bukit Bandaraya had been targeted to complete the survey. From name list of the form 1 and form 2, 350 students are randomly chosen, and only 324 of the students answered the questionnaire completely.

3.4.1 Sampling calculation

The researcher used a sample size calculator to calculate sample size for the study is calculated by using *Rausoft Inc.*software. From the Raosoft Calculator, with confidence level of 95% and margin of error, the recommended size is at least 277. After completed the survey, total of 350 of data managed to be collected from the survey but only 324 can be used.

3.4.2 Inclusion & exclusion of criteria

Study subject who agree to participate in this study by answering the questionnaire had met the selection criteria for the project.

3.4.2.1 Inclusion criteria

- The secondary school students who are willing to participate and present during the period of data collection in the study.
- The secondary school students of form 1and 2 as given permission by the headmaster.

3.4.2.2 Exclusion criteria

- Students who taken important examination (Ministry of Education condition during ethic application)

3.5 Research instrument

Research instrument is the device used to collect the data.

3.5.1 Questionnaire

The questionnaire adapted and modified from Arbiol, et al (2016). This questionnaire had been sent to be translated to an English Lecturer at Faculty of Language and Linguistic.

3.5.1.1 Section A: Social demographic characteristic

In section A, it consists of 9 items. This included the student's age, gender, age, parent's occupation and educational level.

3.5.1.2 Section B: Knowledge

In section B, the secondary school children answered the questionnaire which consists of 16 questions. The researcher provided question to the secondary school children regarding the knowledge of Leptospirosis, including the knowledge of the causative organism and transmission, the sign and symptoms, complications of the disease and prevention. This items consists of True/False/Unknown responses. Score 1 was given for each correct answer, while incorrect answers and "I don't know" responses were scored 0. There are 11 positive statement items and 5 negative statement items. The negative statement items are reversed scoring and tailed with positive statement items. The total knowledge score for each respondent was a sum ranging from 0 to 16.

3.5.1.3 Section C: Attitude

In section C, consist of 8 items. The questionnaire provided includes their attitude on the importance of health prevention regarding Leptospirosis. It consisted of a five-level Likert scale format (1= strongly disagree, 2= disagree, 3= not sure, 4 = agree, 5 = strongly disagree), the total score of each respondents could range from 8 to 40, with the higher scores indicating a more positive attitude towards Leptospirosis which having more optimistic disposition or beliefs about Leptospirosis prevention.

3.5.1.4 Section D: Prevention Practices

Section D, consists of 8 items. The researcher provided questions regarding prevention practices towards leptospirosis which are the prevention and control strategies practiced which include maintaining cleanliness on the surrounding and keeping good hygiene. These include general practice of hygiene and also specific practice on Leptospirosis prevention. It consisted of a five Likert scale question format (1= never, 2= rarely, 3= sometimes, 4=often, 5= always. There are 5 positive statement items and 3 negative statement items. The negative statement items are reversed scoring and tailed with positive statement items. The total score of each respondent could range from 8 to 40, which higher score indicating higher adherence to prevention practices.

3.6 Validity and Reliability

For this study, face validity done by expert panel which are nursing lecturer from department of Nursing , nursing officer and also doctor from infectious disease department in University Malaya Medical Centre (UMMC). The questionnaire was evaluated and had some modification to meet the objective of the study. Furthermore, a pilot study was conducted before the data collection to test the reliability and quality of the questionnaire to be used in the study. A pilot study was conducted among 30 of the secondary school children which 10% out from the Sekolah Menengah Kebangsaan Bukit Bandaraya. Once pilot study is done, Chonbach's alpha was tested for reliability of the questionnaire The questionnaire adapted and modified from Arbiol, et al (2016). The Cronbach's alpha > 0.70 were reported. The reliability test was done by using Cronbach's alpha in SPSS 23.0 for Section B: knowledge of the respondents, Section C: attitude of the respondents and Section D: practice of prevention measures of respondents respectively. The result of reliability tests were greater than 0.7 as shown in Table 3.1. Hence, all the sections were considered highly reliable to use for this study.

Table 3.1 Reliability test on knowledge, attitude and prevention practices toward Leptospirosis among secondary school children (n=30)

Categories	Cronbach's Alpha	Cronbach's Alpha Based Standardized Items	N of Items
Knowledge	.790	.830	16
Attitude	.825	.825	8
Practices	.703	.705	8

3.7 Data collection method

The data collection had done after the researcher obtain ethical approval from the Ministry of Education Malaysia, Kuala Lumpur Federal Territory Education Department and headmaster of SMK Bukit Bandaraya. After pilot study was done to 30 of the students includes form 1 and 2, the data collection had proceed. The researcher went to the school and told the teacher to take sometimes from the students to do the survey. Simple random sampling was used in order to select students to answer the questionnaire. The selected students from of form 1 and 2 were gathered in a hall and the questionnaires were distributed to the students. The data collection was done within September 2018. A total of 350 questionnaires distributed to the students. The researcher obtained the 350 questionnaire after they answered it. However, only 324 can be used as other students does not completed the questionnaire.

3.8 Data analysis

The data collected and analysed using Statistical Product and Service Solutions (SPSS) version 23.0. The researcher use descriptive and inferential statistic to present the data. The descriptive statistics were used to analyse demographic charactheristic. While Chi-square test were used for the association between knowledge, attitude and prevention practices with demographic characateristic and Spearmans' Rho test was used to analyse the relationship between the knowledge, attitude and prevention practices.

3.9 Ethical consideration

Before starting the survey, the researcher had obtained ethical approval from Ministry of Education Malaysia and Kuala Lumpur Federal Territory Department, since this study is conduct in Klang Valley and also obtained ethical approval from headmaster of Sekolah Menengah Kebangsaan Bukit Bandaraya.

For study purpose, informed consent form was obtained from the respondents who agreed to take part in the study. The respondents were freely decided withdraw from this study without giving explanation. The researcher makes sure the confidentiality of the respondents' information. Respondent answers were treated as confidentially and anonymously. Every complete questionnaire had been seal and kept in seal box as to prevent leak of respondents' identity and answer.

3.10 Pilot study

In this pilot study, 10% from the total sample size before conducting the real test. These respondents are excluded in the main study. It is to help the researcher to test whether the instruments use comprehensive, understandable and relevant to test the reliability of the instrument. Besides, pilot study was tested to get the duration of the respondents to complete the research questionnaire.

Pilot study was carried out after researcher get the ethical permission from the Ministry Of Education, District Office, the headmaster of SMK Bukit Bandaraya and also after validation is done by experts. Pilot study was conduct at March 2018. 30 students were chosen and identified to be participant in pilot study. This is to avoid repetition of sample answering the same questionnaire when the researcher done the actual survey.

3.11 Summary

In this chapter, the researcher explained the details of study design, study setting, sampling methods, data collection and data analysis. Furthermore, ethical consideration is important to make sure this study was followed the ethical procedure.

CHAPTER 4: DATA ANALYSIS

4.1 Introduction

In this chapter the researcher describes the analysis of the data collected. The finding is according to the objective from this study. Data collected were analysed to assess the level of knowledge, attitude and practice towards leptospirosis among secondary school children and also to assess association between the level of knowledge, attitude and practices towards leptospirosis among secondary school children and selected socio-demographic towards leptospirosis among secondary school children in SMK Bukit Bandaraya.

4.2 Data screening and data management

Data collected was entered in SSPS according to the respondents' identification number tagged to avoid double entry. Data was screened and missing values detected. From 350 questionnaires, 26 questionnaires were omitted due to the missing values. Normality test was done to the dependent variables (knowledge, attitude and practice towards leptospirosis) and found normally distributed as shown in Table 4.1.

Table 4.1 Normality test

	Mean (SD)	Median	Mode	Skewness		Kurtosis	
				Statistic	Std. Error	Statistic	Std. Error
Knowledge	9.48(2.378)	11.00	22	-.284	.135	.037	.270
Attitude	30.62(4.473)	31.00	31	-1.018	.135	1.601	.270
Practice	30.62(3.827)	32.00	32	-.507	.135	.119	.270

4.3 Response rate

350 questionnaires were distributed by the researcher through face to face with the respondents and were collected. Out of 350, 23 respondents did not complete the questionnaire one or more subsection (especially section A, C and D) of the questionnaire were omitted. This presented a response rate of 92.57%. Therefore, only 324 questionnaires were usable and meet inclusive criteria for this study as discussed in previous chapter.

4.4 Demographic characteristics of respondents

Table 4.2 shows display the details of demographic characteristics of the respondents. This study collected a total of 324 respondents. From the table, it shows that female respondents contributed a total of 170 out of 324 respondents in this study which is 52.5%, while the male respondents contributed 154 out of 324 or 47.5% of the total respondents. In the term of age 13 years old occupied slightly less, contribute percentage of 47.2% (n=153) than age group of 14 which is 52.8% (n=171). The ethnicity consists of four ethnics were Malay, Chinese, Indian and others. From the table, Malay respondents occupied the highest percentage of 83.6% (n=271), while Chinese respondents occupied the lowest percentage which is only 1.5% (n=5). The highest educational level of their parents consists of 2 categories which are educational level that includes secondary school and below and also college diploma and above. Most of their parents are in college diploma and above categories. There are 65.7% (n=213) of the respondents' father have college diploma and above education while there are 63.3% (n=205) of the respondents' mother have college diploma and above education. There are 34.3% (n=111) of the respondents' father education level of secondary school and below and also there are 36.7% (n=119) of respondents' mother education level of secondary school and below. Furthermore, there are 47.5% (n=154) of the respondents' father working in government which contribute as the highest percentage while there are 5.6% (n=18) of the respondents' father are not working which contribute as the lowest percentage for working classification of respondents' father. There are 38.9% (n=126) of respondents' mother working in government which contribute as the highest percentage while there are 23.1% (n=75) of the respondents' mother are working in non-government which contribute as the lowest percentage for working classification of respondents' mother in this study.

Table 4.2 Demographic characteristics of respondents (N=324)

Characteristics	Frequency (n)	Percent (%)	Mean	SD
Age			13.528	0.50
Gender				
Male	154	47.5		
Female	170	52.5		
Ethnicity				
Malay	271	83.6		
Chinese	5	1.5		
Indian	42	13.0		
Others	6	1.9		
Educational level of father				
Secondary school and below	111	34.3		
College diploma and above	213	65.7		
Educational level of mother				
Secondary school and below	119	36.7		
College diploma and above	205	63.3		
Working classification of father				
Government	154	47.5		
Non-government	152	46.9		
Not working	18	5.6		
Working classification of mother				
Government	126	38.9		
Non-government	75	23.1		
Not working	123	38.0		

Table 4.3 Information regarding Leptospirosis (N=324)

Characteristic	Frequency	Percentage (%)
Have heard about leptospirosis?		
Yes	293	90.4

No	31	9.6
Total	324	100.0
Information on health care		
Health care provider	110	34.0
Media mass	119	36.7
Family/Relative	55	17.0
Newspaper/Brochure	32	9.9
Others	8	2.5

Table 4.3 shows display the details on how the respondents get information regarding Leptospirosis. A total of 293 (90.4%) respondents have heard about leptospirosis before and 31(9.6%) never heard about leptospirosis. 110 (34.0%) and 119 (36.7%) respondents get information on health care from health care provider and media mass respectively. 8(2.5%) respondents answer others in the question state they get the information from the internet.

4.5 To assess level of knowledge regarding Leptospirosis among secondary school children

The overall knowledge score of the respondents regarding Leptospirosis is 9.48 (2.378). The knowledge was divided into three categories, poor knowledge with the range of score 0 to 5, moderate knowledge with range score 6 to 11 and good knowledge with the range 12 to 16. As shown in Table 4.4, about 73.8% (n=239) of respondents had moderate knowledge and 5.9 (n=19) had poor knowledge regarding Leptospirosis.

Table 4.4 Knowledge level of secondary school children (n= 324)

Knowledge level	**Range of score**	**Frequency (n)**	**Percent (%)**
Poor knowledge	0-5	19	5.9
Moderate knowledge	6-11	239	73.8
Good knowledge	12-16	66	20.4
Total		324	100.0

Table 4.5 shows the details of item analysis of knowledge regarding Leptospirosis. 53.7% (n=174) of the respondents score correct response for item “Leptospirosis is caused by a bacteria”. 88.6% (n=287) of the respondents score correct response for item “Rat can transmit Leptospirosis”. 46.9% (n=152) of the respondents score correct response for item “Leptospirosis can enter our body through cuts”. 76.5% (n=248) of the respondents score correct response for item “Leptospirosis can enter our body through contaminated food”. 73.8% (n=239) of the respondents score correct response for item “Leptospirosis can be transmitted through mosquito bites”. 49.7% (n=161) of the respondents score correct response for item “Human can infected by shaking hands with infected person”. 84.3% (n=273) of the respondents score correct response for item “Floodwater, river and waterfall can transmitted Leptospirosis”. 22.5% (n=73) of the respondents score correct response for item “Person infected by Leptospirosis may have difficulty in urinating”. 17.3% (n=56) of the respondents score correct response for item “Person infected by Leptospirosis may have jaundice”. 54.0% (n=175) of the respondents score correct response for item “Person infected by Leptospirosis may free from any symptom”. 84.9% (n=275) of the respondents score correct response for item “Leptospirosis can cause death”. 31.8% (n=103) of the respondents score correct response for item “Leptospirosis can cause lung cancer, kidney failure, liver damage and diabetes”. 77.2% (n=250) of the respondents score correct response for item “Avoiding walking, playing and bathing in the flood, river and waterfall can prevent Leptospirosis”. 89.5% (n=290) of the respondents score correct response for item “Maintaining clean surrounding can prevent Leptospirosis”. 62.3% (n=202) of the respondents score correct response for item “Avoiding contact with rats can prevent Leptospirosis”. 346%

(n=112) of the respondents score correct response for item "Wearing boots during flood can prevent Leptospirosis".

Table 4.5 Knowledge of the secondary school children (N=324)

Items	True %(n)	False %(n)	I do not know %(n)	Mean	SD
Leptospirosis is caused by a Bacteria	53.7(174)	17.3(56)	29.0(94)	.537	.499
Rat can transmit Leptospirosis	88.6(287)	5.9(19)	5.6(18)	.886	.318
Leptospirosis can enter our body through cuts	46.9(152)	21.9(71)	31.2(101)	.469	.499
Leptospirosis can enter our body through contaminated food	76.5(248)	10.5(34)	13.0(42)	.765	. 424
#Leptospirosis can be transmitted through mosquito bites	6.8(22)	73.8(239)	19.4(63)	.068	. 251
#Human can infected by shaking hands with infected person	13.3(43)	49.7(161)	37.0(120)	.133	.339
Floodwater, river and waterfall can transmitted Leptospirosis	84.3(273)	3.4(11)	12.3(40)	.842	.364
#Person infected by Leptospirosis may have difficulty in urinating	19.8 (64)	22.5(73)	57.7(187)	.198	.399
Person infected by Leptospirosis may have jaundice	17.3(56)	21.0(68)	61.7(200)	.173	.379
#Person infected by Leptospirosis may free from any symptom	9.9(32)	54.0(175)	36.1(117)	.099	. 299
Leptospirosis can cause death	84.9(275)	4.3(14)	10.8(35)	.849	.359
#Leptospirosis can cause lung cancer, kidney failure, liver damage and diabetes	21.9(71)	31.8(103)	46.3(150)	. 219	.414
Avoiding walking, playing and bathing in the flood, river and waterfall can prevent Leptospirosis	77.2(250)	9.6(31)	13.3 (43)	.771	.420
Maintaining clean surrounding can prevent Leptospirosis	89.5(290)	5.9(19)	4.6(15)	.896	.307

Wearing boots during flood can prevent Leptospirosis	34.6(112)	22.8(74)	42.6(138)	.346	.476

Negative statement items are reversed scoring and tailed with positive statement items

4.6 To assess attitude regarding Leptospirosis among secondary school children

The overall knowledge score of the respondents regarding Leptospirosis is 30.61 (4.473). The attitude was divided into three categories, poor attitude with the range of score 8 to 18, moderate attitude with range score 19 to 29 and good attitude with the range 30 to 40. As shown in Table 4.6, about 66.0% (n=214) of respondents had good attitude and 1.5% (n=5) had poor attitude towards Leptospirosis.

Table 4.6 Attitude level of secondary school children (n= 324)

Attitude level	Range of score	Frequency (n)	Percent (%)
Poor attitude	8-18	5	1.5
Moderate attitude	19-29	105	32.4
Good attitude	30-40	214	66.0
Total		324	100.0

Table 4.7 shows the details of item analysis of attitude towards Leptospirosis. 51.5% (n=167) of the respondents score correct response for item "I believe that Leptospirosis is a serious illness". 6.2% (n=20) of the respondents score correct response for item "I believe that medicine can threat Leptospirosis". 38.0% (n=123) of the respondents score correct response for item "I believe I can do something to prevent myself from being infected with Leptospirosis". 22.5% (n=73) of the respondents score correct response for item "It is important to control rat population". 45.7% (n=148) of the respondents score correct response for item "It is important to follow health advisory during rainy season". 31.8% (n=103) of the respondents score correct response for item "I would worried to walk through flood". 24.1% (n=78) of the respondents score correct response for item "Disposing the dead animal is important". 42.5% (n=170) of the respondents score correct response for item "I would make my environment free from rat".

Table 4.7 Attitude of secondary school children (N=324)

Items	Strongly disagree %()	Disagree %()	Neutral %()	Agree %()	Strongly Agree %()	Mean	SD
I believe that Leptospirosis is a serious illness	2.2(7)	2.5(8)	6.8(22)	37.0(120)	51.5(167)	4.33	.876
I believe that medicine can threat Leptospirosis	4.0(13)	10.5(34)	49.7(161)	29.6(96)	6.2(20)	3.23	.869
I believe I can do something to prevent myself from being infected with Leptospirosis	4.6(15)	5.6(18)	17.9(58)	38.0(123)	34.0(110)	3.91	1.074
It is important to control rat population	7.7(25)	11.4(37)	31.2(101)	27.2(88)	22.5(73)	3.45	1.181
It is important to follow health advisory	4.3(14)	5.6(18)	11.4(37)	33.0(107)	45.7(148)	4.10	1.084

during rainy season							
I would worried to walk through flood	3.7(12)	10.2(33)	19.1(62)	35.2(114)	31.8(103)	3.81	1.104
Disposing the dead animal is important	8.3(27)	9.6(31)	29.0(94)	29.0(94)	24.1(78)	3.51	1.195
I would make my environment free from rat	2.8(9)	2.8(9)	12.3(40)	29.6(96)	52.5(170)	4.26	.971

4.7 To assess level of prevention practices towards Leptospirosis among secondary school children

Table 4.8 shows the overall practice score of the respondents regarding Leptospirosis is 30.62 (3.827). The prevention practices was divided into three categories, poor practice with the range of score 8 to 18, moderate practice with range score 19 to 29 and good practice with the range 30 to 40. As shown in Table 4.8, about 61.1% (n=198) of respondents had good practice and 0.3% (n=1) had poor practice towards Leptospirosis.

Table 4.8 Prevention practices level of secondary school children (n= 324)

Attitude level	**Range of score**	**Frequency (n)**	**Percent (%)**
Poor practice	8-18	1	0.3
Moderate practice	19-29	125	38.6
Good practice	30-40	198	61.1
Total		324	100.0

Table 4.9 shows the details of item analysis of attitude towards Leptospirosis. 13.3% (n=43) of the respondents score correct response for item “I wear waterproof boots when wading on flood water”. 54.0% (n=175) of the respondents score correct response for item “I walk through the flood water”. 30.9% (n=100) of the respondents score correct response for item “I walk barefooted on the soil”. 53.1% (n=172) of the respondents score correct response for item “I store food in sealed or rat proof containers”. 64.2% (n=208) of the respondents score correct response for item “I will make sure my house is free from rat”. 74.4% (n=241) of the respondents score correct response for item “I wash my hand before eating”. 50.0% (n=162) of the respondents score correct response for item “I drink boiled cooled water”. 6.8% (n=22) of the respondents score correct response for item “I bathe in public swimming pool and/or waterfall

Table 4.9 Prevention practices of secondary school children (N=324)

Items	**Never Practiced %()**	**Rarely Practiced %()**	**Sometimes Practiced %()**	**Often Practiced %()**	**Always Practiced %()**	**Mean**	**SD**
I will wear waterproof boots when wading on	42.0(136)	20.1(65)	12.3(40)	12.3(40)	13.3(43)	2.35	1.455

flood water							
#I walk through the flood water	54.0(175)	29.0(94)	9.6(31)	5.2(17)	2.2(7)	4.27	.984
#I walk barefooted on the soil	30.9(100)	26.9(87)	28.1(91)	7.7(25)	6.5(21)	3.68	1.176
I store food in sealed or rat proof containers.	3.1(10)	5.2(17)	9.3(30)	29.3(95)	53.1(172)	4.24	1.028
I will make sure my house is free from rat	4.0(13)	4.6(15)	8.0(26)	19.1(62)	64.2(208)	4.35	1.073
I wash my hand before eating	1.2(4)	2.2(7)	7.1(23)	15.1(49)	74.4(241)	4.59	.814

Negative statement items are reversed scoring and tailed with positive statement items

4.8 Association between knowledge and selected demographic characteristics of secondary school children towards Leptospirosis

Based on Table 4.10, the Pearson Chi-square analysed revealed a non-significant association existed between age of the secondary school children and knowledge level regarding Leptospirosis, $X^2(2, N=324) = 5.556$, $p > 0.05$.

Furthermore, the Pearson Chi-square analysed revealed a non-significant association existed between gender of the secondary school children and knowledge level regarding Leptospirosis, $X^2(2, N=324) = 2.452$, $p > 0.05$.

The Pearson Chi-square analysed revealed a significant association existed between ethnicity of the secondary school children and knowledge level regarding Leptospirosis, $X^2(6, N=324) = 16.116$, $p > 0.05$. Fisher's Exact test also revealed ethnicity of the secondary school children and knowledge level regarding Leptospirosis as $p < 0.05$ (p-value = 0.007).

Among 324 respondents 208 (76.8%) of the Malay respondents, 2 (40%) of Chinese respondents , 27 (64.3%) of Indian respondents and 2 (33.3%) of others which include Chindian, Sikh, India Muslim, Kadazandusun, and Russian respondents have moderate knowledge regarding Leptospirosis.

The Pearson Chi-square analysed revealed a non-significant association existed between father's

educational level of the secondary school children and knowledge level regarding Leptospirosis, X^2(2. N=324) = 1.114, p> 0.05.

The Pearson Chi-Square analysed revealed a non-significant association exist between knowledge level regarding Leptospirosis and mother's educational level of the secondary schoolchildren, X^2(2. N=324) = 1.493, p> 0.05.

Besides, the Pearson Chi-square analysed revealed a non-significant association existed between occupation of the secondary school children fathers and knowledge level regarding Leptospirosis, X^2(4, N=324) =7,033, p> 0.05. Fisher's Exact test also revealed occupation level of the secondary school children fathers and knowledge level regarding Leptospirosis as p> 0.05 (p-value = 0. 116)

The Pearson Chi-square analysed revealed a non-significant association existed between occupation of the secondary school children mothers and knowledge level regarding Leptospirosis, X^2(4, N=324) = 7.103, p> 0.05.

4.9 Association between attitude and demographic characteristics of secondary school children towards Leptospirosis

Based on Table 4.11, the Pearson Chi-square analysed revealed a non-significant association existed between age of the secondary school children and attitude regarding Leptospirosis, $X^2(2, N=324) = 0.186$, $p > 0.05$. Fisher's Exact test also revealed age of the secondary school children and attitude regarding Leptospirosis as $p > 0.05$ (p-value = 1.000)

Besides, the Pearson Chi-Square analysed revealed a significant association exist between attitude regarding Leptospirosis and gender of the secondary schoolchildren, $X^2(2, N=324) = 7.253$, $p < 0.05$. Fisher's Exact test also revealed gender of the secondary school children and attitude regarding Leptospirosis as $p < 0.05$ (p-value =0.019). Among 324 respondents age 13, 123 (72.4%) and 91 (59.1%) age 14 have good attitude towards Leptospirosis.

In addition, the Pearson Chi-square analysed revealed a non-significant association existed between ethnicity of the secondary school children and attitude regarding Leptospirosis, $X^2(6, N=324) = 10.839$, $p > 0.05$. Fisher's Exact test also revealed ethnicity of the secondary school children and attitude regarding Leptospirosis as $p > 0.05$ (p-value = .086).

The Pearson Chi-square analysed revealed a non-significant association existed between fathers' educational level of the secondary school children and attitude regarding Leptospirosis, $X^2(2, N=324) = .343$, $p > 0.05$. Fisher's Exact test also revealed fathers' educational level of the secondary school children and attitude regarding Leptospirosis as $p > 0.05$ (p-value = .901)

Fisher's Exact Test#

Pearson Chi-square analysed revealed a non-significant association existed between mothers' educational level of the secondary school children and attitude regarding Leptospirosis, $X^2(2, N=324) = 2.005$, $p > 0.05$. Fisher's Exact test also revealed mothers'
educational level of the secondary school children and attitude regarding Leptospirosis as $p > 0.05$ (p-value = .364).
Next, the Pearson Chi-square analysed revealed a non-significant association existed between occupation of the secondary school children fathers and attitude regarding Leptospirosis, $X^2(4, N=324) = 5.462$, $p > 0.05$. Fisher's Exact test also occupation of the secondary school children fathers and attitude regarding Leptospirosis as $p > 0.05$ (p-value = .220).
The Pearson Chi-square analysed revealed a non-significant association existed between occupation of the secondary school children mothers and attitude regarding Leptospirosis, $X^2(4, N=324) = 3.373$, $p > 0.05$. Fisher's Exact test also occupation of the secondary school children mothers and attitude regarding Leptospirosis as $p > 0.05$ (p-value = .499).
The Pearson Chi-square analysed revealed a non-significant association existed between ethnicity of

the secondary school children and attitude regarding Leptospirosis, $X^2(6, N=324) = 10.839$, $p > 0.05$. Fisher's Exact test also revealed ethnicity of the secondary school children and attitude regarding Leptospirosis as $p > 0.05$ (p-value = .086).

4.10 Association between prevention practice and demographic characteristics of secondary school children towards Leptospirosis

Based on Table 4.12, the Pearson Chi-square analysed revealed a non-significant association existed between age of the secondary school children and practice level regarding Leptospirosis, $X^2(2, N=324) = 1.224$, $p > 0.05$. Fisher's Exact test also revealed age of the secondary school children and practice level regarding Leptospirosis as $p > 0.05$ (p-value = 0.606)

Fisher's Exact Test#

In addition, the Pearson Chi-Square analysed revealed a significant association exist between practice level regarding Leptospirosis and gender of the secondary schoolchildren, $X^2(2, N=324) = 10.974$ $p< 0.05$. Fisher's Exact test also revealed gender of the secondary school children and practice level regarding Leptospirosis as $p< 0.05$ (p-value = 0.002). Among 324 respondents female respondents, 118 (69.4%) and male respondents, 80 (51.9%) have good practice level towards Leptospirosis.

The Pearson Chi-square analysed revealed a non-significant association existed between ethnicity of the secondary school children and practice level regarding Leptospirosis, $X^2(6, N=324) = 7.054$, $p> 0.05$. Fisher's Exact test also revealed ethnicity of the secondary school children and practice level regarding Leptospirosis as $p> 0.05$ (p-value = 0.685).

The Pearson Chi-Square analysed revealed a non-significant association exist between practice level regarding Leptospirosis and fathers educational level of the secondary schoolchildren, $X^2(2, N=324) = 4.195$, $p> 0.05$. Fisher's Exact test also revealed fathers educational level of the secondary school children and practice level regarding Leptospirosis as $p> 0.05$ (p-value = 0.087).

The Pearson Chi-square analysed revealed a non-significant association existed between mothers educational level of the secondary school children and practice level regarding Leptospirosis, $X^2(2, N=324) = 1.638$, $p> 0.05$. Fisher's Exact test also revealed mothers educational level of the secondary school children and practice level regarding Leptospirosis as $p> 0.05$ (p-value = 0.549).

The Pearson Chi-square analysed revealed a non-significant association existed between occupation of the secondary school children fathers and practice level regarding Leptospirosis, $X^2(4, N=324) = 6.289$, $p> 0.05$. Fisher's Exact test also revealed occupation of the secondary school children fathers and practice level regarding Leptospirosis as $p> 0.05$ (p-value = 0.179).

The Pearson Chi-square analysed revealed a non-significant association existed between occupation of the secondary school children mothers and practice level regarding Leptospirosis, $X^2(4, N=324) = 4.054$, $p> 0.05$. Fisher's Exact test also revealed occupation of the secondary school children mothers and practice level regarding Leptospirosis as $p> 0.05$ (p-value = 0.344).

4.11 Relationship between knowledge, attitude and prevention practice of secondary school children towards Leptospirosis

Based on table 4.13, a Spearman's rank order correlation was run to determine the relationship between knowledge and attitude level of the respondents. The r-value is 0.276. The p value is 0.0001 ($p<0.05$). Thus there is a significant weak positive relationship between knowledge and attitude level. The higher the knowledge level of the respondents towards Leptospirosis, the better the attitude level of the respondents towards Leptospirosis.

A Spearman's rank order correlation was run to determine the relationship between knowledge and practice level of the respondents. The r-value is 0.184. The p value is 0.001 ($p<0.05$). Thus there is a significant weak positive relationship between knowledge and practice level. The higher the knowledge level of the respondents towards Leptospirosis, the better the preventive practice level of the respondents towards Leptospirosis.

A Spearman's rank order correlation was run to determine the relationship between attitude and practice level of the respondents. The r-value is 0.286. The p value is 0.0001 ($p<0.05$). Thus there is a significant weak positive relationship between knowledge and attitude level. The better the knowledge level of the respondents towards Leptospirosis, the better the attitude level towards Leptospirosis.

*. Correlation is significant at the 0.05 level (2-tailed).

4.11 Summary

SPSS version 23.0 was used to analyze the result. The results were tabulated in the table above. The descriptive statistic, Chi-square test and Spearman Rho's test were used. Overall, the respondents moderate knowledge level, good attitude level and good prevention practice level. There was a significant association between knowledge level the respondents' ethnicity. Furthermore, there was a significant association between attitude level and gender. Besides, there is significant ssociation between practice level and gender. In addition, knowledge level of the respondents shows significant weak positive relationship with attitude level and prevention practices level. There is also weak positive relationship between attitude level with prevention practices level.

CHAPTER 5: DISCUSSION

5.1 Introduction

This chapter provided discussion and justification of the findings in each of the objectives of the research study and will be supported by previous study and current literature review. The objectives covered as followed:

a. To assess the level of knowledge regarding Leptospirosis among secondary school children
b. To assess the attitude level towards Leptospirosis among secondary school children
c. To assess level of perceive practices towards prevention of Leptospirosis among secondary school children
d. To assess association between demographic characteristics and knowledge, attitude and prevention practices towards Leptospirosis among secondary school children.
e. To assess the relationship between knowledge, attitude and prevention practices of Leptospirosis among secondary school children

Besides, implications of the study to nursing were also discussed based on the findings that the level of knowledge, attitude and prevention practices of Leptospirosis among secondary school children.

The researcher obtained through study period. Several limitations were further explored, that causes the findings to be affected and impairs its generalization. Furthermore, recommendations from the study will be discussed in order to enhance the future research.

5.2 Discussion

5.2.1 Knowledge level regarding Leptospirosis

Based on the research findings of this study, it showed that most of the secondary school children had moderate level of knowledge regarding Leptospirosis. This is because the respondents know about Leptospirosis but not explore in depth about the Leptospirosis. They only have basic knowledge on Leptospirosis. This is proved by most of them, mostly had good result in how the Leptospirosis transmission and also knowledge of preventive measure of Leptospirosis and the complication of Leptospirosis which can cause death but most of them did not know and had poor knowledge on sign of symptoms of Leptospirosis. These might be due to Malaysia curriculum for school children which not emphasize on disease.

This correspond with study from Selangor, Malaysia (Ismail et. al 2015) for wet market seller, shows majority of the respondents (51.4%) have moderate level of knowledge regarding Leptospirosis. Since they deal with raw substances, they need to know at least basic and common knowledge regarding Leptospirosis as they sell them to the public. If they did not know about it they will not do any prevention to avoid the food from contaminated with Leptospirosis. But majority they only have moderate because lack of emphasize in health education by the Ministry of Health to wet market seller.

In other hand, it is different from study done in Sri Lanka (Samarakoon et. al, 2012) that 52.0% show good level of knowledge regarding Leptospirosis. This may be due to high risk area which most of them including their family member are involve in paddy field cultivation. People who stay in high risk area such as in Sri Lanka which an endemic area tend to more aware on information and knowledge regarding Leptospirosis compare to less endemic area. In addition, their parent involved in job that high risk to be infected with Leptospirosis. Therefore, the secondary school children tend to want to know about it. Therefore, they had good knowledge regarding Leptospirosis. Majority of respondents in this study know the Leptospirosis is transmitted by rat and the respondents know the common sign and symptoms of the Leptospirosis.

5.2.2 Attitude level regarding Leptospirosis

Overall the majority of the respondents in this study had good attitude towards Leptospirosis. Since the secondary schoolchildren have a good score in Leptospirosis transmission and also knowledge of preventive measure of Leptospirosis, they applied in their attitude as they know the important it. Besides, majority of them get health information from the media mass and health care provider. By frequent reminder on the media mass and by the healthcare provider especially during epidemic, they will remain alert on the important of the health preventive measure. Therefore, they have a good attitude regarding Leptospirosis. This is corresponds with study done in Philippines (Arbiol et. al 2015), the respondents get overall mean score of 80.89% which mean, most of them have good attitude towards Leptospirosis. These because of there are campaign done there, for the awareness on how to avoid Leptospirosis especially on the media mass which are the television and radio. Media mass shows the most contribute factor for respondents on the attitude regarding Leptospirosis. Therefore, they become aware on the attitude that can prevent the transmission of Leptospirosis.

In contrast, there are study done in Selangor, Malaysia (Sakinah et. al 2015), which only 6% of the respondents had good attitude. This might because of the study done to non-high risk area as people who stay in less risk area tend to less aware on information and knowledge regarding Leptospirosis compare to people in endemic area. Maybe they know about it but did not want to explore it as or them the disease does not related to them as they are far from epidemic area. Therefore, they are less aware on the important of health prevention and have poor attitude regarding Leptospirosis.

5.2.3 Practice of preventive level towards Leptospirosis

Based on this study, the preventive measure practice level, most of them have good practice level. These because of most of them have the understanding about the knowledge and attitude towards the preventive measure of Leptospirosis. For overall practice of prevention and control strategies practiced which include to maintain cleanliness on the surrounding and keep good hygiene, majority of them gets good score but only in question of 'I will wear waterproof boots when wading on flood water' and 'I bathe in public swimming pool and/or waterfall', majority of them get poor result.

This is consistent to study done in Catbalogan City, Samar, Philippines (Charmaine et. al 2014) that hygienic practices determine factors such practical knowledge of health and concern for taking steps by promoting health and preventing disease which overall result is determine and majority of them have good practice. Basically, they get good result in overall practice of general health prevention practice and also safe work practice to maintain cleanliness on the surrounding and to keep good hygiene. The health workers and barangay officials highly practiced them and the residents always practiced them.

This study is opposite to study from Selangor, Malaysia (Sakinah et. al 2015) which had only 21% respondents had a good preventive practice level. For general practice part which include the items such as walking through flood, cover the food and washing hand before eating, majority of them get goods result. In other hand for safe work practice, which include items such as eat while working, drink while working and smoke while working, majority of them get poor result. This is why this study result is contrast to the researcher study as the researcher's study does not cover the safe work practice prevention towards Leptospirosis as it is done to secondary school children which if this study (Sakinah et. al 2015) done only for general practice, the majority of respondents will get good practices results.

5.2.4 Knowledge, attitude and practice level towards Leptospirosis association with socio-demographic characteristics.

There was a significant association between knowledge level with the ethnicity in this study. Majority of Malay have moderate knowledge towards Leptospirosis. There no any evidence to support this finding.

In study done in Sri Lanka (Samarakoon et. al 2012) which level of knowledge Leptospirosis was significantly associated with parent's involvement in paddy cultivation. This may indicate the

education program had reach families involved in cultivation. Since the researcher study done in a city, therefore, it is difficult to relate the job category that common with Leptospirosis.

Furthermore, there was a significant association between attitude level and practice level with gender. According to a study of Gender Differences in Health Information Behavior done in Finland (Stefan, 2013), female are more concern about health threat. Therefore, this is why when receive information related to health behaviour, more female will remind themselves the important of the health prevention practice and implement it compare to boy although they might receive the same health information. Therefore, girl have good attitude and practices towards Leptospirosis compare to boy.

Overall, these are contrast to the study done in India (Prabu et. al 2014). There were no difference between knowledge, attitude and practice with education level, age, duration of employment but there is significant difference between knowledge, attitude and practice level with job category.

5.2.5 Knowledge, attitude and practices level of leptospirosis among secondary school children.

From the study, knowledge level of the respondents was found to have significant positive weak relationship with attitude level of the respondents towards Leptospirosis ($p=0.001$). The level of knowledge influences the attitude of the respondents towards Leptospirosis. Therefore, secondary school children with better knowledge develop positive attitude within themselves. Since most of them have good results in knowledge of prevention of measures and transmission, which indicate they already know the important of the Leptospirosis prevention measures and then, they develops positive attitude toward Leptospirosis. Study from Mohamad Azfar et al, (2017), improved in knowledge lead to improvement of attitude.

Furhermore, the knowledge level of was also found have significant positive weak relationship with practice level of the respondents towards Leptospirosis ($p=0.020$). The level of knowledge does influence the preventive practice towards Leptospirosis. Since most of the secondary school students in this study have the knowledge on the preventive practice regarding Leptospirosis, therefore, they know the ways to apply and they implement the preventive measure in their daily life. According to Arbiol et al, (2016), knowledge improves individual ability to translate preventive measure into action.

Lastly, attitude of the respondents was found have significant positive weak relationship with practice level of the respondents towards Leptospirosis ($p=0.0001$). Since, they have develops positive attitude towards Leptospirosis, they know and always keep in mind on the important of Leptospirosis prevention. Therefore, when they realize the important of Leptospirosis prevention, they tried to find the ways to prevent themselves from infected and they implement the preventive measure their daily life. According to Arbiol et al, (2016), positive attitude complement with relevant knowledge will improve the individual preventive measures into action.

5.3 Limitation of the study

The study did not examine individual perceptions of Leptospirosis risk and reason for respondents' choices. Future studies may attempt to address limitation by using open-ended qualitative questionnaire to explore more on the individual perceptions of Leptospirosis risk and reason for respondents' choices

Besides, this study done to secondary school children as the infection is more common and severe for them. But it is also known to affect adults. Future research may examine the knowledge, attitude and practices among adult.

Furthermore, the health prevention practices were obtained through self-report. Ideally, practices need to be evaluated through observation, which would have increased the internal validity of the study. Nevertheless, the data were validated and steps were taken to minimize biases.

In this study, the informed consent should be obtained from the parent as the secondary school children age less than 18 years old. In the future, if the researcher need to collect data from secondary

school, the researcher will obtained it from parent.

5.4 Implication of the study

Nursing

Nursing plays an important role in order to educate the public including the school children on the awareness of health prevention regarding Leptospirosis. In this, nurses play the part of educators that offer information to communities that encourage positive health behaviors. From providing knowledge to reinforcing the health prevention practice, health educations are designed to avoid suffering and illness in patients, as well as avoid any type of cost supplementary to disease treatment.

Secondary school children

During secondary school age which at 13 until 18 years old, they are very active and like involve in activities that have high risk towards leptospirosis such as swimming in stagnant water, did not take care of their cleanliness and surrounding. Therefore, they should aware on the Leptospirosis. When they have detects sign and symptom of the infection such as headache, vomiting and jaundice, from themselves and also their family member should seek for medical help. Early prevention can avoid for further complication which also can save life.

Healthcare Organization

The study provides healthcare organization and academic institutions valuable details about how certain secondary school children ' demographics variables such as gender and ethnicity might influence secondary school children' knowledge, attitude and practice towards Leptospirosis. As findings from the study concluded, secondary school children have moderate knowledge, good attitude and practices. In order to improve the knowledge, the healthcare organization should in-charged the healthcare professional to do public talk and give talk at school for the secondary school children and spread the information for health prevention through the media mass such as radio and television especially during the outbreak of the disease.

5.5 Recommendation

Based on the findings presented, the following recommendations are suggested:

i. The researcher recommended that the health education regarding Leptospirosis should be introduce and reinforce to health care provider includes the nurses and doctor. Nurses should always update the latest information regarding Leptospirosis. With that information, nurses able to apply the current nursing care in the hospital. Furthermore, nurses also should be design to give health education to school and also public to reinforce on knowledge regarding the medium of transmission, sign and symptom, complication and also the important of preventive measure taken to prevent Leptospirosis. This can increases the school children' and public's knowledge regarding Leptospirosis and prevent increase in number of Leptospirosis cases.

ii. The researcher recommends that the health awareness regarding Leptospirosis should reinforce to school children by giving talk in the schools. It can also be promoted via other media such as the exhibition and campaign which include the secondary school children. The media mass also the important media in education the public regarding Leptospirosis. The content of the talk should be the focus more on the sign and symptoms as most of them lack on that expects.

iii. The researcher also recommended inserting the content regarding Leptospirosis into the curriculum of the school syllabus. This method can be done to introduce, reinforce and increase the public awareness towards Leptospirosis. The contents should include basic knowledge on the transmission, sign and symptom, complication and preventive measure regarding Leptospirosis. This will increase the awareness towards school children and indirectly will also help to increase the awareness regarding Leptospirosis among the public.

5.6 Conclusion

This study shows the current of knowledge level of the secondary school children in Malaysia is in moderate knowledge while they showed positive attitude and good practice in preventive measure of Leptospirosis. Education is very important to be addressed to the secondary school children. Therefore, they can learn and implement knowledge and preventive measure towards Leptospirosis. Besides, further research are needed to advances more knowledge and benefits the public.

THE EFFECTIVENESS OF CLINICAL PATHWAYS TO IMPROVE THE QUALITY CEREBROVASCULAR ACCIDENT (CVA) INFARCT CARE IN HOSPITAL: A SYSTEMATIC REVIEW

H R Ariyanti[1], Nursalam[1], S R Yuwono[2]
[1]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
[2]Politeknik Kesehatan Kemenkes Surabaya, Indonesia
Email: hani.riska.ariyanti-2017@fkp.unair.ac.id

ABSTRACT

CVA Infarct becomes a major health problem and cause of disability. Clinical pathways as an effort to monitor patient progress in a certain period of time; towards achieving positive results and quality. Clinical pathways purpose to integrate patient care based on the best guidelines and evidence. The objective of review was to strengthen the literature regarding the effectiveness of the implementation of clinical pathways of CVA Infarct patients to improve the quality of care in hospitals. To complete the literature used the database were Proquest, Scopus, Science direct and Medline which has been published at the time limits of 2012-2018. Keywords were used clinical pathway, quality care, CVA Infarct. From 14 of 543 articles were used in this systematic review. The article reviewed mentions how the implementation of the clinical pathway on service quality. Most articles show that increasing the quality of care by the implementation of clinical pathways of CVA Infarct patients effectively. Improve the quality of services by implementing clinical pathways effectively. Service quality includes: decrease in length of stay (LOS) and cost, decreased readmission, reduced incidence of pneumonia, decreased mortality and increased collaboration between health professionals in CVA Infarct patients.

Keywords: clinical pathway, quality care, CVA infarct

1. Introduction

Clinical pathways or integrated care pathways are critical multidisciplinary care plans used by health caregivers to describe the essential measures in the intervention of patients with complex clinical problems [1]. Efforts should be performed to monitor the progress of the outcomes over a longer period to implement a care plan that is needed and evaluated continuously. The implementation of clinical pathways is multidisciplinary in terms of the doctors or dentists, physiotherapists, nurses, pharmacists, nutritionists and others involved. Nurses are included in the intervention, its implementation, continuous evaluation and development in all aspects [2].

CVA infarct becomes a major health problem and a cause of disability. It is the second most common cause of death in Asian countries. Hospital care for CVA patients can reduce the risk of death and disability. There are impressive results in the implementation of clinical pathways (CP) for CVA management on a regular basis [3].

The intervention study can provide a detailed insight into the effectiveness of the implementation of clinical pathways for CVA infarct patients to improve the quality of care in hospitals. The clinical pathway system can significantly reduce errors and the length of stay so then

the quality of health can be more made effective [4]. The length of stay in hospital and the cost of hospitalization was significantly lower for the patients who received the clinical nursing pathway compared to the control group [5]. The clinical pathway can reduce the average length of stay, increasing cost efficiency and thus improving the quality of the health services. The multivariate analysis showed that after adjusting the conventional risk factors, CP application also played an important role in shortening LOS, reducing costs, improving the clinical outcomes, reducing the incidence of nosocomial infections and improving patient safety [6]. The most influential factors for readmission within 31 days were age, the type of stroke, medical insurance status, the type of discharge, the use of clinical pathways, the length of the hospital stay and comorbidities [7].

Clinical pathways in stroke reduce the incidence of aspiration pneumonia, mechanical ventilation requirements and the risk of death when followed up at 90 days [3]. There was a better rate of 30-day survival in patients with severe stroke in the intervention group compared to the control [8].

The aim of this systematic review was to strengthen the literature regarding the effectiveness of the implementation of clinical pathways for CVA infarct patients to improve the quality of care in hospitals.

2. Methods

2.1 Protocol

The systematic review was performed in line with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) statement and checklist [9,10]

2.2 Eligibility criteria

The journal articles were published in the English language from 2012 to 2018. The search strategy used the PICOS framework to identify the keywords.

2.3 Information sources

Four databases were systematically searched (Proquest, Scopus, Science Direct, and Medline) from 2012 until 2018 for the intervention studies describing the effectiveness of the implementation of clinical pathways for CVA infarct patients.

2.4 Search

The search terms used were ‘clinical pathway’ OR ‘integrated care pathway’ AND ‘cerebrovascular infarct’ OR ‘stroke infarct’ AND ‘quality of care’.

2.5 Study selection

The protocol standard for selecting the research studies was as suggested in the PRISMA method for systematic review. This was followed by screening and removing the duplicates. Three reviewers then selected the titles, abstracts and keywords. Irrelevant quotes were deleted according to the selection criteria. The reviewers noted the reasons for choosing the research studies including the selection of the inclusion data. The selection of the research studies by the two reviewers were then

compared to one another to be adjusted for feasibility according to the criteria set. Secondly, to minimize the risk of incorrect study entry in the selection, there are several research studies that were applicable or that could be applied in a review to be included in the next review stage. The full text of the articles were obtained if the title and abstract met the inclusion criteria or if the feasibility study was clearly resolved by a joint discussion between the reviewers.

2.6 Data collection process

The following data was extracted: author, year, journal, study design, participant, intervention study, key findings or if there were relevant secondary outcomes.

2.7 Data items

The information extracted from each included study was on (1) the identity of the study (including author name and year of publication); (2) the setting of the study or the characteristics of the participants; (3) methodology (including the data collection method and analysis) and (4) the major findings relevant for review.

2.8 Risk of bias in individual studies

As both of the randomized controlled trial (RCTs) studies involved an eligible risk of bias, an assessment was undertaken using a tailored tool based on the respective Cochrane Collaboration guidelines [11]. The risk of bias was evaluated for the following domains: (1) selection bias (e.g., randomization and stratification), (2) performance bias (e.g., blinding of participants and personnel), (3) detection bias (e.g., missing data and appropriate confounders) and (4) reporting bias (e.g., selective reporting). The reviewer independently assessed each study for bias, which was coded as high, moderate, low or unclear/unknown. Where appropriate, the direction of bias was noted as favoring the intervention/control or unclear. The overall risk of the bias ratings was determined qualitatively and some of the domains were weighted more heavily than others as recommended [10]. For example, trial performance and detection and analysis were given more weight as studies with a high risk of bias in these domains may be more likely to favor the intervention group. Each reviewer was blind to the assessment of the other reviewer. The reviewers crosschecked their final assessments and resolved any disagreements through discussion.

2.9 Quality assessment

The data was extracted from each study if it met the requirements. The extracted data included the characteristics of the research, the characteristics of the results and the summary of the results. The studies were grouped according to the effects that arise from the implementation of clinical pathways on the quality of nursing care.

2.10 Data analysis

The studies were grouped according to the intervention used and the study population. Where possible, the studies were thereafter grouped according to the time of the follow-up and the type of control group. All of the studies were individually rated for evidence level using the National Health

and Medical Research Council (NHMRC) Hierarchy of evidence guidelines (IV-I, with I being the strongest level of evidence).

2.11 Meta-analysis

Meta-analysis was not possible as the studies were too heterogeneous in terms of the outcome measures used and the time of the follow-up.

3. Result

2.1 Study selection

The results of the journal selection based on the keywords produced 2551 articles. Scopus had 1725 articles, Science Direct had 310 articles, Proquest had 211 articles and Medline had 205 articles. All of the journals that were obtained were then screened based after the duplicate removal of 543 articles. Re-screening was done to get the 6 articles that were in accordance with the criteria, both inclusion and exclusion. All of the journals were interventional study types with a focus on the effectiveness of the clinical pathways in improving service quality (see Figure 1).

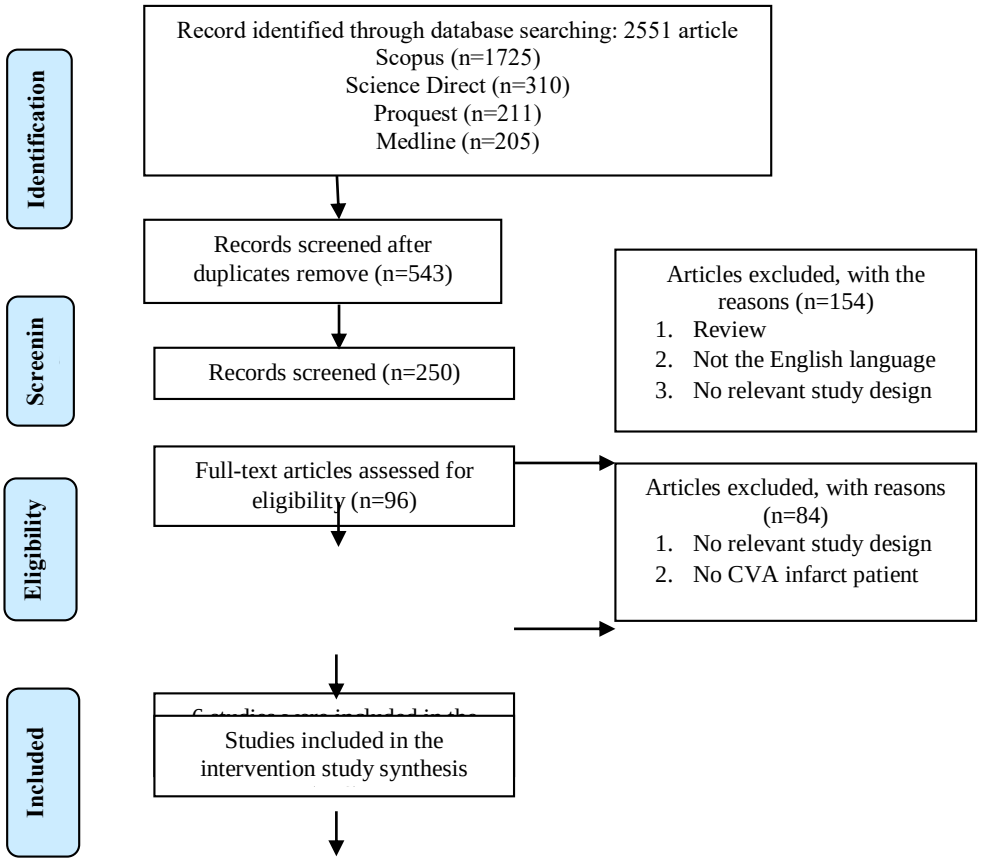

Figure 1. Flow Diagram

2.2 Study characteristic

3.2.1. Type of studies. Four studies used a randomized trial, 1 study used a pragmatic randomized trial and 1 study using a nonrandomized trial (see Table 1).

3.2.2. Type of participant. The included studies involved 52,591 respondents. The patients studied were diagnosed with CVA infarction (see Table 1).

3.2.3. Type of interventions. There was 1 intervention design clinical pathway. This was implemented in the hospital.

3.2.4. Type of outcomes. Each study examined the quality of care outcomes. The outcomes were the patient outcome and professional outcome.

Table 1. Summary of the Findings

Author / Year	Study Design	Respondent	Intervention Group	Control Group	Result
Rai et al., 2016	Cluster randomized study	162	The stroke care pathway (CP) arm (n = 77)	The conventional care (CC) arm (n = 85)	Clinical pathways in stroke reduce the incidence of aspiration pneumonia, mechanical ventilation requirements and the risk of death when followed up at 90 days.
Panella et al., 2012	Cluster randomized trial	476	Clinical pathway arm (CP arm)	Usual care arm (UC arm)	Clinical pathways can significantly improve the outcomes of patients with ischemic strokes, indicating the better application of evidence-based key interventions and of the diagnostic and therapeutic procedures. The patients in the clinical pathway arm had a significantly lower risk of mortality at 7 days and lower rates of adverse functional outcomes.
Field, 2018	Pragmatic randomized controlled trial	488	Clinical pathway (CRT/ Cough Reflex Testing)	Standard care	High patient and clinician satisfaction with CRT was found, with the clinicians reporting additional knowledge and confidence in decision making for dysphagia management. In conclusion, the clinical pathway resulted in minimal increases in the use of clinician resources. While

Author / Year	Study Design	Respondent	Intervention Group	Control Group	Result
					clinicians perceived CRT as beneficial in clinical decision making, the efficacy of CRT for reducing pneumonia rates in acute stroke remains to be established.
Deng et al., 2015	Randomized controlled trial	426	Clinical pathway group (CP group; n=213)	Conventional group (control; n=213)	To date, clinical pathways have been implemented for a great variety of diseases to improve treatment effectiveness and to reduce costs.
Nakibuuka et al., 2016	Nonrandomized controlled trial	127	Integrated care pathway	Usual Care	Mortality within 7 days was higher in the intervention group compared to the controls. There was a better 30-day survival rate for severe stroke patients in the intervention group compared to the controls.
Wen et al., 2018	Randomized controlled trial	50.912	*Care pathway*	*Standard care*	Age, type of stroke, medical insurance status, type of discharge, use of clinical pathways and the length of the hospital stay. The most influential factor for readmission within 31 days was comorbidities.

2.3 Risk of bias assessment

The risk of bias judgments for each paper have been summarised in Table 2. Five articles (83%) were considered to have a low risk of bias and one (13%) had a moderate risk of bias. Poor selection methods, a lack of adjustment for confounding factors and inadequate analyses were the main sources of bias, as in Figure 2. While the inadequate blinding of personnel was a key source of bias, we acknowledge that it is rarely possible to fully blind participants and clinicians when implementing a clinical pathway.

Table 2. Risk of bias based on the title of the paper

PHP-767

No	Study (year)	Selection of bias		Report bias	Other bias	Performance of bias	Detection of bias	Attrition of bias

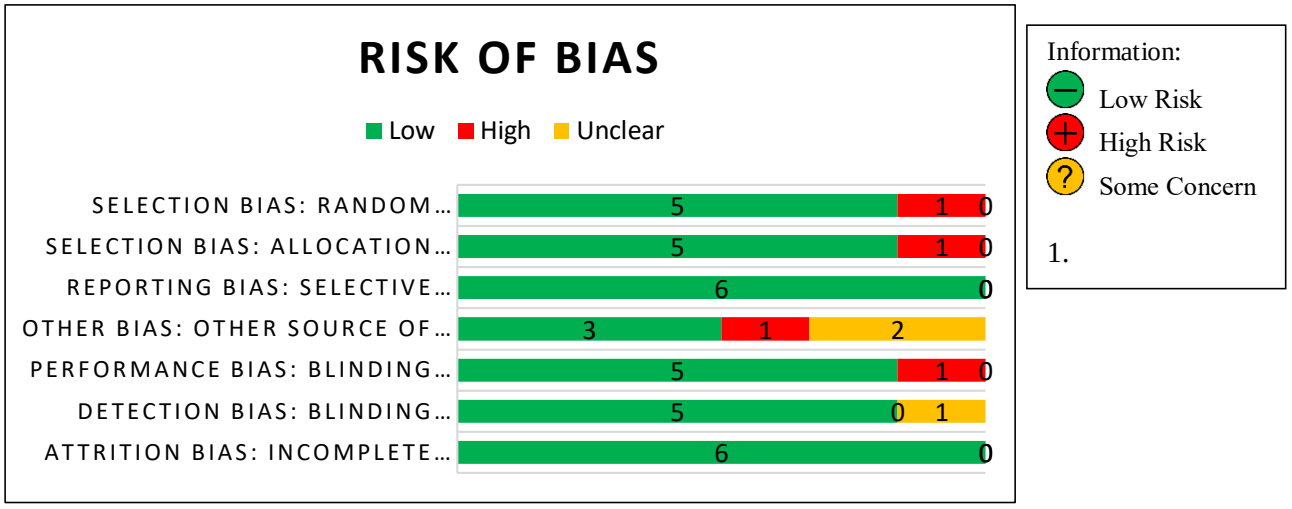

Figure 2. Risk of bias based on the judgments for all papers

2.4 Results of the individual studies

3.4.1. Patient outcome. Clinical pathways can significantly improve the outcomes of ischemic stroke patients, indicating the better application of evidence-based key interventions and of diagnostic and therapeutic procedures. The patients in the CP arm had a significantly lower risk of mortality at 7 days and lower rates of adverse functional outcomes. Clinical pathways in stroke reduce the incidence of aspiration pneumonia, mechanical ventilation requirements and the risk of death when followed up at 90 days [3,12]

Clinical pathways have been implemented for a great variety of diseases to improve treatment effectiveness and to reduce costs [5].

Mortality within 7 days was higher in the intervention group compared to the control groups. There was a better rate for 30-day survival in patients with severe stroke in the intervention group compared to controls [8].

Age, the type of stroke, medical insurance status, the type of discharge, the use of clinical pathways, the length of the hospital stay and comorbidities were the most influential factors for readmission within 31 days [7].

3.4.2. Professional outcome. Clinician satisfaction with CRT was found, with the clinicians reporting additional knowledge and confidence in decision making [13].

4. Discussion

Most articles show that increasing the quality of care through the implementation of clinical pathways for CVA infarct patients was effective at improving the service quality. Service quality includes a decrease in length of stay (LOS) and cost, decreased readmission, reduced incidence of pneumonia, decreased mortality and increased clinician satisfaction.

The clinical pathway arm had a lower incidence of aspiration pneumonia (AP) in comparison with the conventional care arm. The clinical pathway group had a decreased risk of the requirement of mechanical ventilation [3]. The primary outcomes included confirmed pneumonia within 3 months post-stroke and a decreased length of acute inpatient stay. The secondary outcomes were related to the feasibility of implementing a CRT pathway and clinician and patient satisfaction [13]. The CP groups confirmed that each clinical pathway achieved its goal of significantly decreasing the length of hospital stay and thus the overall healthcare costs [5].

In the clinical pathway group, there was an effect from the clinical pathway on reducing mortality in some patients with severe stroke. Patients with severe stroke in the intervention group were significantly more likely to be alive 30 days post-stroke compared to the patients in the control group. It is possible that the more aggressively implemented care (as represented by the stroke care bundle) is the most helpful for individuals with a great amount of impairment and the highest risk of complications. Additional research is needed to more conclusively determine if there may be optimal patient populations on which to focus the clinical pathways. The hospital stay was significantly shorter in the intervention group [8].

Clinical pathways can significantly improve the outcomes of ischemic patients post-stroke, indicating the better application of evidence-based key interventions and of the diagnostic and therapeutic procedures. Age, the type of stroke, their medical insurance status, the type of discharge, the use of clinical pathways, the length of the hospital stay are the most influential factors for readmission within 31 days as comorbidities [7,12].

The systematic review had some limitations. We initially identified 84 relevant studies. However, only 6 studies could be considered as clinical pathways involving intervention studies and they also had to meet our inclusion criteria. The scarcity of publications on the clinical pathway probably results from the fact that clinical pathways have only recently become a popular tool and the associated benefits for CVA infarct interventions is still not clear. Therefore, not many studies could be included to evaluate the effect of clinical pathways on the in-hospital treatment of CVA infarcts.

5. Conclusion

There are several important findings regarding the effectiveness of the implementation of the clinical pathway which will now be discussed in detail, including patient outcome and professional outcome. The patient outcome included improving the treatment effectiveness, reducing the costs and reducing mortality. The professional outcome was the clinicians reporting additional knowledge, being confident in their decision making and satisfaction. The explanation above can be used to conclude that the implementation of clinical pathways can improve the quality of care significantly. Clinical pathways can help to provide better, more comprehensive and more specialized care to a patient affected by a CVA infarct.

ROLE OF FAMILY IN CARING PATIENT WITH POST STROKE AT HOME: A SYSTEMATIC REVIEW

I Choliq1, Z 'Ulya1, A N Izzati 1, and S Tauriana1
[1]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
Email: idham.choliq-2018@fkp.unair.ac.id

ABSTRACT

Stroke is a disease that can cause cognitive impairment or disability. Role and support of family as the closest person is necessary for the post-stroke recovery process. This systematic review aims to identify the effectiveness of the family's role in caring patient with post-stroke at home. There are four steps to define the topic (1) to identify appropriate keywords (post- stroke, community, family, and home), (2) to identify relevant literature based on topic, (3) to identify appropriate inclusion criteria, (4) to analyze the account of various intervention on literature. Search strategy resulted in 849 articles from Scopus, Proquest, Science Direct and SpringerLink with a limit of 2014-2018 and English-language, only 15 journals were eligible for analysis. There are types of family roles to support patient's post-stroke at home: ADL assistance and psychosocial support. The role and support of family put effect into the caring patient with stroke at home, including an increase of ADL, life quality, cognitive function, and self-efficacy.

Keywords: family, home, and post-stroke

1. Introduction

Stroke is blamed for 9% of deaths globally and it is the second cause of mortality after heart disease. It is the first cause of disability in adults. The prevalence of stroke is around 50–100 per 100,000 people[1]. Stroke will cause symptoms after the stroke event itself. Stroke has become the second most common cause of cognitive impairment, disability and death. This disease occurs when the brain cells do not receive oxygen. They stop working and this can cause cell death [2].

If the stroke is treated faster, then the recovery rate will be better. Thus, this is known by the term "the golden period", which refers to the best time to give the stroke patients help. Medical treatment must be done within 3 hours after the stroke first attacked to prevent disability. If it exceeds this time, then permanent disability will occur or even death [3].

The impact of stroke on each patient can be different. It depends on the injury severity, the affected part of the brain related to the injury and their health status [4]. Functional damage via a stroke can cause disability, so the patients become unproductive. Stroke sufferers will experience limited activities related to daily living (ADL) and they will require continuous nursing assistance so then they can gradually carry out independent self-care.

In addition to physical disability, patients with stroke tend to experience emotional disorders, one of which is depression. Post-stroke depression is closely related to low functional values when carrying out their daily activities. Post-stroke motor restriction will cause dependence on ADL. In

addition, changes in their psychological condition will make the patient become slothful. A lack of response toward rehabilitation tends to be emotional and they may show behavior changes [5]. These impacts and restrictions affect the patients; they need support from their family. Family assistance and support is necessary to reduce functional damage and to help the patients to become more independent when doing ADL and other activities even though their motor function is not completely normal.

This is evidenced by the study whose results indicated that the ADL ability in patients post-stroke increases. The complications that occur in patients with a stroke can also be reduced after the patient's family is given knowledge of post-stroke care compared to those who are not given knowledge [6]. Another study conducted by [7] explained that the psycho-socio-emotional and relational approach of the families, especially couples, is very important when it comes to improving quality of life after stroke. Based on various studies, this article aims to identify the effectiveness of the family's role in caring for a patient post-stroke at home.

2. Method

2.1 Literature Search Strategy

The literature search was carried out from August 29th to September 23rd 2018 using several scientific publication databases such as SCOPUS, Springer link, ProQuest and ScienceDirect. It was limited to publications between 2014 and 2018. The scope was post-stroke, community, family and home. In addition, the search was also limited to the area of English nursing.

2.2. Selection Criteria and Process

The chosen literature had to relate to the family role – that of the parents, spouse and siblings - in caring for a patient post-stroke at home. The specified inclusion criteria were male and female patients with stroke, patients aged ≥18 years when the stroke first attacked and having a family. In addition, the chosen study was focused on empirical research (not reviews or articles). The chosen research designs were Randomized Controlled Trial (RCTs), qualitative and protocol. The literature also had to be published in an accredited journal.

After getting items of literature that matched the keywords, the reviewer filtered the titles to see if there were any duplications. After the duplications were deleted, the reviewer was able to sort the literature according to the inclusion criteria and the expected results as stated in the abstract. The following action was done by selecting the journal after reading its full text to ascertain whether the journal met the systematic review requirements (Figure 1).

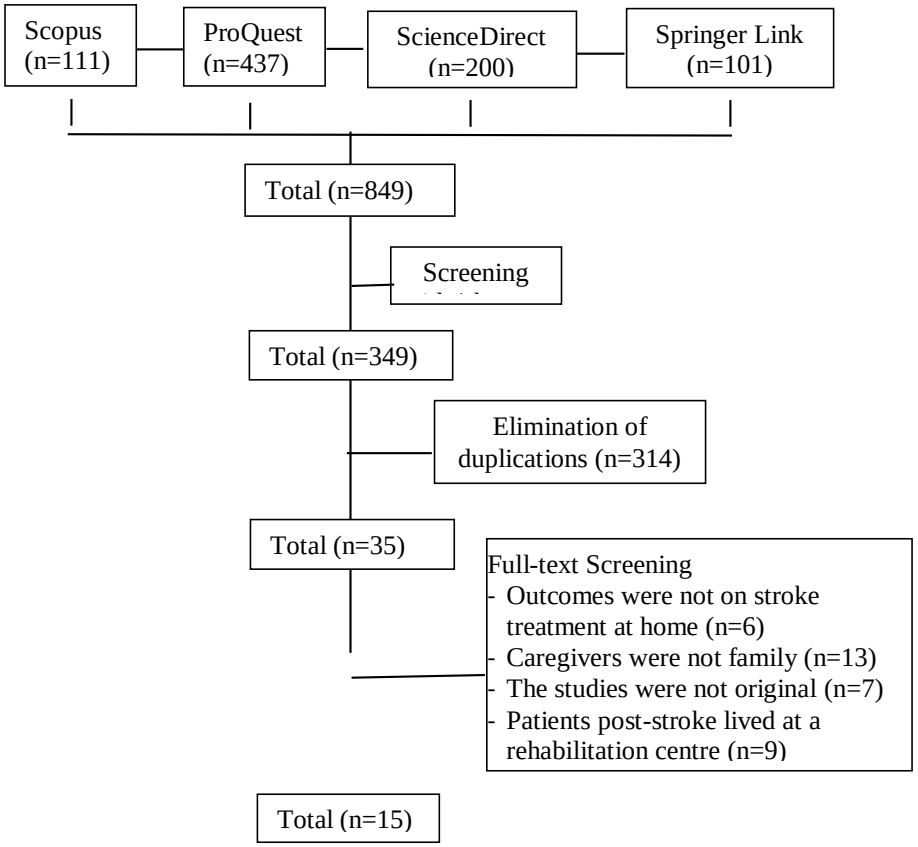

Figure 1. The Process of Journal Selection for the Systematic Review.

3. Result

The search strategy resulted in 849 articles. After filtering editorial titles, 500 articles were eliminated. Following this, 314 duplicate articles were eliminated, leaving 35 articles. The 35 articles were read in terms of their full text and they were adjusted to the inclusion criteria to get 15 articles. The total respondents from this systematic review were 1,418.

(17)	Qualitative study. Grounded-theory.	10 families / caregivers	In-depth interviews	1. Physical management increased 2. Mental health of the patients with stroke increased

Author	Type of Study	Participants	Intervention	Outcome
(18)	Qualitative study. Grounded theory.	40 stroke families / caregivers	In-depth interview	1. Identifying and prioritizing disparity between the patients and the caregiver's capacity 2. Creating a plan to increase the caregivers' readiness
(19)	Qualitative study. Grounded theory.	10 family / caregivers	Semi-structured in-depth interviews	1. The nurse should give better support to the family in terms of caring incontinence

3.1.Domain

3.1.1 Quality of Life. There was one qualitative study that explained that family support could improve the quality of life of patients post-stroke.

3.1.2 Self-Efficacy. There was one study that explained that family support via the telephone had an effect on improving the self-efficacy of patients post-stroke.

3.1.3 Cognitive Function. There was one study that stated that families given education about post-stroke care could affect an improvement in the cognitive function of the patients post-stroke.

3.2.Type of Family Support

3.2.1 ADL Assistance. There were three studies about the effect of family support related to the fulfillment of ADL needs and all of them showed significant results.

3.2.2 Psychosocial Support. One study examined the effect of family support on reducing the depression in patients post-stroke and the results were significant.

4. Discussion

The results of this systematic review showed that there was a positive influence from the role of the family on the care of patients post-stroke at home. There were 3 types of research in this review i.e. quantitative research with a randomized controlled trial, protocol and a qualitative design. The research method and the form of intervention given to the patients post-stroke varied in the physical and psychological aspects. The number of samples used in each journal was different; the smallest sample was 18 and the largest was 410 respondents.

The study conducted in Thailand found that there was an increase in family knowledge and the ability to treat patients with a stroke. The intervention group which consisted of patients post-stroke had an increased ability related to ADL compared to those in the control group. Other studies also

showed that family support could reduce tension and improve the coping skills of the patients post-stroke.

The research conducted by [8] stated that the family's ability to care for the patients with a stroke at home could encourage a more positive direction of change. The family-centered care research conducted by [9] showed that the families play a role in improving the management of physical functioning and the mental health of the patients post-stroke.

The research with a qualitative design was reviewed using the phenomenology approach, content analysis and grounded theory. The phenomenological study conducted by [7] emphasized a comprehensive approach consisting of the psycho-social, emotional and relational factors as related to married couples to ensure the quality of life of the family members who had suffered from a stroke. The content analysis conducted by [10] produced a general theme about the promotion of total recovery with 3 main themes: functional recovery, improving psychological health, and strengthening social roles.

Grounded theory research was carried out by [19] and [18]. Tseng observed the family's experience in treating patients post-stroke who suffered from urinary inconsistencies and they got the main theme of creating a new meaning of life. Lutz identified the condition of unpreparedness in the families caring for stroke patients after returning from rehabilitation. There were 3 things that were found to be necessary to be prepared for i.e. the examination of the family condition, the identification of patient needs and preparedness and plans.

The role of the nurse was very important when it came to giving the intervention to the family either before the patient returned home or when the patient was at home. [11] explained that the education given by the nurses would reduce the family burden, allow them to avoid mistakes and reduce the use of inadequate health services by the stroke patients. [1] said that the nurses had to involve the closest communities to them, especially their family, in order to treat and reduce post-stroke complications. [15] explained that the family felt boredom, anxiety and depression. Thus the nurses had to provide encouragement and they also had to emphasize the importance of the role of the family in caring so then they would not feel burdened and tired of caring for their family members who had had a stroke.

The systematic review carried out had several limitations. First, the search strategy only included studies in English; other languages were ignored even though the topic was related. Second, the heterogeneity of the research method and the type of family support made this systematic review difficult to draw on as a whole.

5. Conclusion

The role of the family had a significant effect on the care of the patients post-stroke. The form of care that could be given by the family to them was varied and affected by various aspects, both physically and concerning their quality of life. The nurses played a role in providing family knowledge and facilitating the ability to treat the patients post-stroke.

Implication for Practice; Family support was an important aspect of caring and recovery in the patients post-stroke at home. The family must have good knowledge and abilities when it comes to caring for them. Therefore, nurses must provide support to the family starting from health education and through to ongoing assistance. Before the patients were sent bac to their home, the nurses had to provide systematic discharge planning and they involved the family in the process of caring for the

patients in the hospital. This was so then when they returned home, the family was ready to treat them. The nurses also had to do a periodic follow-up to ensure the development of the patient's condition.

ABSTRACT

Hepatitis B is a preventable and treatable disease, one way to prevent it is by giving immunization. Hepatitis B control starts from the treatment of pregnant women who have hepatitis and immunization in babies born, this will break the first chain of transmission of hepatitis. This control program needs to be implemented seriously considering the number of hepatitis patients continues to increase from year to year. This study aims to determine the description of Hepatitis B screening in pregnant women. Articles searching done through some electronic databases included Scopus, and Pro Quest. This search is limited to journals starting in 1995-2018. English keywords used were screening, Hepatitis B, pregnancy, and prevalence. Of the entire journals, 7 journals on topic has selected and then observed and performed systematic review using PRISMA. The most susceptible hepatitis B problems in pregnant women, children become susceptible subjects to contract, therefore prevention of vertical transmission is one of the most important aspects in breaking the chain of transmission of hepatitis B.

Keywords: screening, hepatitis B, pregnancy, systematic review

Background

Hepatitis is a disease related to public health in the world, including in Indonesia. Hepatitis B consists of hepatitis A, B, C, D and hepatitis E. Hepatitis B is a serious infectious disease and generally infects the liver caused by the hepatitis B virus (HBV) which can cause acute and chronic diseases (Health Protection Surveillance Center, 2012) The most susceptible hepatitis B problems in pregnant women, children become susceptible subjects to contract, therefore prevention of vertical transmission is one of the most important aspects in breaking the chain of transmission of hepatitis B (Kemenkes RI, 2013).

Hepatitis B is one of the most common infectious diseases in the whole world. According to the World Health Organization (WHO) in 2012, around 2 billion people were infected with HBV, more than 240 million suffered from chronic liver. Perinatal transmission is one of the most common routes of transmission. HBV screening from pregnant women has been commonly recommended for transmission. The risk of developing HBV between children born to HBsAg + (B hepatitis antigen) and HBeAg + (initial hepatitis B virus antigen) mothers is 70-90% or more, and more than 85% of them become chronic carriers. Preventing transmission of HBV from mother to child is only possible if the disease is diagnosed during pregnancy or before delivery. Therefore, key elements for controlling infection and establishing gram pro prevention for this disease include epidemiological

patterns, prevalence, and risk factors. Previous studies have assessed the prevalence and risk factors of HBV in pregnant Iranian women. (Badfar, Shohani and Parizad, 2018). Hepatitis viruses are a major cause of morbidity and mortality, and are ranked as the cause of the seven major deaths in the world. The hepatitis B virus (HBV) causes 70% of the viruses associated with death hepatitis (Mbangiwa *et al.*, 2018).

A comprehensive review of HBV prevalence rates in pregnant women taking into account different geographical areas and socioeconomic status is still lacking. This will be very important for HBV prevention and control programs. Thus, this systematic review and meta-analysis was conducted with a focus on HBV prevalence rates in pregnant women from various parts of the world (Behzadifar *et al.*, 2018). Preventing vaccination of adults at risk of infection with HBV. Preventing perinatal transmission depends on testing all pregnant women for HBsAg and timely prophylactic administration (Hep B vaccine and hepatitis B immune globulin [HBIG]) for babies born to infected mothers. universal vaccination that HepB of all infants starting at birth provides critical protection and prevents infection in infants born to HBsAg positive mothers not identified before birth. Routine HBV screening is recommended during pregnancy the purpose of hepatitis B (HBV) remains a significant public health burden, despite effective therapy. Routine HBV screening is recommended for low risk of vertical transmission, but the rates of follow-up care for peri-partum patients are low (Kwong *et al.*, 2018).

We searched the following electronic databases included "Scopus, and Pro Quest". This search is limited to journals starting in 1995-2018. English keywords used were Skrining, Hepatitis B, *Pregnancy,* dan *Prevalence* . Of the entire journal selected 7 journals on topic. 7 journal articles are then observed and performed Systematic Review

Study Design/ Selection criteria

We included Randomized controlled trial design (RCT) and quasi-experimental evaluating the effects in critically ill patients receiving mechanical ventilation for at least 48 hours.

Population

all pregnant women were tested for hepatitis B surface antigen (HBsAg), and HBsAg-positive samples were tested for hepatitis B

Primary outcomes

Perinatal transmission is one of the most common routes of transmission

Study selection

The compilation of the review system follows the guidelines of the literature (Liberati *et al.*, 2009) obtained from PRISMA

Result

Search of journals, from figure 1 there are 241 who first discovered and 7 articles that meet the criteria set out in the systematic review (see Figure 1). Most journal articles that include the use of chlorhexidine study group and control group using plasebo. From 10 articles can be concluded that

the use of screening hepatitis B in pregnancy. There are 5 journal still undetermined differences were statistically significant differences between the groups

Discussion

The most susceptible hepatitis B problems in pregnant women, children become susceptible subjects to contract, therefore prevention of vertical transmission is one of the most important aspects in breaking the chain of transmission of hepatitis B.

Conclusion

Hepatitis B control starts from the treatment of pregnant women who have hepatitis and immunization in babies born, this will break the first chain of transmission of hepatitis. Age did not seem to be a risk factor for HBV infection as there was no difference in ages of the women with HBV versus those without HBV. New and ambitious elimination targets provide an ideal opportunity to focus resources on optimizing the prevention of vertical HBV transmission.

ABSTRACT

Sedentary lifestyle in adolescents can cause hypertension, obesity and myopia. Families as the closest parties to adolescents have a role to prevent sedentary lifestyle in adolescents. The purpose of this study to analyze the factors of the role of families for adolescents with sedentary lifestyle based on the theory of planned behavior. Design used was descriptive with cross sectional approach. Population was families (mothers) of student in Muhammadiyah 10 Senior High School Sugio who have adolescents 15-17 years old. A total of 122 respondents were chosen by startified cluster sampling method. Varibles in this study were attitudes, subjective norms, perceived behavior control (PBC), and intention of family. Data were collected by using a questionnaire and described by using frequency and precentage distribution. The results had showed the family's attitudes mostly were suficient (68,9%). The family's subjective norms mostly were sufficient (61,5%). The family's PBC's mostly were sufficient (74,6%), and the family's intentions a half were sufficient too (59%), to change the role of preventing the sedentary lifestyle of adolescents. Future research was suggest health workers increase family confidence in improving attitudes, subjective norms, PCBs, and intention to change family roles for adolescent with sedentary lifestyle

Keywords: family, role, sedentary, lifestyle, adolescent

1. Introduction

A sedentary lifestyle is a habit of life that is characterized by a low level of physical activity[1]. Sedentary lifestyle habits include sitting or lying in everyday life both at school (working in front of a computer, reading, etc.), at home (watching TV, playing games, playing mobile phones etc.) and on trips / transportation (buses, trains, motorbikes) but not including bedtime [2]. An adolescent sedentary lifestyle that is uncontrolled mainly occurs at home because there are no written rules that regulate the time spent using HP or watching TV [3].

In the sedentary lifestyle of teenagers in America, 28% watch TV over the recommended time, which is more than 3 hours a day and 24% use computers for more than 1 hour [5]. In addition to this, 33.5% of people >10 years in Indonesia also spend >6 hours a day being sedentary. Adolescents in East Java total as many as 30.1% of the population aged >10 years old who spend >6 hours of their time being sedentary [2].

The impact of the sedentary lifestyle can be seen from the obesity rate in the Health Profile of East Java Province in 2016, which is 15.48% and the obesity rate in Lamongan Regency is higher at 23.56%. One of the schools in Lamongan, Muhammadiyah10 Senior High School Sugio, reported that the results of the screening conducted in September 2018 showed a prevalence of overweight by 9.6% and obesity by 5.3%. In addition, 29.4% of students experienced myopia. The results of a preliminary study on October 20th, 2018 conducted on 10 adolescents in the school, showed that 7 students were in the high category for sedentary lifestyle namely >5 hours, 2 were in the moderate category and 1 was a mild category student. The impact that has been seen is that 10% were obese, 40% were overweight, 50% had blood pressure above normal and 40% had myopia.

Each family carries out their respective family roles which can influence the selection of education methods for the children. The role of the family can be a key factor that determines choosing for the children to live in places that have written regulations or living in a place without regulations [6]. The choice of residence is related to the level of sedentary lifestyle of the adolescents [7]. The role of parents is very important because it can play a role in reducing the sedentary lifestyle of adolescents, including in terms of choosing for there to be a sedentary environment [4].

The results of the interviews with the families of teenagers on the date selected showed that 6 out of 10 families represented by the mothers showed negative behavior. According to Bounova's (2018) study, behavior in relation to carrying out negative family roles can be seen from the family-reported support for poor physical activity, as evidenced by the statement that mothers never exercise or invite the adolescents to exercise. Negative behavior can also be seen from the family's screen-based behavior as evidenced by the statement of the mothers who also admitted to often having a sedentary lifestyle. The mother's family concern was also lacking because she stated that she reprimanded the adolescent if they had a sedentary lifestyle but she was left alone because it was considered adult and she felt that there were no health impacts, even though some adolescents were examined and found to be overweight. The mother's role in family modeling was also lacking because they stated that they had taught the children a healthy lifestyle but when they entered adolescence, it is rarely done.

The results of the interviews show that there are problems with the family roles, especially the role of the family represented by the mother when caring for a teenager with a sedentary lifestyle. The role of the family is a set of interpersonal behaviors, traits and activities related to the person in the family environment with the intention of achieving certain goals based on their respective functions [8]. Previous research used a behavioral theory approach, namely the theory of planned behavior, to describe the behavior within a sedentary lifestyle[9]. The theory of planned behavior emphasizes the nurse’s role in terms of giving the intervention based on the client’s behavior. Bridging the gap between the client’s belief behavior and professional belief behavior is important in the context of maintaining health. Based on this theory, there are 4 factors that influence individual families, groups and the community’s health behavior, including attitude, subjective norms, perceived behavioral control and intention [10]. There was an overwhelming amount of research that examined the factors affecting the family role and

how it related to the adolescents with a sedentary lifestyle, but it was rare that the researchers used the theory of planned behavior as the conceptual framework.

Various efforts have been made by the government to prevent sedentary lifestyle in adolescents with a family approach[11]. However, the problem of a sedentary lifestyle in adolescents still hasn't been solved yet. Therefore in this paper, we analyze the factors of the role of families for adolescents with sedentary lifestyle based on the theory of planned behavior on Families of student in Muhammadiyah 10 Senior High School Sugio, Lamongan. The nurses need to develop interventions or health promotion strategies that are culturally sensitive in order to promote a healthy lifestyle and to prevent a sedentary lifestyle in adolescents within a family approach.

2. Methods

The design used was descriptive with a cross-sectional approach. The population was families with adolescents (15-17 years old) at Senior High School Muhammadiyah 10 Sugio. A total of 122 respondents were chosen using the stratified sampling method from 3 different places where the student stayed after school. The variables in this study were the attitude toward to the behavior, the subjective norms, perceived behavioral control and intention. The data was collected using a modified questionnaire from the previous research about the parental role. The analysis was done using frequency and percentage distribution. This study got ethical clearance from the ethical commission of the Faculty of Nursing, Universitas Airlangga.

3. Result

Table 1 - Frequency and percentage distribution of the respondents based on the variables (n=122)

Variables	Category	n	%
Attitude towards the behavior	Good	22	18,0%
	Sufficient	84	68,9%
	Deficient	16	13,1%
Subjective norm	Good	28	23%
	Sufficient	75	61,5%
	Deficient	19	15,6%
Perceived behavior control	Good	19	15,6%
	Sufficient	91	74,6%
	Deficient	12	9,8%
Intention	Good	32	26,2%
	Moderate	72	59%
	Deficient	18	14,7%

Table 1 presents that most of the families (mothers) who had been caring for the adolescent had attitude, subjective norm, perceived behavior control and the intention to change the role of the adolescents related to having a sedentary lifestyle in the sufficient category (68,9%).

4. Discussion

Table 1 presents that most of the families (mothers) who had been caring for their adolescent had attitude to change the role of the adolescents with a sedentary lifestyle in the sufficient category (68,9%). The family felt that the family role that was carried out had a positive impact such as agree on limiting the time that the adolescent spends sitting for a long time using a computer. This is because it will harm the adolescents. They feel that reducing the time that the adolescents spend playing electronic games is important and that it can prevent a sedentary lifestyle in adolescents. However, the respondents felt that the family's role had a negative effect because they could not reduce the time spent playing on their phone, as an example.

Attitude is the amount of positive or negative feelings towards an object (favorable) or negative (unfavorable) person, an institution or activity [12]. The attitude of the parents when carrying out the roles relates to the sedentary lifestyle of adolescents [13]. The factor that most determines family attitude is belief. Family beliefs about adolescent health determines the role of the family in relation to a sedentary lifestyle in adolescence [14].

The results are consistent with the previous research indicating that a large family feels that their role that is both positive and negative, and that they determine the attitude that the families face when it comes to the sedentary lifestyle of adolescents. Most of the attitudes of the families are still in the sufficient category, so there needs to be action to build belief in a positive direction so then the family can optimize their role to prevent a sedentary lifestyle in the period of adolescence.

Most of the families (mothers) who had been caring for their adolescent had their subjective norm in the sufficient category (61,5%). The families feel that the approval of another family enhances their role if family have adolescent with sedentary lifestyle is sufficient. All parties that are considered to be important by the family agree to increase the role of the family with adolescents with a sedentary lifestyle. Everyone believes that families need to increase their role if they have adolescents with sedentary lifestyle.

A subjective norm is a person's perception of the agreement of others towards an action. In the theory of planned behavior, subjective social norms are seen to influence behavioral intention, which can lead to behavior change [10]. Other people's agreements relate to sedentary lifestyle in adolescents because the subjective norms can be defined as a social group's expectations of behavior. They indicate what is considered to be appropriate or inappropriate in certain circumstances [15]. Other people's agreements relate to family support for adolescent health, including the prevention of a sedentary lifestyle because the way that the families carry out their roles is influenced by the approval of others [14].

The results of this study are in line with the previous research and the theory that the agreement of other people such as other families (neighbors), religious leaders and community leaders to improve the family's role in relation to the adolescent lifestyle determines the intention to change roles which are then manifested in behavior. Most subjective norms are still in the fairly good category because there is a regulation from the regent to get the families to guide adolescents to learn from 6.00 pm until 8.00 pm. This regulation will indirectly reduce

the time that the teenagers spend playing games, being on their cellphones and watching television. However, the monitoring of the implementation has not been done, so some families still have the subjective norms aspect in the lesser category. Other causes of subjective norms that are in the good category are still deficient because of the way that the families carry out their roles based on their social groups. Other families also have similar perceptions, namely reducing the attention paid to adolescents because they are considered to be adults.

Most families (mothers) who have been caring for their adolescents have perceived behavioral control in the efficient category (74.6%) based on the factors that hinder and support the role of the family. Most of the factors that support the family's role are intact family forms. The average family role model of the parents has not prevented the sedentary lifestyle of adolescents. Families at the developmental stage of having teenagers do not have experience in caring for teenagers previous. Most of the factors that hinder the family relate to there being no facilities for joint sports and there are no regulations that apply in the family when using HP, laptops and TV. Another inhibiting factor that is not controlled by the family is that there is only one TV and it is not in the teenager's room.

Perceived behavioral control is related to conducting their lifestyle such as walking to school, which in previous studies relates to family structures (whole or divorced families or single parents) [16]. The factors associated with affective response related to preventive sedentary lifestyle activities show that the affective appraisal of physical activity is considered to be related to the fundamental aspects of exercise experience [17]. Families who have cared for adolescents before or who have a family role models such as their parents who have previously had experience in joint exercise training will be different in terms of the family roles carried out compared to those who do not have experience. The families with proximal environmental contexts (e.g., access to home exercise equipment) and policy level factors can promote positive behaviors in adolescents and prevent the amount of sedentary time [18]. Previous research on the association is that the home environment with screen use is mainly focused on the number of TVs and DVDs at home or in the child's bedroom[7].

The results of this study are in line with the previous studies that indicating that the family support factors that shape the perceived behavioral control of carrying out the family roles are the family format. Adolescents from intact families have sufficient attention from both parents. The respondents of this study were large in terms of family size with the family developmental stage being with adolescents. Perceived behavioral control in the associated category was sufficient because they did not have the experience of raising adolescents. Most families also did not have a role model in the form of previous parents that would help to prevent the sedentary lifestyle of teenagers because there was no cellphones, televisions, computers or video game, so there are thus no examples of how to prevent excessive use. Most of the family income was in the category of being under the regional standards, so they did not have enough money to buy fitness equipment and more than one television. Subsequent interventions are expected to provide solutions to improve joint sports activities without using fitness equipment. Simple solutions that are easy to implement are expected to be able to improve the perceived

behavioral control which can change the intention to increase roles which then allow the family to run optimally.

Half of the families (mothers) who had been caring for their adolescent had intention in the sufficient category (59%). The intention of the families to change their role was, for more than half, in the sufficient category and most of the rest were in the good category. The average family approved a statement indicating the intention to increase the role of the family in terms of limiting the time spent playing on their mobile phones, watching TV and using a computer or laptop. The family also intends to watch TV with teenagers. However, most families still do not agree to exercise with teenagers every day of the holidays and make regulations for the time spent by teenagers playing mobile phones and watching TV.

The intention of parents to care about adolescent health behavior is the strongest predictor that determines adolescent behavior [13]. A previous research is in line with the Theory of Planned Behavior in that social support and the influence from one's friends and family has a large influence on the adolescents' behavior and their intention to engage in sedentary behavior, including screen time[19].

Most of the family's intention to increase the family's role in relation to the sedentary lifestyle of adolescents was in the sufficient category because the family still considers the sedentary lifestyle not to cause illness, so their concern is still lacking. Family care will determine the intention to improve their role. The family influences the adolescent's intention to prevent a sedentary lifestyle so a further intervention is also expected to focus on aspects of the family role if they want to prevent a sedentary lifestyle in their adolescent.

5. Conclusions

Based on theory of planned behavior, the factors that influence the role of the family when caring for an adolescent with a sedentary lifestyle were sufficient family attitude, sufficient family subjective norms, sufficient family perceived behavioral control and the family intention to change the role of the family. Otherwise, the family intention to change their role can relate to the strength of the family.

A family with a sedentary lifestyle in relation to their adolescent should be more active in accessing information about strategies to increase their role in order to prevent said sedentary lifestyle. Community health nurses are expected to develop health promotion strategies based on the research findings to prevent a sedentary lifestyle in adolescents with a family approach.

EFFECTIVENESS OF COMPLEMENTARY SPIRITUAL THERAPY INTERVENTION IN PALLIATIVE CARE FOR IMPROVING THE QUALITY OF LIFE IN CANCER PATIENTS : A SYSTEMATIC REVIEW

Irfan Wabula, Yulia Kurniawati, Made Dian Kusumawati, and Hurin'in Aisy Baridah
Master Student, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
Email: irfan.wabula-2018@fkp.unair.ac.id

ABSTRAK

Cancer diagnosis caused psychological stress that can threaten the quality of life for cancer patients. The death rate from cancer in 2015 was 112.8 people per 100,000 population. Psycho-oncological treatments especially spiritual care was very important for cancer patients. Spiritual therapy helped cancer patients to increase the peace although they were in the final phase of life. Spiritual therapy can reduce psychological stress, increase the meaning and the purpose of life in cancer patients so that they can improve their quality of life. The systematic review was to assess the effectiveness of spiritual therapy on improving the quality of life for cancer patients. The method used was to search a journal with pre- determined keywords quality of life, cancer, palliative care, spiritual well-being, spiritual therapy, supportive group therapy through a database of "Scopus, Pro Quest, Science Direct and Ebsco". The search was limited to journals starting in 2010-2017. Study results showed that the complementary spiritual therapy intervention in palliative care was effective to improve the quality of life in cancer patients. That Spirutual therapy can be a reference for health workers in their comprehensive care programs to improve the quality of life in cancer patients.

Keywords : Quality of life, cancer, palliative care, spiritual well-being, spiritual therapy, supportive group therapy

1. Introduction

Cancer is universally recognized as the main health problem of the century with there having been an increase for the last few decades. It has a detrimental impact on all aspects of physical, emotional, spiritual, social, and economic human life that has made experts more concerned with cancer than ever before[15]. According to the data from the World Cancer Report in 2014, cancer is one of the most serious critical health problems where, while there were much progress in therapy, cancer deaths cannot be avoided. A total of 14 million new cases and 8.2 million cancer-related deaths were reported worldwide in 2012[6]. Around the world, cancer has challenged patients, families, nurses and the community. The data from the World Health Organization in 2015 showed that cancer was the main cause of death and that the number of new cases was expected to increase by around 70% over the following two decades[1].

Psychologically, patients diagnosed with cancer will feel scared for future events and experience fear and depression. After the patients received their diagnosis, patients diagnosed with cancer will immediately experience a sense of life that ends and disappears. In addition, people diagnosed with cancer reported feelings about a loss of control, helplessness, consideration of the future, anger, confusion, guilt, anxiety and depression[14]. Therefore, psycho-oncological care that includes spiritual care is very important for cancer patients[12].

Several approaches had been used to improve the quality of life of cancer patients. The interventions include exercise, peer support groups, awareness-based stress reduction programs and cognitive behavioral therapy (CBT) and they have all shown that they can have a positive effect on the quality of life in cancer patients[7]. When facing a cancer diagnosis and its challenges, many cancer patients sought comfort in spiritual beliefs, which in some cases was associated with positive psychological results. Psycho-oncological treatments, especially spiritual care, are very important for cancer patients. Spiritual therapy helps the cancer patients to increase their sense of peace, even when they are in the final phase of life. Spiritual therapy can reduce psychological stress and increase the meaning and purpose of life in cancer patients so then they can improve their quality of life[2].

Spiritual therapy methods in several journals had different effects when compared to one another. However, all of the spiritual therapies focused on the patients can allow them to obtain positive energy from within themselves related to cancer. The patients will be focused on the three types of relationship that can be disrupted because of cancer, namely the relationship with themselves, others and God. The participants were encouraged to talk to God based on their religious and spiritual beliefs and to ask for God's help so then God could help them in their healing process. To achieve complete health according to the definition of the World Health Organization, it was important for individuals to have a sense of spiritual well-being[4]. Effective spiritual therapy is expected to provide an improved quality of life and better management in the life of cancer patients[8].

The purpose of this systematic review was to find out the effectiveness of complementary spiritual therapy interventions in palliative care for improving the quality of life of cancer patients.

2. Methods

2.1 Research Design

This study used a systematic review to find out the effectiveness of complementary spiritual therapy interventions in palliative care related to improving the quality of life of cancer patients.

2.2 Search Strategy

The search for the articles used the keywords determined through several English-language journal databases namely Scopus, Pro Quest, Science Direct and Ebsco within the years 2010 to 2017. The keywords used in the journal search were quality of life, cancer, palliative care, spiritual well-being and spiritual therapy.

2.3 Inclusion and Exclusion Criteria

The studies were selected in the systematic review based on the inclusion criteria: 1) the study design used randomized controlled trials and non-randomized controlled trials; 2) the participants of the studies were adult cancer patients; 3) the cancer patients in the studies were advanced cancer patients (stage III-IV); 4) the studies were conducted from 2010 to 2017; 5) the intervention provided was a spiritual therapy intervention; 6) the factors that one had to measure in the studies were quality of life, spiritual well-being, the meaning of life, emotional suffering and spiritual needs as outcome variables. The studies were rejected based on the following exclusion criteria: 1) the studies were not published in English and 2) the samples were composed of pediatric cancer patients.

2.4 Selection of Articles

This systematic review was not only limited to the research using randomized controlled trials but it also allowed for a non-randomized controlled trial design. There were no restrictions in terms of the method of the spiritual therapy or if it focused on individuals or groups in the systematic review. The data was abstracted from all of the selected articles using an extraction table that was designed specifically for this review. The categories used in the abstraction tool included the demographics and populations studied, the spiritual therapy intervention given (method; duration and the implementer), the study design and the effects of the spiritual therapy interventions on quality of life, spiritual well-being, the meaning of life and emotional suffering (Table 1).

3. Results

1. Literature search and study selection

From the search results using the predetermined keywords, 188 nursing journals were found which were screened by looking at the title and reading the abstract first, which was narrowed down to 25 journals. From the 25 journals, 16 journals were selected that included the inclusion and exclusion criteria. Some journals were not selected because they did not include their inclusion and exclusion criteria. The detailed process of the mechanism for selecting the research articles can be seen in Figure 1. In the 16 journals chosen, there were 6 studies that used a randomized controlled trial design, 3 studies that used a quasi-experimental design, 3 studies that were cross-sectional, 1 study using a prospective non-randomized single cohort design, 2 pilot studies and 1 study that was qualitative.

2. Participants

Most of the participants in the studies were female. Among the cancer diagnoses, breast cancer was the most common followed by other cancers. There were 4 studies that recruited only breast cancer patients. The mean age of the participants in each study ranged from 35 years to 55 years.

3. Intervention

The spiritual therapy given consisted of several stages. These stages were different between one study and another. However, when they gave the spiritual therapy, all of the studies focused on the relationship between the patients and themselves, others and how they treated themselves with affection. The patients discussed how they felt regarding God such as guilt, anger or neglect. The patients were encouraged to talk with God on their religious and spiritual beliefs. The patients asked God to help and to be with them when they faced their cancer. The methods used for giving the spiritual therapy were done by given interventions individually, in groups or in a combination of individuals and groups. There were 6 studies using individual methods and 10 studies using group methods. The process of spiritual therapy can be done in the area of palliative care in hospitals, forests (natural) and green environments.

There were 16 studies examined in this systematic review. They all had different durations. There were 2 studies that did the spiritual therapy interventions for 4 months, 3 studies for 3 months, 2

studies for 6 months, 3 studies for 2 months, 1 study for 7 weeks, 1 study for 3 consecutive days, 1 study for 1 month, 2 study for 1 year and 1 study for 9 months.

The spiritual therapy was done by spiritual therapists (clerics, pastors), professional health workers in palliative care (doctors and nurses who had been trained by spiritual therapists) and health workers who had undergone spiritual therapy training. From the 15 studies, there were 4 studies where the spiritual therapy was given by spiritual therapists (clerics, pastors), 8 studies conducted by professional health workers in palliative care (doctors, nurses who had been trained before by spiritual therapists) and 3 studies conducted by health workers who had undergone spiritual therapy training.

The finding of the systematic review were 1) quality of life: In the 16 studies that assessed quality of life, a lot of them showed a significant improvement at the time of evaluation; 2) Spiritual well-being: In the 16 studies, the 7 studies that assessed spiritual well-being showed a significant increase during evaluation but there were also studies that showed that spiritual therapy did not significantly improve spiritual well-being; 3) Emotional suffering: In 16 studies, there were 3 studies that showed that the emotional suffering decreased during the evaluation; 4) The meaning of life: In 16 studies, 3 studies showed that the meaning of life increased in cancer patients at the time of evaluation.

4. Discussion

Spiritual therapy interventions have been proven to be effective for cancer patients. This was consistent with the research conducted by Sankhe, Dalal, Agarwal and Sarve in 2017, indicating that spiritual therapy had a significant effect on the patients report on their spiritual needs and the meaning of life even in their sleep[6]. The patients were actively involved in getting themselves positive energy to fight the cancer. The patients were focused on improving the 3 relationships that can be disrupted when they face cancer, namely the relationship with themselves, their relationship with others and their relationship with God. The patients were encouraged to speak to God based on their religious beliefs and to ask God so then He can help them in the healing process of their illness. This made it possible to improve the quality of life of cancer patients[7].

Several studies showed that the spiritual aspects of the cancer patients must be paid more attention to by the professional health workers when they give palliative care. Some aspects such as quality of life, spiritual well-being and meaning of life experienced significant improvements after the cancer patients attended spiritual therapy. The decline of emotional suffering showed that this intervention can have a positive effect on the lives of cancer patients[1]. There were, however, studies that showed that spiritual therapy did not significantly improve spiritual well-being[10].

In practice, spiritual therapy for cancer patients is able to be done individually or in groups. The implementation of spiritual therapy is able to be carried out in a calm and comfortable environment for the patients such as in a forest (nature), in a green environment or in a palliative care setting in hospitals. Spiritual therapy in this study had to be adapted to the patient's beliefs and spirituality so then it was easily accepted and implemented by the patient[12].

Not everyone was able to give the spiritual therapy in their particular form of implementation. In the interventions, there had to be someone qualified at providing spiritual therapy (cleric, bikhsu, pastor etc)[9]. Besides an ustad, bikhsu or pastor, spiritual therapy can also be provided by health professionals who had undergone spiritual therapy training.

The limitations and weaknesses of this systematic review were that some of the studies did not use a control group and non-random sampling techniques, so there could be an increased risk of bias in the outcome of the various studies.

5. Conclusion

Spiritual therapy is one of the interventions that has been found to have an effect in terms of improving the quality of life of cancer patients. This systematic review can support the implementation of spiritual therapy programs in cancer patients that have proven to be effective at improving their quality of life and spiritual well-being, to fulfill their spiritual needs, to give them a better meaning of life and to reduce their emotional suffering. Spiritual therapy can be used as an intervention in palliative care for cancer patients which involves various professional health workers such as doctors, nurses, pharmacists and psychologists. Further studies with larger sample sizes are needed to allow for more definite conclusions to be drawn.

Nurses as caregivers have to do their role well when they provide nursing care to the cancer patients in order to improve their quality of life and spiritual well-being. In the future, professional health workers, such as doctors and nurses, have to pay more attention to the spiritual aspects of cancer patients.

6. Figures

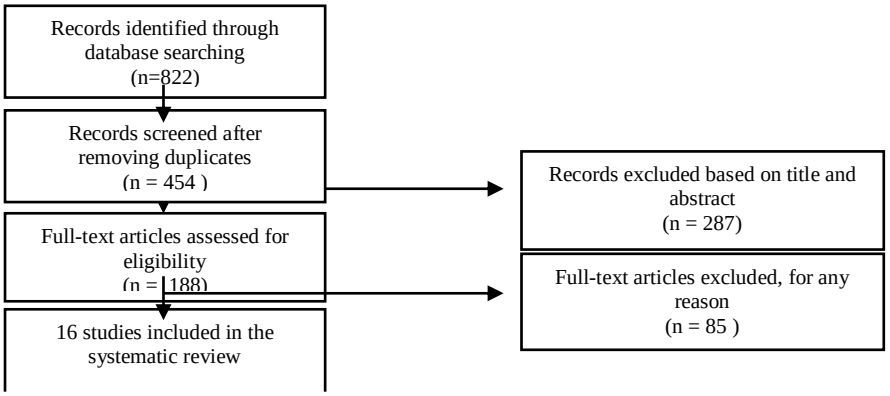

Figure 1. Diagram summarising the search of the literature

Table 1. Summary of the Studies Reviewed

Author	Sample	Intervention / Implementer	Therapy Method	Duration	Result
Chimluang J, Thanasilp S, Akkayagorn L, 2017[1]	48 adult patients with various cancer diagnoses	Spiritual therapy intervention based on basic Buddhist principles / spiritual therapists	The participants were divided into 6 groups	The intervention was comprised of 3 sessions over 3 consecutive days (2-3 hours/day)	Improvement in spiritual well-being and quality of life
Ã WB, Rosenfeld B, Gibson C, Pessin H, Poppito S, Nelson C, et al, 2010[5]	120 adult patients with various cancer diagnoses (stage III-IV)	Individual Meaning-Centered Psychotherapy (IMCP) / spiritual therapists	The participants were divided into 8-10 groups	The intervention was comprised of 8 sessions/day for 7 weeks	Improvement in spiritual well-being and the meaning of life
Breitbart W, Poppito S, Rosenfeld B, Vickers AJ, Li Y, Abbey J, et al, 2012[13]	90 adult patients with various cancer diagnoses (stage III-IV)	Individual Meaning-Centered Psychotherapy (IMCP) / spiritual therapists	The participants were divided into 8 groups	The intervention comprised of 7sessions/day for 2 months	Improvement in spiritual well-being and quality of life; decrease in emotional suffering
Emami H, Loghmani A, Bahrami F, Jafari N, Zamani A, Jafari N, et al, 2013[2]	65 female patients with breast cancer	The spiritual therapy intervention over 6 sessions focused on the relationship between the participants and God / spiritual therapists	The participants were divided into groups	The intervention was comprised of 6 sessions/day for 6 weeks	Improvements in their spiritual well-being and quality of life
	65 female patients	Spiritual therapy intervention over 6		The intervention	Improvement in their

Jafari N, Zamani A, Farajzadegan Z, 2013[7]	with breast cancer	sessions focused on the relationship between the participants, other people and God / spiritual therapists	The participants were divided into groups	was comprised of 6 session (2-3 hours/day) for 4 months	overall quality of life
Pearce MJ, Coan AD, Herndon JE, Koenig HG, Abernethy AP, 2012[11]	150 adult patients with various cancer diagnoses (stage III-IV)	Spiritual therapy experience analysed using an interview with the participants / professional health workers	The interviews were conducted individually	The study was done for 12 months	Participants improve their spiritual well-being, quality of life and the meaning of life
Study NS, Dalal ASK, Sarve VAP, 2017[6]	107 adult patients with various cancer diagnoses	The spiritual therapy intervention was given on the basis of the MATCH guideline / health workers who had undergone spiritual therapy training / spiritual therapists	The participants were divided into groups	The study was done for 9 months	Improvements in spiritual well-being and quality of life
Patel, JaivikaGovindbhai Bhise, Anjali R 2017[16]	150 adult patients with various cancer diagnoses	The participants filled in their data in order to answer the spiritual needs survey and the European Organization for Research and Treatment of Cancer QoL Questionnaire-C30. These were collected by the professional health workers	The interviews (questionnaires) were conducted individually	The study was done for 3 months	There was found to be a relationship between spiritual needs and QoL in cancer patients. This should improve quality of life and fulfill their spiritual needs
Qandil AMA 2017[14]	150 female patients with breast cancer	The participants completed the Arabic version of the Functional Assessment of Chronic Illness Therapy-Spiritual Well-being / professional health workers	The interviews (questionnaires) were conducted individually	The study was done for 3 months	Spiritual intervention contribute to an increase in spiritual well-being; an enhancement in total health and QoLand and a decrease in emotional suffering
Zamaniyan S 2016[15]	24 female patients with breast cancer	The spiritual therapy intervention over 12 sessions was	The participants were divided into 2 groups	The intervention was comprised of 12 sessions	Improvements were seen in spiritual well-

		focused on the relationship between the participants and the God / spiritual therapists		(120 minutes/7 days) for 3 months	being and quality of life
Piderman KM, Johnson ME, Frost MH, Atherton PJ, Satele D V, Clark MM, et al. 2014[4]	130 adult patients with various cancer diagnoses	The spiritual therapy intervention via 6 sessions was based on the physical, emotional, social and spiritual domains of QOL / spiritual therapists	The participants were divided into groups	The intervention was comprised 6 sessions (90 minutes/1 day) for 6 months	Improvements were seen in quality of life and the meaning of life; there was a decrease in emotional suffering
Vallurupalli M, Lauderdale K, Balboni MJ, Phelps AC, Block SD, Ng AK, et al. 2012[3]	69 adult patients with various cancer diagnoses (stage III-IV) who got radiation therapy	A spiritual therapy interview was given about the characteristics of the patients spirituality, religiousness, religious coping and the relationship of these variables to quality of life (QOL) from the participants / professional health workers	The interviews (questionnaires) were conducted individually	The study was done for 2 months	Spirituality and religious coping were The contributors to better QOL. Spiritual therapy in advanced cancer care is very important.
Geer J Van De, Groot M, Andela R, Leget C, Prins J, Vissers K, et al. 2016[8]	85 participants	The hospital staff were trained on the spiritual therapy intervention in the context of palliative care / health workers who had undergone spiritual therapy training	The participants got the intervention individually	The study was done for 1 month	Improvements seen in terms of the positive effect on the quality of care and quality of life of cancer patients
VanderWeele TJ, Kachnic LA, Lauderdale K, Phelps AC, Peteet JR, Block SD, et al. 2011[9]	69 patients with various cancer diagnoses (advanced stage) who got radiation therapy (RT)	The participants filled in the SCs questionnaires, including 11 items assessing spiritual struggles and 5 items assessing spiritual seeking. Their answers were examined professional health workers	The interviews (questionnaires) were conducted individually	The study was done for 4 months	The role of spiritual care in palliative cancer management is very important. Spiritual care is able to make the quality of life of cancer patients better

Yang GM, Tan YY, Cheung YINBUN, Lye WKIT, Hui S, Lim AMY, et al., 2016[10]	144 participants	Doctors and nurses did the spiritual care training program. Then they applied it to the cancer patients in palliative care. There were also health workers who had undergone spiritual therapy training	The participants got the intervention in groups	The study was done for 2 months	Improvement in quality of life
Nakau M, Imanishi J, Imanishi J, Watanabe S, Imanishi A, Baba T, et al. 2013[12]	22 adult patients with various cancer diagnoses	The intervention consisted of forest therapy, horticultural therapy, yoga meditation and support group therapy / spiritual therapists	The participants were divided into groups	The intervention comprised of one session/weekly for 12 weeks	Improvements were seen in quality of life, the meaning of life and spiritual well-being and there was a decrease in emotional suffering

ABSTRACT

Pulmonary tuberculosis is a contagious disease caused by tuberculosis germs. Tuberculosis has been around for thousands years and still becomes a major health problem. Tuberculosis can cause morbidity in ten million people every year and is one of ten the main caused of mortality in the world. This study aimed to determine the effectivity of the role of primary caregiver in the family in preventing tuberculosis transmission. The article search through the databases of ProQuest, Scopus, Ebscohost, and Science Direct with the range of year limitation was five years (2014-2018) and using the keywords "tuberculosis, family role, prevention". The analysis from the article search found 15 suitable articles with the term required. The result showed that the role of primary caregiver in the family (searching for informations about basics of tuberculosis, household awareness, active case finding, sputum collection and transportation) were strategies to prevent pulmonary tuberculosis transmission. The role of primary caregiver in the family was effective to prevent pulmonary tuberculosis transmission.

Keywords: tuberculosis, family role, prevention

1. Introduction

Tuberculosis remains a major public health issue in many developing nations and is the leading cause of death worldwide in people living with HIV/AIDS. The current global estimate is that over 8.8 million tuberculosis cases emerge each year and that nearly 1.5 million people die from TB yearly: 98% of these cases and deaths occur in developing countries [1,10]. Tuberculosis is considered to be a social disease, with many socio-cultural factors contributing to the disease burden [2].

Pulmonary tuberculosis is an infectious disease caused by Mycobacterium tuberculosis and it most often manifests in the lungs. The mycobacterium is transmitted through droplets in the air so a patient with pulmonary tuberculosis is the cause of pulmonary tuberculosis transmission in the population in the vicinity. The clinical symptoms may include coughing continuously and phlegm for 3 weeks or more, sputum mixed with blood (hemoptysis), shortness of breath and pain in the chest, weakness, a loss of appetite and weight loss, discomfort (malaise), night sweats without activity and fever chills for more than one month [3].

The transmission of pulmonary tuberculosis and the development of the majority of diseases are driven by social factors such as adverse environmental conditions including occupant density and ventilation in homes that does not meet the minimum health requirements

Early diagnosis and appropriate treatment for the vast majority of people who develop pulmonary tuberculosis is the epidemiological basis of global tuberculosis control efforts [5]. According to the International Standards for tuberculosis care, all persons with an otherwise unexplained productive cough lasting 2 - 3 weeks or more should be evaluated for tuberculosis.

The global target for reducing the Tuberculosis (TB) incidence, prevalence and mortality for 2015

has been outline by the Stop TB Partnership. These targets are set within the overall context of the Millennium Development Goals (MDGs) and they indicate that the global tuberculosis incidence rate should

be falling by 2015. Additionally, tuberculosis prevalence and death rates should be halved by 2015 compared with their level in 1990 [7, 8]. In the South-East Asia Region, the WHO data shows that pulmonary tuberculosis kills about 2000 people

each day and that about 40% of cases of pulmonary tuberculosis in the world located in Southeast Asia. Two of the three countries with the largest number of patients with pulmonary tuberculosis in the world, namely India and Indonesia, are in this region. Indonesia is under India, followed by China. Compared with other infectious diseases, pulmonary tuberculosis has become the number one killer in the region, where it amounts to 2 - 3 times the number of deaths caused by HIV/AIDS, which is ranked second [9].

The knowledge of the family is very important when it comes to providing insights into the attitudes and actions of a person. Knowledge is the result of knowing and this happens after a person performs the sensing of a particular object. According to the occurrence of knowledge, there are 2 types, namely: a priori knowledge that occurs without experience that is obtained through analytic thinking (general-specific) and aposteriori knowledge that occurs because of experience, where the way of thinking is synthetic (specifically-general). Knowledge is a very important factor for the formation of a person's actions (over behavior). Family knowledge about the prevention of pulmonary tuberculosis is a very important factor for the formation of actions to prevent and cope with pulmonary tuberculosis because if someone does not know about an object, then the object would not interest them [14].

The primary caregiver of the family has an important role in relation to the prevention of disease among their family members, particularly with respect to their education and knowledge of disease. Family knowledge and attitudes about the dangers of pulmonary tuberculosis has a role in preventing disease. Sufficient knowledge and attitudes will enable a person to make steps aligned with the prevention and protection of a disease. This study aimed to determine the effectiveness of the role of the primary caregiver in a family in preventing tuberculosis transmission.

2. Methods

This study employed the systematic review design. The data of this study was taken from the databases of ProQuest, Scopus, Ebscohost and Science Direct in 2014 - 2018. The articles were searched for with the following keywords: tuberculosis, family role and prevention. Every article that was included in this systematic review had obtained ethical clearance approval.

The literature selection was determined using the following inclusion criteria: (1) the study sample was a family with tuberculosis, (2) the articles were published between 2014 – 2018, (3) the articles were published in English and (4) the articles focused on the family role. The exclusion criteria were patients with Multidrug-Resistant Tuberculosis.

3. Results

From the article and journal searching, 520 papers were found from within the 4 databases, including 135 articles in ProQuest, 125 articles in Scopus, 120 articles in Ebscohost and 140 articles in Science Direct. The detailed identification and selection processes of the papers was according to the inclusion criteria and the articles were given a sequence number to facilitate the review process (Table 1).

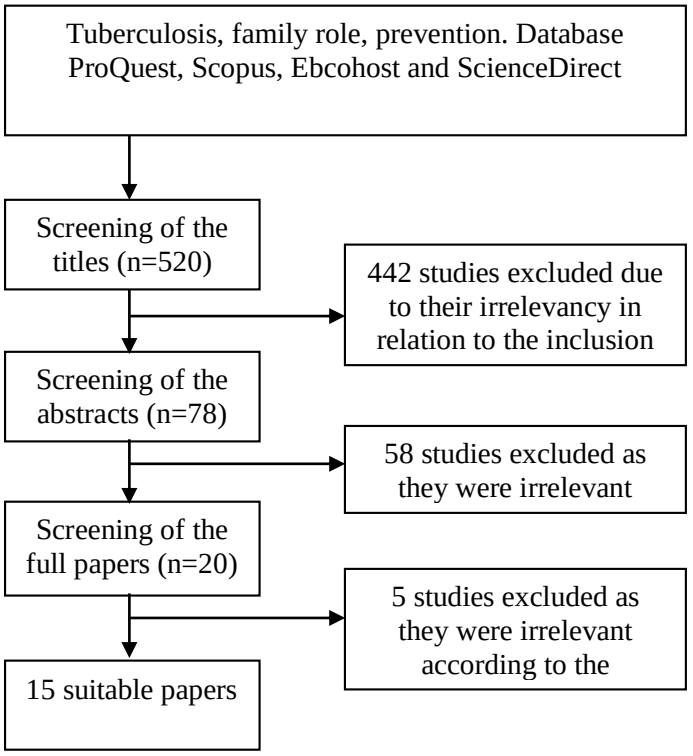

Figure 1: The Paper Selection Processes

Title and Authors	Purpose	Design	Outcome
Knowledge and Attitudes with Family Role in Prevention of Pulmonary Tuberculosis in Maros, Indonesia (Yermi, et al., 2018)	Determine the relationship between knowledge and attitude with the role of the family in relation to Pulmonary TB in Turikale District, Maros Regency	Cross-sectional	This study shows there to be a significant relationship between knowledge and attitude with the role of the family in the prevention of pulmonary tuberculosis
Increased adolescent knowledge and behavior following a one-time educational intervention about tuberculosis (Hatzenbuehler et al., 2017)	Evaluating the influence of an Educational Intervention (EI) on Tuberculosis (TB) focused on the internal changes tied into the knowledge and participation of adolescent students in TB prevention programs.	Prospective	Focus groups show that EI stimulates the students to learn about TB and that the groups increase their willingness to participate
Assessment of Patients' Knowledge,	Assess the patients' knowledge, attitudes and	Cross-sectional	The majority of respondents have some misunderstandings about TB. TB control programs are needed to

Title and Authors	Purpose	Design	Outcome
Attitude, and Practice Regarding Pulmonary Tuberculosis in Eastern Amhara Regional State, Ethiopia: Cross-Sectional Study (Esmael et al., 2013)	practices related to TB in the Eastern Amhara region of Ethiopia		consider advocacy, communication, and social mobilization to address gaps in the research location
Impact of a Structured Tuberculosis Awareness Strategy on the Knowledge and Behavior of the Families in a Slum Area in Chhattisgarh, India (Samal and Dehury, 2017)	Assessing impact Tuberculosis (TB) awareness strategies that are structured towards the knowledge and behavior of the residents of slums, Durg, Chhattisgarh, India.	Prospective interventional .	For the knowledge component, the increase occurred above 90% among the study participants in all components except for two; TB transmission mode and the availability of free care facilities. For the behavioral segment, after the implementation of strategy awareness, 53% and 92% of respondents reported visiting government health facilities to seek help from their generals and their respective TB related problems respectively. Likewise, the response to not approaching government health facilities for TB care changed after the implementation of strategy awareness and 36% of respondents said that they preferred visiting government health facilities for TB treatment.
Assessing the Impact of a Structured Tuberculosis Training Activity on the Knowledge and Attitude of Community Volunteers (Samal and Dehury, 2017)	Assessing the impact of structured TB training activities on knowledge and attitudes, including a post-training assessment of activities among the Community Volunteers	Descriptive	Very significant (p = 0.0042) impact observed in the knowledge segment but the same thing did not happen with the attitude segment (p = 0.0676). The average value of knowledge and attitudes is 9.20 (SD = 2.97) and 12.70 (SD = 1.42) for the pre-test and the average score of knowledge and attitude is 3.00 (SD = 0.94) and 2.10 (SD = 0.74) each for the post-test. Of the 10 CVs trained, eight CVs were placed in jobs related to various types of community level activities
Knowledge and perception on tuberculosis transmission in Tanzania: Multinomial logistic regression analysis of secondary data (Ismail and Josephat, 2014)	Analyze the knowledge and perceptions of TB transmission in Tanzania	Cross-sectional	The findings indicate that socio-demographic factors such as age, education, place shelter and having a telephone or radio vary systematically according to the knowledge of tuberculosis transmission.
Predictors of treatment seeking intention among people with cough	Assess the intention of people to seek treatment with a coughs for more	Cross-sectional	TPB significantly predicted the intention to seek treatment among the study participants. The attitude and silent beliefs held by the

Title and Authors	Purpose	Design	Outcome
in East Wollega, Ethiopia based on the Theory of Panned Behavior: a community based cross-sectional Study (Yohannes et al., 2014)	than two weeks, and to identify predictors.		respondents plays an important role and it must be given emphasis in terms of the prevention and control of tuberculosis
Randomized controlled trial of family-based education for patients with heart failure and their carers (Srisuk et al., 2017)	Develop and evaluate family-based education programs for HF patients and their caregivers in rural Thailand.	Randomized controlled trial	The linear mixed effects model revealed that the patients and caregivers who received educational programs had higher knowledge scores at 3 and 6 months than those who received regular care. Among those who received the education program, when compared to those who received regular care, the patients had better care and self-care self-confidence. They were also associated with better health quality of life scores at 3 and 6 months and better self-care management scores at 6 months, while the caregivers had a control score that was higher at 3 months.
Reducing disability via a family centered intervention for acutely ill persons with Alzheimer's disease and related dementias: protocol of a cluster-randomized controlled trial (Fam-FFC study) (Boltz et al., 2018)	Testing the effectiveness of interventions at improving the physical and cognitive recovery in people admitted to hospitals living with Alzheimer's Disease and Related Dementias (ADRD), increasing the Family Caregiver's readiness and experience.	Experimental design: longitudinal design	The family-centered intervention had a positive impact on the patients with cognitive impairment that was very mild to moderate
Effect of organizational citizenship behavior on family-centered care: Mediating role of multiple commitment (Mahooti, Vasli and Asadi, 2018)	Know the effects of citizenship organizational behavior on family centered care	Cross sectional	Organizational behavior and commitment can improve health quality
The effect of an education program based on the family-centered empowerment model on addiction severity among	Knowing the effect of family -centered empowerment-based training interventions on the severity of damage caused by addiction among the users of	Randomized trial	Training interventions based on the family-centered empowerment model can improve the health status of users of methamphetamine

Title and Authors	Purpose	Design	Outcome
methamphetamine users (Ghasemi et al., 2015)	methamphetamine (MA).		
Effects of Family Centered Empowerment Model Based Education Program on Quality of Life in Methamphetamine Users and Their Families (Ghasemi et al., 2014)	Knowing the influence of family-centered empowerment models on social support and the quality of life of the users of methamphetamine and their families	Randomized clinical trial	Family-centered empowerment models can be easily applied to the users and families of methamphetamine to improve their social support and quality of life.
Effects of Family-Center Empowerment Model on the Lifestyle of Heart Failure Patients: A Randomized Controlled Clinical Trial (Rakhshan, Kordshooli and Ghadakpoor, 2015)	Knowing the influence of family-centered empowerment models on the lifestyle of heart failure patients	Randomized controlled clinical trial	Family-centered empowerment models can be used to improve or enhance the lifestyle of patients and their families.
Effects of family-centered empowerment intervention on stress, anxiety, and depression among family caregivers of patients with (Etemadifar et al., 2018)	Knowing the effects of family-centered empowerment intervention on stress, anxiety and depression among the family caregivers of patients with epilepsy	Cross-sectional	The results show that family-centered intervention programs reduce caregiver stress, anxiety and depression because of the appropriateness, simplicity and intervention utility. The program is focused on the psychological caregiver problems, and the emphasis on empowering them, and how it helps them in managing their problems in care situations and when achieving greater psychological potential in the care process.

4. Discussion

2.1 Searching for Information about the Basics of Tuberculosis

The findings showed that the respondents aged between 15 and 19 years old were less likely to accept that TB spreads from person to person through the air when coughing compared to those who were aged 45 - 49 years old. Those aged between 20 - 24 years old were less likely to accept that TB spreads through air when coughing compared to those with an age between 45 - 49 years old. The respondents with an age between 25 - 29 years old were less likely to accept that TB spreads from person to person through air when coughing compared to those with an age between 45 - 49 years old. Those with an age between 30 - 34 years old were less likely to accept that TB spreads from person to person through the air when coughing compared to those with an age between 45-49 years old. Those with an age between 35 - 39 years old were less likely to accept that TB spreads from person to person through air when coughing compared to those aged between 45 - 49 years old. Those with an age between 40 - 44 years old were less likely to accept that TB spreads from person to person through the air when coughing compared to those with an age between 45 - 49 years old. The respondents aged between 15 and 44 years old were less likely than those aged 45 years and above to accept that TB spreads from person to person through the air when coughing. The respondents who had no education and those with primary or secondary education were less likely to accept that TB spreads from person to person through the air when coughing compared to those with the highest level of education.

2.2 Household Awareness

Family attitudes such as a positive attitude towards preventive measures including Bacillus Calmette Guerine (BCG) immunization for babies, a health check if there are family members who have had a cough with phlegm for more than three weeks, cleaning the environment around the house and so on. A negative action towards an individual based on his/her health or social status is considered to be a discriminating attitude[9].

2.3 Active Case Finding

Active Case Finding strategy involves a one-time cross-sectional house-to-house visit among high risk community groups to identify TB symptomatic individuals and to link them to the appropriate services. This strategy is designed to create awareness of TB. The primary objective of this strategy is to visit the houses of marginalized and vulnerable communities and to inform them about TB, its symptoms, diagnosis and treatment.

2.4 Sputum Collection and Transportation

The sputum collection and transportation was to the nearest Designated Microscopic Centre from the community and to qualified private practitioners as well. After diagnosis, if it was found to be positive, the patients were put on DOTS.

5. Conclusion

In conclusion, the study showed that those of a younger age, a lower level of education and people in rural areas were all less knowledgeable about TB transmission. It is therefore important that more effort is made in strengthening the public health education that is directed at people.

LONELINESS INCREASED THE RISK OF DEVELOPING DEMENTIA AMONG OLDER ADULTS : A SYSTEMATIC REVIEW

F N Fiddaroini[1], M J A Heru[1] , A Syamsudin[1] , M E A Budiman[1]
[1]Faculty of Nursing Universitas Airlangga, Mulyorejo, Surabaya, Indonesia
E- mail: fakhrun.nisa.fiddaroini-2018@fkp.unair.ac.id

ABSTRACT

Loneliness is an unpleasant subjective experience for the older adults because several important criteria of social relations are hampered or not fulfilled. These deficiencies can be quantitative the relations does not acquire ideal friends and qualitative where social relations cultivated is modest or unsatisfactory. The aim of study to analyze the relationship between loneliness and dementia. Systematic review was carried out by searching four databases including Proquest, PubMed, Google Scholar and Scopus articles from 2014 until 2018. The collected articles is the carried out with a critical appraisal in accordance with the objective to be achieved. Fifteen articles which include criteria for analysis. The result of this systematic review can present that a more accurate loneliness increased the risk of developing dementia in older adult may be explained in several ways. In addition, the effect of loneliness on the risk of dementia varies by sex. Spesifically, men who feel lonely are more likely to suffer from dementia than women. The result of this review should be considered when developing interventions aimed at reducing and support the development policy at preventing the onset of dementia.

Keywords: loneliness, dementia, elderly, older adults

6. Introduction

Loneliness is defined as a related feeling of dissatisfaction with the differences between the actual and desired social relations of an individual[1]. Previous research shows that in intensity, loneliness varies between men and women and loneliness is more strongly related to an adverse mental health condition in men than in women [2]. It is impossible and perhaps even undesirable that loneliness is removed from the list of common human experiences. Loneliness occurs when there is a mismatch between a person's actual social relationships and a person's needs or desires for social contact. Sometimes loneliness results from changes in a person's social needs and not from changes in their actual level of social contact [3]. Loneliness is relatively common among the elderly with weakened social networks [4]. Social networks are measured by the size, frequency and nature of their interactions with friends and family, the number of social and recreational activities involved in the presence of a partner and the number of close relationships. Research on the relationship between social networks and loneliness on the onset of dementia has attracted attention recently [5].

Dementia is a syndrome that is basically brain failure that affects the higher brain functions[6]. Dementia is caused when the brain is damaged by diseases such as Alzheimer's disease or by a series of strokes. Alzheimer's disease is the most common cause of dementia but it is not the only one. The

specific symptoms experienced by a person with dementia will depend on the damaged part of the brain and the disease that causes dementia[7]. Dementia is also a multi-causal medical condition with high prevalence that is increasing in both developed and developing countries. Alzheimer's disease and vascular dementia constitute 90% of cases[8]. Prevalence and incidence studies show that the number of people with dementia will continue to increase. It is estimated that there are 46.8 million people with dementia worldwide, with projected numbers almost doubling every 20 years. There will be around 9.9 million new cases of dementia in 2015, equivalent to every 3.2 seconds[9].

The stronger progression of dementia is contributed to by social isolation [10]. Environmental factors such as social isolation are defined as not or no longer being married, living alone, having small social networks, having little participation in activities with others or having a lack of social involvement (social connections). These have been shown to be associated with cognitive decline and Alzheimer's disease. Fewer studies have focused on emotional predictors such as sensitivity to psychological distress, emotional isolation, dissatisfaction with social interactions and feelings of loneliness in relation to the onset of dementia [8]. The variables related to loneliness include the presence of mental disorders including anxiety disorders, self-life, marital status, frequent economic problems, quality of life, satisfaction with life and satisfaction with social relations [11].

Previously, the current study investigated the relationship between perceived loneliness, depression and the general cognitive status of the elderly. The result of the study findings are that perceived loneliness is associated with a worsened general cognitive status only among those who reported higher levels of depressive symptoms. This indicates there to be a slightly significant positive relationship between loneliness and general cognitive status [12]. Therefore, the purpose of this review is to analyze the relationship between loneliness and dementia in the elderly.

7. Method

2.1. Eligibility criteria

In this systematic review, we intended to investigate the relationship between loneliness and dementia in the elderly. Regarding the research design of the 15 selected articles, most of them used a cross-sectional, cohort, prospective observational or longitudinal study design.

2.2. Participants

The study included participants who were older adults aged ≥ 55 years.

2.3. Setting and time frame

This systematic review encompassed community-living older persons.

2.4. Report characteristics

We included articles that had an English abstract, that were original quantitative or qualitative research, that were a full report written in English, that were a study on human participants with a mean age ≥ 55 years and that were published from 2012 through to 2019 within the areas of nursing, medicine and psychology.

2.5. Exclusion criteria

The exclusion criteria in this study were if an article did not report original data, if it did not explain the association of loneliness and dementia in the aging population and if the published articles were before 2012. Reviews and opinion articles were excluded.

2.6. Information sources

The information resources comprised of the following electronic databases: Scopus, PubMed, Google Scholar and Proquest. The search strategy was primarily developed and completed in Scopus. The same strategy was then pursued in other databases. The reference section produced reviews and articles that passed the initial critical appraisal. They were then checked manually to ensure that all relevant articles had been included.

2.7. Search strategy

The search keyword in this systematic review included "loneliness" AND "dementia" AND "elderly" AND "older adults". The next step was to identify the title of each article that was considered to be close to the research focus desired.

2.8. Selection process

The articles were collected in the first step. Each were first selected according to the title and abstract, followed by grouping the articles chosen into related articles, not related and not yet decided. Articles that were considered "inappropriate" were removed from further analysis. The author then updated the articles list for those that must be included in the review.

2.9. Data items

The following information was collected from each article: author and year of publication, article title, purpose and design, characteristics of the sample and setting (participants, age etc).

2.10. Risk of bias in individual studies

The risk of bias analysis will discuss the limitations and suitability, the research methods and the research itself. In particular, the studies will discussed critically regarding their design, collecting the data, the analysis method, selection bias, integration, confounding, friction and reporting. Longitudinal cohort studies with a larger sample size or a longer duration of follow-up are needed to clarify the cause of the relationship between loneliness and dementia events, which is transient when measuring if there is adequate bias [4].

2.11. Data synthesis

In the final report, the results of the individual studies have been summarized according to their narratives as in [Table 1]. Finally, this systematic review recorded the associations between loneliness and dementia in the aging population. The selection included a quantitative study.

2.12. Strengths and limitation

This systematic review can present more accurately that loneliness increases the risk of developing dementia in the elderly which can be explained in several ways. This systematic review carried out

the primary screening of articles, the data extracted and the quality critical appraisal in order to minimize the probability of personal biases. However, the review did not include databases in languages other than English. This limitation may cause language bias.

8. Result

The result of this systematic review can present that loneliness increases the risk of developing dementia in the elderly. There were 15 articles in total that were reviewed. Out of the 15 articles, 6 were cross-sectional [13][14][11][15][5][16], 4 were a longitudinal study[17][18][15][19], 3 were a cohort study [4][20][8], 1 article was a prospective observational cohort study [10] and 1 article was across-sectional longitudinal study [12]. There were no qualitative studies that met the criteria for inclusion in this review.

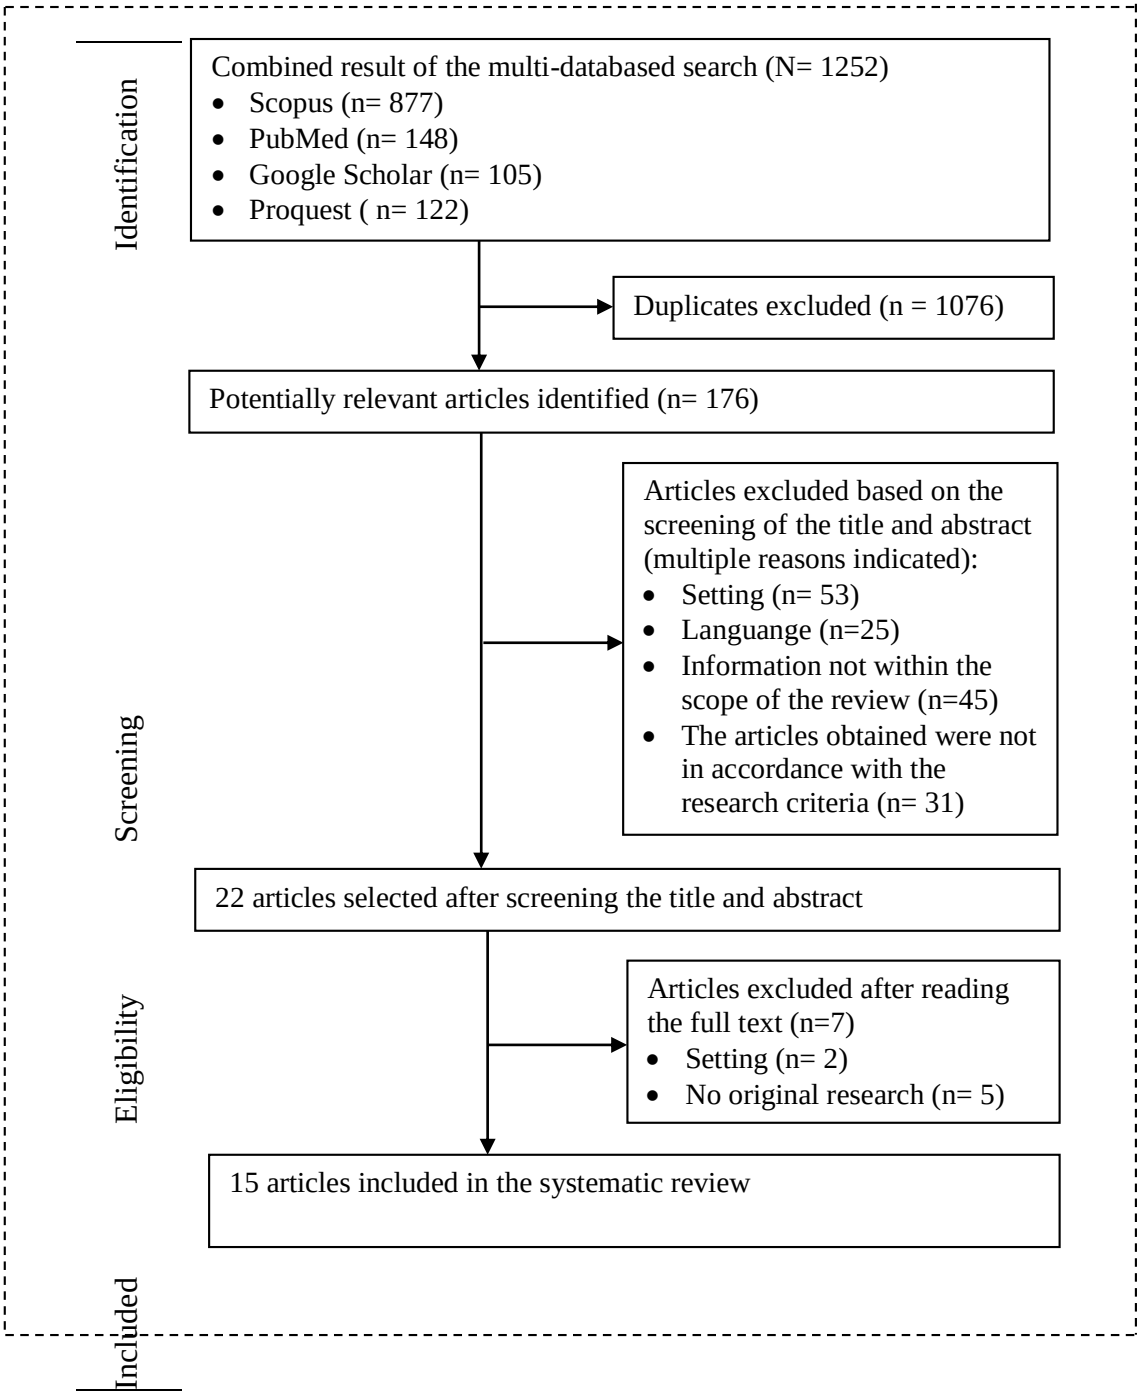

Figure 1. Study selection flow diagram

The result of the analysis of the relationship between loneliness and dementia was associated with an adjustment in their lifestyle, baseline health status and socio-demographic characteristics. A relationship between loneliness and gender was also found. The participants were selected from 22 out of 31 provinces in China and they were all aged ≥ 65 years[4]. In general, the similarities found showed that 28% of older Chinese adults reported feeling lonely and loneliness, which both affects and was affected by their social activities, solitary leisure activities, physical exercise, emotional health, self-rated health and functional limitations over a 3-year period[13]. The research conducted by [11] also showed that the loneliness-associated variables included living alone, marital status, the frequency of their economic problems, quality of life, satisfaction with life, satisfaction with their social relationships, the presence of a mental disorder and having an anxiety disorder [Table 1].

Another research conducted by [21] showed that the association of loneliness with cortical amyloid burden in cognitively normal older adults suggests that loneliness is a neuropsychiatric symptom relevant to pre-clinical Alzheimer's Disease. The result of the investigation is that there is an effect of living alone on the development of dementia in people with mild cognitive impairment (MCI) as found by [18]. This shows that living alone increases by 50% the risk of developing dementia among older adults. The research conducted by [14] also found that for all of the psychological and health variables, there were strong associations, with the strongest being between the WHO-5 and self-rated ($p< 0.001$). The value was $p< 0.001$, which means that the hypothesis is accepted. The result of this review should be considered when developing interventions aimed at supporting the development policy related to preventing the onset of dementia [Table 1].

9. Discussion

The aim of this systematic review was to analyze the association between loneliness and dementia in the aging population. Overall, the findings from the 15 articles largely indicate that loneliness is positively associated with dementia. Multiple logistic regression was used to examine whether baseline loneliness is associated with dementia at a 3-year follow-up, calculated with 95% confidence intervals for this relationship. The main findings were a significant and positive relationship between loneliness and dementia in the elderly that can be explained in several ways, such as the feeling of loneliness contributing to developing a risk of dementia[4]. The study by [5] showed that social loneliness is more common in the elderly with dementia than in the elderly without dementia, but there was no difference for emotional loneliness.

This finding is consistent with the existing studies examining the relationship between social isolation (alone, unmarried, without social support), feelings of loneliness and incident dementia in a cohort study among 2173 elderly people who did not have dementia. Feeling lonely rather than alone is associated with an increased risk of future clinical dementia and it can be considered a major risk factor which, apart from vascular disease and other confounding factors, deserves clinical attention. Feelings of loneliness may indicate an early stage of prodromal dementia. A better understanding of the background of the feelings of loneliness can help us to identify vulnerable people and to develop interventions to improve the outcomes in elderly people at risk of dementia[8].

The finding overall is that loneliness could contribute to developing dementia among older adults, with perceived loneliness being common in older people and with the variables often being associated with living alone. In this study, it was found that greater loneliness was independently associated with a decline in multiple cognitive domains and a doubling of the risk of Alzheimer's

disease and dementia[11]. This is consistent with the present study's findings that sought to examine and analyze the relationship between depression, loneliness and cognitive functioning among the elderly. This study found there to be a significant moderating effect of depressive symptoms on the relationship between perceived loneliness and general cognitive status. This finding highlights the importance of taking depressive symptoms into account when examining the relationship between cognitive function and loneliness [12].

The study of [16] also found there to be a significant relationship between loneliness and a non-confiding network in relation to cognitive function, after controlling for mental distress, physical burden, the psychological factors, their socio-demographic characteristics and depression in older adults. More specifically, the findings show there to be a significant interaction effect between loneliness and the number of family members in a network that is not confident in relation to cognitive function. Loneliness also predicts accelerated cognitive decline over 12 years regardless of their basic socio-demographic factors, social network, health condition and depression[15]. Loneliness affects and is influenced by social activities, leisure activities, physical exercise, emotional health, self-valued health and functional limitations over a period of 3 years[13].

In addition, loneliness may predict subsequent cognitive decline and vice versa. This loneliness–cognition relationship is partially explained by the impact that is has on physical health[19]. In addition, loneliness can predict subsequent cognitive decline and vice versa. This loneliness-cognition relationship is partly explained by its impact on physical health[19]. Another study also suggests that impoverished conditions such as nursing homes or the social isolation of solitary people contributes to a stronger progression in and of dementia[10].

Other studies investigated the effect of living alone on the development of dementia in people with mild cognitive impairment. The findings show that living alone increases by 50% the risk of developing dementia[18]. The research conducted by [5] found that there was a lack of research on social networks in people with Alzheimer's disease. Their research shows that the factors related to quality of life, well-being and life satisfaction in people with dementia are the factors associated with relationships and social involvement associated with a better quality life. Thus, supporting friendships for people with dementia may be done to improve their quality of life[20]. The causal relationship between loneliness and developing dementia should be further investigated and being critical would be a better determinant of the mechanisms underlying the association.

This systematic review has both strengths and limitations. The strengths were that the data was collected from a highly representative sample in a community-dwelling for the elderly and this finding highlights the important where the subjective feelings of loneliness do not depend on the objective social environment.

The limitations in the study were that the incidence of dementia led to some bias. The limitations may cause language bias, as the review did include databases in languages other than English.

The results of the review of various studies showed that nurses can be involved and considered to develop intervention strategies to reduce the incidence of dementia. Nurses can play an important role in advising and supporting the recipient caregivers of people with dementia. A better understanding of this perspective can provide them with important information to support self-management. Proactive approaches including information and support offered at the start of the trajectory of conditions/care may have the potential to delay progression to the more dependent

stages. Health care professionals also need to implement activities that are meaningful to institutionalized people and for people who are lonely to eliminate the negative effects of such an environment.

10. Conclusion

The result presented in this systematic review highlights some of the predictors of loneliness in older adults. The goal is to intervene before the feelings of loneliness set in. These results discuss loneliness as a clinical marker of social and emotional stress associated with depression and cognitive decline in older adults. Further longitudinal analysis shows that biological markers are needed to determine the temporal and causal relationship between loneliness, depression and dementia in later life. Feelings of loneliness have been shown to be repeatedly associated with cognitive decline in older adults. This finding is in line with other studies that show that individuals who live alone and have limited social ties are more prone to dementia later on in their lives.

Feelings of loneliness are associated with the development of dementia even when the objective indicators of social isolation and other covariates are controlled. Both social isolation and depression cannot explain this relationship, suggesting that other mechanisms might be involved. Further research is needed to investigate whether cognitive decline and dementia are a consequence of feelings of loneliness or whether feelings of loneliness are behavioral reactions to decreased cognition. To develop a better understanding of these feelings, we need to know whether they are signals from the prodromal dementia stage, as a direct result of neurodegenerative pathology that affects social skills or whether feelings of loneliness are indicators of a vulnerable personality, personality changes or other weakness factors. As a result, policies about loneliness in parents should be directed at developing different intervention strategies so then the emotional and social loneliness is reduced.

A SYSTEMATIC REVIEW: THE INFLUENCE OF NURSES CAREER DEVELOPMENT ON JOB SATISFACTION

J Retnowati , M H Haryono , F Chandra
Master Student, Faculty of Nursing, Universitas Airlangga, Surabaya
Email: jajukretnowati@yahoo.com

ABSTRACT

Nurse as health care providers have an important role in providing nursing care continuously. The professionalism in nursing is managing human resources and giving awards to nurses. Nurse career development is the implementation of a planned career that places nurses in accordance with their expertise and becomes an opportunity for their potential and abilities. The purpose of this study is to conduct a systematic review of nursing career development and job satisfaction of nurses. The main databases was used include CINAHL Plus, Web of Science, MEDLINE, Google Scholar, and PUBMED. The keywords used were career development, nurse, and job satisfaction. Limitation research determine 2012-2018. There were 36 articles found. Filtering out duplicate articles and focus on criteria inclusion. Twelve articles was reviewed and most studies showed that nursing career development and job satisfaction were positive and significant impact. There is evidence of a contribution between job satisfaction and nurse career development. Professional career development is a system to improve performance and professionalism in accordance with the field of work through increasing competence.

Keywords: career development, nurse, job satisfaction

1. Introduction

The development of a nurse's career is focused on the implementation of a career plan that can be used for the placement of nurses at a level according to their expertise, allowing for the provision of better opportunities according to the nurses' abilities and potential[1]. To maintain the quality of service professionally, the nurse’s career path must be documented and organized in the orientation system, placement and reward systems, therefore the career path is seen of as structured. Management and the entire nursing profession must know about the career path of their profession in relation to their professional development both formally and informally.

Job satisfaction is individual. Each individual will have different levels of satisfaction in accordance with the applicable values. Employees will feel satisfied at work if aspects of the work and aspects of themselves are supported and if any aspects are not supported, then the employees will feel dissatisfied[2]. Career development is a strategy used to improve the quality of patient care by advancing the appreciation and recognition of experience and competencies achieved by the nurses in clinical practice systematically[3]. Career success is defined as a collection of individual real achievements as an effort resulting from their work experience[4].

The purpose of this study was to conduct a systematic review of nursing career development and the job satisfaction of nurses.

2. Research Methods

The main databases used included CINAHL Plus, Proquest, Web of Science, Science Direct, Medline, Google Scholar, Elsevier and PUBMED. The keywords used were career development, nurse and job satisfaction. The research had to have been published between 2012 - 2018.The search languages were English and Indonesian. The papers were critically reviewed and the relevant data was extracted and synthesized using an approach based on the Preferred Reporting Items for Systematic Reviews and Meta Analysis (PRISMA).There were 36 articles found. The researcher then filtered out duplicate articles and focused on the criteria for inclusion. Twelve articles were finally reviewed.

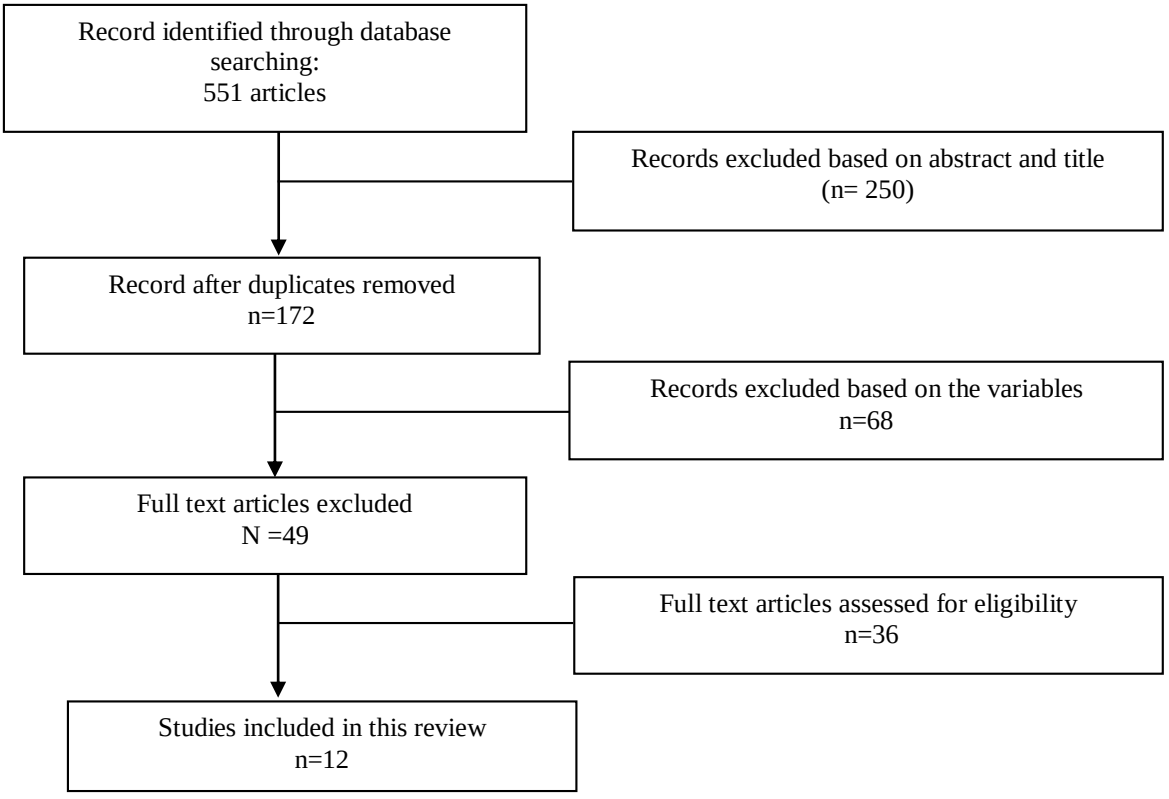

Figure 1. PRISMA flow diagram

3. Results

Most of the results of the study showed that there is a strong relationship between professional values and career development and that job satisfaction and career development are positively correlated. Nurses with high levels of job satisfaction are highly motivated to remain in their jobs. Their expertise is needed to maintain the profession and to develop a career in the future. Job satisfaction and career development have an influence on retention and additional findings indicate that their intention to keep working is higher[5].

The results show that the relationship between job satisfaction that is consistent with career adaptability and the expected pattern can have implications for future research in the form of ideas about how to maintain and improve the older workers' career adaptations and job satisfaction. We

have also found that the ability to develop a self-career is positively related to job satisfaction and the motivation to continue working, suggesting that career adaptability can be a step towards retaining older workers[6].

The results of this study indicate that career attention skills significantly explain the level of satisfaction of the participants about career and development opportunities in relation to the characteristics of the work offered. The research findings show that goals, future careers and plans are important to maintain[7]. Individuals who are very concerned about their careers and their future also tend to care more about the nature of their work. Job characteristics have been regarded as intrinsic motivators and aspects of individual subjective career success and job satisfaction [8][9][10].

4. Discussion

Increasing the nurses' careers from one level to another higher level is based on the required competence, experience and meeting the formal education requirements, in addition to continuing education. Career path improvement for nurses is always followed by awards in the form of education that is sustainable or related increased revenue. The mechanism of the improvement in income must be based on the achievement of success related to their competence.

5. Conclusion

Maintaining experienced nurses can be done by providing facilities and opportunities to develop their careers and this contributes to quality patient care and guidance from novice professionals. Middle career nurses are likely to be senior nurses later on. Senior career nurses have a lot of experience and stability in terms of providing quality health services, while new career nurses have new ideas and improved facilities with technology.

Appendix

Table 1. Selected papers

Title /Author / Year	Study Design / Participants	Result
Development and validation of a nursing professionalism evaluation model in a career ladder system (Kim et.al, 2017)[11]	RCT N = 200	Clinical competence was determined by the 5 dimensions of nursing practice: scientific, technical, ethical, aesthetic and existential. The structural model explained 66% of the variance. Clinical competence scales, peer reviews and face-to-face interviews directly determined nursing professionalism levels.
The relation of career adaptability to satisfaction and turnover intentions (Chan&Mai, 2015)[12]	RCT N = 368	This study has demonstrated that the current CAAS form has robust possibility for use in vocational intervention and career expansion research for working adults, referring to low-ranking employees in particular.
The influence of satisfaction and promotability on the relation between career adaptability and turnover intentions (Chan, 2016)[13]	RCT N= 431	Career adaptability was significantly and positively related to both promotability and CS after controlling for the influences of the demographic variables including age, gender, education and tenure.
Competencies of older workers and its influence on career success and job satisfaction (Hennekam, 2016)[14]	RCT N = 1112	It was found that motivation, integrity and social skills all had a positive relationship with job satisfaction: the higher the older workers scored for those competencies, the more satisfied that they were with their job. Motivation and social skills were also positively related to extrinsic career success, while integrity was unrelated.
The importance of continuing professional development on career satisfaction and patient care: meeting the needs of novice to mid- to late-career nurses throughout their career span(Price & Reichert, 2017)[15]	RCT N = 185	Healthy work environments were identified by the nurses as those that are invested in continuing professional development opportunities to ensure continuous growth in their practice, allowing them to provide optimal quality patient care.
Older workers' age as a moderator of the relationship between career adaptability and job satisfaction (Zacher&Griffin, 2015)[5]	RCT N = 577	The results showed that the older workers' age but not their motivation to continue working moderated the relationship between career adaptability and job satisfaction consistent with the expected pattern. Implications for future research on age and career adaptability as well as ideas on how to maintain and improve older workers' career adaptability and job satisfaction have been discussed.

Professional values, job satisfaction,career development, and intent to stay (Yarbrough et.al, 2016)[4]	RCT N = 67	The findings indicate a strong correlation between professional values and career development and both job satisfaction and career development correlated positively with retention.
Career adaptability and academic satisfaction: Examining work volition and self efficacy as mediators (Duffy, Douglass, Autin, 2015)[16]	RCT N = 412	In an effort to explain these relations, work volition and career decision self-efficacy (CDSE) were examined as potential mediator variables. Using structural equation modeling, work volition significantly mediated the control to satisfaction relation and CDSE significantly mediated the concern, control and confidence within satisfaction relations. After including all of the variables in the model, none of the career adaptability components were significantly related with academic satisfaction.
The longitudinal relationship between protean career orientation and job satisfaction, organizational commitment and intention-to-quit (Supeli & Creed, 2016)[10]	RCT N = 168	We tested 3 cross-lagged models (standard causal, reverse causal, and reciprocal causal) and found support for the standard causal model. Higher levels of protean career orientation at T1 were associated with lower levels of organizational commitment and job satisfaction and higher levels of intention-to-quit at T2 after the effects of T1 were controlled for. The results indicate poorer individual and organizational outcomes after 6 months for employees with higher levels of protean orientation.
Meeting career expectation: can it enhance job satisfaction of Generation Y? (Kong, 2015)[3]	RCT N = 30	Finally, the findings of this study highlight the importance of providing creative management activities to Generation Y employees. Generational differences are critical in determining management practices in the workplace.
Exploring the path through which career adaptability increases job satisfaction and lowers job stress: The role of affect (Fiori, Bollmann, Rossier, 2015)[2]	RCT N = 1671	Overall, the results support the conception of career adaptability as a self-regulatory resource that may promote a virtuous cycle in which the individuals' evaluation of their resources to cope with the environment (i.e., career adaptability) shapes their affective states, which in turn influences the evaluation of their job.
Employees' satisfaction with retention factors: Exploring the role of career adaptability (Coetzee&Stoltz, 2015)[6]	RCT N = 321	The results showed that career adaptability, especially career concern, significantly explained the participants' level of satisfaction with their experience of career opportunities, work–life balance, training and development opportunities and the characteristics of the jobs offered by the company.

ABSTRACT

Today depression is one of the problems that is often experienced by the elderly, one of the interventions that can overcome this problem, namely cognitive therapy. Aim to conduct a literature review systematically on the study of the effectiveness of spiritual cognitive therapy to reduce the level of depression in the elderly. Review is carried out by following the PRISMA alloy. This literature is reviewed from the Scopus, PubMed and Cochrane electronic databases Database of Systematic Reviews for studies published between 2013-2018 with relevant keywords. A total of 15 articles identified through systematic searches and six inclusion criteria from 148 articles found to show decline in depression in the elderly. The results stated that there was a significant decrease in depression over time from before arriving after treatment using spiritual power. Spiritual cognitive therapy can be used as a non-pharmacological intervention to overcome health problems related to depression.

Keywords: cognitive therapy; spiritual; depression; elderly

1. Introduction

Becoming elderly is the final stage of the human life cycle and it is a part of the life process that cannot be avoided. It will be experienced by every individual. In the Republic of Indonesia Law No. 13 of 1998 concerning elderly welfare, it is expressly stated that the so-called elderly are men or women aged 60 years old or more.

Globally, the population with an increasing age of 60 years old and above worldwide is expected to increase by 22% by 2050 [1]. Advanced aged ≥ 60 individuals suffer from a mental or neurological disorder (not including headaches) by as much as 20%. The most common mental and neurological disorders in the elderly are depression (7%) and dementia (5%)[2]. Mental health problems, namely depression, are less identified by the health care workers and the elderly themselves, as there is a stigma that this condition makes the elderly unwilling to seek treatment.

Depression in the elderly aged ≥65 can cause functional disorders in their daily life. Elderly people with depressive symptoms have worse functioning levels compared to the elderly with chronic pain conditions [2]. Depression can affect their quality of life and social interactions, and it can cause suicide in the elderly [3]. The prevalence of depression in the elderly with an age range ≥ 65 years that occurs in people living in Indonesia ranges from 7.2% - 33.8% [4]. While depression or depressive symptoms are higher in the elderly who live in nursing homes compared to those living in communities in Western countries such as the United States, the prevalence of depression is found to be 21.6% [5]. In Canada it is 19.0% [6] and in Singapore[7].

Depression factors that occur in the elderly are caused by stress such as negligence due to mental health or chronic disease, impaired mobility, long-term care, pensions and other disabilities causing a loss of independence, feeling lonely or isolated and having difficulties when carrying out their daily activities, which is also considered to be a problem related to depression in the elderly.

Depressed elderly have a worse condition than the elderly who suffer from chronic diseases. These special conditions have an impact on increasing the perceptions of poor health, th utilization of health services and health care costs[1]. Elderly people who live in nursing homes with a depressed condition have a higher desire to commit suicide, which can be further backed by those who live in nursing homes who are 60-74 years of age, living alone and experiencing spiritual distress have a desire to end themselves [8]. Seniors with depression tend to have negative judgments and views of themselves, the environment and the future. These negative thoughts (views) affect the elderly to behave negatively. Depressive symptoms often result in emotional and physical suffering, a decreased quality of life and an increased risk of death.

Seniors who are cognitively good can be aware of activities in the institution and they have clear perceptions about the environment of their residence, the care received and they realize the state of separation from their family and friends in the environment in which they lived. A research study conducted by [9] reported that more than half of the elderly population without a cognitive impairment experienced symptoms of depression while living in a nursing home [9]. Some elderly people face and suffer from various life pressures that can have a negative impact on their quality of life. Spirituality has been found to be positively related to health which is considered to be very important for the elderly. The development of individual spirituality involves a person's cognitive, behavioral and skill abilities and these can be shaped and expressed through social learning and practice [10]

The management of medications to treat depression problems can be done pharmacologically by administering antidepressant drugs that can improve both the depressive symptoms and work function. However, the continuous use of antidepressant drugs can cause various side effects such as anxiety, nausea and insomnia[11]. To minimize the use of chemical treatment, several non-pharmacological treatment therapy programs have been carried out, including the results of a study by [11], which states that significantly higher spirituality predicted better treatment responses in the depressed patients.

2. Methods

This systematic review used a guide based on the Preferred Reporting Item for Systematic Review and Meta-Analysis (PRISMA).

2.1. Strategy for Literature Search

The literature used in this Systematic Review involved 6 (six) electronic databases, namely Scopus, ScienceDirect, Pubmed and Springerlink published within the limits of January 2013 through to November2018.The keywords used were "cognitive therapy" AND "spiritual" OR "depression" OR "elderly".

2.2. Eligibility Criteria

2.2.1 Types of study research. 1) non-randomized pre-test / post-test design, (2) cross-sectional randomized controlled trial study (3) and (4) experimental study design study that we used

2.2.2 Types of participants. The main inclusion criteria for the participants was that they were elderly (60 years or older) with a state of depression.

2.2.3 Types of intervention. Spiritual cognitive therapy meets the requirements, so no studies were issued based on the comparator / control group used.

2.2.4 Types of outcome measure. The main outcome expected is that it can reduce depression in the elderly.

2.3. Selection of the Studies

The guideline standard for the study used in this systematic review was based on the PRISMA method followed by filtering by removing duplicates. Then the reviewer selected the titles, abstracts and keywords, and then removed any irrelevant quotes. The selection of the articles that had been obtained were then re-compared with each other to adjust their suitability according to the criteria set.

3. Results and Discussion

3.1. Search for the literature and the selection of the studies

A total of 15 studies were identified to be used in the systematic review. The search was done using the Scopus database and the PubMed Cochrane Database of Systematic Reviews which has provided quotes of 28,140 citations. After screening by removing the duplicates until 9,796 citations were found, from that number as many as 140 studies were discarded after reviewing the abstract and any that did not meet the criteria. The full text of the remaining 60 citations was then reviewed in detail until 38 studies were found that did not meet the inclusion criteria. The study total that was finally obtained to be included in the review of 15 quotes; see the flow diagram in Figure 1.

3.2 Characteristics of the Study

3.2.1 Methods. The 15 studies chosen for review used (1) a non-randomized pre-test / post-test design, (2) a cross-sectional randomized controlled trial study (3) and (4) the experimental study design study that we used.

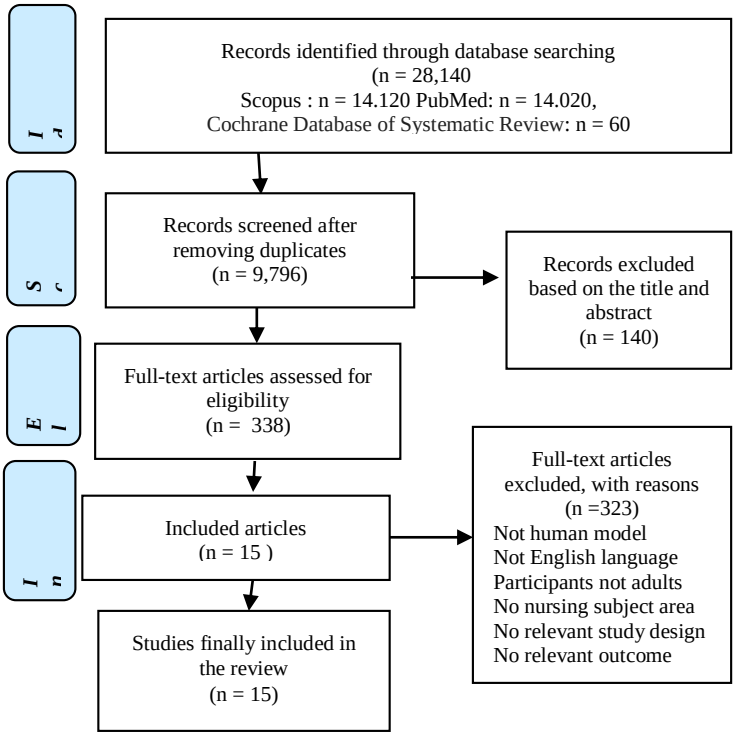

Fig. 1. Flow Diagram

3.2.2 Population. The study in this systematic review involved 1991 participants within the terms of the inclusion criteria, namely individuals who were elderly (60 years or more) with depression.

3.2.3 Interventions

Table 1 shows the characteristics and interventions of the 15 studies. Five studies evaluated cognitive functioning that was spirituality related. Three studies evaluate spirituality itself.

3.2.4 Results

In all of the studies obtained, the results assessed were on reducing depression in the elderly which could come in various forms.

3.3. Results from the individual studies

3.3.1 Spiritual cognitive therapy. Cognitive therapy, which is an extensive therapist training program carried out on Health Administration veterans, showed a 30% reduction in PTSD symptoms upon completing the analysis. There was shown to be a large increase and it is an affordable program for 9/11 victims suffering from PTSD. There is no significant difference between those who were assigned to the BSS and PCGT groups based on age, sex, education, income or the proportion of ethnic minority participants. There were no significant differences between groups at baseline on symptom scores or spiritual distress variables[12]. Overall, these results indicate that the participants did not report various levels of PTSD symptoms over time and that the two groups did not differ in the average level of PTSD symptoms reported or in terms of changes in the PCL-C scores over time. The model was limited to pre- and post-treatment time points only, and the effect was significant

over time (F [1,103.51] = 9.42, p = 0.003) but not in the groups (F [1,139.74] = 0.98, p = 0,325) or between time with group interactions (F [1,103.51] = 1.38, p = 0.244) and PCL-C. The effect size for time across the groups was d = 0.24, and the effect size for the group was d = 0.15.

The results of the study [4] showed that the level of depression was lower in the elderly who were spiritually good. In the multivariate analysis, without controlling for all of the other variables (complete models), spirituality had a strong relationship with the level of depression (OR = 1.767; 95% CI; 1,331 to 1,345). Similarly, when using the model that controlled for all of the variables (adjusted models), there appears to be a stronger relationship between spirituality and depression levels (OR = 1,869; 95% CI; 1,422 to 2,458). These results indicate that older people who identify as an atheist because they are less spiritual are twice as likely to experience depression than those who identify as being very spiritual. This finding is consistent with the results published by Smith et al. who found that there was a negative correlation between religiosity and depressive symptoms, indicating that that greater religiosity was associated with a lower level of depression symptoms. Similarly, Koenig found that out of 444 participants, 272 (61%) reported there to be a negative relationship between spirituality and depression. Furthermore, the results from 70 prospective cohort studies showed that 39 cohorts (56%) reported that a greater sense of spirituality resulted in lower levels of depression or a faster remission from depressive symptoms. In addition, from 30 reviewed clinical studies, 19 (63%) found that the spiritual interventions produced better results than standard care interventions or control groups.

4. Discussion

This systematic review was to find out about the effectiveness of spiritual cognitive therapy in patients with depression. The study used a heterogeneous research design. There are several findings related to the various interventions regarding excellence. In accordance with the results of a review of the research studies conducted, it was explained that the pre- and post-therapy scores of spiritual and depression did not have a significant difference. This might be related to the small number of samples.

Another important aspect of spiritism is spiritual medicine for mental and physical health disorders. There have been 10-23 large presentations of residents utilizing spirits centered on spiritual medicine to cure or relieve the symptoms of the various health problems that are experienced through spiritual therapy. In a recent study evaluating the characteristics of complementary religious medicine carried out by spiritual centers in the city of Sao Paulo (Brazil), there was an average of 261 people per week attending spiritual sessions [13]. Some researchers have suggested that religion might reduce the vulnerability to depressive symptoms through various substantive psychosocial mechanisms. Such findings indicate that religion can protect people against the symptoms of depression by helping them to avoid the negative psychological sequelae that often occur related to stressful life events. The magnitude and increasing number of studies indicates that religious or religious beliefs and practices can be used to overcome them or to adapt to stressful living conditions.

There are several potential limitations associated with this systematic review: (1) the heterogeneity of the research design and (2) What we consider to be the main results is not always the same as in the initial study.

5. Conclusion

Spirituality has a significant relationship with level of depression. Mental health problems are quite common in the elderly. It is clear that there is a great need for a strategy that enhances the role of

spirituality in the effort to reduce the risk of depression in the elderly

ABSTRACT

Elderly people sustain various decrease in anatomical, physiological, social and economic aspects. Elderly has resulted increasing demand in aged friendly health systems for management of chronic diseases. It caused elderly people need aged friendly health systems. The objective of this research was to identify age friendly health systems for elderly. In this article, the authors conducted a relevant systematic review in various data using the keywords "age friendly,health system, elderly". Data based based on SCOPUS, Science Direct, Proquest, Pubmed and Google Scholar. The criteria consisted of full text published in criteria were five years limit journal (2013-2018) use article in English. The Results as much as 386 articles found, and selected 15 article that suitable with criteria The Result introduction of age friendly health system based on the WHO guidelines in the following areas:Information, education and training, community-based health care management systems, and the physical environment. Discussions aged friendly health system to support older adults health of choronic diseases, well-being, and ability to age in place.

Keywords: age friendly, health system, elderly

1. Introduction

The elderly experience a decrease in the anatomical, physiological, social and economic aspects of their lives [1]. The elderly have shown that there was an increasing demand for age friendly health systems for the management of chronic diseases. This can cause the elderly people to need age friendly health systems[2]. Based on the focus groups found and backed by the background research and a consensus meeting of experts, the WHO developed a set of age-friendly principles. The first dimension of the principles is in the areas of information, education and training; the second is in the area of community-based health care management systems and the third is in the

area of the physical environment. These principles can be adapted to outpatient services and hospitals in addition to primary care centers or clinics[3].

An age friendly health system is a health care system that aims to provide the elderly with the best care possible, reducing the health care-related harm to the elderly and optimizing value of all, including the patients, their families and caregivers, health care providers and the health systems[4]. The patient's goals and preferences are valued, the family caregivers are supported and included in the treatment plan and there are safe and better transitions of the patients from different care settings. The systems intend to enhance the quality of care for the elderly and optimize the value of the health systems in measurable ways[5].

In an age-friendly health system, health care-related harm to the elderly is dramatically reduced and approaches zero; the elderly get the best care possible and are satisfied with their care. Value is optimized for everyone and the initiative builds upon a number of fundamental characteristics common to existing geriatric care models, including leadership committed to addressing ageism, the reliable use of evidence-based care, the use of nurses who are specifically trained and proficient in the care of older adults, high performing care teams focused on measurable outcomes, a systematic approach for coordinating care with other organizations and for engaging with the patients and their families and caregivers and a clear process for eliciting patient goals and priorities and using those goals to individualize care [6].

The implementation of age-friendly health systems would reduce the risk of harm for the elderly and improve their health outcomes while avoiding unwanted or duplicative care. In addition, ensuring the reliable execution of these interventions requires a set of foundational elements including leadership, teamwork and good information and communications systems. Importantly, the goal of the initiative is to improve the care for the elderly across all care settings: inpatient, post-acute, and in-home and ambulatory settings[7].

Based on all of the studies, an age friendly health system based on WHO's guidelines are according to the following areas: information, education and training, community based health care management systems and the physical environment[8]. This systematic review aims to identify age friendly health systems for the elderly.

2. Methods

This systematic review was reported in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) Statement[6].

2.7 Data Sources and Searches

The databases searched within included SCOPUS, ScienceDirect, Proquest, Pubmed and Google Scholar, in order to provide studies related to identifying age friendly health systems for the elderly from between 2013 and 2019.

2.8 Study Selection

The studies were selected according to the inclusion criteria. They were open access, cross-sectional and qualitative studies with elderly participants in the form of full-text articles in the English language. We excluded the studies with non-elderly participants and with poor study protocols.

2.9 Data extraction and quality assessment

All of the citations retrieved from the electronic databases were imported into the Mendeley Program. Two reviewers (BU, SNK) independently analyzed the titles and abstracts of every study retrieved from the literature search to identify potentially eligible studies. The full text of the remaining studies was obtained for further examination. The last review was conducted by the first reviewer (TPD).

In this article, the authors conducted a relevant systematic review of the data using the keywords "age friendly", "health system", "elderly". The data of the studies was independently extracted by the same two reviewers by including the first author's name, the year of publication, the sample size, the study design, the duration of the trial and the general characteristics of the participants (age and gender). A detailed description of the age friendly health system was also included. The WHO's guidelines were the main outcome of this systematic review.

3. Result

3.1 Study Size

We conducted the identification of 567 studies using database sources. Seven duplicate studies were excluded, continued by 401 studies due to containing non-elderly participants, being irrelevant studies or using poor study protocols. The 6 remaining studies were included in the current systematic review.

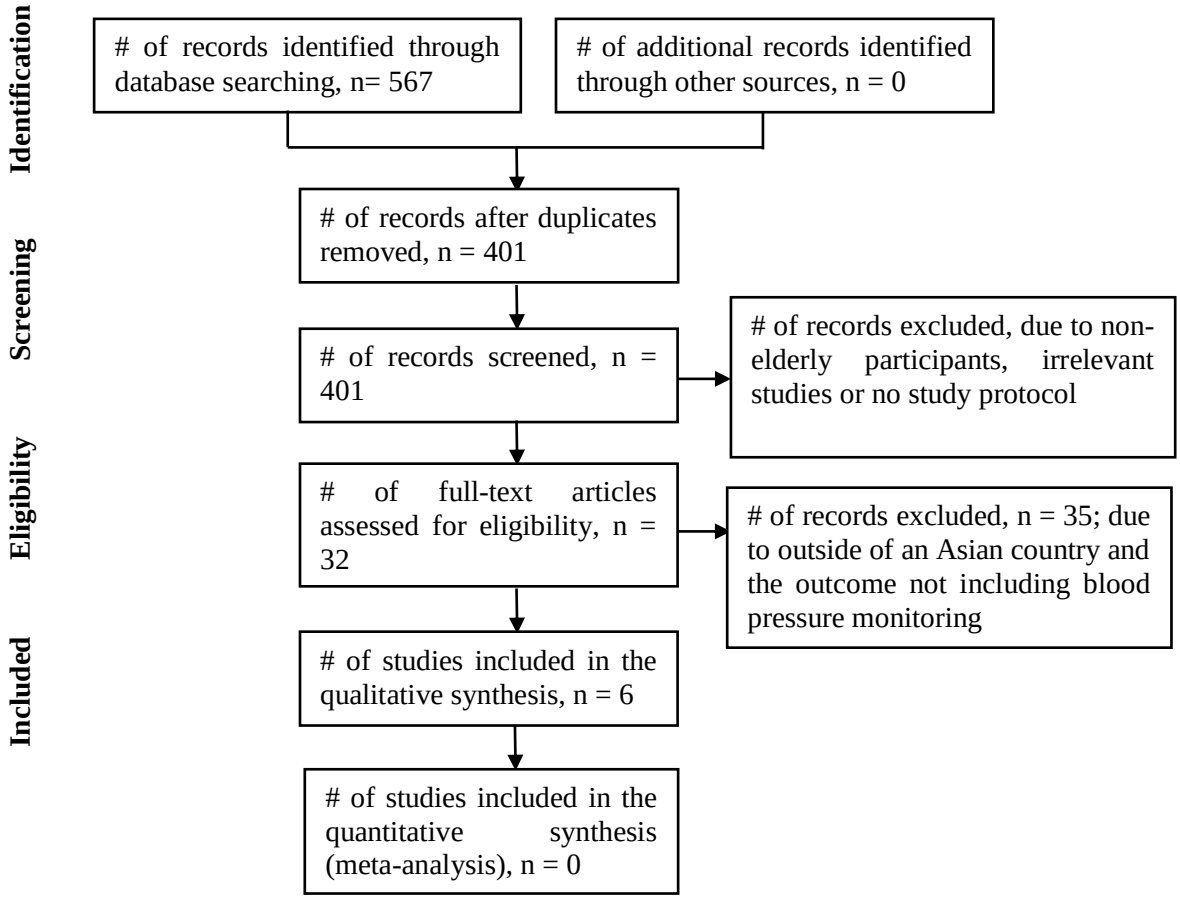

Figure 5. Flow diagram of the literature sources used to identify age friendly health systems

3.2 Study Characteristics

The data was extracted from each study according to the requirements. The extracted data included the characteristics of the study, the characteristics of the age friendly health system, the characteristics of the results and the summary of the results.

The standard protocol was used for selecting the studies as suggested in the systematic review method guide, PRISMA. The steps taken were:

1. The removal of duplications.
2. The examination independently of the titles, abstracts and keywords and deleting citations that were not relevant according to the inclusion criteria.

3. If the title and abstract are likely to be in accordance with the inclusion criteria and the objectives of the systematic review, then the next step was the selection of journals where the full text was available.
4. The final step was the selection of the articles.

PHP-806

3.3 Description of the study characteristics, including the outcome, measurement, interventions and results.

	First Author (Year)		**Study Characteristic** **1. Design** **2. Sample**	**Outcome and Measurement**	**Intervention** **1. Treatment group(s)** **2. Type, dose, frequency and administration method** **3. Duration per session/Total number of sessions/Total Duration of intervention**	**Results**
1	Alhamdan AA *et al* (2015)	Evaluation of the health care services provided for older adults in primary health care centers and their internal environment. A step towards creating age friendly health centers	1. Cross-sectional 2. 564	Age-friendly PHCC toolkit of the WHO	-	The clinical management of patients reached an acceptable level. However, the aspects related to information, physical barriers and transportation must be improved
2	Cramm, Van Dijk, & Nieboer, (2018)	The creation of age-friendly environments is especially important for frail older people	1. *Cross-sectional* and Qualitative 2. Sample a. *Cross-sectional* : 558	*Age friendly cities with 8 domains according to the WHO framework*	-	7 of the 8 domains of the WHO Framework (transportation, housing, social participation, respect and social approval, civic participation, communication and information and community support and health services) show significant results. Interviews were

			b. Qualitative : 32				conducted with weak and non-weak elderly people.
3	Xie, (2018)	Age-Friendly Communities and Life Satisfaction Among the Elderly in Urban China	1. Survey 2. 9965	*Age-Friendly Community Indicators. Housing. Local amenities. Community services. Social inclusion*	-		Age friendly communities affect the subjective well-being of the elderly and this significantly increases the life satisfaction of the elderly.
4	S. Park & Lee, (2017)	Age-friendly environments and life satisfaction among South Korean elders: person - environment fit perspective	1. *Cross sectional* 2. 1657	*Indicators from the World Health Organizations (WHO) framework for age friendly cities (ACF)*	-		Consistent with the environmental docility hypothesis, the members of the most vulnerable subgroup in the Korean context are older adults who are living alone and the poor, who are more likely to have higher life satisfaction when they have higher levels of support in their physical and social environments. Interestingly, a higher level of support in the service environment was related to lower life satisfaction for this subgroup.
5	Wang, Gonzales, & Morrow-Howell (2017)	Applying the WHO's Age-Friendly Communities Framework to a National Survey in China	1. *Cross-sectional* 2. 453	*The CHARLS community survey contained the questions used*	-		In the domain of applying the WHO community and health service Age-Friendly Communities Framework, there was a significant effect on both the rural (0.08) and urban (0.46) populations. Applying the WHO Age-Friendly Communities Framework is needed

							for rural elderly people.
6	Woo, Mak, & Yeung (2013)	Age-Friendly Primary Health Care: An Assessment of Current service Provision for Older Adults in Hong Kong	1. Qualitative 2. 12 hospital staff working in a public system, consisting of geriatrics (5), nurses (4) and health staff (1)	-	-		Age-Friendly Primary Health Care was able to improve the Current Service Provision.

PHP-806

4. iscussion

The age-friendly environmental factors may have something of an effect on the health results. Several factors that may hinder the health care of the elderly have been found to be related to physical difficulties when accessing
the health centers in terms of both their structure and in the transmission of information[4].

Finally, 7 out of the 8 domains of the WHO Framework (transportation, housing, social participation, respect and social approval, civic participation, communication and information, community support and health services) showed significant results. Interviews were conducted with both weak and non-weak elderly people. The results showed that gender, age and especially fragility were related to the environmental characteristics. The elderly who were aware of their fragility admitted that they needed an age friendly environment[9]

Age friendly communities affect the subjective well-being of the elderly and significantly increase the life satisfaction of the elderly as well[10]. Age friendly environmental characteristics include the modification of the environmental resources that can improve the well-being of the psychology of the elderly.

According to the WHO, the community and health service Age-Friendly Framework had a significant effect on both rural (0.08) and urban (0.46) populations. The WHO Age-Friendly Communities Framework is needed for the rural elderly [11]. The Age-Friendly Primary Health Care was able to improve the Current Service Provision [3].

5. Implication

The purpose of this systematic review was to identify age-friendly health system. Based on the results of the analysis, there were many positive effects provided by the age friendly health system for the elderly. Based on a review of the journals selected, it was found that the elderly need an age friendly health system according to the reviewed environmental characteristics. This could increase the well-being of the elderly,

6. Conclusion

An age-friendly health system can support the elderly health concerning chronic diseases, well-being, and ability to age in place. Based on this data, we fully recommend the use of age friendly health systems for the elderly applied to elderly health services.

Email: firman.oswari-2017@fkp.unair.ac.id

ABSTRACT

Preoperative education interventions are effective in informing patients who undergoing surgery, thus can reduce anxiety and postoperative fear. This systematic review aimed to identify effects of preoperative education on anxiety undergoing surgery, follow the PRISMA statement guidelines. In this study, articles taken from some electronic data bases such as Scopus, PubMed, and Science Direct from 2014 – 2018. All included studies were access base on (1) random controled trial, (2) case-control studies and (3) quasi experimental. There are 15 selected articles from 2589 articles included in this study. Preoperative patients are given education with written, verbal and video methods. Most measurements of anxiety results using STAI. Preoperative education interventions are very effective to reduce anxiety levels in patients undergoing surgery.

Keywords: education, preoperative, anxiety

1. Introduction

Surgical patients often experience anxiety before surgery, which is believed to start immediately after the surgical procedure is planned and they are made aware of it [1]. Patient knowledge deficits regarding anesthesia and the role of the anesthetic in care can contribute to their fear and anxiety [2]. Increased anxiety may lead to pathophysiological responses such as hypertension, an increase in pain sensitivity and the refusal of the surgical procedure [3].

Previous patient surveys about anesthesia revealed that as many as 8-55% of patients were extremely scared during anesthesia [2]. Patients undergoing orthopedic surgery felt anxiety by as much as 52% out of the total sample of 90 people [3].

The effect if the anxiety didn't immediately resolve itself was physiological changes occurring such as fear and uncertainty that affect the prognosis of the disease [3] and healing [4]. During the pre-surgery stage, the patients are exposed to a variety of conditions that trigger the anxiety condition such as incisions, needles, going into the operating room and anesthesia and it is also associated with a lack of awareness or control, medical errors and the ongoing consequences of the surgery, discomfort after surgery, privacy, quality of care and so on. Anxiety can change the patient's thoughts, cognitive, feelings and behavior [5].

Surgical preparation and postoperative care are very important in order to reduce the risk factors and complications. Health education provided to operating patients is a standard of care that must be done to fulfill their belief in healing. Preoperative education can also correct misunderstandings, give

the patients a sense of control over their role and responsibilities in terms of their care and it can contribute to positive surgical outcomes [6].

Many studies conducting an assessment of preoperative health education on anxiety levels used the face-to-face method, video and booklet methods, but there had been no previous systematic review discussing the effect of preoperative education on anxiety for those undergoing surgery so then health care workers can provide these interventions to the patients undergoing surgery. The purpose of this systematic review was to determine the effect of preoperative education on the anxiety level of patients undergoing surgery.

2. Method

This systematic review used a guide based on the Preferred Reporting Item for Systematic Reviews and Meta-Analyzes (PRISMA) guidelines ***[7].***

2.1 Literature search strategy

Using electronic databases, such as Scopus, PubMed and Science Direct with the publication copyright between 2014 and 2019, the search was carried out with "education", "preoperating" and "anxiety" as the main keywords. All of the databases were searched from 2014 through to January 2019, using the PICOS framework to identity the keywords themselves.

2.2 Inclusion and exclusion criteria

The inclusion criteria for this systematic review were English language journals and where the research subject was adults undergoing surgery. Randomized controlled trials, quasi-experiments and pilot studies were included in this review. The main outcome measured was the level of anxiety in preoperative patients who were older than 18 years of age.

2.3 Study selection

The titles and abstracts were independently screened by the reviewer against the inclusion criteria. The reviewer assigned the inclusion codes of yes, no or unsure. The full text articles were then obtained and assessed for eligibility. The reviewers compared the screening results and discussed any disagreements regarding the study eligibility.

3. Result

A total of 2604 articles were found using the selected keywords. Screening was then carried out by looking at the titles and abstracts obtained of the 603 articles. There were 14 articles that met the criteria of this input using the keywords "education", "preoperating" and "anxiety". The articles used were heterogeneous in terms of their research designs. There were several findings related to various pre-operative educational interventions.

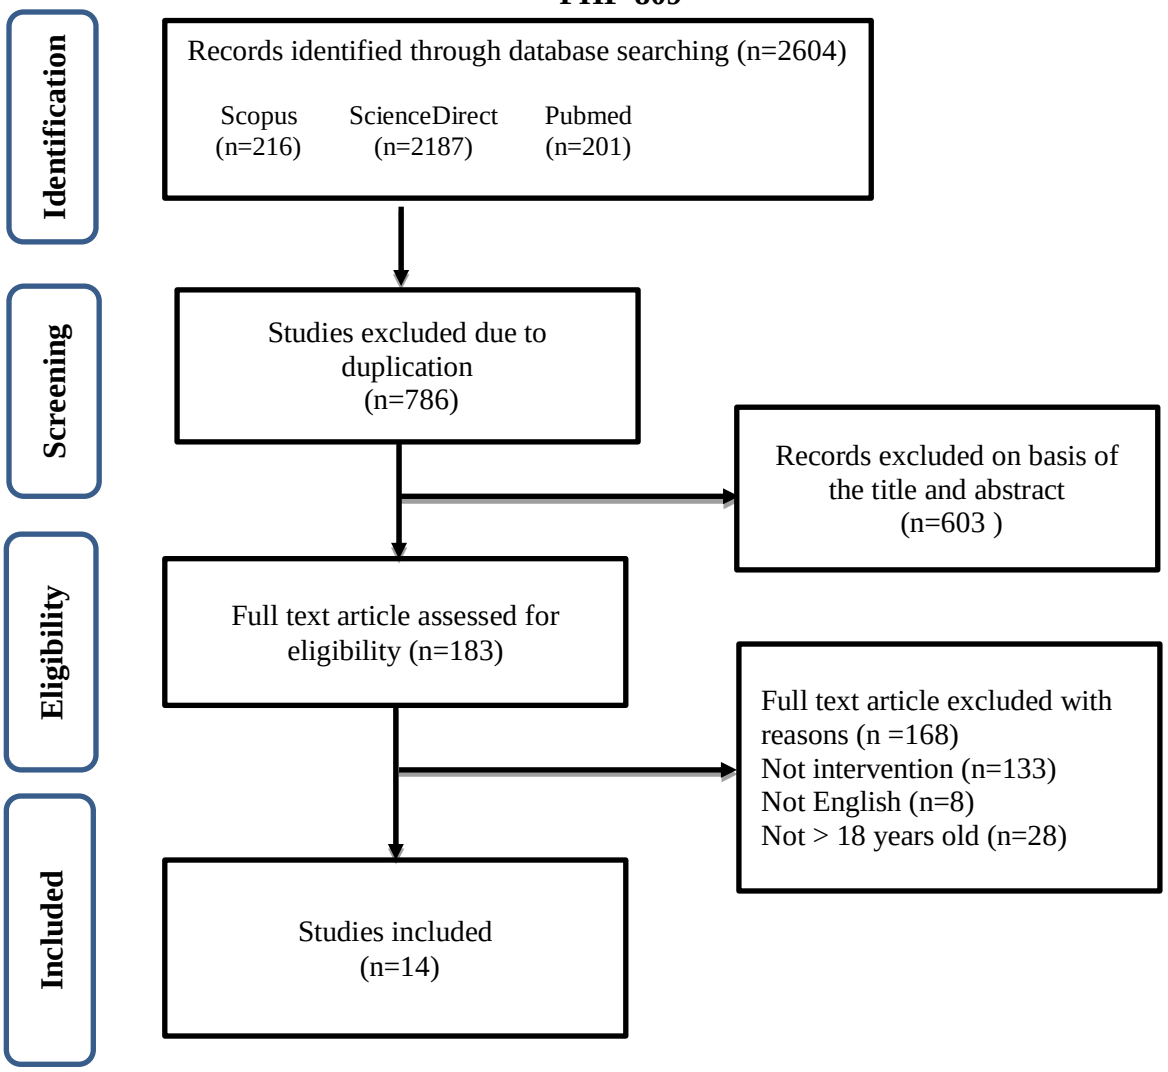

Figure 1. Study inclusion based on the preferred reporting items for systematic reviews

The total respondents in the selected literature were 2482 respondents in the range of 20600 - 1364 respondents per study. The respondents were between the ages of 18 - 60 years old. The PICOT table shows the characteristics and interventions carried out in the study. Some of the articles used video, booklet and multimedia methods; 14 articles were included in this review.

4. Discussion

The majority of the articles reviewed showed that preoperative education can reduce anxiety in the patients undergoing surgery. There was only one article that said that the education given to the patients scheduled for thyroid surgery using written ingredients did not affect their anxiety [6]. Some of the media used in preoperative education have also proven to be effective at reducing the patient's level of anxiety. In the patients undergoing surgery, the hemodynamic value was lower in the group receiving preoperative education compared to the group that did not receive preoperative education [8]. Likewise in cervical herniation and the patients undergoing surgery, the results of the integrated education are more effective than conventional models at reducing patient anxiety and uncertainty[4]. The video method, via a 5-point Likert Scale score for measuring postoperative satisfaction, was found to be significantly different between the two groups [1]. There were significant differences between the mean scores of the verbal booklet groups and education [5]. The instrument used in the

majority of the measurements of anxiety was STAI.

During the preoperative phase, the patients are exposed to various conditions that trigger anxiety. This condition is often because of needles and incisions, going into the operating theater, the anesthesia and the associated lack of awareness or control, medical mistakes and on-going consequences of surgery, discomfort after surgery, privacy, quality of care and so on. Anxiety can change one's thoughts, cognitive, feelings and behaviors. It is associated with postoperative pain and it has been shown that it can reduce the safety of the body and delay recovery [5]. Preoperative anxiety and fear may lead to increases in the levels of the stress hormones, resulting in undesirable metabolic responses before anesthesia, including high systemic catecholamine levels that result in increased arterial blood pressure and heart rate [8]. Preoperative anxiety has been classically related to the patient's concerns about disease, hospitalization, anesthesia and the surgery itself. Moreover, fear of the unknown is one of the most important sources of anxiety among surgical outpatients presenting in the pre-anesthetic consultation, especially before invasive surgery [8]. Short-term psychological interventions may prevent preoperative anxiety in cancer patients [8]. Preoperative anxiety has been shown to be reduced when additional anesthesia information in print and video format is made available prior to surgery [8]. Audio visual media is a type of media used in learning activities involving both hearing and sight in one process or activity [9]. The advantage of video-based education is the ability to create continuity in the data storage, easy application and cost effective [10]. Education using video or audio visual media can be as effective as using the face to face method [11]. The previous studies have shown that a preoperative education video on anesthesia can increase the patient´s knowledge about the surgical procedure and it enhances the patient's education, thus reducing preoperative anxiety [12].

5. Funding

This systematic review explains that education in the form of an intervention before the operation is very effective when it is given to reduce the levels of anxiety in the patients undergoing surgery. Preoperative education is very important to improve the health status of the postoperative patients. Media that can be used in delivering education such as videos, booklets and other multimedia have already been proven to be effective. Preoperative patients are given education with written, verbal and video methods to reduce their anxiety levels which are mostly measured using the STAI instrument. The most effective way to reduce anxiety levels is to use a combination of verbal and video methods.

FACTORS RELATED TO NURSING JOB SATISFACTION: A SYSTEMATIC REVIEW

Miranti Dea Dora[1], **Stefanus Supriyanto**[2], **Tiyas Kusumaningrum**[3]
[1]Student Program Master Nursing, Universitas Airlangga Surabaya, Indonesia
[2]Lecturer Faculty of Public Health, Universitas Airlangga Surabaya, Indonesia
[3]Lecturer Faculty of Nursing, Universitas Airlangga Surabaya, Indonesia
Email: Mahardika.putri.kaonang-2017@fkp.unair.ac.id

ABSTRACT

Job satisfaction is an important thing related to nurse performance, also related to increasing patient satisfaction. The purpose of this article is to identify factors that are related to nurse job satisfaction. The author conducts a review of the relevant literature using the keywords "job satisfaction, nursing, factors". The source of the articles used is obtained from the search through limited Scopus starting from 2015 to 2017. The results of these reviews produce factors related to nurse job satisfaction namely leadership style, praise from superiors, autonomy, circumstances, work environment, desire to keep working, aggression in the workplace, psychological stresses, social capital, organizational commitment, nursing organizational culture, nurse collaboration - doctors, practical safety, long shift, quality nurse's life, supervisor's emotional support, social support, work involvement, and racial differences.

Keywords: Job satisfaction, nurse performance

1. Introduction

Health care facilities have the main task of providing quality and safe health services for the community. Nurses provide a huge contribution by facilitating the comprehensive health services offered to the clients. The nurses must be professional when carrying out their work in terms of providing nursing care. With this work, the nurses are expected to get job satisfaction. The nurses can be interpreted as human resources when providing health services in the hospitals because the number of nurses is dominant compared to the other types of health worker. Nurses are professions that provide continuous health services and they often interact with patients over 24 hours. Therefore, nursing services contribute to determining the quality of care for a hospital. In terms of improving the quality of the nursing services provided, one of the methods is by trying to improve the performance of the nurses. Satisfaction is a model of the gap between expectations (supposed performance standards) and the actual performance obtained by the consumers or customers. Job satisfaction is a positive or pleasant emotional state in work that is related to welfare[4]. Job satisfaction is a multi-dimensional concept that is influenced by several factors such as demographic characteristics, organization-related variables and other turnover relationships.

2. Methods

This systematic review was reported in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) Statement[16].

2.10Data Sources and Searches

The literature used in this Systematic Review consisted of 3 electronic databases, namely Scopus, MEDLINE and CINAHL. The search was limited to the last 4 years between 2015 and 2018.

2.11Study Selection

The protocol standard for selecting the research studies was PRISMA followed by screening to remove any duplication. Then the researcher conducted title-based and abstract screening for the elimination of articles with irrelevant topics. The articles found were then identified based on the inclusion criteria (eligibility criteria) that were determined by reading the text as a whole. Articles that met the criteria were used in the systematic review.

Literature Search

In this article, the authors conducted a relevant systematic review in variously of data used the keywords “job satisfaction”, “organizational factors” and “nursing”.

3. Result

3.1 Study Size

A total of 13 articles were identified to be included in this systematic review. Searching through the Scopus, MEDLINE and CINAHL found 338 articles. After the duplication screening, there were 285 articles left. Of these, 257 articles were eliminated because of irrelevant topics. The full text article identified and eliminated as many as 25 articles on the grounds that it was a review article, the publication was not in English, the research design was not correlational and the outcomes are irrelevant. A total of 13 articles met the criteria for a systematic review.

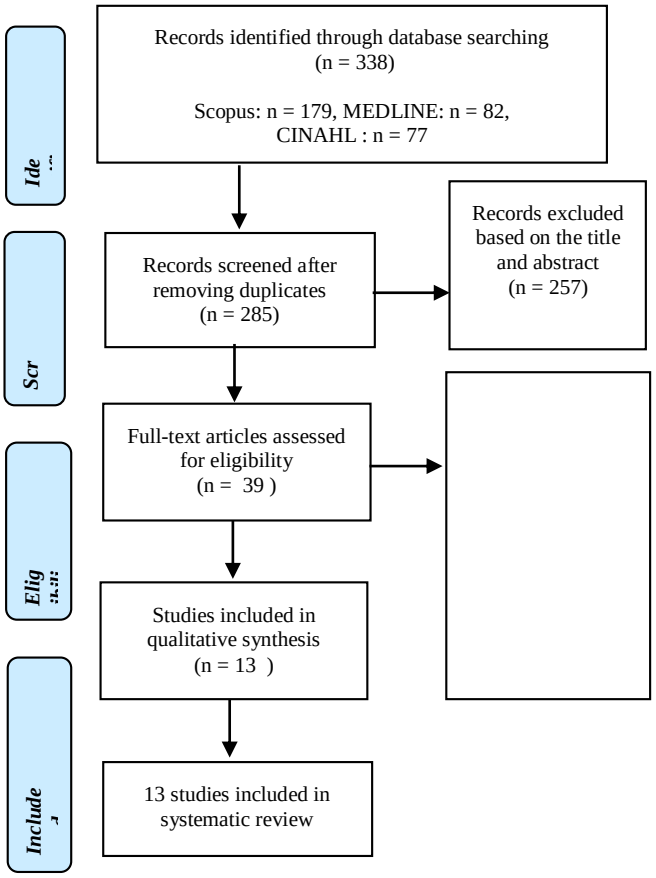

Figure 1. Flow Diagram

3.2 Study Characteristics

The total of 13 studies reviewed were published between 2015 - 2018 and they were conducted in 13 countries: South Korea, European Union, Italy, Palestine, United States, Iceland, Jordan, the USA, Iran and Belgium. The research design of the 13 selected articles was a cross sectional design. The nurse participants consisted of nurses who worked in hospitals. The outcome of the articles reviewed consisted of 2 groups of factors related to nurse job satisfaction, namely individual factors and organizational factors.

4. Discussion

Nurses are a professional that provides continuous health services and they often interact with patients around the clock. Therefore, nursing services make a big contribution in determining the quality of care provided by a hospital. In improving the quality of nursing services, one of ways to do this is by trying to improve the performance of the nurses themselves. Job satisfaction is an important thing related to nurse performance and it is also related to increasing patient satisfaction. The purpose of this systematic review was to explain the factors that are related to nurse job satisfaction so then they can be used get important knowledge in order to optimize nurse performance.

The research examined in this article all used descriptive cross-sectional methods to determine the factors related to nurse job satisfaction. The respondents in this research review were nurses in several

hospitals in various countries. The research was conducted to determine the factors related to nurse job satisfaction, namely leadership style, praise from their superiors, autonomy, circumstances, the work environment, workplace aggression, psychological stresses, social capital, organizational commitment, organizational culture, collaboration, practical safety, shift length, supervisor emotional support and social support.

The role of the supervisor's emotional support refers to the employees' beliefs about the extent to which their supervisors care about them and value the contribution of their work. Employees will see favorable or unfavorable treatment from their supervisor as an indication of perceived and accepted support. Supervisor support is recognized as an important source of employee satisfaction. Such support is often divided into two, namely instrumental support and emotional support. Supervisors provide instrumental support by providing information related to their work and feedback. Supervisors can also provide emotional support to help their employees manage their emotions. Such support includes sympathy, attention, comfort and encouragement. At the individual level, supervisor emotional support is positively related to job satisfaction. For supervisor emotional support at the group level, there is a positive relationship between job satisfaction and work involvement at the individual level[9].

In the past few decades, there has been an increase in the number of hospitals that apply 12 hours per shift, namely day and night. However, a 12 hour shift or more significantly allows for poor quality care and a decrease in patient safety when compared to the nurses who work an 8 hour shift. In addition, it also increases the error rate when working a 12 hour shift compared to shorter shifts. This is because working continuously without adequate rest between shifts can increase fatigue and this can pose a safety threat[2].

As a diverse health workforce can encourage greater cultural health, better service support and diverse population cultures, it should also be associated with greater job satisfaction in care. Nurses who are of a minority face more barriers to promotion and progress in their careers than white nurses[3].

Job satisfaction in each of these studies was measured using several questionnaires, including the *JSS* (*The Job Satisfaction Scale*)[11,[7], *Global Job Satisfaction* by Shepard[[8], the *General Job Satisfaction Scale*[6], Sheingold and Sheingold's questionnaire [10], *the Organizational Satisfaction Questionnaire* by Cortese[1], the *Job Descriptive Index / Job in General* (*JDI/JIG*) [11] and *the Index of Work Satisfaction* by Cortese (2007) and Stemps (1998)[[3].

This systematic review has implications for nursing practices. The results of several of these studies are intended to improve the working conditions through effective measures, such as flexibility in the work shifts, utilizing the nurses' skills to the maximum, the appropriate division of shift hours, scheduling, adequate staff, good quality collaborations with doctors, clear definitions regarding their job descriptions and assignments, reward systems / work praise, an appropriate leadership style, good quality of life, the determination of appropriate wages, high practice safety, encouraging nurse participation in organizations and decision making, creating a satisfying work environment, paying attention to the emotional responses of the nurses and encouraging them to keep their job.

Nursing administrators, policy makers and the heads of professional associations need to institutionalize appropriate policies and regulations to reduce the conflict between as many work and family lives as possible. They also need to develop workplace policies that target the identification, management and prevention of both work subtypes and conflict. Organizations must strive to develop

policies to balance work against cultural differences. This also requires attention and an intervention from the nurses, nurse educators, researchers, administrators and policy makers to deal with the conflict.

In addition, this study provides additional evidence of the benefits that hospitals can achieve and obtain through staff emotional support. This suggests the importance of promoting a healthy work environment through education and supervisor training to increase the support for the nurse's work and to improve the communication between the nurses and their supervisors. Therefore, this study provides valuable insights for the hospital health managers who must consider supervisor emotional support as an effective means of nurse welfare.

The aforementioned is an effort to improve the work satisfaction of all nurses, in order to influence the desire of the nurses to keep working and to prevent nurse turnover. In addition, it is important for an organization to carry out a management strategy to improve the high quality of the nurse-doctor collaboration so then the nurses are able to work effectively with their colleagues, improve the quality of the nursing services and increase the number of patients accessing quality health services.

5. Conclusion

The results of the systematic review focused on the research conducted in 15 journals about the factors related to nurse job satisfaction included leadership style, praise from their superiors, autonomy, the work environment, the desire to keep working, aggression in the workplace, psychological stress, social capital, organizational culture, collaboration, practical safety, long shifts, supervisor emotional support and social support.

3.3 Description of the study characteristics, outcomes, measurements, interventions and results.

First Author (Year)	Title	Study Characteristic	Outcome and Measurement	Results
Abdelhafiz (2015)	Impact of Leadership Style Adopted by Head Nurses on Job Satisfaction: a Comparative Study Between Governmental and Private Hospitals in Jordan.	3. Quantitative, *cross-sectional*, komparatif and correlasionaldesain 4. 225 respondents	1. Descriptive statistics for the demographic data, MLQ and job satisfaction. Differences between the groups were identified using a T-test and ANOVA. 2. Identify the strength of the relationship between 2 continuous variables with the Pearson Product-Moment correlation	1. Transformational leadership is more widely used by the nurse head managers. 2. The level of job satisfaction between the nursing staff in public hospitals is higher than in private hospitals. 3. There is a positive relationship between transformational leadership and nurse job satisfaction. 4. There is a positive correlation between transactional leadership and nurse job satisfaction. 5. There is a negative correlation between passive-avoidant leadership and job satisfaction.
Sveinsdottir, et.al (2015)	Praise Matters: The Influence of Nurse Unit Managers' Praise on Nurses' Practice, Work Environment and Job Satisfaction: a Questionnaire Study is especially important to frail older people	3. *Cross-sectional explorative survey design* 4. 383 nurses in the surgery room	1. Job satisfaction questionnaire (JSS / The Job Satisfaction Scale) 2. Professional practice questionnaires (PPS- / The Professional Scale – Opportunities and PPS-IO / The Professional Practice Scale-Importance of Opportunities) 3. Workload questionnaire (WLS / The Work Load Scale). 4. Work climate questionnaire 5. Questionnaire on organizational commitment	Nurses who receive frequent praise very often show a high level of job satisfaction.
Athey, et.al (2016)	How Important are Autonomy	3. *Cross-sectional* 4. 8311 practicing nurses licensed	1. Questionnaire on the social-	1. There is a relationship between autonomy and the working conditions.

	and Work Setting to Nurse Practitioner's Job Satisfaction ?	from several countries in the United States	demographic characteristics. 2. Questionnaire with 5 dependent variables that measures the aspects of nurse job satisfaction. 3. Autonomy aspect questionnaire (list of arrangements, approval of the utilization of nursing skills, relationship with doctors in nurse practice) 4. Questionnaire aspects focused on the working conditions (type of practice and specificity)	2. There is a significant relationship between autonomy and nurse job satisfaction. 3. There is a significant relationship between the working conditions and job satisfaction. 4. The highest satisfaction is in the indicators of nurse skills that are maximally utilized. The working conditions show a low level of relationship with job satisfaction.
Al-Hamdan, et. al (2016)	Jordanian Nursing Work Environments, Intent to Stay and Job Satisfaction	3. *Quantitative descriptive cross-sectional survey design* 4. 650 registered nurses working in 3 hospitals in Jordan	1. Questionnaire on the social-demographic characteristics. 2. Questionnaire about the nurse's work environment (The PES-NWI). 3. Questionnaire about the desire to keep working (The McCain Intent to Stay Scale). 4. Questionnaire about job satisfaction (Shepard's (1974) Global Job Satisfaction).	1. There is a positive relationship between the work environment and nurse work satisfaction. 2. There is a positive relationship between the nurse's work environment and the desire to keep working. 3. There is a positive relationship between the work environment, the desire to keep working and nurse job satisfaction.
Jaradat, et. al (2016)	Workplace Aggression, Psychological Distress, and Job Satisfaction among Palestinian Nurses : A Cross-Sectional Study	3. *Cross sectional* 4. 372 nurses	1. Questionnaire on the social-demographic characteristics. 2. Questionnaire about workplace aggression (WHO). 3. Questionnaire about psychological pressure (General Questionnaire, GHQ-30). 4. Questionnaire about job	1. Exposure to verbal aggression is most commonly received by the nurses in the workplace. Patients and the patients' families are the main source of aggression. Men have the highest percentage of exposure to aggression. Younger nurses have a higher exposure to aggression. 2. There is a relationship between exposure to workplace aggression,

			satisfaction (Generic Job Satisfaction Scale).	psychological distress and nurse job satisfaction.
Jilin Shin &Eunjooee, (2016)	The Effect of Social Capital on Job Satisfaction and Quality of Care among Hospital Nurses in South Korea	3. *Cross-sectional correlational design* 4. 432 nurses from 2 teaching hospitals in South Korea	1. Social capital questionnaire (The Social Capital Outcome for Nurse (SCON)). 2. Job satisfaction questionnaire (Sheingold and Sheingold (2013)). 3. The QoC questionnaire with Service Quality (SERVQUAL) was developed Parasuraman (1994) and revised Lee (2005) in Korean.	a. Nurses have a higher level of trust, cohesiveness, and closeness with their colleagues in the workplace but their external trust is lower in the executive section of the hospital and others. b. The level of social capital is significantly different from the length of clinical practice and the length of their career in the unit. c. There is a positive relationship between social capital, job satisfaction and service quality.
Kim, et.al (2016)	The Impact of Organizational Commitment and Nursing Organizational Culture on Job Satisfaction in Korean American Registered Nurses	1. *Cross-sectional design* 2. 163 Korean American Registered Nurses (KARNs) who work in US hospitals	1. Job satisfaction questionnaire with a job satisfaction index. 2. The nursing organization culture questionnaire was developed by Yang (1998) and modified by Lee (2003). 3. The organizational commitment questionnaire was developed by Mowday, Steers, and Porter (1779) and revised by Kim (1986).	1. Organizational commitment has the highest mean score, followed by job satisfaction and there is a slightly lower level of organizational culture. 2. There is a significant relationship between organizational commitment, the organizational culture of nursing, marital status and the workplace with job satisfaction. 3. Organizational commitment is the strongest variable related to job satisfaction, followed by organizational culture.
Galleta, et.al (2016)	*The Effect of Nurse-Physician Collaboration on Job Satisfaction, Team Commitment, and Turnover Intention in Nurses*	1. *Cross-sectional study* 2. 1,024 nurses in 72 units from three hospitals in Italy	1. Questionnaire about job satisfaction (The Organizational Satisfaction Questionnaire validated by Cortese (2001)). 2. Questionnaire about team affective commitment (The Organizational	1. There is a relationship between job satisfaction and the intention to leave with affective commitment. 2. There is a positive relationship between nurse-doctor collaborations with the team's affective commitment. 3. There is a positive relationship between

			Commitment Questionnaire validated by Pierro, Tanucci, Cavalieri, and Ricca's (1992)). 3. Questionnaire about intention to leave the unit (Hom, Griffeth, &Sellaro (1984)). 4. Doctor-nurse collaboration questionnaire (The Nursing Work Index-Revised (Aiken & Patrician, 2000)).	nurse-doctor collaborations and the level of job satisfaction with the team's affective commitment.
Morsiani, et.al (2016)	How Staff Nurses Perceive The Impact of Nurse Managers' Leadership Style in Terms of Job Satisfaction : a Mixed Method Study	1. *Mixed Method Study* 2. 87 staff nurses from the Department of Internal Medicine from 3 acute hospitals in Northern Italy (Genoa, Modena and Florence)	1. The Multifactor Leadership Questionnaire (MLQ) questionnaire by Bass and Avolio (1995) based on the Full Range Leadershio Development Theory. 2. Focus group with semi-structured questions.	The leadership style that is mostly related to nurse job satisfaction is transformational leadership style
Hurtado, et.al (2017)	Nurses but not Supervisor Safety Practices are Linked with Job Satisfaction	1. *Cross-sectional study* 2. 1052 nurses in 94 units from 2 hospitals in Boston	1. Job satisfaction questionnaire (response variable). 2. Safety practice questionnaire (predictor variable).	1. The value of supervisor safety practices is better than their unit staff. 2. Job satisfaction was higher for the nurses in units with better safety practices than for the nurses in units whose average safety practices were lower.
Jane Ball, et. Al (2017)	Cross-Sectional Examination of The Association Between Shift Length and Hospital Nurses Job Satisfaction and Nurse Reported Quality Measure	1. *Cross-sectional* 2. 2917 nurses from 12 European Union countries and 3 international partner countries outside of Europe	The questionnaire was closed (practical environment, staff and number of patients at the last working shift, quality and safety measures, frequency of side effects, no final treatment, job insecurity and working hours).	a. The duration of the shift is significantly related to the low quality of nursing services. b. There is a significant relationship between job dissatisfaction and the length of the nurse's shift. c. The cancellation of the remaining care measures in higher levels for nurses working> 12 hours.
Pohl &Galleta (2017)	The Role of Supervisor Emotional	1. *Cross-sectional study*	1. Job satisfaction questionnaire (The Index of Work	There is a significant relationship between the supervisor's emotional support

	Support on Individual Job Satisfaction : a Multilevel Analysis	2. 323 nurses from 3 hospitals in Belgium	Satisfaction (Cortese, 2007; Stamps, 1998)). 2. Work engagement questionnaire (Utrecht Work Engagement Scale / UWES: (Schaufeli et al., 2006)). 3. Nurse's emotional support questionnaire; The Perceived Organizational Support (POS) scale (Eisenberger, Huntington, Hutchison, & Sowa, 1986)	and the level of nurse job satisfaction.
Orgambídez-Ramos & Almeida (2017)	Work Engagement, Social Support, and Job Satisfaction in Portuguese Nursing Staff : a Winning Combination	1. Cross-sectional study, descriptive, correlational 2. 215 nurses from 3 hospitals in Portugal	1. Social support questionnaire (The Job Content Questionnaire (JCQ)). 2. The Work Scale (UWES) questionnaire. 3. Questionnaire about job satisfaction (The Job Satisfaction Scale (JSS))	1. There is a positive relationship between social support and job satisfaction. 2. There is a positive relationship between work involvement and job satisfaction.

INTERVENTIONS FOR IMPROVING MANAGEMENT OF HYPERTENSION IN THE COMMUNITY SETTING: A SYSTEMATIC REVIEW

Z 'Ulya[1], A N Izzati [1], I Choliq1, and S Tauriana[1]
[1]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
Email: zakiyatul.ulya-2018@fkp.unair.ac.id

ABSTRACT

Hypertension management is an effort used as a comprehensive control of hypertension. These efforts need to be carried out routinely and consistently in order to maintain the patient's health condition. Some interventions were carried out to improve hypertension management capabilities on patients with hypertension. This study aimed to examine what interventions could be done to improve hypertension management in the community. Articles were collected by implementing five stages i.e. (1) determining the topic, (2) identifying keywords, (3) identifying articles in accordance with the research topic, (4) identifying articles based on predetermined inclusion criteria, (5) analyzing search results. The search results found 15 relevant articles from Scopus, EBSCO, and Proquest with experimental designs and diverse interventions to improve hypertension management. There were several interventions used to improve hypertension management implementing both electronic media and manual to involve families and groups such as follow-up from health workers, health coaches, group-based programs, family members based, telehealth, and empowerment.

Keywords: self-management, hypertension, community

1. Introduction

Hypertension is one of cardiovascular diseases that is still a health problem globally. The prevalence of hypertension is estimated to increase every year. The data collected by the American Heart Association in 2017 showed that the number of patients with hypertension is increasing for men aged 20 - 44 years, from 11% to 30%, while the number of women who are younger than 45 years old has risen from 10% to 19% [1]. The prevalence of adults with hypertension is estimated to reach 1.56 million by 2025.

Hypertension is often called the silent killer because it is an unexpected disease with uncertain causes. It can cause potential complications if it is not controlled properly. Uncontrolled hypertension can lead to complications that can be compared to other diseases. It can even cause death. The WHO estimates that 7.4 million people die each year due to the complications of coronary heart disease while 6.7 million people die because of stroke [1]; 9.4 million people die each year in the world caused by a complication of hypertension [2]

Although hypertension develops slowly and surely, some efforts can be undertaken to control blood pressure. The management of hypertension can be done as one of the efforts to control hypertension in order to prevent the complication of other diseases [3]. The management of hypertension includes giving a combination of drugs and enhancing the lifestyle modifications i.e. limiting their salt intake, exercise, having a rest, controlling stress, regular treatment and checking

their blood pressure routinely [1] . Low awareness and poor willingness to improve their health condition is still a problem when it comes to managing hypertension [4] .

We synthesized several studies focused on the interventions that can be done to improve the management of hypertension and who could be involved in this effort. We reviewed quantitative type research to examine which interventions could be used to improve hypertension self management.

2. Methods

2.1 Literature search strategy

This study started through a search for articles in the Scopus, Proquest and Ebsco databases that took place February 8th through to February 23rd. The articles were limited to the last 5 years for publication, from 2014 to 2019, with keywords such as "self-management" AND "hypertension" AND "community". The studies were also limited to the areas of nursing articles written in English.

2.2 Inclusion and exclusion criteria

2.2.1 Study Design. The articles were chosen through an experimental study that was published in the reputation database that was reviewed in English.

2.2.2 Population. The population criteria of this study were patients with hypertension aged greater than or equal to 18 years old, inclusive of both men and women.

2.3 Intervention

The actions given were in the form of nursing interventions in the patient's community. Some of the articles formed a class for the purpose of health coaching, education and the simulation of a lifestyle that can be applied to the patients. All of the interventions involved the families, groups and the sufferers in order to improve the management of hypertension in the study group. In contrast, in the control group, only standard interventions such as the provision of knowledge without any other intervention that could support the expected goals were implemented.

2.4 Clinical outcomes

The criteria of the results expected from intervention were measured using the Hypertension Self-Management Form score and a blood pressure monitor.

3. Results

3.1 Selection Criteria and Process

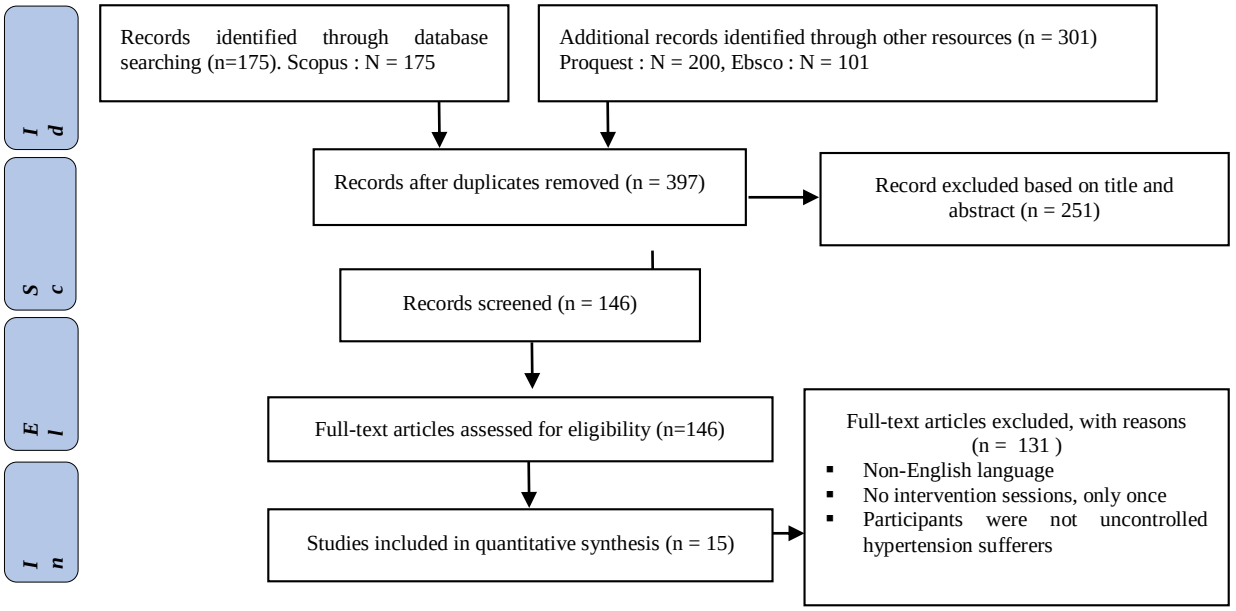

Figure 1. PRISMA study flow diagram

The selection of the articles was based on a predetermined topic, related to the nursing interventions in order to improve the management of hypertension in the community area. After obtaining 476 articles that matched the keywords, the reviewers filtered the editorial titles in order to find out if there were duplicate journals. After deleting the duplicate journals, the reviewer sorted out the articles according to the predetermined inclusion and exclusion criteria. Next, the reviewer read the full text to ascertain whether the articles were in accordance with the systematic review that would be done by the reviewer. There were 15 selected articles: [5], [6], [7], [8], [9], [4], [10], [11], [12], [13], [14], [15], [16], [17] and [18] . These articles were in accordance with the criteria expected by the reviewer (Figure 1). The total respondents involved in this systematic review were 2.731.

3.2 Kind of Intervention

The interventions carried out in this systematic review consisted of several types: health coaching [5] [6]; [10], mobile phone monitoring [7]; [8]; [11]; [13]; [14], an education program and improving the management program of hypertension overall [9]; [12]; [16]; [17]; [4]; [15]. All of the interventions were carried out by the people around the patient and they involved the patients directly so then they were active in the programs. The supervision was carried out by nurses and other health workers.

3.3 Result Measurement

There were several types of instrument used to measure hypertension self-management abilities after being given the intervention: The Perceived Competence Scale for Hypertension Self-Management [5], blood pressure [16]; [6]; [8]; [10]; [18], the Morisky Medication Adherence Scale (MMAS-8) [6]; [18], the Hypertension Self-Management Form [4], the Short-form Chronic Disease Self-Efficacy Scale [7]; [4] and self-care behavior [9]; [11].

Table. 1 Type of Study in the Setting up of the *Systematic Review*

Author	Type of Study	Participants	Intervention	Outcome
[5]	Quasi-experimental	146 participants	All of the participants got information about hypertension, physical activity, nutrition, medication management, stress management and an individualized action plan. They were measured at 8 weeks and 16 weeks.	Health coaches for hypertension control (HCHC) could improve the self-management of hypertension among the populations
Yatim et al. (2018)	Quasi-experimental	45 participants	Each educational program about Hypertension Self-Management Education was given for about 2 hours weekly	HSME can improve the knowledge and practices about management hypertension
[19]	Cluster randomized trial	554 participants	The patient and their family were trained and the family had the task of supervision	Family supervision had a positive effect on monitoring blood pressure and taking the antihypertensive medication

Author	Type of Study	Participants	Intervention	Outcome
			related to antihypertensive medication, blood pressure monitoring and seeking professional health care	
Wu et al. (2018)	Quasi-experimental	477 participants	The intervention of Taking Control of Your Blood pressure (TCYB) given through a phone coaching program for 12 months	There was an increase in medication adherence and controlled diastolic pressure
Zhu et al. (2017)	Quasi-experimental, a single-blind randomized controlled trial	134 participants	The study group got a 12 weeks intervention in the form of nurse-led hypertension management: i.e. the delivery system design, decision support, clinical information system and self-management support	1. Decreased blood pressure of the study group 2. Increased self-care of hypertension in the study group
Kim et al. (2016)	Quasi-experimental	95 participants	A wireless self-monitoring program about health behaviors, medication adherence and the control of blood pressure given for 6 months	1. Increased motivation and the management of hypertension 2. Improved health behavior in the patients with hypertension
Shin et al. (2016)	Quasi-experimental,	77 participants	12 month intervention through an	The ability of the management of hypertension increased

Author	Type of Study	Participants	Intervention	Outcome
	pre-test-post-test controlled design		Empowerment Program for Self-Management (EPSM) given to the participants	among rural older adults
Kilic (2018)	Quasi-experiment, pre-test-post-test	155 participants	An educational program based on the Roy Adaptation Model supported by the Hypertension Management Guide for 1 hour weekly completed in 6 weeks	4. Patients awareness about hypertension increased 5. Improving the health-promoting lifestyle
Otubuah (2018)	Quasi experimental, pre-test-post test	300 participants	There were 3 sessions every week for 4 weeks on the intervention about health coaching in the self-management hypertension of blood pressure and medication adherence	1. Patients can control their blood pressure 2. Medication adherence was improved by this intervention
Calano et al. (2019)	Quasi-experimental, one group pre-test post-test design	50 participants	Blood pressure monitoring, health education, motivational interviews and house to house visits every 2 weeks for 2 months	This intervention can improve knowledge, motivation, adherence and blood pressure control
Jung & Lee (2017)	Quasi-experimental	64 participants	Intervention of eHealth Self Management based in the	Self-efficacy, self-care behavior and social support increased in the intervention group

Author	Type of Study	Participants	Intervention	Outcome
			community for 24 weeks	
Han & Park (2017)	Quasi-experimental, a one group pre-test post-test design	23 participants	Hypertension Management Program based on Self-Efficacy (HMPS) performed for about 8 weeks	**1.** Self-efficacy didn't have a significant result **2.** Improved knowledge of hypertension management **3.** Blood pressure can significantly be controlled
Pan et al (2018)	Quasi-experimental	110 participants	Home telemonitoring for blood pressure was given for 3 months	This intervention is effective at controlling blood pressure
[20]	Quasi-experimental, non blinded randomized controlled trial	350 participants	The study group used a Hypertension Personal Control Program (HPCP) and a Home Blood Pressure Monitoring device (HBPM) for 6 month	This intervention can support blood pressure monitoring
Maslakpak et al. (2018)	Quasi-experimental, single-blind randomized controlled trial	100 participants	An educational program about the management of hypertension held in 4 months	This intervention gave a significant result in the management of hypertension

3.4 Analysis of the Intervention

3.4.1 Health Coaching. The Health Coaching program could be used in the management of hypertension. It facilitated the control of hypertension, consisting of nutrition, physical activity, smoking, stress management, medication and lifestyle [5]. It has a positive influence on self-monitoring for the management of hypertension because the health workers provided more integrated

health education, focused on the patients and they were involved in providing the patient with support for self-management. The provision of continuous health coaching and follow-ups could help the patients to maintain their hypertension management even though the program had stopped, meaning that the patient's blood pressure could be controlled properly.

The patients felt cared for and fully supported in improving their health by the provision of this program. The intervention helped them to be motivated and it made their health behavior change [10]. Its provision also helped the patients to understand the information needed when doing the admission in the class provided [6]. In addition to providing a positive influence on patients with hypertension, it also helped the coaches to understand the disease. It increased the coach's knowledge and attention to hypertension and lifestyle, so then they would not be affected by the disease [5].

3.4.2 Mobile-phone monitor. The regular monitoring of the behavior and blood pressure of patients with hypertension could help them to control their health behavior. They could interact and consult with the nurses by telephone or through an application [7] . This intervention also provided access to the patients' family and friends to encourage them to support the patent such as through blood pressure monitoring, education about hypertension and positive behavioral changes for managing hypertension [8]. In addition, this intervention could also be used by the patients who live alone. The existence of a mobile-phone monitor helped them to remember what needs to be done and it also facilitated consultation with the health workers even if not face-to-face [11]; [13]. This intervention could be used both as a reminder of the things to do and to take the patient's health record [14].

3.4.3 Program for Improving the Management of Hypertension. The program for improving the management of hypertension provided by the nurses was in the form of education, simulation, counseling and supervision. The education and counseling program provided by the nurses could help patients have a better understanding and knowledge of their current health condition. The education program provided was also not just a lecture but there were also management simulations that could be done every day so then it was easier for patients to understand [4]. The nurse also provided homework that must be completed by the patients [12]. In addition, the supervision carried out by the family also helped them when applying the knowledge obtained from the education program [17]; [15].

This intervention could be carried out by individual patients or in groups formed to facilitate the intervention. Patients with hypertension who are collected into group and given education could increase their awareness and motivation in order to perform good health behavior [16]; [9]. A program given to the community around the patients would also support them in terms of carrying out good health behavior [18].

4. Discussion

There were 15 articles about nursing interventions that can be used to improve the self-management of hypertension. Health coaching had a significant influence on improving the management of hypertension capabilities and controlling blood pressure. There were 3 studies (n = 923) that used health coaching for 16 weeks, 24 months and 4 weeks respectively. There were 5 studies (n = 753) that used mobile-phone monitor interventions for 12 weeks, 24 weeks and 6 months respectively. The last intervention obtained in this systematic review was the management program for hypertension. There were 7 studies (n = 1,004) that used a management program as a form of

hypertension intervention with the support of the family, community and the patients themselves to improve the management of hypertension on health behavior.

The three types of interventions found in this systematic review had a significant influence on knowledge, self-efficacy, motivation, self-management ability and blood pressure control. The intervention involved groups, families and health workers. The analysis of the interventions found that health workers can collaboration with the patients' family and with the community. All of the community-based programs effectively incorporate the trained family and volunteers in order to promote professional information about hypertension and coaching on the health behavior for the patients with hypertension. The patients with hypertension felt cared for and supported, so they were motivated enough to behave to promote their good health. In addition, they also found it easy to access information about hypertension, the about development of their health condition and about what needs to be done in their daily lives as an effort to control hypertension. The surrounding environment involved in systematic review interventions could become a form of supervision or control if the patient is neglectful in managing their hypertension. The follow-up was conducted at least every 2 weeks and regularly after the intervention. This could be used as an evaluation to find out whether the program really affects the patients even though the intervention itself was over.

This study had several limitations. For example, randomized controlled trials were not implemented in all of the research designs. There were a number of articles that did not have a control group, so they could not examine the extent of the influence of the intervention compared to an untreated group. The reviewers were limited to only English being used in the articles, so there might still be other interventions that could improve the management of hypertension that have not yet been analyzed because they used a language other than English.

5. Conclusion

The conclusion of this systematic review was that the management of hypertension could be improved through the interventions of health coaching, mobile-phone monitoring and the improvement of the management program of hypertension including education, simulation, counseling and supervision. In addition, these interventions could also allow the patients to easily control their blood pressure. The involvement of the surrounding environment was very important in terms of supporting the patients to do good self-management so then they could achieve better health conditions. Nurses should use some of these interventions to help to improve the ability of the patients with hypertension to carry out the self-management of hypertension and thus to reduce the likelihood of disease recurrence, the possibility of the condition becoming worse and the complications of other diseases emerging. The nurses must involve and empower the communities around the patients to support and assist the patients in carrying out good health behaviors. Evaluations also need to be done routinely to find out how the health conditions of patients with hypertension develop in the community.

EXPERIENCE OF STIGMA BY FAMILY CAREGIVERS OF PEOPLE WITH SCHIZOPHRENIA : A SYSTEMATIC REVIEW

W. Holis[1], Ah. Yusuf[1], A.S Suhardiningsih[2]
[1] Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
[2] Stikes Hang Tuah Surabaya, East Java, Indonesia
Email: willi.holis@gmail.com

ABSTRACT

Problems related to stigma don't only affect persons suffering from mental illness but also families. This systematic review sought to incorporate the experiences of stigma faced by family caregivers of people with schizophrenia. The literature review was employed the experiences of stigma faced by family caregivers of people with schizophrenia. The databases, Scopus, and sciencedirect were systematically searched. Authors independently rated the reporting of the qualitative studies included. Thematic synthesis was used to analyse the data. The search identified 329 papers. Five teen research papers met the study inclusion criteria. Being socially rejected and being oppressed by others and nine subcategories were identified during thematic analysis as pivotal factors across the experience of stigma. In being socially rejected, others do not have a desire to communicate and start or continue cohabitation with the patients and their families and distance themselves from them with fear. Identifying and highlighting the importance of psychosocial problems in family caregiver with schizophrenia will ultimately influence positive outcomes families have the unpleasant and upsetting experiences of stigma. The findings reveals the need to develop strategies to help patients and their families effectively encounter stigma.

Keywords: stigma, family, caregivers, schizoprhenia, mental disorder

1. Introduction

The prescence of schizoprhenic patients in the middle of the family often creates a burden on the family. More than 21 million persons worldwide are diagnosed with schizophrenia (World Health Organization, 2014) and in Indonesia have been reported to be 18.5 million (Riskesdas, 2018). Lack of family knowledge of mental problems makes the burden of the family complex. Aggressive behavior worsens social stigma, and increases discrimination against people with mental disorders. The social stigma in schizoprhenic patients not only has negative consequences for sufferers but also for their family members [1]. Stigma becomes a social problem when the environment gives a negative label for a person's behavior. Social stigma is strongly influenced by myths that have developed in society, including mental illness is a disease caused by God's curse [2].

As a result of such stigma, resistance attitudes develop, both in people with mental disorders and their families. Such stigma ultimately makes families feel the need to hide family members with mental disorders, and even encourage them to take pasung actions. Stigma soisal is associated as a source of shame that is embedded in individuals with mental disturbances by society. Caregivers who have kinship relationships with people with mental disorders can also experience stigma and eventually experience higher symptoms of depression [3]. Families affected by stigma will limit their relationship with friends and family so that social support received by the family will be low [3].

Study conducted by [4] specifically explores the extent to which guilt and shame contribute to the burden of caregivers. Gonyea in his research was influenced by Transactional Theory [5] which was developed by Lazarus and Folkman (1987) which showed that the cognitive assessment process mediated stressful relationships between people. Thus, variations in adaptation to the same stressors can be associated with differences in individual expectations, interpretations and evaluations of stressful events. Lazarus & Folkman (1987) classifies stressors into two domains, Personal Stresor (commitment and trust) and Environmental Stresor (every aspect outside the personal that can be a threat to one's personal condition). In the primary appraisal, the individual will determine the meaning of the event he experienced. Primary appraisal is the process of determining the meaning of an event experienced by an individual, whether the event is perceived as positive, neutral or negative by the individual. This systematic review research question is how stigma affects family life as caregivers. This systematic review aims to describe how stigma affects the lives of families of schizophrenic patients as caregivers.

2. Methods

The method used in Systematic Review begins with the selection of the topic of stigma in the family of schizoprhenic patients. Then the keywords are determined to find the articles with multiple databases such as EBSCO, Science Direct, Scopus, and ProQuest. The keywords used are "stigma", "schizoprhenia", and "family". This search is limited to the last 10 years from 2008 to 2018. Found 9 articles in Science Direct, and 320 on Scopus.

Articles were selected for review based on studies that were in accordance with the inclusion criteria. Inclusion criteria in this systematic review are English articles, stigma in families with schizophrenia patients, and research designs are qualitative studies with phenomenological approaches, case studies, ethnography, and focus group discussions. 15 best articles reviewed.

3. Result

3.1 Study Selection and Eligibility Criteria

Table 1 shows a number of studies that were screened in this systematic review. Inclusion criteria are English-language articles, stigma in families with patients with schizophrenia, and research designs are qualitative studies with phenomenological approaches, case studies, ethnography, and focus group discussions.

The following criteria are used as inclusion and exclusion criteria for this systematic review:

1) Primary results: This article should include schizophrenia (not limited to the age group studied) with a primary focus on the stigma experienced by the family.

2) Measurement of primary outcomes: This study should include a description of the stigma experienced by families with schizophrenia.

3) Study design: Qualitative studies with phenomenological approaches, case studies, ethnography, and focus group discussions. Other quantitative studies are included if the research design is explained. Articles are excluded if they are review articles, editorials,

letters, opinion papers, general practice papers, meta-analyzes, multiple publications, protocol papers only, or published outside the review time frame.

4) Language or location: Studies from all countries are included if published in English to enable a global understanding of stigma in families with schizophrenia.

3.2 Study Characteristics

The study reviewed in this article is 15 articles for stigma in families with schizophrenia. The research method is used by various articles ranging from qualitative studies with phenomenology approaches, case studies, ethnography, and focus group discussions.

3.4 Result of Individual Studies

3.3.1 Being socially rejected indicates. Being socially rejected indicates the feeling of loneliness and takes shape as a result of the unwillingness of others to communicate with the patients and their families [6]. Persons move away from the patients and their families and avoid helping them in times of need. Being socially rejected is a common sense in all or most of the patients and their families and is characterized and experienced with attributes including the feeling of being rejected, being ignored by others, others' refusal to start or continue cohabitation with the patient, or the family member and others' fear of the patient [6].

Caregivers spoke profusely about the emotional distress they experienced because of having a family member with mental illness [7].

A small number of caregivers reported negative reactions directly as a consequence of 'Others finding out', for example being labelled and avoided as a member of a 'mad house'[8]. This experience of being socially devalued simply by close association with an ill relative can also be explained using the concept of 'contamination' put forward by Goffman and taken up in later studies on family stigma [9]

3.3.2 Being opressed by other. This concept refers to that the patients' and their families' rights are violated in different situations and they encounter discrimination by others. They feel that others have an inappropriate judgment toward them and behave aggressively with them. Also, the patients and their families encounter others' humiliating and ridiculing behaviors because of the disorder. Being oppressed by others is common for most of the patients and their families and is characterized and experienced with attributes, including sadness from others' prying, encountering the aggressive behavior of others, sadness from the misjudgment of others, facing injustice by others, and being humiliated and ridiculed by others [6].

Consistent with the findings from participants with schizophrenia, narratives characterizing perceived discrimination and reduced social engagement are two important dimensions of internalized stigma experienced by family caregivers. Although no caregivers in the semistructured interviews spoke directly about their reputation being tarnished because of mental illness in the family (a scale item in the Affiliate Stigma Scale), they depicted in detail a variety of situations in which they were looked down upon or ostracized socially [7].

Particularly salient were experiences of being blamed, and critical comments and avoidance by others, which were linked to emotional distress, hopelessness and social withdrawal [8].

The extreme example of a caregiver whowas asked by villagers to kill her own daughter who had behaved aggressively to her in public illustrates the high social importance of adhering to behavioural codes of conduct [8].

4. Discussion

Few studies explore the stigma of schizophrenia using qualitative techniques, and only a few use focus groups. Family members reported discrimination against them. They felt that any discrimination towards their mentally ill relatives was also directed against them [10].

The findings of the review revealed that the patients with schizophrenia spectrum disorders and their families have the experiences of being socially rejected and being oppressed by others. In being socially rejected, others do not have a desire to communicate and start or continue cohabitation with the patients and their families and stay away from them with fear. In being oppressed by others, persons behave aggressively with the patients and their families, violate their rights, and humiliate and ridicule them with their incorrect judgment [6]

5. Conclusion

Patients with schizophrenia spectrum disorders and their families have the unpleasant and upsetting experiences of stigma and it imposes pressures and extreme difficulties on them, besides the difficulties that are related to the nature and the symptoms of the disorder.

SCHOOL-BASED PROMOTION AND PREVENTION IN DENTAL AND ORAL HEALTH: A SYSTEMATIC REVIEW

A A Adinata[1], Nursalam[1], M Triharini[1]
[1] Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
E-mail: ach.arfan.adinata-2017@fkp.unair.ac.id

ABSTRACT

Dental and oral health is an integral part of overall body health which greatly affects public health. Dental caries is the most common dental health problem in school children. The aim of this systematic review was to describe the effectiveness of school-based dental promotion and prevention studies conducted among student between 2014 and 2019. Four electronic databases were searched for effective papers using standardized search methods, and key findings of effective studies were summarized. Studies retrieved concerned dental health promotion and prevention activities was conducted in school. Key search terms were developed and used to search selected databases, which identified 956 articles. Ten articles met the inclusion/exclusion criteria and were included in the review. Of these studies, the type of oral health promotion and prevention tasks and instructions in dental and oral health was conducted varied. The school is considered an important platform for oral health promotion and disease prevention. Healthy lifestyles including regular tooth brushing with use of fluoridated toothpaste are essential to achieve better dental health of children. This can be more readily achieved when the family and schools are involved in oral health promotion.

Keywords: school-based, promotion, prevention, dental, oral

1. Introduction

Dental and oral health is very important for the health of the body, which affects quality of life. This can affect more general health conditions [1]. Dental caries are still a major health problem in most industrialized countries because it affects 60 - 90% of school-aged children and most adults [2]. In the Southeast Asia region, it affects 70% to 95% of the population. The average number of cavities, be they missing and filled (DMFT), reported in the Project database of the WHO Profile / WHO Oral Health Region for the Regional Member Countries was 1.87 in 2011[3].

Most dental caries can be prevented or even recovered well from if they are detected at an early stage and if an effective intervention is available. However, the effectiveness of oral health education and clinical prevention programs in improving oral health outcomes is still questionable. Dental health promotion can increase knowledge but it does that mean dental and oral health behaviors will be a matter of debate [4].

Socio-demographic factors, a weak belief in the importance of regular brushing and joint events of general health risk behavior are identified as the possible risk factors for poor dental health status and/or poor oral health behavior [5,6]. Many low-income children do not have access to oral health services and community interventions [7]. The promotion and prevention of dental and oral health has been carried out supported by a recent systematic review. It shows strong evidence that dental and oral health can be improved by promoting and preventing models of psychological behavior change as a basis for the intervention [8]. Health education usually uses various methods and the media involved is varied, so each method and media used will produce different results. Evaluating the various types of promotions and the prevention of dental health through various methods and media is an important part of finding out the most effective forms of promotion so then they can be used as part of health education programs in schools.

Across the world, the school is considered to be an important platform for the promotion of oral health and disease prevention. This is as the school environment, with a comprehensive approach, can be integrated and participatory related to the promotion of oral health which may be the most effective at reducing the incidence of dental caries in children. A healthy lifestyle, including brushing your teeth regularly using fluoridated toothpaste, is very important to achieve better dental health in children. This can be more easily achieved when both the families and schools are involved in oral health promotion [9,10]. The main aim of this review was to systematically examine all of the relevant evidence that might explain the promotion and prevention of dental and oral health carried out in schools.

2. Research methods

2.1 Eligibility Criteria

Types of Studies: the selection of the studies was focused on randomized controlled trials or cluster randomized trials and pre-test-post-test. The search was not limited by state because the need for promotion and prevention of oral health is universal. However, the articles entered were limited to English. *Type of Participant*: school children aged 2-14 years in both public and private schools. *Type of Intervention*: studies that implement a promotion and prevention that was effective at improving the dental and oral health in schools. *Type of comparison*: studies comparing the participants who were given a promotion and prevention in relation to oral and dental health compared with those not given the intervention. *Type of outcome*: the research was chosen which leads to beneficial results obtained from education and health interventions that educate and improve on dental and oral health.

2.2 Information Sources

The systematic exploration of the existing literature on the promotion and prevention of oral health in schools was done by searching the computerized electronic databases for relevant studies, including PubMed, Science Direct, SAGE Journal and Scopus. They were searched for English language articles between 2014 (January) and 2019 (February).

2.3 Data Collection Process

Duplicates will be deleted using the Mendeley duplicate identification tool and then manually as needed. The remaining studies will then be filtered into 2 stages. The first phase will consist of the title and screening of the abstracts. Any studies that are not set in a school and not including health results will be removed in this phase. The second stage, full-text screening, will be carried out independently, which will follow the prescribed inclusion criteria. The search results and screening process will be presented in the study flow diagram, following the PRISMA template[11]. The studies included will be presented in the "Study characteristics included" table, which contains the methods, participants, interventions, their results and notes.

2.4 Search Strategy

This systematic review was conducted to identify and explore the various ways of promoting and preventing dental and oral health carried out in school-aged children in the school environment, both in terms of awareness and in terms of the behaviors related to health and health outcomes.

Table 1. Search strategy of this study

In [Title]	In [Title, Abstract, Keyword]
((("Oral Health/education"[Mesh]) AND ("Oral Health"[Mesh] OR "Health Education, Dental"[Mesh])) AND "School Health Services"[Mesh]) AND "Health Promotion"[Mesh]	"(Effectiveness[Title,Abstract, Keyword])" OR "(Effect[Title,Abstract, Keyword])" OR "(Impact[Title,Abstract, Keyword])" OR "(Evaluation[Title,Abstract, Keyword])" OR(Influnce[Title,Abstract, Keyword])" OR Health Education, Dental [MeSH Terms]

2.5 Data collection and managem

The standard data collection form will be used to extract the data from the included studies for the assessment of the quality of the studies and to facilitate the synthesis of the evidence. The information extracted will include the population characteristics (number of participants, age range, nationality and basic characteristics), the details of the intervention (control conditions, number of sessions delivered, duration and frequency of sessions, delivery format), the methodology (design and duration of study, characteristics of recruitment level and completion)

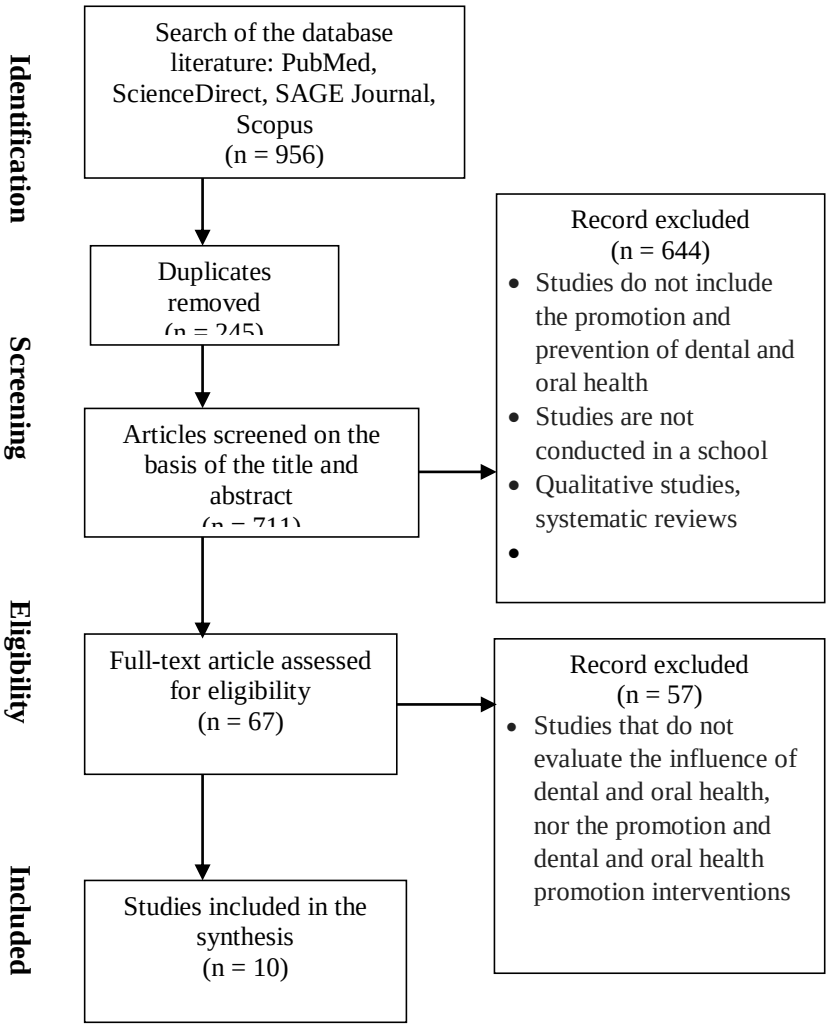

Figure 1. PRISMA flow diagram

and the results (type of outcome measure and measurement time).

2.6 Risk of bias assessment

The risk of bias was assessed using the Cochrane Collaboration tool, which encourages judgment in the following areas: randomization, quality of randomization (any important imbalance at baseline), the concealment of allocation, level of disguise, incomplete data results (due to friction or vice versa), selective reporting and other sources of bias, considering other factors such as making an the intention to handle the analysis and having a funding role in the study[12]. No study was excluded based on the risk of bias assessment.

3. Results

3.1 Study Selection

A total of 10 studies were identified to be included in the review. Searching through the PubMed, ScienceDirect, SAGE, and Scopus databases provided a total of 956 articles. After adjusting for duplicates, this dropped to 711 articles. Of these, 644 studies were discarded because after reviewing the abstracts, it appeared that the papers clearly did not meet the criteria. Among others the study did not include promotion and prevention of dental and oral health, the studies were not carried out in schools or they were qualitative and systematic study reviews. The full text of the remaining 67 articles was examined in more detail; 57 articles did not meet the inclusion criteria as described, as illustrated in Figure 1.

3.2 Study Characteristics

3.2.1 Methods. The 10 studies finally selected for review consisted of cluster randomized trials and only one pre-test-post-test. The studies were published in English where the duration of the interventions ranged from 1 month to 3 years with a follow-up that also varied from 2 weeks to 2 years in the form of 1 - 3 follow-ups.

3.2.2 Participants. The study involved a total of 8170 participants. The main inclusion criteria were that the study must have been carried out in a school and that the intervention was carried out involving school children or those in pre-school (2-16 years). The studies incorporated both public schools and private schools.

3.2.3 Interventions. Studies conducted throughout the world are not restricted by the State because the need for the promotion and prevention of dental and oral health is universal. Most of the interventions carried out are oral health education, which is delivered by professionals, trained teachers or their peers with a variety of media. Training on the brushing of the teeth is also an option as an intervention and the latest is to intervene to create a Sense Of Coherence (SOC), where the purpose of the intervention is to make the school environment a place to develop children's oral health awareness by involving the teachers, school staff and children.

Outcomes

Out of all of the studies, the results assessed partially were changes in Oral Health Knowledge (OHK), Oral Health Behavior (OHB) and child oral health-related quality of life (COHRQoL) in addition to clinical examinations such as caries events with two indices: DMFT Composite (the number of teeth decaying, missing and filling due to dental caries, scores 0–28) and OHS-Composite (number of oral cavity sextants free of dental plaque, bleeding on probing and calculus, score 0-12).

3.3 Syntheses of Result

The examination shows that the knowledge of dental and oral health, oral and dental health behaviors and quality of life related to children's oral health can be improved through oral health prevention interventions and health promotion. Nine out of 10 studies showed a positive impact. Agouropoulos [13] observed that the application of fluoride varnish tended to reduce the incidence of real caries

and early enamel lesions (p = 0.05). Blake [14] reported that the knowledge of oral health and oral health behavior increased significantly and persisted until the follow-up 6 weeks after the intervention. Freeman [15] observed significant effects on toothbrushing knowledge and fluoride health (p <.03) and that it had a limited effect on COHRQoL (p <.06).

Author, Country	Year	Design	Sample size (n)	Age (Years Old)	Interventions	Outcomes	Duration	Follow Up
Tomazoni, Brazil	2019	CRT	356	8-14	Education	Attitude and OHRQoL were increased	2 mo	2 wk and 3mo
Bardawel Syria	2018	CRT	220	10-11	1. E-Learning 2. Leaflet	Oral and gingival health was increased	3 mo	6 wk and 12 wk
Qadri Germany	2017	CRT	854	9-12	Education	Increasing dental health, Reduce caries incidence	18 mo	19 mo
Haleem Pakistan	2016	CRT	935	10-11	Education	OHK and OHB were increased		6 mo and 12 mo
Hilgert Brazil	2015	CRT	242	6-7	1. Supervised tooth-brushing, 2. Sealants 3. Treatment	Reduce caries incidence	3 y	2 y
Petersen Thailand	2015	CRT	3.706	4-6	Education.	Reduce caries incidence	2 y	-
Freeman Ireland	2015	CRT	383	7-8	Education	OHK, OHB and COHRQoL were increased	1 y	1 y
Hedman Sweden	2015	CRT	534	12-16	Education	OHK and OHB were increased	2y	-

Blake UK	2014	Pretest Post-test	1050	9-12	Education	OHK and OHB were increased	1 mo	6 wk
Agoropoulos Greece	2014	RCT	424	2-5	Education	DMFS increments	2 y (Twice a year)	2 y

CRT=clustered randomized trial; RCT=randomized control trial; OHRQoL=oral health-related quality of life; COHRQoL=child oralhealth-related quality of life; OHK=oral health knowledge; OHB=oral health behavior,

Petersen [9] observed that the DMFT and DMFS increment *("enamel and dentine")* was 1.19 and 1.91 for the control group and 1.04 and 1.59 for the intervention group. These represent a 12.6% and 16.8% reduction in caries respectively. The DMFT and DMFS increments *("dentine threshold")* were 0.26 and 0.44 for the control group and 0.19 and 0.29 for the intervention group, representing a 26.9% and 34.1% reduction in caries respectively. Haleem observed that the adolescents' oral health knowledge (OHK) in the DL and PL groups increased significantly by a single OHE session compared to their baseline knowledge ($p < 0.05$) and that the increase was sustained over 6 months. Although one-time OHE resulted in a significant improvement in the adolescents' oral health behavior (OHB) related to the prevention of gingivitis in the 2 groups ($p < 0.05$), no significant change was observed in their behavior towards the prevention of oral cancer. One-time teacher-led OHE was ineffective at improving the adolescents' OHK and OHB. The oral hygiene status (OHS) of the participants in all 3 groups did not change statistically after one-time OHE. The OHK, OHB and OHS indices increased significantly 6 months after RR-OHE than the initial scores ($p < 0.001$), irrespective of the OHE strategy[16].

Qadri showed that a significant incident rate ratio between the caries increment was found, with a 35% higher risk in the control group. However, the parents' socioeconomic characteristics modified the effect of the program on their children, as a high socioeconomic status in the intervention group was associated with a 94% reduction in the incidence risk ratio ($p < 0.001$)[17]. Bardaweel reported that the leaflet cluster (107 participants) had statistically significant better oral health knowledge than the E-learning cluster (104 participants) at 6 weeks ($P < 0.05$) and at 12 weeks ($P < 0.05$) (leaflet cluster:100 participants, E-learning cluster:100 participants). The mean knowledge gained compared to the baseline was higher in the leaflet cluster than in the E-learning cluster. A significant reduction in the Plaque Index (PI) means at 6 weeks and 12 weeks was observed in both clusters ($P < 0.05$) when compared to the baseline. The children in the leaflet cluster had significantly less plaque than those in the E-learning cluster at 6 weeks ($P < 0.05$) and at 12 weeks ($P < 0.05$). Similarly, a significant reduction in the Gingival Index (GI) means at 6 weeks and 12 weeks was observed in both clusters when compared to the baseline ($P < 0.05$). Children in the leaflet cluster had statistically significant better gingival health than the E-learning cluster at 6 weeks ($P < 0.05$) and 12 weeks ($P < 0.05$)[18]. Tomazoni reported that children from the Sense of Coherence (SOC)-based intervention group reported fewer impacts from their oral health on their daily lives (Child Perceptions Questionnaire mean, 7.22) than those from the control group (9.14). The intervention group also

reported greater improvement of SOC at 2 weeks (SOC mean, 52.98) and 3 months (52.75) than the control group (52.21 and51.65, respectively)[19].

4. Discussion

Of all of the activities related to dental and oral health carried out in schools, oral health education is the most common activity followed by supervised brushing exercises, fluoride applications, using E-Learning multimedia games and leaflets. Five studies showed a significant increase in Oral Health Knowledge (OHK) and Oral Health Behavior (OHB)[14–16,18,20]. Three studies showed a positive impact in reducing the incidence of caries [9,13,17] and 2 studies showed an improvement in quality of life [15,19]. However, the study conducted by Hilgert showed no difference in the caries prevention effect between School-based Supervised tooth-brushing (STB) and no intervention related to the occlusal surface low caries risk in the first permanent molar over 3 years[21].

The results of the study conducted by Bardaweel shows that leaflets are effective tools in improving oral health and they can be used in education as part of a school-based oral health promotion with positive results. It can thus be concluded that short-term oral health promotion programs can be beneficial at improving oral hygiene practices in children[18]. School-based oral health promotions informed by behavioral theory can be properly delivered by primary dental care practices and they can improve the children's knowledge of oral hygiene and some aspects of oral hygiene behavior[14]. The research findings from Haleem suggest the complementary role of trained teachers and peers who can act as available experts throughout the school system to periodically repeat and reinforce the messages because repetition and reinforcement plays a key role in the success of school-based OHE programs[16].

5. Conclusion

The purpose of this study was to identify and explore the effectiveness of the various ways to promote dental and oral health as carried out in school-aged children in the school environment. This study shows the effectiveness of the promotion and prevention of dental and oral health carried out in schools both short and long term. For the long term, it requires repetition and strengthening. In the delivery of the promotions and prevention of dental and oral health, this can be done by professionals, trained teachers or their peers. The results of this systematic review can be demonstrated by the stakeholders as being an effective promotion and prevention determination carried out in schools. This is because interventions in the school environment have been identified as the most creative and cost-effective way to improve dental and oral health.

THE INFLUENCE OF DIABETIC FOOT EXERCISE IN SENSORY PERIPHERAL NEUROPATHY WITH MONOFILAMENT TEST ON DIABETES MELLITUS CLIENTS

Tintin Sukartini[1], Candra Panji Asmoro[1], Putri Nandani Alifah[1]
[1]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
Email: tintin-s@fkp.unair.ac.id

ABSTRACT

Peripheral neuropathy is a long-term complication that attacks the nerves and loses the sensation of protection which affects about 50% of people with diabetes mellitus (DM). Diabetic foot exercises can help blood circulation, especially in the legs or lower limbs. This researched aimed to analyze the effect of diabetic foot exercise on sensory peripheral neuropathy in DM clients. The study design used quasi-experimental pre-post test with control group. Samples were 28 respondents using purposive sampling and divided into two groups of 14 respondents each. The independent variable is diabetic foot training, and the dependent variable is peripheral sensory neuropathy. Interventions are carried out 3 times a week for 4 weeks. The research instrument was Weinstein Monofilament 10 g Semmes and a diabetic foot training checklist. Data analysis using the Wilcoxon-signed rank test and Mann Whitney test with $\alpha \leq 0.05$. The Wilcoxon-signed rank test in the treatment group showed differences in sensory peripheral neuropathy after treatment (p=0,000) and no difference in the control group (p=0.564). The Mann Whitney test results showed differences in sensory peripheral neuropathy between the treatment group and the control group after treatment p=0.039. Diabetic foot exercises can be used as an alternative measure to improve sensory peripheral neuropathy

Keyword:
sensory peripheral neuropathy, diabetic foot exercises, monofilament test

1. Introduction

International Diabetes Federation (IDF) in 2017 stated that Indonesia ranks 6th in the number of diabetics in the world [1]. In 2017 the number of diabetics in Indonesia reached 10.3 million people and among them 73.7% were unaware that they had diabetes. The prevalence of diabetes mellitus (DM) in Indonesia has reached 9.1 million people. IDF estimates that the number of diabetics in Indonesia will continue to soar to reach 16.7 million in 2045 [2].

Increased prevalence of DM patients can increase complications such as heart disease, nephropathy, retinopathy, diabetic foot injury, and neuropathy. Neuropathy is one of the long-term complications that affects about 50% of people with diabetes. Peripheral neuropathy is a broad and potentially disabling pathological condition that includes more than 100 different forms and manifestations of nerve damage. The diverse pathogenesis of peripheral neuropathy affects autonomic, motor and / or sensory neurons, and symptoms that describe these conditions are abnormal skin sensations, muscle dysfunction and, especially, chronic pain [3]. Neuropathy is strongly associated with the duration and severity of hyperglycemia. Disease prevalence increases with increasing duration of DM and poor glycemic control [4].

About 11.9 million adults in the United States aged> 40 years have been diagnosed with diabetes and among them, 3.9 million (32.7%) have diabetes neuropathy and 1.6 million (13.1%) have comorbid neuropathy and retinopathy [5]. The prevalence of diabetic peripheral neuropathy

ranges from 16% to 66%. Amputation in diabetics is 10 to 20 times more common than non-diabetes [1]. Patients with diabetic neuropathy are more often hospitalized than other diabetes complications. Diabetic neuropathy increases in patients within 5-10 years after the onset of this disease. Diabetic peripheral neuropathy (DPN) has a strong association with other complications such as diabetic retinopathy (67% versus 21%) and micro albuminuria (51% vs 41%). It has been observed that 56% of patients with DM less than 5 years have moderate / severe DPN [4]. As many as 1,785 DM patients in 2008 to 2009 in Indonesia experienced 63.5% of neuropathy complications, 42% diabetic retinopathy, 73% nephropathy, 16% spectacular, and 27.6% microvascular complications [6]. Research in Persadia Units at dr. Soetomo Hospital Surabaya showed that 30.8% of 26 respondents who did not experience diabetes ulcers complained of neuropathy [7]. One of the factors that trigger diabetic foot ulcers is neuropathy. International Diabetes Federation reports that 1 in 6 diabetics will experience diabetes ulcers during their lifetime [8]. Diabetic foot exercises are activities or exercises carried out by DM patients to help blood circulation, especially in the legs or lower leg [9].

Based on a preliminary study at the Gedongan Community Health Center in Mojokerto, East Java, DM was included in the list of the 10 biggest diseases in the last 3 years. People with DM every year always experience an increase, in 2015 there were 2,434 patients, in 2016 there were 3,085 patients, in 2017 there were 3,343 patients. In March 2018 there were 32 DM patients with neuropathy. Observations and interviews during preliminary studies with outpatients at the Gedongan Community Health Center with DM showed that 7 out of 12 patients complained of frequent leg pain, calluses, and dry feet. The Gedongan Community Health Center in Mojokerto has not yet intervened specifically in diabetic neuropathy to reduce the incidence of foot ulcers. The intervention given to DM patients is to schedule control patients, health education, and anti-diabetes drugs on a regular basis according to the doctor's advice.

Most cases of peripheral neuropathy cannot be fully treated because the underlying cause is unknown or incurable, so the main goal associated with the treatment of most forms of peripheral neuropathy is to control or correct troublesome symptoms [10]. Exercise is known to increase several metabolic factors that can affect nerve health [11]. Based on previous reviews, researchers were interested in conducting research on the effects of diabetic foot exercise on sensory peripheral neuropathy in DM patients at Gedongan Health Center, Mojokerto City.

2. Methods

The research design used was quasy experiment (pre-post test with control design) and the project was approved by the Health Research Ethics Committee of Faculty of Nursing Universitas Airlangga (ethical number 989-KEPK). The sample in this study was DM clients at Gedongan Health Center, Mojokerto. The sample size in this study were 28 clients who were divided into two groups. The sampling technique used in this study was purposive sampling. The instrument used was a 10 g monofilament type type diabetes test Semmes-Weinstein monofilament neuropathy measuring 10 g with a thickness of 5.07 and a checklist for diabetic foot exercises.

Retrieval of data in this study was conducted at Gedongan Community Health Center, Mojokerto City, then followed up and routinely intervened through clients' home visits. Samples were divided into treatment groups and the controls were matched pairs. The researcher explained the objectives, benefits, procedures, and research time in detail to the respondents. After that, the researchers asked the respondents for their consent to participate by signing an agreement letter in the study. At the first home visit the researchers conducted a pre test to determine the initial value of

the dependent variable by examining the value of sensory neuropathy using a 10 g monofilament device in the treatment and control groups. Foot gymnastics interventions were carried out every 3x / week for 4 weeks, referring to Harmaya (2014) in the treatment group while intervention was not carried out in the control group [12]. At the end of the fourth week the researchers conducted a post test to determine the final value of the dependent variable, namely the value of sensory peripheral neuropathy with 10 g monofilament in the tre

The research analysis was carried out with the help of SPSS v16 software. Bivariate analysis used the Mann Whitney Test statistical test using the degree of significance $\alpha \leq 0.05$ to compare the results of the treatment and control groups. The Wilcoxon signed rank statistical test compared the results of the pretest and posttest in the intervention group and the control group.

3. Result

Table 1. Characteristics of Respondents

Characteristics of Respondents	Treatment Group (n=14)		Control Group (n=14)	
	n	**%**	**n**	**%**
Gender				
Men	4	28,6	4	28,6
Woman	10	71,4	10	71,4
Total	14	100	14	100
Age				
36-45 years	0	0,0	2	14,3
46-55 years	9	64,3	4	28,6
56-65 years	5	35,7	8	57,1
Total	14	100	14	100
Duration diagnosed with DM				
<5 years	5	35,7	6	42,9
5-10 years	5	35,7	2	14,3
>10 years	4	28,6	6	42,9
Total	14	100	14	100
Profession				
Do not have job	8	57,1	5	35,7
Pensionary	1	7,1	2	14,3
Civil servants	1	7,1	2	14,3
Entrepreneur	3	21,4	2	14,3
Other	1	7,1	3	21,4
Total	14	100	14	100

Most of the respondents were women (71.4%). The majority of respondents were in the range of the early elderly and the late elderly (92.85%); age of 46-55 years (46.43%) and age 56-65 (46.43%). Most of the patients who participated in this study were diagnosed for less than 5 years (39.28%). Most of them do not have job (46.43%).

Table 2. Sensory peripheral neuropathy before and after diabetic foot exercises in the treatment and control groups

Groups	Mean		p value Wilcoxon signed rank test	p value Mann-Whitney test	
	Pretest	Posttest		Pretest	Posttest
Treatment group	2,64	1,64	0,000	0,541	0,039
Control group	2,57	2,64	0,564		

In the treatment group before diabetic foot exercise, the average value of sensory peripheral neuropathy was 2.64, which meant that the DM patients in the treatment group had sensory peripheral neuropathy on average. After diabetic foot exercise, the mean sensory peripheral neuropathy showed a decrease to 1.64, meaning that sensory peripheral neuropathy scores improved. The results of statistical tests showed that there were significant differences between the values of sensory peripheral neuropathy before and after diabetic foot exercise in the intervention group (p = 0,000) while in the control group it meant that there were no differences in sensory peripheral neuropathy (p = 0.564). Whereas in the post-intervention results there were differences in sensory peripheral neuropathy between the treatment and control groups (p = 0.039).

4. Discussion

Patients with diabetes and neuropathy are associated with low nerve conduction due to demyelination and loss of large myelin fibers, and decreased potential for nerve action due to loss of axons [13,14]. In patients with peripheral diabetic neuropathy, loss of sensation in the foot causes recurrent minor injuries (calluses, nails, foot deformities) or external causes (shoes, burns, foreign objects) that are not detected at that time and consequently can cause foot ulceration. This can be followed by ulcer infection, which can eventually cause amputation of the foot, especially in patients with peripheral arterial disease [15]. In diabetic patients, regular physical activity reduces weight, increases blood glucose control and insulin sensitivity which all lead to a reduced risk of developing neuropathy [9].

The results of this study indicate that diabetic foot exercise can reduce sensory peripheral neuropathy. Exercise positively influences other pathological factors associated with diabetic peripheral neuropathy, by promoting microvascular function and fat oxidation, by reducing oxidative stress and increasing neurotropic factors [16,17]. Exercise-induced Neurotrophin-3 (NT3) increases are associated with increased peripheral nerve conduction velocity and reduction in neuropathic pain [18]. Neurotrophin-3 (NT-3) is known to promote the survival and differentiation of existing neurons and to encourage the growth of new synapses and neurons.

Foot and toes exercises are one of the exercises that can modulate the level of sorbitol in the body so as to prevent a decrease in blood flow in the endoneural blood flow [19]. Providing stimulation in the form of exercise or leg exercises can produce potential action resulting in depolarization which results in increased Na + / K + ATP activity, axonal transport is increased, patients feel sensory sensations / sensory responses. Foot exercises can help smooth and improve blood circulation in the legs. It also helps in the process of wound healing in diebetes foot ulcer [20]. In addition to this effect, the main reason for a large increase in blood flow during exercise is a decrease in oxygen in the tissues, which is one of the chemical factors found in diabetic patients. The

decrease in oxygen causes dilation because of its direct effect on muscle arterioles. Muscles consume oxygen quickly during exercise, and the amount of oxygen in the tissue decreases. In the absence of oxygen, the arteriolar wall cannot continue to contract, and lack of oxygen causes the release of vasodilators. This causes vasodilation of local arterioles so that all capillaries are open and blood flow increases. Blood circulation that smoothly carries oxygen and nutrients to the tissues and nerve cells that will affect the metabolic process of Schwann cells so that axon function can be maintained. The optimal function of nerve cells in DM patients will maintain sensory function of their feet [21].

Foot exercises play a role in controlling blood glucose levels to improve peripheral blood circulation which can be seen from the value of the Ankle Brachial Index (ABI) in DM patients [22]. Decreasing glucose levels in the blood will improve myelin nerve function and axons so that DM patients will be able to feel pain, heat, vibration, and pressure. In other words, the nerve endings of patients experience increased conduction and recurrent sensitivity in protection against risky conditions, which are detected by examining the sensation of protection using monofilament 10 g.

5. Conclusions

DM patients who perform foot exercises will experience a decrease in the value of peripheral sensory neuropathy because foot exercise movements can improve myelin nerves and axon function so that nerve endings undergo improved conduction and sensitive return detected by monofilament 10 g. There was a decrease in sensory peripheral neuropathy in the intervention group and there was no decrease in the value of sensory peripheral neuropathy in the control group proving the theory above that foot exercise can help smoothen so as to improve blood circulation and sensitivity to prevent numbness. Community health nurses can provide education about foot exercise to DM patients, especially patients with peripheral neuropathy. DM patients are able to do leg exercises independently at home to improve the status of sensory peripheral neuropathy so that it can prevent the occurrence of ulcers.

**Email : masita.widiyani-2018@fkp.unair.ac.id*

ABSTRACT

Chronic Renal Failure patient undergo haemodialysis therapy along their life, so they need good psychological adaptation to the therapy. People who suffer chronic illness such as chronic renal failure need family support for their life. The aimed was to determine the correlation between family support to psychological adaptation of haemodialysis therapy in patients with chronic renal failure. Correlation study used as design. Sample was selected using purpossive sampling technique and obtained 35 samples**.** Data collected by questionairre of family support and psyvhological adaptation. Data was analyzed by *Spearman Rank test***.** The result showed significant relationship between family support and psychological adaptation in hemodialysis patient. Individual with good psychological adaptation has a confidence to face various unpleasant condition, like haemodialysis therapy. While family support can provide a buffer effect which withstand the negative effects of stress to the physical health and to improve health.

Keywords: haemodialysis, Chronic kidney failure, psychological, family, support

1. Introduction

Chronic renal failure is incompetence of kidney function irreversibly which involve the failure of kidney to maintain the balance of metabolic, fluid and electrolytes [1]. Chronic renal failure involve the hyperthropy of nefrons resulting the produce of high amount of filtrate causing the decrease of glomerulus filtration rate while tubule reabsorbtion is still increase [2]. Haemodialysis is one of medical management of chronic renal failure by excrete the fluid and waste product using machine when kidney are incompetence to do this function. The aim of haemodialysis is to maintain patient's well-being. Individual with long-term haemodialysis feel worry about their live. Haemodialysis caused alter of the lifestyle in family. Some activities like social activities, family time will be lost and it could create conflict among family member, frustration, gulity feeling and depression. The long term effect of haemodialysis is not only influent family member relationship but also the self-psychological adaptation [1]

According to WHO and Global Burden Disease (GDB), kidney and urinary tract disease contributes 850.000 of deaths every year. Data from Dr.Soetomo hospital in 2004-2006 is found that around 2000 patients are diagnosed with chronic renal failure, whereas 60-70% are being in late phase of treatment. Patient who undergo haemodialysis in long period can suffer physical, mental stressed, and alter of lifestyle and personality [1]. According to research in hemodialysis patient of Moewardi Surakarta hospital showed that 30% patient experience light level of stress, 40% on medium level of stress and 30% on high-stress level. Self adaptation is individual ability to reconcile themself appropiately by using adaptation mechanism. Family is group of people who is connected by marriage, adoption and born which aimed to create and maintain culture, impove development of physical, mental, emotional and social in each members [2]

According to research of [3], it is showed that the family support on patient with chronic disease is still low. While according to family support model show that family is the main part whom needed by patient with cronic disease as a support. Another research prove that many factors like family lifestyle, socio-economic status and belief of illness can affect the progress of illness [6]. Therefore, it's need good psychological adaptation so it has good therapeutical impact on patient. But not a little patient who undergo hemodialysis therapy feel badmood and give up to pass the process.

According to that problems, researcher aim to explore about relation of famiy support and psychological adaptation in chronic renal failure who undergo haeemodialysis. The research location was done in Rumah Sakit Tentara (army hospital) of Dr. Soepraoen Malang in hemodialysis unit. Rumah Sakit Tentara (army hospital) of Dr.Soperaoen is type B hospital.

2. Materials and Method

2.1 Research Design, population, sample and variables

Type of the study is analytic observational with cross sectional design. The population of this study was patients with chronic renal failure who undergo hemodialysis as many as 64 people. The eligibility criteria for this study was 18-65 years old, undergo hemodialysis ± 1 month, subject has a willing to participate the study, capable in reading and writing, and able to be verbally communicate. The exclusion criteria was patient with physical disability and sedative drug consumption. After screening the population based on inclusion and exclusion criteria, there was 35 samples obtained. The sampling technique was used in this study was purposive sampling. The independent variable in the study was family support. The dependent variable in this study was psychological adaptation in hemodialysis therapy.

2.2 Instruments

The instruments used in this study were family support questionairre and psychological adaptation to hemodialysis questionairre. Family questionairre used likert scale with graded answer, like always, often, sometimes and never. Family support questionairre used three domains to be assesed. Those three domains were emotional support, self-appreciation support and informational support. The number of question was 21 with score 0-3 and range of scores 0-63. The total score intepretation is the higher score showed the better family support on individu. The validity and reliability test for family support questionairre was 0.87 (r=0.87).

The psychological adaptation to hemodialysis used 5 domains to be assesed. Those were emotional regulation, self- effication, optimism, objective-realistic and empathy. Psychological adaptation questionairre used likert scale with graded answer, like always, often, sometimes and never. The number of question was 18 with score 0-3 and range of scores 0-54. The total score intepretation is the higher score showed the better psychological adaptation on individu. The validity and reliability test for psychological adaptation to hemodialysis questionairre was 0.75 (r=0.75).

2.5. Research procedures

The sample collecting was done by observing and interviewing the candidate in Hemodialysis Unit at Rumah Sakit Tentara (Army Hospital) Soepraoen Malang based on eligibility criteria. After the participants was selected, researcher did a home visit to give them an inform consent to participate in this study. Then, the participants would be asked to fill the questionairres. This study held on January, 23rd- March, 6th 2015.

2.6 Analysis of Data

The collected data was analyzed using *Spearman Rank* analysis using SPSS 16 program for Windows

2.7 Ethical Clereance

This study was approved on January, 18, 2015 by Legal Ethic Comitte at Medical Faculty of Brawijaya University Malang with the series number of ethical clearance 043/EC/KEPK-S1-PSIK/01/2015.

3. Results

Characteristic respondents on [Table 1] showed that the majority of the respondents are female. The average of age of respondents is 48-60 years old. The majority of occupation status was unemployed. The majority of education level was elementary school. The majority of haemodialysisi period was 1-7 months. From the 35 samples studied [Table 2], it was found that the highest aspect of family support was the aspect of emotional support, which was 100% (35 people) while the lowest was in the aspect of informational support which was 60% (20 people). The result will be represent in diagram pie below.

Based on these result, most of the psychological adaptations of patients to hemodialysis therapy are good at 89% (30 people). From the 35 samples studied [Table 3], it was found that the highest aspect of psychological adaptation was emotional regulation, which about 33 people (94%) while the lowest was in the aspect of empathy, which about 18 people (54%).

Based on data analysis using the Spearman Rank test with the SPSS 16.0 for Windows Evaluation Version computer program and the significance level of 95% ($\alpha = 0.05$), it was found that there was a relationship between family support and psychological adaptation with p value 0.006. Where is the value of sig $<\alpha$ ($0.006 < 0.05$). Whereas in the Spearman correlation (r) value was (+0.458) which indicates that the correlation (r) was positive and had moderate strength. Positive means that the higher the family support given, the higher the level of adaptation of patients with Chronic Kidney Failure to Hemodialysis therapy or vice versa, the lower the family support given, the lower the level of adaptation of patients with Chronic Renal Failure to Hemodilaisis therapy.

4. Discussion

4.1 Family Support

Family is a place where there are rules, emotional attachments, and their respective roles in family members [7] so that they can strengthen family relationship. The majority of participants of this study were 48-60 years old (about 22 people). The early age of elderly can influence the aging process and cause various problems, both biologically, mentally, and economically. When someone is getting older, they will get declining in physical ability, so that it can lead to a decline their social role [8]. Therefore, it is necessary to help elderly individuals to maintain maximum dignity and autonomy even in situations of physical, social and psychological loss [1]. Social support for elderly is important, because it can decrease parental depression and protect them from negative depression [9].

Based on the results of the study, related to socio-economic status, family support with a good category was given more to participantss who did not work as many as 27 people (87%) compared to those who worked only 5 people (16%). This is in accordance with the results research stating that patients who do not work either only as housewives or retirees, the intensity of meetings between patients and families is often [10].

In addition, based on the results of the study, the majority of participantss who received family support in the good category came from participantss who lived together, either husband or wife, as many as 17 people (57%). This is in accordance with the statement of which explains that, social support will be more meaningful to someone if given by people who have a significant relationship with the individual concerned, in other words, the support is obtained from parents, partners (husband or wife), children and other family relatives [11]. Social suport can be effective to be done by close relation person, for example, family or close friend [12]

According to result of Family Support on emotional support domain, it showed that of 35

participants (100%) had good emotional support from partnerships. This result is also supported by [13] research on cancer patient who undergo chemotherapy, showed that from 50 respondents, there was 3 respondents (6%) got low family support, 17 respondents (34%) showed moderate family support, and 30 respondents (60%) who got high family support**.** This is also agreed to the opinion [14] which states that patients who receive support from family will feel comfortable, possessing, peaceful, and loved.

On the appreciation support domain, it showed that 23 people (66%) got good appreciation support from their family. Appreciation support from family is the form of affective function of family on elderly people which can increase psychososial status [7].

4.2 Psychological Adaptation

Based on the results of the study, there were 33 participants who had emotional regulation in high category, while 2 participantss had moderate emotional regulation and no participantss were in the low emotion regulation category. This is in line with the opinion of ([15]) that adaptive people are a person who is able to express their emotion both positive and negative emotions

Based on the results of the study, there were 31 participantss in the category of high self-efficacy and 4 participantss with the category of moderate self-efficacy. This statement is agreed with statement of [16], individuals who have high self-efficacy will be very easy in facing challenges. The individual does not feel doubt because he has good self-confidence. This individual according to [16] will quickly face problems and be able to get up from the failure that he experienced.

Based on the results of the study, there were 27 people with a high optimism category and 8 people with a moderate optimism category. Optimistic individuals are healthier than pesimistic person and less depressed, better at school, more productive at work, and more victorious in sports [15].

On the objective-realistic attitude, it showed that 23 people (66%) who had high objective-realsitic attitude. Individual with good psychological adaptation could accept their weakness and superiority, had a sharpness to see the reality and handle their reality fairly [17].

On the empathy domain, it showed that 18 people (53%) had high empathy. The high empathy skill is needed because another people want to be understood and appreciated**.** The real form of ths pattern is through communication about expectations, through appropriate norms, through rewards and punishments and giving coping assistance [18]. When someone gets family support, the patient will feel calm, get encouragement, and consent from his family [17]. Family support can provide a buffer effect which withstand the negative effects of stress to the physical health and to improve health. This is also agree with research of [19] which stated that in hemodialysis patients, one component of psychological adaptation (psychological adaptation), namely self-efficacy and emotions can be a buffer effect from the onset of depression or stress.

5. Limitation of the study

Limitation in this study was the data collection technique for this study based on questionairre only. The weakness of this method could possibly made the respondets are not honest when they answered the question. The method could be better if it also used interview to validate the respondent's answer.

6. Conclusion

Patients with chronic renal failure receive family support of 89% in the good category. The level of psychological adaptation of patients with chronic kidney failure was 89% in the good category. There is a significant relationship between family support and the level of psychological adaptation of patients with chronic renal failure to undergo hemodialysis therapy. In future, researchers could develop the family intervention which can help patient to reach optimal psychological adaptation.

ABSTRACT

Older adult is one of the stages of life which is marked by deterioration of physical and mentally functions. The purpose of the research is to identify the factors associated with performance of cadres of Posyandu Lansia (integrated health service for older adult at the Puskesmas Mokoditek. This study is a quantitative research that utilizes descriptive analytical method based on the Cross Sectional research design. Samples are derived using Total Sampling method from a sample frame with total sample size of 30 people. The analysis with Chi-Square resulted in values of p = 0,039 where p was larger than α =0,05 = (0,000> 0,05). Therefore it can be concluded that there was a correlation between the cadres' knowledge and interest toward cadres performance at Posyandu Lansia of Puskesmas Mokoditek of the District of Bolaang Mongondow Utara.

Keywords: knowledge, interest, performance.

Introduction

A country is said to have an old structure if it has an elderly population above seven percent. Increased life expectancy (Life Ecpectancy).

In the world the percentage of elderly people in 2015 reached 12.3% and it is estimated that in 2025 it will increase to 14.9% while in ASIA the elderly population in 2015 will be 11.6% and estimated in 2025 will increase to 15% (Ministry of Health , 2017)

Increasing life expectancy (Life Ecpectancy) is one indicator of the success of health development in Indonesia. This can be seen from the data on the percentage of elderly people in Indonesia in 2013 who reached 8.9% and in 2017 it reached 9.03% of the total population from 2013 to 2017 an increase. Women have a higher life expectancy of 9.53% compared to 8.54% in men. In Indonesia there are 19 provinces (55.88%) in the Indonesian province which have an old population structure and the three provinces with the largest percentage of elderly are DI Yogyakarta (13 , 81%), Central Java (12.59) and East Java (12.25%). While there are three provinces with the smallest percentage of elderly being Papua (3.20%), West Papua (4.33%) and Riau Islands (4.35%) (Ministry of Health, 2017).

According to data from the 2017 Bolaang Mongondow Health Office, there are 8451 people with a population of elderly. The number of elderly people in the working area of the Mokoditek health center is 463 people, males number 174 people, women number 289 people. Elderly people

who actively participated in the elderly posyandu from six posyandu service units were 244 people and 219 were inactive because some of the elderly entered the mokoditek working area lived with children outside the work area of the Mokoditek Health Center. The increasing number of elderly people raises problems, especially in terms of health and welfare of the elderly. This problem if not handled will develop into a more complex problem.

Inactivity of cadres in running posyandu also occurred in four posyandu under the responsibility of the Mokoditek Health Center. This condition has been seen from the results of the initial survey conducted by researchers who monitored the operation of the posyandu that the posyandu activities were still not in accordance with targets expected and the number of cadres who are not active in carrying out their duties.

The Mokoditek Health Center has six posyandu units, with a cadre of 30 people. Each posyandu unit has five cadres, but at the posyandu activity the cadre attendance is only 3-4 people, and many still need help from local health workers to carry out posyandu services with a "five table pattern".

Research Methods

Research design is a forum to answer research questions or test the truth of hypotheses (Setiadi, 2007). In this study conducted using quantitative methods with Cross Sectional design, namely studying the relationship between the dependent variable (Knowledge, Cadre Performance) and Independent Variables (cadre interest) through momentary measurement or just one time and carried out at the same time.

Cross Sectional Design is used based on the purpose of the research, which is to find out the Factors Associated with the Performance of Elderly Posyandu Cadres in the North Bolaang Mongondow Mokoditek Health Center Work Area.

Research Tools and Materials

The sample in this study were all cadres in the work area of the Mokoditek Health Center with a total sampling technique and the number of samples taken was 30 people. The sample in this study was taken according to the criteria set by the researcher, namely according to the criteria of inclusion:

1. Elderly Posyandu cadres who are still active

2. Aged 20-40 years

3. Willing to be a Respondent

RESULTS

1. Characteristics of Respondents

a. Age cadre

Table 5.1 Frequency Distribution by Age of Respondents in Bolaang Mongondow North Mokoditek Health Center, June 2016

Umur	Frekuensi (f)	Percent (%)
20-25 tahun	6	20
26-30 tahun	10	33,3
31-40 tahun	14	46,7
Total (N)	30	100

Source: Primary Data

Based on the table above it can be seen that the characteristics of respondents based on age showed that the most respondents were 31-40 years, 14 people or 46.7%.

b. Level of education

Table 5.2 Educational Frequency Disribution Respondents at Bolaang Mongondow North Mokoditek Health Center, June 2016

Pendidikan	Frekuensi (f)	Percent (%)
SD	2	6,7
SLTP	4	13,3
SLTA	24	80
Total (N)	30	100

Sources: Primary Data

Based on the table above, it was seen that the characteristics of the respondents were mostly high school students, namely 24 people or 80%.

2. Univariate analysis

a. Knowledge of older adulth Posyandu Cadres.

Table 5.3 Frequency Distribution in Knowledge of Respondents in Bolaang Mongondow North Mokoditek Health Center, June 2016.

Pengetahuan	Frekuensi (f)	Percent (%)
Baik	26	86,7
Kurang	4	13,3
Total (N)	30	100

Sources: Primary Data

Based on the table above, it can be seen that the characteristics of respondents based on knowledge show that the most are categorized as good, namely 26 people or 86.7%.

b. Interest in Older Adult Posyandu Cadres

Table 5.4 Frequency Distribution by Interest of Respondents in Bolaang Mongondow North Mokoditek Health Center, June 2016

Minat	Frekuensi (f)	Percent (%)
Baik	27	90
Kurang	3	10
Total (N)	30	100

Sources: Primary Data

Based on the table above, it can be seen that the characteristics of respondents based on knowledge show that the most are categorized as good ie 90 people or 10%.

c. **Performance of Older Adult Posyandu Cadres**

Table 5.5 Frequency Distribution According to the Performance of Respondents in Bolaang Mongondow North Mokoditek Health Center, June 2016

Kinerja	Frekuensi (f)	Percent (%)
Baik	27	90
Kurang	3	10
Total (N)	30	100

Sources: Primary Data

Based on the table above it can be seen that the characteristics of respondents based on knowledge show that the most are categorized as good, namely 27 people or 90%.

3. Bivariate Analysis

a. Relationship between Knowledge and Performance of Elderly Posyandu Cadres at North Bolaang Mongondow Mokoditek Health Center

Table 5.6 Cross Tabulation of Knowledge Relating to the Performance of Elderly Posyandu Cadres at North Bolaang Mongondow Mokoditek Health Center.

Pengetahuan	Kinerja Kader					
	Baik		Kurang			
	n	%	n	%	n	%
Baik	25	83,3	1	3,3	26	86,7
Kurang	2	6,7	2	6,7	4	13,3
Total (N)	27	90	3	10	30	100

Based on the table above shows that there is a relationship between knowledge with the performance of the elderly posyandu cadres in the North Bolaang Mongondow Mokoditek Health Center with the Chi-Square Signed Rank Test results on respondents, namely there is a significant relationship with the value p = 0.039 and can be seen in the cadre knowledge level as many as 26 people or 86.7% with the performance of cadres in either category 27 people or 90%.

b. Relationship between Interest and Performance of Elderly Posyandu Cadres at North Bolaang Mongondow Mokoditek Health Center

Table 5.7 Cross Tabulation of Interest Related to the Performance of Elderly Posyandu Cadres at North Bolaang Mongondow Mokoditek Health Center

Minat	Kinerja Kader					
	Baik		Kurang			
	n	%	n	%	n	%
Baik	27	90	0	0	27	90
Kurang	0	0	3	10	3	10
Total (N)	27	90	3	10	30	100
Signifikan, 0,000						

Based on the table above shows that there is a relationship between knowledge with the performance of the elderly posyandu cadres in the North Bolaang Mongondow Mokoditek Health Center with the Chi-Square Signed Rank Test results on respondents that there is a significant relationship with p = 0,000 and can be seen as much as good category cadre interest 27 people or 90% with the performance of cadres in either category 27 people or 90%.

Discussion

1. Cadre Knowledge About Elderly Posyandu

The results of the study were found from 30 respondents with a good level of knowledge of as many as 26 people or 86.7% and in the poor category as many as 4 people or 3.8%. This is due to the fact that most education is graduated from high school. The higher a person's education, the easier it is to receive information so much knowledge possessed. Conversely, less education will hinder the development of interest in the values introduced.

Knowledge is the result of knowing and this happens after people do sensing an object. Sensing occurs through the five human senses, namely the senses of sight, hearing, smell, taste and touch so that most human knowledge is obtained through the eyes and ears. This knowledge domain is very important for the formation of one's actions (Notoatmodjo, 2007).

2. Cadre Interest About Elderly Posyandu

The results of the study were found from 30 respondents with the interest of the elderly Posyandu cadres in the good category, namely as many as 27 people or 90% and the poor categories as many as 3 people or 10%. This is because not about one's knowledge but because of someone's willingness to carry out their duties.

Good or less knowledge does not become a benchmark in carrying out an action because someone's interest is based on a high willingness to do something.

3. Performance of Elderly Posyandu Cadres

The results of the study found 30 respondents with the performance of elderly posyandu cadres in the good category, namely as many as 27 people or 90% and the poor category as many as 3 people or 10% people. This is due to the fact that the cadres are the driving force for posyandu, the management of a posyandu is said to be successful, largely determined by the performance of the cadres.

Performance is someone's success in carrying out tasks And Responsibility. In this case the performance can be measured based on the description of the work both during the implementation of the posyandu and outside the day of the implementation of the posyandu (Ministry of Health, 2011).

4. Related Knowledge with the Performance of Elderly Posyandu Cadres at North Bolaang Mongondow Mokoditek Health Center

The results of the study were 30 respondents about the relationship of knowledge with the performance of elderly posyandu cadres at the North Bolaang Mongondow Mokoditek health center through testing using the SPSS program v. 20 shows that a significant value of 0,000 where the value is smaller than $\alpha = 0.039$ thus H1 is accepted. This shows that there is a relationship between knowledge with the performance of posyandu cadres in the performance of elderly posyandu cadres at the Bolaang Mongondow North Health Center.

Knowledge is the result of knowing and this happens after people do sensing an object. Sensing occurs through the five human senses, namely the senses of sight, hearing, smell, taste and touch so that most human knowledge is obtained through the eyes and ears. This knowledge domain is very important for the formation of one's actions (Notoatmodjo, 2007)

From the results found in this study, the researcher assumes that if the cadre's knowledge about the elderly posyandu can affect good performance as well. Knowledge of assignments is very important for every cadre at work. Good knowledge of tasks and responsibilities within an organization tends to be will improve the quality of his work. This research is in line with the research conducted by Latief (2010), where sufficient knowledge can improve the performance of one's cadres. Similarly, the research conducted by Adliana (2013) said that the higher the level of knowledge of cadres, the better the performance of these cadres.

Thus the researcher concludes that if the cadre's knowledge is good or sufficient, the performance of the elderly posynadu cadre will be good so that the elderly posyandu can run well.

5. Relationship of Interest with the Performance of Old Posyandu Cadres in North Bolaang Mongondow Mokoditek Health Center

The results of the study of 30 respondents about the relationship of interest with the performance of elderly posyandu cadres at the North Bolaang Mongondow mokoditek health center through testing using the SPSS v.20 program showed that a significant value is 0,000 where the value is smaller than $\alpha = 0{,}000$ so H1 is accepted there is a relationship between knowledge with the performance of posyandu cadres in the performance of elderly posyandu cadres at the Bolaang Mongondow North Health Center.

According to Sutjipto, 2001 interest is the tendency of someone to behave based on his interest in certain types of activities and someone's interest in something will be more visible if the person has a sense of pleasure in the object. From the results found in this study, the researcher assumes that if the interest of cadres is good, the performance of cadres is also good because if someone is interested in a job then its performance will be good because it pursues the work it does. Previous research by Bangsawan (2013) showed that there was a relationship between interest and cadre performance in implementing posyandu on the elderly with P-Value = 0.02. Behavior in implementing Posyandu is what affects the assessment of cadre performance.

Thus the researcher concludes that if the interest of posyandu cadres is good or sufficient, it can improve the performance of cadres in carrying out their duties as posyandu cadres for the elderly.

Conclusion

1. Almost all interests of elderly cadres at the posyandu in the elderly at the Mokoditek health center are in good category.
2. Almost all knowledge of elderly cadres at the posyandu in the elderly at the Mokoditek health center are in good category.

3. Almost all the knowledge of the performance of elderly cadres at the posyandu in the elderly at the Mokoditek health center are in a good category.
4. Analyzed the relationship between knowledge and performance of elderly Posyandu cadres in the North Bolaang Mongondow Mokoditek Health Center work area
5. It was analyzed that there was a relationship between the interest and the performance of elderly posyandu cadres in the North Sumatra Bolaang Mongondow Mokoditek Health Center work area.

Suggestion

Based on the conclusions described above, the suggestions that can be given are as follows:

1. For educational institutions

   The results obtained in this study are expected to be a reference material for use in research then related to cadre performance.

2. For research locations

   The results of this study are expected to be a consideration for relevant parties in the Bolaang Mongondow North Mokoditek health center in determining the direction of policy and development in improving the performance of elderly posyandu cadres in optimizing the services of elderly posyandu

3. For researchers

   It is expected to be the basis and learning experience for researchers to better understand and understand the interests and performance of elderly posyandu cadres.

FACTORS AFFECTING THE DIETARY COMPLIANCE OF SASAK'S ELDERLY WITH HYPERTENSION BASED ON TRANSCULTURAL NURSING THEORY

Y A Nugraha, E Mishbahatul, S Hadisuyatmana, and E D Wahyuni
Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
Email: yanuar.aga.nugraha-2018@fkp.unair.ac.id

ABSTRACT

The low compliance of dietary hypertension can cause uncontrolled blood pressure. Sasak's elderly have any culture consumption a lot of salt. The transcultural nursing theory used to know health behaviour according to cultural. This study aimed to analyze factors affecting dietary compliance of the elderly with hypertension. Design of this study was cross-sectional. Samples taken used purposive sampling and obtained 52 elderly. Data were collected through questionnaires and analyzed using Spearman's Rho test with a significance level 0.05. This study showed education level did not have a correlation (p= 0.7, r=0,039) and there were correlation between economy factor (p= 0.000, r=0,542), family support (p= 0.000, r=0,542), culture and lifestyle (p= 0.000, r=0,542) with dietary compliance of elderly with hypertension. Those meant that economic, family support, culture, and lifestyle were factors that affect dietary compliance of elderly with hypertension. The elderly expected to maintain compliance by involving a healthy lifestyle with family support to control bloodpressure.

Keywords: factors, dietary compliance, elderly, hypertension

1. Introduction

Hypertension is a systemic increase of arterial blood pressure which gradually occurs over a long period of time. The diagnosis of hypertension is intended for conditions when blood pressure readings are over 130/80 mmHg [1,2]. Uncontrolled hypertension can cause disruption of the blood circulation system, including acute myocardia, blood vessels swallowing, heart failure, brain hemorrhage, and stroke. Moreover, hypertension also can causes blindness, kidney failure, cognitive impairment, and death [1].

Together with increasing age, peripheral blood vessel resistance will also increase and can lead to hypertension. In elderly people, the blood vessels have hypertrophy occurring naturally with age, making it lose elasticity, so that the blood flow is inhibited and increases blood pressure [3]. So, it causes hypertension in elderly people [4]. A definitive causative factor of hypertension in elderly people remains unclear. Some articles have found that age, lifestyle, education and a high sodium diet are risk factors of hypertension. Lifestyle related to diet preference has an impact on the incidence and prevalence of hypertension. Junk food consumption, low fiber diet, high fat and high sodium diet also contribute to the incidence of hypertension. Furthermore, alcoholism, smoking, and a sedentary lifestyle are also high risk lifestyle behaviors which cause hypertension [5–8].

A previous pilot study in Tanjung Karang Village (including in the working area of Tanjung Karang Primary Health Care) has shown that 12 out of 20 elderly are diagnosed with hypertension

(60%). Most of the elderly said that their family didn't provide a low sodium diet for them. Only 4 out of 12 hypertension elderly patients (33.33%) have ever tried a low sodium diet, but they said the taste of the food was not good and they didn't want to obey the diet. Based on family explanations, they usually add one or more teaspoons of salt to their food. This indicates that the consumption of salt among Sasak's elderly remains high. The recommendation for salt consumption per day is not more than 1.5 teaspoons or 5-6 grams/day [6].

Badan Pusat Statistik Nusa Tenggara Barat (2014) reported that 107,364 elderly are diagnosed with hypertension, 5,000 people among them live in Mataram (Dinkes Kota Mataram, 2014). In 2013, there were 920 elderly with hypertension under the working area of Tanjung Karang Primary Health Care, which increased to 1,006 people in 2014. From the previous pilot study, specifically in Tanjung Karang Village, there are 74 cases of hypertension among 120 elderly. Every month Tanjung Karang Primary Health Care have already done *Posyandu* for elderly, which has several activities such as gymnastics for the elderly, general check-up, provision of medicine, and education or socialization of the elderly about hypertension. Socialization about hypertension as an issue is important because most of the elderly and their families still do not have awareness to control their sodium consumption.

High sodium intake can increase the risk of hypertension incidence. A high concentration of sodium will increase plasma volume inside the body and cause high blood pressure [5,6,9]. The conclusion from the previous pilot study is that the elderly in Mataram still can't control their sodium intake. This habit is suspected to have a correlation with culture and local wisdom of the community. Some cultures are well known to have a strong relationship with the health of the community, for example the way of cooking, eating pattern, also preference and acceptability of food. This kind of culture will influence the health of the community, whether it gives positive or negative impacts [10].

Socio-economic factor, occupation, education, local facilities, genetic factors, eating patterns, and culture are strongly related to the risk and disease pattern in a community [11]. Therefore, transcultural nursing is used as an approach to explain individual or community behaviors which are related to health. Transcultural nursing focuses on 7 factors that influence behavior such as family or social support, cultural value and lifestyle, educational background, family finances, religion and life philosophy, law and politics, and technology [12]. Up to now, research about factors which influence behavior, especially about diet compliance, among elderly in Tanjung Karang is still limited. So, further research is necessary for this issue.

Based on the explanation above, this research is aimed to analyze factors related to dietary compliance of Sasak's elderly with hypertension in the working area of Tanjung Karang Primary Health Care through a transcultural nursing approach. The research will include some factors to be observed, i.e. family or social support, cultural value and lifestyle, and educational background. Meanwhile, some factors like family finances, religion and life philosophy, law and politics, and technology are not included in the research.

2. Research Methods

2.1 Research design

This study was a correlational study and used s cross sectional design to analyze factors affecting adherence of diet hypertension among Sasak's elderly.

2.2 *Population and sample*

The population of this study is the elderly with hypertension in Tanjung Karang Primary Health Care work area, amounting to 74 elderly. The samples are that 52 elderly were matched with inclusion and exclusion criteria. Inclusion criteria in this study is people over 60 years old living in Tanjung Karang, elderly who are in Sasak's tribe, living with their families, and agreeing to be a sample in this study. The exclusion criteria in this study were elderly with hearing loss, cognitive and psychiatric disorders.

2.3 *Variables*

The independent variables in this study are family support, culture, lifestyle, educational level, and economical status. The dependent variable is the elderly's hypertension related to diet.

2.4 *Instruments*

Questionnaires was used to collect data. This study used 3 questionnaires to collect data i.e. hypertension diet compliance questionnaire, family support questionnaire, and culture and lifestyle questionnaire. Each questionnaire has been tested for validity and reliability before the study was conducted, namely the hypertension diet compliance questionnaire has a Cronbach alpha value of 0.788, the family support questionnaire has a Cronbach alpha 0.812 value, and culture and lifestyle support questionnaire has a Cronbach alpha value of 0.873.

2.5 *Research procedures*

The study was carried out at the work area of Tanjung Karang Health Center on January 8-15, 2016. Before this research, the proposal was subject to an ethical test at the Health Research Ethics Commission, Faculty of Medicine, Airlangga University. Ethical feasibility was declared with certificate number 424 / EC / KEPK / FKUA / A / 2016 so that research can be conducted. Data collection used the questionnaires and was conducted by home visits.

2.6 *Analysis of research*

The collected data was use analyzed by Spearman rho to know the association between both variables with a significance level of <0.05. Correlation coefficient (r) was used to know how strong the correlation is between two variables..

3. Results

Table 1. The characteristics of respondents

Characteristics	n	%
Sex

Diet of Hypertension		
Not Obey	35	67.3
Obey	17	32.7

Table 1 shows the participants' gender, with 33 female (63.5%) and 19 male respondents (36.5%). The participants' age category was 60-74 years with 44 respondents (84.6%) and at the age of 75-90 years with 8 respondents (15.4%). Based on the number of families the minimum count is 3 people with 5 respondents (9.6%). The education level of respondents is up to elementary school

(38.5%) and another one has no schooling. Respondents' economic condition are 41 respondents (78.8%) under regional minimum salary (less than 1,400.000) and 11 respondents more than UMR (more than 1,400.000). The majority of family support of respondents overall is less than 84.6% and family support is good at only 8 respondents (15.4). Respondents' culture and lifestyle is 38 respondents adhering to the culture (73.1%) and 14 respondents (26.9%) unadhering to the culture to eat too much salt. That shows that the majority of Sasak's elderly adhere to the culture and often consume over 1.5 teaspoons of salt. Respondents' compliance with diet hypertension is 35 respondents (67.3%) not obeying diet hypertension, and only 17 respondents (32.7%) were obeying diet hypertension.

Table 2. The correlation of education level and diet adherence

Education level	Diet Adherence				Total	
	No		Yes			
	n	%	n	%	n	%
No school	22	42.3	10	19.2	32	61.5
SD	13	25	7	13.5	20	38.5

PT	0	0	0	0	0	0
Total	35	67.3	17	32.7	52	100
***Spearman's rho* p=0.7 r= 0.039**						

Table 2. Showed that p=0.7 (p>0.05) or H_1 rejected, it means that there is no correlation between education level with adherence of diet hypertension.

Table 3. The correlation of economical level and diet adherence

Economic level	Diet adherence				Total	
	No		Yes			
	n	%	n	%	n	%
Under UMR	33	63.5	8	15.4	41	78.9
Top UMR	2	3.8	9	17.3	11	21.1
Total	35	67.3	17	32.7	52	100
***Spearman's rho* p= 0.000 r= 0.542**						

Table 3. Showed that p=0.000 (p>0.05) or H_1 accepted, it means that there is a correlation between economic condition and diet adherence. *Correlation coefficient* r=0.542 means a positive correlation, a better economic level so a better level of adherence.

Table 4. The correlation of family support with diet adherence

Family Support	Diet Adherence				Total	
	No		Yes			
	n	%	n	%	n	%
Bad	35	67.3	9	17.3	44	84.6
Good	0	0	8	15.4	8	15.4
Total	35	67.3	17	32.7	52	100
***Spearman's rho* p= 0.000 r= 0.612**						

Table 4. Showed that p=0.000 (p<0.05) or H_1 accepted, it means there is a correlation between family support with diet adherence. *Correlation coefficient* r=0.612 means a positive correlation, better family support so a better level of adherence.

Table 5. The correlation of culture and life style with diet adherence

Culture and Lifestyle	Diet adherence				Total	
	No		Yes			
	n	%	n	%	n	%
Following culture	34	65.4	4	7.7	38	73.1
Not following	1	1.9	13	25	14	26.9
Total	35	67.3	17	32.7	52	100
***Spearman's rho* p= 0,000 r= 0.779**						

Table 5. Shows that p=0.000 (p<0.05) or H1 accepted, it means there is a correlation between culture and lifestyle with diet adherence. *Correlation coefficient* r=0.779 means a positive correlation, a better culture and lifestyle so a better level of adherence.

4. Discussion

Based on the research findings, there was a correlation between economic level with hypertension diet adherence and a positive middle correlation. It means that a high economic level will have high adherence to diet hypertension. The result was matched with transcultural nursing from Leininger (1984), where people who are sick will use all the material sources to become healthy. This theory showed that family income will affect health behavior [12]. Families with low income couldn't fulfill their need for diet hypertension.

Respondents in this study lived with little family in their home so the income that they had should be divided and not focused on the elderly needed. The researcher thought that economic status effects adherence to diet hypertension, with a good economic status the family and elderly can buy any foods based on diet DASH.

This research finds that there was a correlation between family support with diet adherence and a positive strong correlation. It means that good family will support and motivate a family sickness in regard to health behavior. This study matched with transcultural nursing, family support will give time, notice, and remind respondents to fulfill their physical, mental, and social needs. Family support is a core factor that impacts health behavior [12]. In other research, Haastrup, et al (2014) stated that living with a supportive family can increase compliance of the diet regiment [13]. That means the

family is a support system for elderly with hypertension in serving healthy food for their diet and increasing diet adherence.

The majority of respondents in this research were living with their family, but they have not got good support from family. Their families do not know about hypertension, what they should do when hypertension relapses, and they do not accompany the elderly to go to public health. Most of the respondents' families cooked for the elderly but it is not relevant with diet hypertension. This condition makes the elderly have a low adherence of diet hypertension.

According to the results of the research, there is a strong positive correlation between family incomes and dietary compliance of elderly with hypertension. This finding supports transcultural nursing theory, that culture and lifestyle are some factors which influence someone's behavior, including health behavior [12]. In another way, it also can be said that culture and lifestyle have an impact on the dietary compliance of the elderly with hypertension.

The results of much of the research shows that most of the elderly practice a culture and lifestyle which didn't support them in their diet, so that it lowers dietary compliance among them. Based on research from Tailakh (2014) in Arab, culture and lifestyle influence blood pleasure and cause Arab people to have a positive culture such as: they know about a healthy lifestyle, how to reduce health risks, and eat a heart healthy diet. Arab people often consumption vegetables, fruits, healthy fat, nuts, etc. [14]. From this research we know if the culture in the community is healthy, it can influence a diet of hypertension. Cultural acculturation provides a positive impact for a diet of hypertension but if the culture is bad this makes for wrong health behaviors. Some of Sasak's elderly with hypertension who adhere to the culture have a bad diet because their culture consumes a high level of salt.

To overcome those culture and lifestyle factors the nursing process should adopt a strategy which accommodates the local wisdom of the communities' culture [12]. Not all cultures should be eliminated. Yet, some cultures which have a positive influence on health should be promoted in order to increase the health of the community. From the research, it was also known that salt consumption among the elderly was >1.5 teaspoons/day and they consumed another sodium source like MSG and preserved food [6].

Eating behavior which is high in sodium consumption should be changed because it is not good for the elderly, especially for elderly with hypertension. Even though most of the elderly still practice a high sodium diet, some of them are already aware that they need to manage their diet by consuming high-fiber food such as vegetables, fruits, nuts and minimize their consumption of meat and preserved food. That kind of diet is well known as the DASH (Dietary Approaches to Stop Hypertension) diet. DASH diet has already proven to have benefit in lower and control blood pressure. The principle of the DASH diet is limiting fat consumption and eating more foods which are rich in potassium, calcium, and magnesium. Examples of suggested foods for this diet are fruits, vegetables, cereals, and low-fat milk. Besides, this diet also recommends consumption of plant-based protein sources like nuts, rather than animal-based protein sources i.e. meats, poultry, and fish [15,16].

5. Conclusion

Based on the research findings, it is known that there is no correlation between educational background and dietary compliance among the elderly with hypertension in Tanjung Karang Village

(including in Tanjung Karang Primary Health Care). This happens because the elderly already have access to knowledge about hypertension from their environment. On the other hand, socio-economy, social/family support, cultural value, and lifestyle are positively correlated with dietary compliance among the elderly with hypertension in Tanjung Karang Village (including in Tanjung Karang Primary Health Care).

The transcultural nursing approach can be made as one of recommendation to provide a nursing process in a community which still has low awareness about dietary compliance for elderly with hypertension. Primary Health Care should give more education about hypertension to increase social/family support and motivation for the elderly with hypertension. This is so that dietary compliance among them could also be improved. For the researcher, further study in the field of factors that influence or correlate with dietary compliance among elderly with hypertension is still necessary. The scope and sample size for future research could be improved in order to get a more accurate result and additional findings. For the research instrument, it is suggested to use a more detailed questionnaire such as FFQ (Food Frequency Questionnaire).

SMARTPHONE ADDICTION AND INTERNET ADDICTION: PREDICTORS OF PHUBBING (TOXIC IN INTERPERSONAL RELATIONSHIPS): SYSTEMATIC REVIEW

Antonia Helena Hamu, Ah Yusuf, Yuni Sufyanti Arief
Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
Email: antonia.helena.hamu-2017@fkp.unair.ac.id

ABSTRACT

The development of communication and information technology which followed the development of the internet gave rise to a reality called new media. One form of new media that is experiencing rapid development is smartphones, with all the conveniences offered by features, people forget about the negative effects, such as the behavior of Phubbing. Phubbing behavior is the act of seeing a smartphone while having face-to-face conversations with others, highlighting a number of factors that can cause someone to use their smartphone while having face-to-face conversations with others including smartphone addiction, SMS addiction, social media addiction, internet addiction, and game addiction on line. The purpose of this article is to identify predictors from phubbing. Reviews are carried out in the following databases: Scopus, Science Direct, PubMed, SAGE, ProQuest, Spinger links. The keywords used are: Smartphone addiction, Internet Addiction, Phubbing. The journal is limited by the year of publication 2013-2019. Of the 56 jounals obtained, 15 journals identified smartphone addiction and internet addiction as predictors of phubbing. Of all the journals obtained by the main predictor from phubbing is smartphone addiction and internet addiction.

Keywords: smartphone addiction; internet addiction; phubbing; interpersonal relationship

1. Introduction

Phubbing is a term taken from the words Phone and Snubbing. Phone means mobile phones, smartphones, gadgets. While snubbing is a modern behavior that is ignoring, refusal, or also what is considered insulting during social interaction (interpersonal communication)[1] [2] [3] [4] [5]. Phubbing is a behavior in which someone is more focused on smartphones when interacting with other people, whether in the form of communication between two or more people or when interacting, where someone starts playing with a smartphone without a clear purpose. The goal is not to start talking to other people, not responding to other people's talk[6].

Recent research reports that 90% of people use smartphones as smart devices for social activity and interaction, 69.1% experience smartphone addiction[7]. Smartphones have become a part of human life. Many people feel inseparable from their smartphones. The age group of mobile phone users is dominated by 13-20 years. It often has an impact on dependence regardless of the surrounding environment. At this age good interaction skills are needed. So that, peer relations can be guaranteed well[8].

Data from the Adult Research Center showed that 46% of smartphone users in the United States claimed that they could not live without a smartphone. Many of them were experiencing mental disorders, such as phubbing. In India, teenagers who experience phubbing behavior are around

49.3%, smartphone users: 77%, using social media features like Facebook and WhatsApp: 62.4%. Phubbing duration 1-2 Hours: 79.1%; frequency ½ to 1 day around 89.3%, adolescents phubbing at home: 65.9%, and having been favored 1-3 times/day: 51.2%[13]. The research conducted by Hanika [14] in 2015 found that 54% felt anxious, 82% do phubbing; 54% do phubbing by receiving calls (calls) and messages; 36% experience intensity of using a smartphone throughout the day, and 64% did not ask permission from the other person to use a smartphone during interaction/communication.

The preoccupation with our smartphones has changed the way we interact with other people. Despite the many advantages of smartphones, it can damage our personal relationships and our well-being. We show the harmful effects of phubbing, revealing that phubbed individuals experience a sense of social exclusion, which leads to an increased need for attention and generates individuals who are tied to social media[15].

Phubbing is a new term. There was less research about phubbing and its predictors. So that, this systematic review was aimed to identify the predictors of phubbing.

2. Research Methods

This systematic review was reported in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) Statement.

2.12Data sources and searches

The results obtained were obtained from databases: Scopus, Science Direct, PubMed, SAGE, ProQuest, Springer links. There were 59 journals found, which included: Scopus database 12 articles, Science Direct 10 articles, Springer links 8 articles, SAGE 7 articles, PubMed 10 articles, and ProQuest 12 articles. Keywords used were “smartphone addiction” AND “internet addiction” AND “phubbing” AND “interpersonal relationship”. All journals that have been obtained were then screened according to the journal psychology area, computer sciences, art and humanities, and social sciences. Only 56 articles remained.

2.13Study selection

The papers went through 3 stages of screening to determine accuracy and avoid duplicate titles, citations, and abstracts. In the first stage, filtering all relevant data is based on the content. Second, all articles were read at least 3 times and each article was independently assessed by the researcher. In the last step the researcher finalized the data to determine the appropriate articles before extracting and analyzing.

2.14Data extraction and quality assessment

All citations retrieved from electronic databases were imported to Mendeley Desktop. Two reviewers (AY, YSA) independently analyzed the titles and abstracts of every study retrieved from the literature search to identify potentially eligible studies. The full text of the remaining studies was obtained for further examination. The last review was conducted by a first reviewer (TPD).

The research data was extracted independently by the same two reviewers by including the first author's name, year of publication, sample size, research design, and general characteristics of

participants (age).. A detailed explanation of the phubbing predictor factors and the negative impact on relationships when face-to-face interactions are documented. We use a smartphone and internet addiction as the main results of this systematic review.

Data of included studies were independently extracted by the same two reviewers by including first author's name, year of publication, sample size, study design, characteristics of participants (age) and the main outcome of interest is the predictors of phubbing.

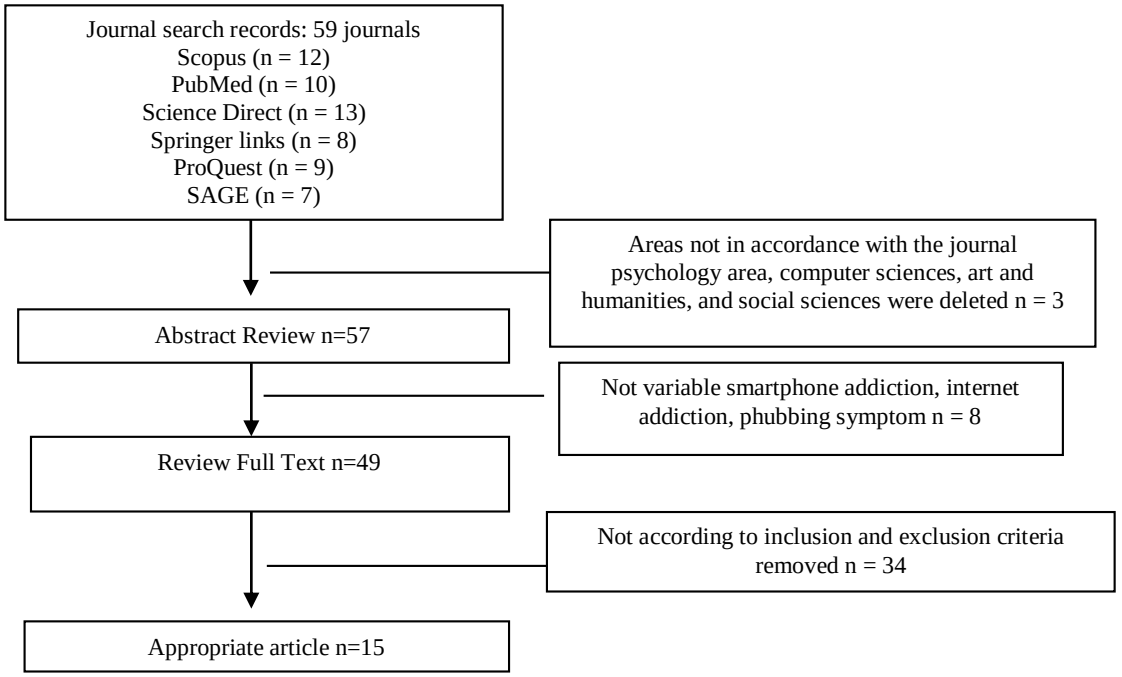

Figure 1. Flowchart of literature search

3. Results

From 15 journals reviewed, the number of samples varied between 125 - 1475 respondents, and involved respondents between the ages of 14-55 years. The total number of respondents was 6,666. The study used various designs, such as: descriptive analysis, comparison, correlation, experimental and qualitative, cross-sectional, and mixed method (qualitative and quantitative). The study was conducted in various countries, including: Turkey, England, Brunei, America, Germany, Poland, India, and Belgium.

The results of the study conducted by Karadağ et al. [16] involved 409 respondents, which were selected randomly. Data were obtained from 8 students (who gave the same score for all items and who were believed to have responded dishonestly), which might negatively affect the reliability of the study, and which was deleted before the start of the analysis. Thus, data from 401 participants were used in the study. Of the 401 participants, 114 were male (28.4%), while 287 were male (71.6%). Their average age is 21.9. In total, 70% of participants have smart phones, 92% use social media, and 75% spend 2 hours or more on the Internet per day. The findings indicate that the highest correlation value explains pubbing is mobile addiction, other correlation values reflect a dependence on cell phones. There is an increasing tendency towards cell phone use, and this tendency

is the basis of phubbing. According to Chotpitayasunondh and Douglas [17], in a study in the UK, with 276 respondents aged 18-66 years, the results revealed that there was a positive correlation between smartphone addiction and phubbing behavior.

Research by Davey et al. [13] in India with 400 respondents aged 15-29 years for 6 months (November 15, 2016-May 15, 2017), found that the prevalence of phubbing is 49.3%. The most important predictors associated with phubbing were internet addiction ($p<0.0001$, OR=2.26), smartphone addiction (OR 25.9), fear of missing out (OR 18.8), and lack of self-control ($p<0,0001$, OR=0.73-1.72).

4. Discussion

Phubbing is the behavior of ignoring others in the social environment when two or more people are interacting and when they are more focused on smartphones[29]. This phenomenon occurs when someone suddenly turns his gaze to their phone in the midst of social interaction[17]. Phubbing is considered an impolite behavior; can damage emotional closeness in human interactions, which can then hinder relationships[11]. This is due to smartphone and internet addiction[24]. People will become anxious (nomophobia)[18]. So that, they are more apathetic towards the environment because it is more focused on what is in his hand. Communication should extend from the heart to the finger, which is far closer. This can be seen anywhere when eating together, meeting, lecturing, or gathering with friends or family[30] [31]. For many couples phubbing behavior occurs when they are together at home, in bed, and when eating together[21].

The reason people do phubbing is: receiving calls, texting, chatting/social media, playing games, watching movies, bored with the other person, to be happy, and bored during lectures or lessons [2][14]. According to research in Denmark involving 25 students aged 16-20 years, students feel annoyed at being harassed for the sake of smartphones, because they are more carried away with Facebook and Instagram when spending time with friends and family[32].

This phubbing behavior arises from people who are addicted to smartphones and the internet[17][33]. People with addiction will focus more on smartphones and the internet, rather than talking to other people in the real world (interaction), and who will experience nomophobia. Phubbing is considered an impolite behavior which can damage emotional closeness in human interaction, which can then hinder relationships[11], lead to negative emotions, and being close-minded. Viewing a smartphone will hamper the communication in the relationship between two people during face-to-face interactions[28].

"Smartphones are making my housemates and me become anti-social. We may be sociable in virtual social network, but virtual is virtual, and it's difficult to correlate with real life. . . Staring at my cell phone will estrange my friends from me. At the end, I just want to tell my dear friends, when spending time with people you care about, please put your smartphone away" [34].

A predictor of phubbing is smartphone addiction, including: addiction to short messages, social media, internet and games[16], fear of missing out[17], and PIU (Problematic Instagram Use), causing phubbing higher than fear of missing out[22].

The negative impact of phubbing is interference with romantic relationships and social interactions between parents in children, which can be almost non-existent. This is unfortunate,

because empirical studies also show that phubbing is associated with a number of negative interpersonal consequences such as lower communication quality[35], feeling less satisfied during interaction[4] [26], and mood decreasing because the couple gives more time to the media and their smartphone than to the their partner[36]. It threatens four basic needs: belonging, self-esteem, meaningful existence, and control[35]. If it is not realized, the quality of communication is poor[37], with lower relationship satisfaction[38], and dissatisfied relations between parents and children[19]. Problematic parent-child relationships will be worse when viewed from smartphone addiction behavior by children[19], and lack of warm feelings from parents involved in phubbing[39]. Many problems that arise in couples are uncomfortable when one partner is more focused on the smartphone [27][40].

The role of smartphones everywhere in everyday life gradually demands a lot of attention. The use of smartphones is not constructive and are used to post more on social media, online shops, communicate virtually, and online games. Given the lack of research on this and reference.

Nurses must work with professionals from various disciplines and conduct education planning in hospitals to promote healthy use of the Internet and smart phones. Nurses who interact with educators, parents, and adolescents in the fields of public health, adolescent health, and psychology know the impact of internet and smartphone use on adolescent development. Nurses can also do further research to prevent phubbing.

5. Conclusion

This systematic review identifies smartphone and internet addiction as the predictors of phubbing. The parent's role in assisting children who use smartphones is needed, also to restrict the use of smartphone for young aged children. Nurses as educators must be able to provide education related to restrictions on the use of the internet and smartphones.

Appendix

Table 4. The characteristics of the study evaluated the predictors of phubbing

Author	Title	Country	Design	Population/Sample	Age	Analysis	Results
E. Karadağ *et al* [16]	Determinants of phubbing, which is the sum of many virtual addictions: A structural equation model	Turkey	Correlational	409 students	The average age is 21 years	As a result of the Pearson product-moment correlation analyses to check for multicollinearity Multiple Regression Analysis	Predictor of phubbing is an addiction to smartphones, addicted to SMS, addicted to social media, addicted to the internet, addicted to games.
V. Chotpitayasunondh and K. M. Douglas [17]	How "phubbing" becomes the norm: The antecedents and consequences of snubbing via smartphone	English	Cross-sectional	276 Students	Ages 18-66 years old	Spearman's A Mann-Whitney U test	Smartphone addiction is predicted to be a significant cause of phubbing behavior (b ¼ 0.45, p <0.001). Next, when the effect is active smartphone addiction from every variable counted, then that is revealed that internet addiction (b ¼ 0.41, p <0.001) and fear loss (b ¼ 0.33, p <0.001) was a positive predictor addicted to smartphones, while self-control negatively predicts smartphone addiction (b ¼ 0.12, p ¼ 0.016).
M. Anshari, Y. Alas, G. Hardaker, J. H. Jaidin, M. Smith, and A. D. Ahad [18]	Smartphone habit and behavior in Brunei: Personalization, gender, and generation gap	Brunei	Cross-sectional	589 respondents	Ages 15-55 years old	T-test	High usage patterns with almost two thirds of respondents showing smartphone use for more than 6 hours per day. This high level is combined with the fact that more than 46% of respondents indicated that they cannot live without a smartphone, they make it clear that there are mental disorders such as nomophobia and phubbing.
B. T. Mcdaniel, A. M. Galovan, J. D. Cravens, and M. Drouin [19]	Technoference" and implications for mothers' and fathers' couple and co-parenting relationship quality	America	Cross-sectional	182 respondents	The average age is 32-37 years	Multilevel structural equation model (SEM)	Individuals felt insecure, more phubbing from their partners (b ¼ 0.26, p <0.001). We also found that their partners had greater media use (b ¼ 0.13, p <0.05) and that many problems from couples were more likely attributed to the use of smartphones (b ¼ 0.46, p <0.001) and greater phubbing behavior with their partners. Furthermore, the relationship between phubbing and problematic

							phone calls from partner use was stronger for women than men (b ¼ 0.22, p <0.05).
J. A. Roberts and M. E. David [20]	My life has become a major distraction from my cell phone: Partner phubbing and relationship satisfaction among romantic partners	America	Cross-sectional	308 respondents	Ages 18-29 years old	Chi-square	The use of media and problematic telephone calls from partners significantly causes phubbing, so the more time and attention their partners give to the media and their calls, and the more disturbed they will be in their relationships.
H. Krasnova, O. Abramova, I. Notter, and U. Bern [21]	Why phubbing is toxic for your relationship, understanding the role of smartphone jealousy among " generation y" users	German	Qualitative Quantitative	1475 respondents	Ages 26-40 years old	Wilcoxon rank-sum test and Mann-Whitney Partial Least Squares (PLS)	The use of smartphones by couples on a regular basis, this technique allows to reduce the process of answering questions by helping respondents to focus on certain situations with the highest memory. About one third of the respondents (33.6%) claimed that the incident occurred when spending time together at home, 19.6% remembered that their partners too often used smartphones in bed before going to sleep. Furthermore, phubbing couples are seen when they eat together at home (10.8%), while on a trip at a place public transportation or in the car (9.8%), and when out (4.5%). Other opportunities are less prominent, with respondents considering watching TV (2.1%), walking (2.4%), or shopping (0.7%). 22 respondents (8.4%) stated that their partners had never used a smartphone for too long.
S. Balta and E. Emirtekin [22]	Neuroticism, trait fear of missing out, and phubbing: the mediating role of state fear of missing out	Turkey	Cross-sectional	423 respondents	Ages 14-21 years	Path analysis	Fear of missing out/FoMO (β = .30, p <.001; 95% CI [.16, .43]) and PIU (problematic Instagram use) (β = .54, p <.001; 95% CI [.37, .71]) are directly related to phubbing while trait-FoMO (β = .35, p <.001; 95% CI [.26, .44]) and neuroticism (β = .09, p <.05; 95% CI [0.00, 0.19])

	and problematic Instagram use						were indirectly related to phubbing through each country-FoMO and PIU. The dual mediation model describes 25% of FoMO countries, 50% of PIUs, and 73% of phubbing ones. Parallel to the hypothesis, neuroticism is not directly associated with phubbing through the use of troubled Instagram. Neuroticism is related to the use of higher troubled Instagram, and in turn, problematic use of Instagram causes higher phubbing.
A. Błachnio and A. Przepiorka [23]	Be aware! If you start using Facebook problematically you will feel lonely: phubbing, loneliness, self-esteem, and Facebook intrusion. A cross-sectional study	Poland	Cross-sectional	597 respondents	The average age is 21 years	equation models	Women scored higher than men on both phubbing factors of communication disorders, Women ¼ 2.05, SD ¼ 0.73, Mmen ¼ 1.86, SD ¼ 0.70, F (1, 613) ¼ 9,370, p 00 .002, and on telephone obsession, Mwomen ¼ 3.06, SD ¼ 0.82, Mmen ¼ 2.73, SD ¼ 0.83, F (1, 613) ¼ 20,634, p <0,001. Low loneliness contributes to Facebook's intrusion, but a high level of Facebook intrusion leads to an increase in loneliness and affects both phubbing dimensions, namely, communication disruption and telephone obsession.
S. Davey *et al.* [13]	Predictors and consequences of "Phubbing" among adolescents and youth in India: An impact evaluation study	India	Qualitative quantitative	400 respondents	Ages 15-29 years	Chi-square test	The prevalence of phubbing is 49.3%. The most important predictors associated with phubber were internet addiction (p <0.0001, Odds Ratio 2.26), smartphone addiction (OR 25.9), fear of being left behind (OR 18.8), and lack of self-control (p <0, 0001, OR = 0.73-1.72). Phubbing also has significant consequences for social health, relationship health, and self-development, and is significantly associated with depression and distress. Logistic regression analysis showed a significant effect of phubbing predictors on the consequences of phubbing in phubbers, especially in depressed and depressed states.

E. Karadağ *et al.* [24]	The virtual world's current addiction: phubbing	Turkey	Qualitative	759 respondents	Young adults	Factor analysis (EFA) Confirmatory factor analysis (CFA) to test two models	Support structure which is consistent with the original validation study, with two factors: communication disorders and telephone obsession. Internal consistency found adequate evidence of concurrent validity is given through a hierarchical regression model that shows a positive relationship with a measure of internet addiction, Facebook intrusion, and fear of missing out.
L. Simone [25]	The mere presence of mobile phones during parent-teen interaction	America	Experimental and qualitative	200 respondents	Age of 18-29 years	ANOVA	Experience of the quality of conversation, closeness of conversation, and conversation (listening) of partners when interactions occur in front of a cellphone which has a detrimental effect on interpersonal relations.
Epps Courtney [26]	An exploration of how technology use influences relational ethic scores of emerging adult romantic relationships	America	Correlation	248 respondents Ages 18-25		MANOVA	Negative perceptions of the impact of using technology on respondents' relationships are associated with lower relational outcomes for relational ethics, trust, intimacy, and relationship satisfaction.
González-Rivera, S. Abreu, and Urbiston do-Rodrígue z [27]	Phubbing in romantic relationships: cell phone use, couple satisfaction, psychological well-being and mental health	America	Comparison	252 participants	An average age of 33 years	Comparison analysis t test equipment T-test SEM	The greater the phubbing of partners, the greater the conflict in smartphone use, dissatisfaction in partner relationships, and disruption to mental health (anxiety, depression and stress). The structural model results from Phubbing in the Couple were phubbing predicting lower satisfaction in the pair (β = -, 57, p<0.001). In turn, low satisfaction leads to low psychological well-being (β = .44, p<.001) and greater negative mental health, which is higher depression, greater anxiety and greater stress (β = -.28, p <.001). Regarding the direct effects of phubbing, we found a significant effect on mental health (β = .25, p <0.001), but did not affect psychological well-being (β = .95, p> .001). In addition, the indirect effects observed of

							the meaning between phubbing and negative mental health (β = .16, 95% CI [.06, 18]) and between phubbing and psychological well-being (β = -.24, 95% CI [-. 72, -.39]).
M. M. P. Vanden Abeele, M. Postma-nilsenova, M. M. P. Vanden Abeele, and M. Postma-nilsenova [28]	More than just gaze: an experimental vignette study examining how phone-gazing and newspaper-gazing and phubbing-while-speaking and phubbing-while-listening compare in their effect on affiliation	Belgium	Experimental	125 respondents	The average age is 24 years	ANOVA	Stare at the smartphone during the interaction harms the relationship more than staring at the newspaper. Also, looking at a smartphone is hampering affiliation when listening rather than when talking. These findings indicate that looking at a smartphone raises the assessment of relationships in interaction partners.

ABSTRACT

Leprosy is a complex and a high burden disease to the community. The Chronic Problems caused by leprosy are often amplified by local socio-cultural in many parts of the world. This systematic review aims to identify and describe the socio-cultural dimensions of leprosy in Asian. Electronic searches were undertaken using ProQuest, Scopus, ScienceDirect, EBSCO, and PubMed databases. All relevant articles written in English and focuses on socio-cultural of leprosy were included. 15 articles were included in this review. On the process of the analysis of the articles showed that the socio-cultural dimensions of leprosy comprise stigma; discrimination against women was higher than men; traditional and religious healers; misconceptions about disease; and negative attitudes towards leprosy patients in most communities. The socio-cultural has been shown to be a factor influencing access to health services and treatment adherence. Appropiate interventions are needed in accordance with the local socio-cultural to achieve a change in the health seeking behavior.

Keywords: leprosy, socio-cultural demensions, asian

1. Introduction

Leprosy is a contagious disease that causes serious problems and is very complex because it is not only medical but also includes social, economic, cultural, security and social security issues [1]. The risk of leprosy transmission is higher in one family, this is because family members relate directly to patients every day and these relationships last a long time [2]. The implementation of the program to prevent leprosy transmission has often encountered several obstacles related to differences in community characteristics, differences in culture in the family, and coverage of areas far from health care facilities [3].

The existence of a culture that is believed by individuals can influence the perception and selection of care undertaken by lepers [4]. Errors in decision making for the treatment of leprosy will greatly affect the prognosis of the disease suffered. In leprosy if there is a delay in case finding, it causes the sufferer of leprosy to suffer fatally from the condition, namely permanent damage or disability in the limbs. In addition, in the presence of inadequate treatment, it is difficult for the M. leprae bacteria to be turned off, resulting in the development of the spread of leprosy [5].

When diagnosed with leprosy, patients often try to conceal the disease, for example by seeking treatment from a health center at some distance from their home. To avoid negative behavior from their community, leprosy patients and, on occasion, their spouses may withdraw from communication with other members of their community [6]. In addition to self-isolation practiced by leprosy patients, community members also express their negative attitudes by avoiding them, forcing them to leave,

gossiping about them, and refusing to share public transport with them [7]. Such behaviors have a negative impact on the physical, psychological and socio-economic status of people affected by leprosy.

Psychologically, they may suffer mental stress and anxiety leading to depression and even, in some cases, suicide. In many cases, their economic situation may decline, their marital partner may reject them, and opportunities for further education may be reduced [8]. To prevent stigma and to reduce the manifestations that cause so much suffering to individuals and their families, effective interventions are needed [9]. This systematic review aims to identify interventions that have been used to reduce such stigma and to assess their efficacy. The results of this review will be useful for health personnel and other professionals who wish to develop interventions to address leprosy-related stigma.

2. Methods

Data retrieved from databases ProQuest, Scopus, ScienceDirect, EBSCO, and PubMed. Search articles using keywords leprosy, Hansen disease, socio-cultural, and Asia. The selection of articles using the following criteria: written in Thai or English, using qualitative, quantitative, or mixed methods. All publication years were included.

On the process of the analysis of the articles showed that the stigma, traditional and religious healers, misconceptions and negative attitudes towards leprosy patients in most communities.

A total of 906 articles were found, the results came from four databases: 304 articles in ProQuest, 92 articles on Scopus, 108 articles on EBSCO, 198 articles on PubMed, and 204 articles on ScienceDirect. The results of the article selection are in accordance with the inclusion criteria of 15 articles, then given the serial number and analysis of the article to facilitate the review process. The socio-cultural has been shown to be a factor influencing access to health services and treatment adherence.

In this systematic review of the 15 studies is about all populations were Leprosy patients, the number of samples varied between 1-500 Leprosy patients. The research was conducted in Asia, Middle East, Including Indonesia, India, Pakistan, China, Bangladesh, and Nepal.

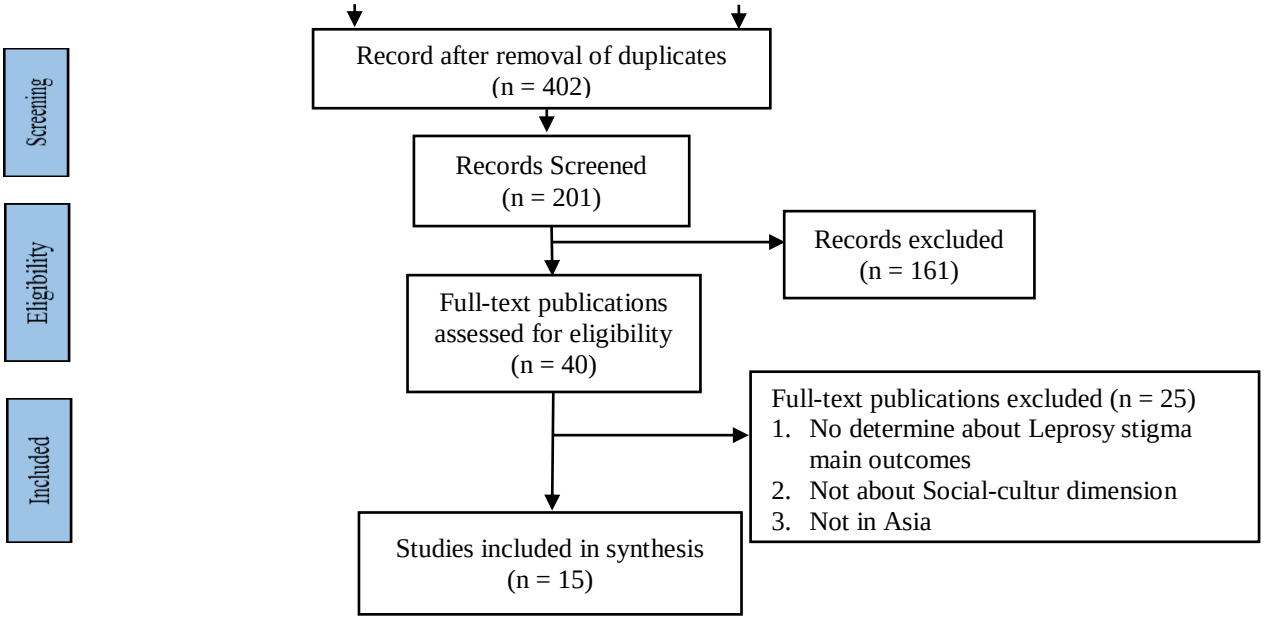

Figure 1. Selected paper Process
Figure 1. Selected paper Process

3. Results and Analysis

3.1. Stigma

The systematic review found 5 journals describing stigma about discrimination. The journal compiled by Varkevisser *et al.* in 2008 stated that strong traditions, low status of women, limited mobility, illiteracy and low knowledge of leprosy appear to be important social cultural factors that explain why women are not reported. However, accessible and well-known services increase women's participation and help reduce stigma, which in three of the four communities appears to be greater for women than men [10]. In addition, in the journal Zodpey *et al.* in 2000 it is stated that leprosy patients are isolated and refrain from various activities in the family which would have a significantly greater effect on women than men. Similarly, though, men and women are equally affected in terms of their social life, women suffer more isolation and rejection from society [11].

In the systemic review it was also that found some articles describe socioeconomic and culturally-defined social-pattern interactions which are considered as the most important thing in the spread of diseases transmitted through person-to-person contact. An understanding of contact patterns in this region can help to develop more effective control measures. Focus group discussions are used in exploring patterns of social contact in northwestern Bangladesh. The patterns of social contact that are very relevant in the home and environment, across age groups and sexes, are reported in all group discussions. This concept requires further exploration but control programs in the South Asia region can benefit from considering differences in gender-based social contact patterns for risk assessment and planning for preventive interventions [12].

Kazeem and Adigun in their 2011 journal also stated that stigma is still an important feature of the leprosy landscape that leads to seclusion, job loss, housing loss, ridicule and rejection from the community. The reason leprosy depends on history and culture on mythology is in terms of origin and transmission of disease, and its aesthetic features such as confusing physical disability, and ulcers that are typical of untreated leprosy [13]. Whereas Bedford in 2008 researched and published his journal which discussed the status of them (Leprosy sufferers) as an indigenous minority in Peninsular Malaysia, leprosy in the Orang Asli community assumed an additional social configuration beyond its clinical manifestations. The stigma that occurs is mostly in India, Malaysia and Bangladesh.

3.2. Discrimination Against Women Was Higher Than Men

From a number of journals that have been reviewed, only a few journals discuss discrimination of women with men. Among others are Varkevisser *et al* journal in 2008 where the low status of women appears to be the important social cultural factors that explain why women are not reported. However, accessible and well-known services increase women's participation and help reduce stigma, which in three of the four communities appears to be greater for women than men [14]. In addition, Zodpey *et al.* in 2000 in the journal states that leprosy patients are isolated and refrained from various activities in the family which would have a significantly greater effect on women than men. Similarly, though, men and women are equally affected in terms of their social life, women suffer more isolation and rejection from society[11].

3.3. Traditional and Religious Healers

In the journal of Mull 1989 in Pakistan the findings of this study emphasize the need for better training from doctors and other health care providers in early diagnosis of leprosy and better health education than diagnosed patients so that it is truly effective [15]. Treatment of leprosy should include extended family counseling and broad community education and increased communication with the patient itself.

3.4. Misconception

In the results of a journal review on the topic of misunderstanding only 1 journal was found from several journals. As in the Sabiena journal in Bangladesh, 2013 explained the spread of transmitted diseases through person-to-person contact, while Desancha in 2015 in Nepal explained the understanding of biomedical disease, namely non-biomedical beliefs about injuries and the broad application of traditional 'hot-cold' disease models used to explain foot ulceration [12].

4. Discussion

There are several studies in Asia that discuss socio-culture in leprosy. in this discussion the focus will be on how socio-cultural can negatively influence the selection of health services (access to diagnosis, treatment, and adherence) to lepers [16]. To improve our understanding of socio-culture in leprosy patients we must understand the factors that can affect socio-cultural conditions in leprosy first [17]. At most the health prevention and care behaviors of leprosy are influenced by local perceptions and complex psychosocial factors [18].

Socio-cultural has been found as a factor that causes patients to delay in seeking access to health services. As we have analyzed, some studies show that patients affected by leprosy come late to health services after being disabled [19]. A study found that people who have leprosy are ashamed of their scars and try to hide them [10]. Another study shows that lepers prefer to come to religious leaders and traditional medicine, so the time to come in health services is already late and transmission in a community is increasing [4].

The existence of negative factors from the local socio-cultural leprosy patients, consequently inhibits control efforts (13). Finally are the patients who reported being late and disabled. In the study, it was explained that discretion in women was greater than men, making leprosy patients late to health services, delayed diagnosis and inadequate treatment [20].

Leprosy patients avoid free care in government health services because the condition of leprosy patients can be identified in public by the community [11]. Leprosy patients prefer to religious leaders and traditional medicine because leprosy patients consider their illnesses to be caused by a curse of God or ghost and the condition of leprosy patients can be more easily hidden [21]. The consequence of this behavior is that patients receive ineffective treatment from religious leaders and traditional medicine [22].

5. Limitations

Most of the articles related to socio-cultural are either cross-sectional or qualitative studies. One important limitation of the data is its limited geographic coverage. Thus, these findings may not be representative of all endemic areas affected by these diseases in Asia. Sample sizes tended to be small in many of the studies, and selection/observation bias was not taken into account properly. Therefore, it is necessary to be cautious with generalizing the results.

6. Conclusion

The socio-cultural has been shown to be a factor influencing access to health services and treatment adherence. Appropriate interventions are needed in accordance with the local socio-cultural to achieve a change in the health seeking behavior.

The tradition of the kyai or the physician in finding a cure for illness is wrong and must be justified in the context of health in leprosy. In addition to handling leprosy, the community's stigma regarding leprosy and even discrimination between women and men should be abolished. Likewise, misconceptions must also be straightened out with the correct knowledge related to leprosy, so that the handling will be even more effective and even reduce the stigma and transmission chain.

Table 1. Description and Paper Analyze

No	Author, Country, and Years of Publication	Study Design	Number of Samples	Research's Subject and Kind of method	Main Results
1	Haidarali Abedi *et al.,* Pakistan 2013	Qualitative: Phenomenology	10	▪ Individual + family ▪ In-depth interview, containing participants experience about idea and feeling of health and knowledges family about Leprosy (economic and health)	The health, family and economic situation which is negatively affected by leprosy requires a comprehensive health care program. Such as, a comprehensive health promotion program that must be planned as a comprehensive community-based program.
2	Sabiena G. *et al*., Bangladesh 2013	Qualitative	12	▪ Individual ▪ Focus Group Discussion (Social contact pattern)	Socioeconomically and culturally-defined social-pattern interactions are considered as the most important thing in the spread of diseases transmitted through person-to-person contact. An understanding of contact patterns in this region can help to develop more effective control measures. Focus group discussions are used in exploring patterns of social contact in northwestern Bangladesh. The patterns of social contact that are very relevant in the home and environment, across age groups and sexes, are reported in all group discussions. This concept requires further exploration but control programs in the South Asia region can benefit from considering differences in gender-based social contact patterns for risk assessment and planning for preventive interventions.
3	Mull J.D. *et al.* Pakistan 1989	Qualitative: Phenomenology	128	▪ Individual ▪ In-depth interview by questionnaire	The findings of this study emphasize the need for better training from doctors and other health care providers in early diagnosis of leprosy and better health education than diagnosed patients so that it is truly effective. Treatment of leprosy should include extended family counseling and broad community education and increased communication with the patient itself.
4	Varkevisser C.M.. *et al* Netherlands 2008	Partially qualitative and quantitative	500	▪ Individual ▪ partially quantitative (analysis of the records of patients who according to prescription could have completed treatment) and partially qualitative (interviews/focus group discussions)	Biological factors appear similar in four countries: regardless of the M / F ratio, there are more men than women who are registered with multi-bacillary leprosy (MB). Strong traditions, low status of women, limited mobility, illiteracy and low knowledge of leprosy appear to be important social cultural factors that explain why women are not reported. However, accessible and well-known services increase women's participation and help reduce stigma, which in three of the four communities appears to be greater for women than men. This positive effect can still be higher if the service will improve community education and patients with active participation of patients and former patients themselves.
5	Zodpey S.P. *et al.* India 2000	Quantitative : Structural interview	486	▪ Individual ▪ the Modified Kuppuswamy' s scale of socio-economic status (SES) classification, using occupation, education and per capita income as parameters	It was observed that leprosy patients isolated and refrained from various activities in the family would have a significantly greater effect on women compared to men. Similarly, though, men and women are equally affected in terms of their social life, women suffer more isolation and rejection from society.

6	Desancha M. *et al.* Nepal 2015	Qualitative: Exploratory	21	▪ Individual ▪ Three focus groups and a series of field observations were used to explore the explanatory models of foot ulceration thought to be used by leprosy affected people to understand and explain this specific comorbidity	The findings indicate that there are a variety of health beliefs including those outside the understanding of biomedical disease, namely non-biomedical beliefs about injuries and the broad application of traditional 'hot-cold' disease models used to explain foot ulceration.
7	Kazeem O & Adegun T. UK 2011	Qualitative: Phenomenology	36	▪ Individual ▪ In-depth interview containing leprosy stigma in various context and managing leprosy stigma	Stigma is still a critical feature of the leprosy landscape that leads to seclusion, job loss, housing loss, ridicule and rejection from the community. Leprosy relies on history and culture on mythology about the origin and transmission of disease, and its aesthetic features such as enigmatic physical defects, and ulcers that are typical of untreated leprosy.
8	Peters R.M.H. *et al.* Netherlands 2014	Qualitative: Phenomenology	53	▪ Individual ▪ semi-structured in-depth interviews focus on six points who knows, care, social stigma, feelings, self-isolation and agency.	Women overcome this through acceptance, self-comfort, trust in God, focus on recovery, friendship or finding inspiration in others.
9	Staples J. India 2011	Qualitative: Phenomenology	1	▪ Individual ▪ In-depth interview	Such biographical analysis, with a broader background in ethnographic research, allows a more subtle reading of the stigma associated with leprosy, contextualized in relation to various intersecting socio-political, cultural and economic problems.
10	Bedford, K.J.A Tannessee 2008	Open inductive qualitative	32	▪ Individual ▪ In-depth interview with key interlocutors (patients, community members, and health care professionals), focus group discussions, case studies and narratives, and direct and participatory observation	In the context of Gombak Hospital, leprosy is an illness where notions of responsibility, compliance, and stigma collide, and where experiences of health, illness, and treatment-seeking behavior are expressed along ideological and ethnic lines. In light of their status as the indigenous minority of Peninsular Malaysia, leprosy in the Orang Asli community assumes additional social configurations beyond its clinical manifestations.
11	Susanto T. *et al.* Jember Indonesia 2017	Qualitative: Phenomenology	17	▪ Individual ▪ Focus group interviews, which the investigators had arranged	This analysis identifies five themes around the experiences of people participating in the SCG in the community: self-perceived conditions, adherence to treatment, ability to carry out personal care, types of assistance and services received, and acceptance and support of people affected by leprosy. Based on participants' adherence to taking treatment, participants in this study were divided into obedient or non-adherent groups, where the drug administration was related to discomfort or complaints experienced by participants as a side effect caused by treatment. Compliance with treatment is associated with a lack of confidence in the

					treatment provided by the "Puskesmas", understanding of short-term and long-term MDT therapy regimens, and efforts to reduce side effects from treatment.
12	Peters R.M.H. *et al.* Netherlands 2013	Qualitative: Phenomenology	53	▪ Individual ▪ In-depth interview and 20 focus groups discussions.	The continued need for implementation of leprosy services in Indonesia is very evident. The diversities in people's experiences with leprosy indicate a demand for responsive leprosy services to serve the diverse needs, including services for those formally declared to be "cured
13	Kolay S.K. *et al.* Turki 2016	Quantitative : Cross-sectional study	101	▪ Individual ▪ Pre-tested close-ended questionnaires	The study noted that the tribal people were affected by leprosy not only in terms of the physical problems, but also by the stigmatization that affects their social participation. These need to be addressed by the progress of the national leprosy program.
14	Lal V. *et al.* India 2014	Qualitative: Phenomenology	20	▪ Individual ▪ In-depth interview to explore the experiences of parents with regard to the diagnosis of leprosy and the treatment of their child	No parent has knowledge about reactions. Although the current strategy has enabled early case detection, there are related challenges to ensuring treatment completion. Emphasis should be placed on interpersonal communication to empower parents, enabling them to value side effects and recognize complications early and actively engage as treatment partners when their children use MDT.
15	Pradhan S. *et al.* Australia 2016	Qualitative: Phenomenology	2	▪ Individual ▪ Case study	Hansen (HD) can have disastrous effects on the quality of life of patients, especially when treatment is delayed. Nerve damage and its sequel are a major concern for health care providers. Early diagnosis and treatment is the only way to reduce damage caused by HD. Sometimes cultural beliefs and practices become obstacles to early diagnosis and initiation of multi-drug therapy (MDT). Two cases reported late arrivals because of their belief that tattoos not only prevent the spread of the disease but also contain diseases, allowing healing.

ABSTRACT

Background. Wandering is defined as the behavior of aimless mobilization or disorientation of dementia client which has its own pattern such as hitting, repetitive, or walking aimlessly, irregular frequency, overreaching, and difficulty finding the right path. Wandering behavior affects walking aimlessly, missing for days, risk of injury, and death. Treatment of wandering behavior so far still uses traditional methods. The aim of this study is to provide an overview of the management of wandering behavior interventions optimally in the care facility and community settings. Method. This systematic review comes from RCT articles obtained from SCOPUS, Science Direct, Google Scholar, ProQuest, CINAHL, and CNBI published in English. The given intervention was well documented, as was the management program provided. Results. Ten articles identified for review. Study settings include NH, elderly care facilities, and communities. This study was conducted in several countries from four continents, mostly from Australia. Participants consisted of 542 residents and 31 NH. The intervention given has an effect on decreasing wandering behavior. Conclusion. Alternative interventions given can be applied in care facilities. The wandering care management program is recommended to be used asplan for the wandering care program by nurses.

Keywords: optimally, management, wandering, dementia

1. Introduction

Dementia is a condition that describes a decline in cognitive function and mental deterioration, usually found in the elderly where everything will have an impact on the patient's ADL accompanied by changes in behavior [1]. Dementia is a degenerative disease that is considered terrible and presents its own challenges for clients, families, caregivers, and health workers, so it requires special care, easy access, high costs, and related care quality issues [2]. Symptoms of dementia include progressive setbacks in memory and other cognitive abilities, decreased personal ability to implement ADL, disorientation and wandering [3].

Wandering is one of the problems of dementia behavior and is very dangerous, so it requires special handling by caregivers, clients, and health workers. Wandering behavior is likely due to loss of memory, anxiety, suspicion, illusion, and aggression. Risks that can occur in wandering behaviors include falls, injuries, hip fractures, and loss [3]. Basically wandering is defined as the behavior of

aimless mobilization or disorientation of people with dementia who have their own patterns (hitting, repetitive, or walking aimlessly), irregular frequencies, overreaching, and difficulty finding the right path [4].

The prevalence of dementia is estimated at 35.6 million in 2010 globally and will double every 20 years [1]. The increased population of dementia was certainly accompanied by an increase in wandering behavior, in the Netherlands, there were 80% of cases of wandering behavior in clients of dementia, 15% - 28% occurred in the nursing home and/or other health facilities [5]. A study in Texas in the United States said one in five people with dementia had to wander and 40% were lost, and needed help to go home [6].

Wandering behavior is a problem for the caregiver even in nursing practice. Treatment for clients with wandering behavior still uses traditional methods so far, namely by providing restraint and/or neuroleptic therapy [7]. Furthermore, it gives stress and anxiety to caregivers and nurses so that it becomes one of the causes of increasing caregiver burden. This is more due to the lack of information and alternative interventions about wandering care management, so the aim of this article is to provide an overview of the management in wandering behavior optimally in the care facility and community.

Studies conducted on wandering behavior are still rarely found. Studies that aim to reduce the behavior of wandering and prevent the occurrence of elderly people are lost. Programs for treatment on wandering have not specifically focused on the main problem. So the alternative intervention provided is still common. This review will discuss the management of optimal care in reducing wandering behavior, which has not found a similar review until now.

2. Method

2.1 Search Strategy

This review aims to review articles by exploring them systematically and conducting critical assessments of articles that discuss interventions on wandering behavior in dementia clients. This review is based on the PRISMA-P (the preferred reporting items for Systematic Reviews and Meta-Analyzes) statement [8].

This review is based on several articles obtained from published literature in various international journals. Journal search strategy used the keywords wandering, dementia, and elderly. Journal entries included years between 2013 - 2018, English, nursing, Psychology, Professional Health, and publication titles including Alzheimer's and Dementia, The American Journal of Geriatric and Psychiatry, Geriatric Nursing, International Journal of Nursing Studies, Archives of Gerontology and Geriatric. This search was done on the SCOPUS database, Science Direct, CINAHL Plus, PubMed Central, Google Scholar, and CNBI. The article that appears an election process by separating the title and abstract of the article according to the keyword.

Articles found from search results are then exported to Mandalay, whereas if duplicate articles are found they are moved or deleted. Then the article was reviewed based on full text and summarized into the PICOT table. The PICOT table is able to well describe the intentions and contents of the contested articles.

Screening of titles, abstracts, and full text is done independently by the AK, the final decision is made by AY, AV, and RF.

2.2 Eligible Criteria

This review includes articles with a quasi-experimental design [9], [10], [11], [12], [13], [14], [15], [16], [17], and [18]. The article includes articles with a control group and without a control group and pre-posttest design. This is intended to obtain various articles and can deepen the process and results of the review.

2.3 Participants

Participants in the review of this article are elderly with dementia who are treated or who are outpatients in the care facilities of elderly [10], [13], [14], [18], nursing home [9], [12], [15], [16], [17], community [11], which later this client was called resident, youth, and caregiver. These diverse participants provide their own challenges in reviewing them because they have a different mindset. But because the entire article has the purpose of providing input and/or an overview of the interventions for decreasing wandering behavior, the article plays a role in the process and results of this review.

2.4 Setting

A nursing home (NH) is a care facility that has a domestic environment and provides 24-hour service that serves as a supporter and caregiver to clients who need assistance in implementing ADLs, clients who need help with their health problems, and are at high risk or susceptible to disruption [19]. The settings used in these articles are nursing home, dementia care facility, and hospital. In addition, community settings also exist in the article but do not include the order of the community at home or in the family.

2.5 Intervention

The article provides various alternative wandering interventions, both simple to complex interventions [9], [10], [11], [12], [13], [18], [16], in the form of a program care [14]. Alternative interventions can be implemented or applied in the care facility or community, so as to be able to provide input or other alternatives in the provision of interventions or care for wandering clients.

The articles that provide intervention are those that use the control group [10] and some do not use the control group [15], [16], [13], [18]. Articles with more than one intervention group consisted of 2 intervention groups [11], [17], [12], [18], and more than 4 small groups [9].

2.6 Comparison

In this review process, articles that provide a comparison or difference from the intervention given are [10], [11], [17], [12], [9], [18]. Articles that only look at the effects of an intervention or only compare before and after intervention are [13], [14], [16].

2.7 Outcomes

The articles used in this review also explained the results of their studies in the form of health-related conditions, especially wandering and/or articles that provide an overview of interventions and provide treatment programs to wandering clients [14].

These articles provide an overview and incidence of wandering behavior in residents both in the nursing home, hospital inpatient room, psychogeriatric clinic, dementia care facilities, and the community. Wandering behavior that occurs at the resident is a big burden for the caregiver and

resident himself, which can cause the resident to be lost from the care home or residence for days and some can even return but there are also those who do not return and are even found dead.

Exclusion. Wandering residents who get intervention with traditional methods, namely restraint and neuroleptic therapy which causes side effects from the provision of these therapies.

2.8 Data Extraction

The data needed in this review is taken from articles that have been sorted out by AK and carried out by AY, RF, and AV. The data needed is then recorded in a special note which is agreed upon. Eligible articles are articles that provide information according to selected data, namely: study characteristics, non-pharmacological interventions (protocol, frequency, duration, method, type of activity/intervention provided), and data on wandering and dementia. In addition to this, all data relating to wandering and non-pharmacological interventions are also recorded such as intervention programs, agitation, the risk of falling, and others.

2.9 Quality Assessment

The articles used in this review also carried out an assessment of the risk of bias using a risk bias instrument from the National Institutes of Health (NIH) [20]. The instrument used is a quality bias instrument for the Intervention Control Study (consisting of 14 questions), Pre-Post Study without Group Control (consisting of 11 questions). Instruments consisting of 14 questions are given the following criteria: good (low bias) if the value is 12-14, medium (moderate bias) if the value is 7-11, low (high bias) if the value is 0-6.

2.10 Summary Measures

Data relating to the objectives of the study in the article are recorded and well presented. The data is in the form of demographic data, intervention and/or program data, success or decline data from wandering, and other data related or influential to the study conducted. Although in this review it does not show the meta-analysis of the review, the data plays a major role in describing the results of the studies conducted, making it easier to understand the review process.

3. Result

3.1 Quality of Included Studies

The articles were assessed for risk of bias given the results that were obtained: for articles on intervention control the results were 2 articles with good or low bias articles, 4 articles with moderate result or moderate bias, and 2 articles with bad or high bias. Two articles with Pre-Post design tests without control group found moderate results or moderate bias 1 article and good results or low bias 1 article.

3.2 Term and Definitions

Articles that display definitions related to wandering behavior such as "absences" [10], "lost" [9], "missing" [14], "mobility" or "ambulation" [16], "motor activity" [12], and "wandering" [18], [15], [11], [17], [9], [13]. All articles reviewed show the intervention given. Articles that show programs offered are in articles [14].

3.3 Overview of Finding Studies

The extracted article came from 10 Quasi-Experiment studies. These articles are all used in compiling this review.

3.4 Study Characteristics

The articles with quasi-experimental design study included in the study countries were 10 articles, namely Australia 4 articles [10], [12], [13], [16], from Japan [15], Hong Kong [14], New York [9], France [11], Finland [18], and Spain [17]. While for articles in the form of intervention programs [14]. All of the study articles were published between 2013 and 2018.

The articles all show the conduct of research and displays the time of studying it.

3.5 Characteristics of Participants

Participants in the study articles were varied, namely there were 542 resident participants, 31 in a nursing home. In reviewing this article, articles with research respondents consisted of 30 youth groups with 30 elderly groups [11].Articles involving caregivers as respondents with clients [13], [14].

3.6 Characteristics Searching Articles

was Article searches were run in September 2018 and were found with keywords "wandering and elderly and dementia" there were 7789 journals consisting of 1580 Google Scholar, Scopus 290 articles, CINAHL 451 articles, ProQuest 866 articles, CNBI 834, and Science Direct as many as 2665 articles. Then the search is continued by giving restrictions "in English, area Nursing, Psychology, Professional Health, and publication titles including Alzheimer's and Dementia,

The American Journal of Geriatric and Psychiatry, Geriatric Nursing, International Journal of Nursing Studies, Archives of Gerontology and Geriatrics, years 2013 - 2018 "in Science Direct obtained 122 articles, Scopus 42 articles, while from Google Scholar with restrictions in 2013 - 2018 as many as 227 articles, ProQuest 117 articles, CINAHL 104 articles, and CNBI 89 articles.

Duplication of articles obtained as many as 124 articles, which were then analyzed based on the title to, as many as 159 articles. Furthermore, the selection based on abstract found as many as 63 articles. At the end of the selection of articles based on full text, 10 articles were selected.

3.7 Characteristics Outcome

Based on the results of the study presented in articles relating to health problems, the results are in the form of interventions and apply to as many as 10 articles from 10 Quasi-experiment articles. For results in the form of a treatment program there was one.

Six articles provide alternative interventions that can be included in the elderly dementia program and are useful for reducing wandering behavior. Three articles with interventions to detect wandering behavior and prevent the incident of elderly dementia missing.

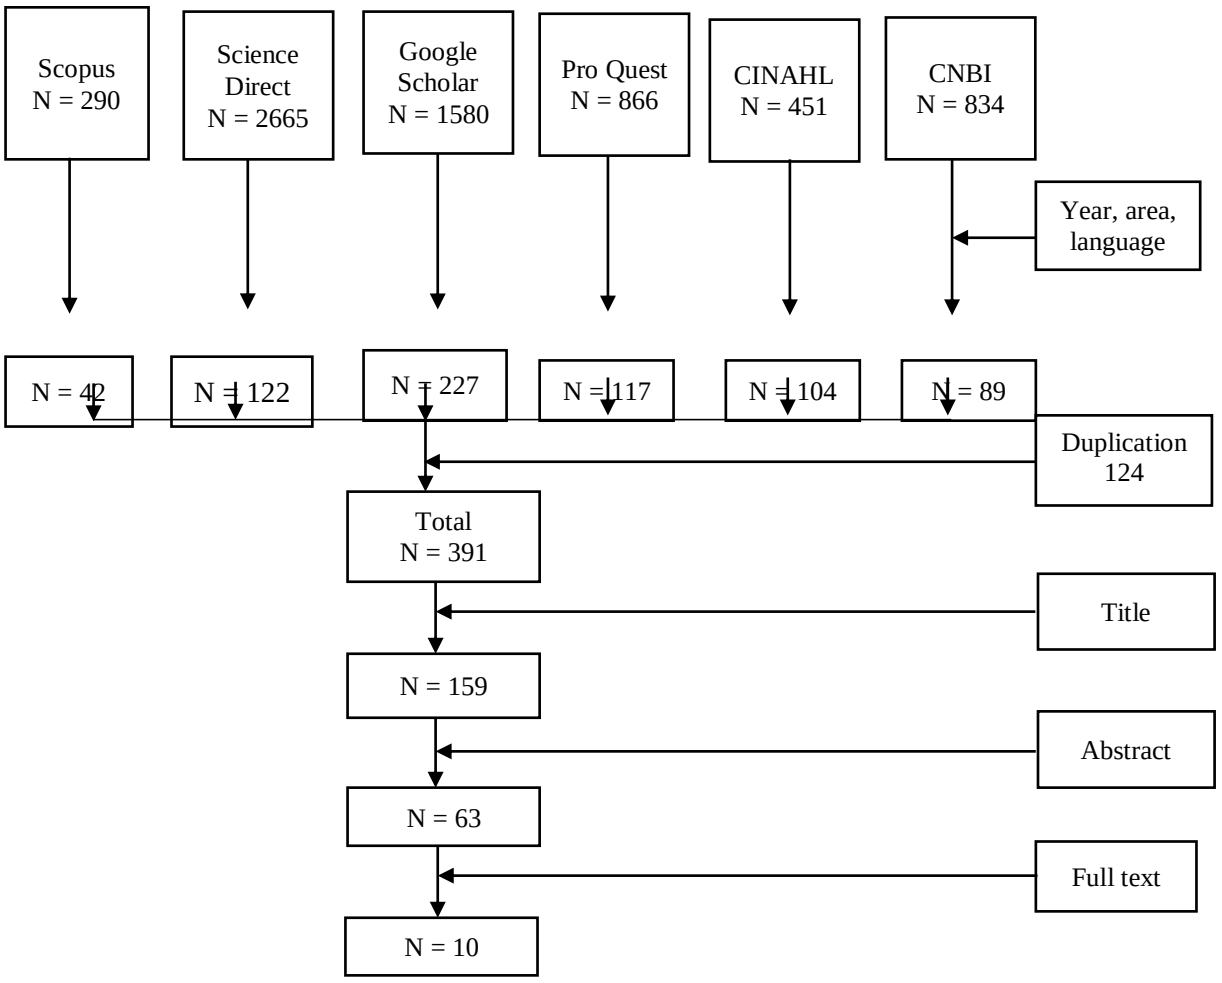

Figure 1. Flowchart of literature search

4. Discussion

The systematic review article that discusses the reduction in wandering behavior interventions for dementia clients during the search for this article has not been found. Studies discussing interventions for wandering are limited. Interventions for wandering still focus on a single modality of intervention to dementia. However, a multi-dimensional approach can provide a better outcome versus a single modality of intervention, which might be not applicable to all patients [14]. This is because interventions or programs for managing wandering behavior are still focused on intervention in care facilities, thus causing a lack of information about alternative interventions and/or programs that are able to provide new input or alternatives in providing care to dementia clients with wandering behavior. The home-based program and most of the interventions were tailor-made according to the needs of the patients and knowledge of caregivers [14]. So it is not surprising that the care of wandering clients often causes a source of stress and anxiety for clients and caregivers which ultimately creates a heavy burden on caregivers [2].

There has not been a definite definition of "wandering", based on the search for existing articles which found several wandering terms so far. Due to the wide variety of behaviors and typologies that wandering involves, a formal definition of the wandering concept does not exist, the number of definitions of wandering is significant [17]. Wandering is defined as the event of going missing or trying to run aimlessly caused by a decrease in psychological functions such as anxiety, suspicion, illusion, and aggression [2]. Wandering is also defined as behavior that is a manifestation of dementia syndrome which includes memory loss, language/communication problems, decreased attention, inability to make decisions, confusion, and visual problems [1]. Another article mentions wandering as a condition of mobilization behavior without any purpose or disorientation of people with dementia who have certain patterns, with certain frequencies, overreach, and inability to find the right path [5]. A literature review mentions the definition of wandering as follows:

"*a syndrome of dementia-related locomotion behaviour having a frequent, repetitive, temporally-disordered, and/or spatially disoriented nature that is manifested in lapping, random, and/or pacing patterns, some of which are associated with eloping, eloping attempts, or getting lost unless accompanied*" [15].

Based on the conclusions of the 10 articles, it was found that wandering behavior can be intervened upon by providing interventions that are appropriate to the client's needs and which are easily implemented in nursing facilities as well as in the community. The intervention is basically an easy and inexpensive intervention to implement, but for GPS intervention [7] on wandering clients who leave the house, it is still difficult to apply in developing countries, this is more of an economic problem from the client's family or caregiver. Caregivers avoid uses device for reduction wandering. That because a minority of caregivers can afford the cost of high technological tracking devices, compliance to wearing these devices, aged or uneducated caregivers also encountered difficulty in using devices [14].

Other interventions that are still difficult to implement which are also found are interventions in the form of application-based applications on Android that provide various information relating to wandering [21].This application actually has great benefits because it can help overcome caregiver problems wherever they are. But this application is also quite difficult to implement because it takes sufficient time to provide training in applying the application and educating in regard to the importance of the application, in addition to the caregiver's economic problems or the client's family.

In addition there are also interventions in the form of computerized programs [22], [23], [17], and robotic pet programs [12] which should be able to be implemented in care facilities also constrained by facilities and infrastructure and the ability of staff from hospitals, nursing homes or other dementia care facilities. This intervention also requires good coordination by an organization that is able to protect against a variety of unwanted actions that might be able to emerge.

Various interventions that can be applied easily and cheaply in the treatment facilities include providing meaningful activities for clients but which give effective and efficient value. Such as interacting with officers and/or with other residents [6], giving light assignments and setting rules that must be obeyed by clients [16], giving therapy Snoezelen [10], providing a therapeutic environment for clients [24], applying communication styles that are in accordance with the culture of the client [25], providing activities that are able to be comfortable and relax clients [26], and

provide physical activities such as gymnastics, walking, etc. [13]. These interventions will be very useful in providing care to wandering clients with continuous and routine implementation [27], healing gardens and activities to do in the garden [28], and it will be better if the intervention is included as a list of interventions that can be implemented in the service facilities in the form of activities or programs, as well as standards operational procedure. The significant reduction in missing episodes or elopement might be related to heightened supervision of the caregivers, home adaptation, and engagement of patients in purposely designed activities [14].

In some countries with advanced dementia care facilities, dementia care programs have been established as a service procedure to their residents. In developing countries, implementation for wandering still uses restraint and neuroleptic drugs. Treatment for wandering still uses the traditional method so far, which given restraint or combining with neuroleptic drug, where those given cause much side effects that are difficult to intervene upon [29].

The program to manage wanderers includes programs to prevent clients from elopement by identifying missing risks, assessing the type of wandering and risk of missing clients, developing and implementing risk prevention strategies, managing emergency responses and responding to missing events that include conditions when the client returns safely and the risk of recurrence is lost [30]. Other programs that might be able to be implemented are cultural transformation programs, the transformation of service facilities design, the transformation of client care at home and in the community, the transformation of acute service utilization, the transformation of care costs, the transformation of nursing home changes into elderly villages, and the transformation of community-friendly elderly [31].

Intervention programs for nursing include behavioral management programs, risk reduction prevention, end-of-life care, and rational use of antibiotics. Other programs that can be implemented are programs to increase awareness and knowledge of dementia, care focuses on early detection in primary health care facilities, plays a role in client care, improves disease therapy processes, protects clients and manages behavioral and psychological problems, records all clinical decisions of dementia, build relationships with caregivers and health workers, develop services that are aimed at improving the quality and care of organizations, plan all forms of existing services, arrange coordination of care, facilitate access to information and compile a list of convenient of priorities[27].

The optimally program managing for wandering have to apply both of detection of risk of losing and most alternative interventions, and administration management. Where those are not only set-up facilities, management or administration, but also staff knowledge, nursing or caregivers skill, and good communication under them. Nurse or caregivers have to owned skill for found need wanderer, culture wanderer and community around, and found the most intervention applicable for wanderer.

5. Discussion

This review is able to provide positive value for dementia service facilities, especially those who care for clients with wandering behavior. The findings of this review are important in improving the quality of care through improving client care programs or at a minimum through increasing interventions for wandering, especially those focusing on health care facilities and communities.

This review is also able to provide evidence for the application of alternative interventions offered and the client management programs provided. Future studies are expected to increase understanding and prevention of the risk of wandering behavior in order to achieve maximum service quality.

IMPROVING BEHAVIOR BEHAVIOR OF TUBERCULOSIS TRANSMISSION THROUGH COUNCELING IN THE WORKING AREA OF PUCANG SEWU HEALTH CENTER, SURABAYA

Ade Nasution
Universitas Muhammadiyah Surabaya, Indonesia
E-mail: adesusantynasution@gmail.com

ABSTRACT

The increase in cases of pulmonary tuberculosis can be a picture of the risk of high disease transmission in the community. East Java Province ranks second in Indonesia in the discovery of clients of pulmonary tuberculosis smear positive for new cases. Prevention of transmission of pulmonary tuberculosis can be done by maintaining a healthy lifestyle such as paying attention to the ethics of coughing, removing phlegm in place, eating nutritious food , adequate rest, regular exercise, avoid smoking and alcohol. Health education has increased knowledge, but it is not enough to change the prevention behavior of tuberculosis transmission. Counseling is an interaction process to facilitate changes in client behavior. In this case the role of nurses in improving the behavior of preventing tuberculosis is to provide counseling to clients and families about the importance of wearing masks and disposing of phlegm which is not carelessly disposed of in a closed place that has been given a disinfectant to prevent transmission. This study aims to determine the effect of counseling on improving the prevention behavior of pulmonary tuberculosis transmission. This type of research is analytic with the design of "Non Equivalent Control Group Design". The population was all pulmonary tuberculosis patients in the work area of PucangSewu Health Center in Surabaya, which was recorded in 2017 as many as 70 people. The sampling technique used purposive sampling a sample of 32 people divided into 4 groups, 2 treatment groups and 2 control groups. Counseling is done in 2 meetings, then 4 home visits are carried out. Data collection using questionnaires and analyzed using statistical tests "Wilcoxon Sign Rank test". The results of the study obtained a value of ρ: 0,000, smaller than α = 0.05 indicating a significant difference from transmission prevention behavior before and after counseling. Indicators that can be used in measuring the effectiveness of counseling are behavior change, positive mental health, problem solving, achieving personal effectiveness, and decision making. In conclusion, counseling can influence the increase in prevention behavior of pulmonary tuberculosis transmission. The process of adopting new behaviors requires more time so that giving counseling repeatedly so that behavior can change so as not to transmit to others.

Keywords: counseling, knowledge, attitude, pshycomotor, behavior of tuberculosis patiens

Introduction

Tuberculosis is major global health problem, estimated is 10 million people develop TB disease, and caused 1.3 million deaths (WHO, 2017). In Indonesia there were 360.770 cases and 162.412 new cases (Ministry of Health, 2016). East Java Province determined the second place in Indonesia in the discovery of clients of pulmonary tuberculosis smear positive for new cases. The case finding in 2014 was 52%, with the number of cases of positive smear TB as many as 21,036 clients (East Java Health Office, 2014). The amount of data on patients with pulmonary tuberculosis with positive smear in the Pucang Sewu Health Center area of Surabaya in 2015 cases of pulmonary tuberculosis included 60 cases 36 or 60% cases of positive smear, 2016 cases of tuberculosis patients cases 62 cases 42 or 67% cases of positive smear and in 2017 cases of pulmonary tuberculosis which included 70 cases, 51 or 73% of cases suspected of positive smear. Increased risk of positive smear tuberculosis from 2016 to 2017 (UPTD Puskesmas Pucang Sewu Surabaya, 2017).

The source of transmission of pulmonary tuberculosis is through sputum microorganisms that are released by tuberculosis patients who do not wear masks. Infection will occur if another person breathes air containing the infectious sputum. When coughing or sneezing, the patient spreads germs into the air in the form of sputum (nuclei droplet). One cough can produce around 3000 sputum spills (Ministry of Health, 2014). Risk factors for contracting pulmonary tuberculosis depend on several factors, including environmental factors, increased concentration of germs in the air influenced by air ventilation and lighting of the environment, age and immunity of a person's body (Ministry of Health, 2014). Therefore prevention of transmission of pulmonary tuberculosis can be done by maintaining a healthy lifestyle such as paying attention to the ethics of coughing, removing phlegm in its place, eating nutritious food, adequate rest, regular exercise, avoiding cigarettes and alcohol (CDC Government, 2016).

From the data mentioned that 90% of TB transmission in Pucang Sewu Health Center is caused by Environment, 85% due to behavior and 25% due to lack of understanding about TB, Behavior is one of the high enough factors causing risk of contracting pulmonary tuberculosis in Pucang sewu Health Center (UPTD Pucang Sewu Health Center, 2017). Although counseling to prevent transmission of TB has been carried out but their behavior has not changed, this indicates a lack of awareness of the patient on the behavior of preventing tuberculosis.

Lack of awareness of clients of pulmonary tuberculosis will have a negative impact on clients and families which can result in other family members experiencing transmission of tuberculosis. Awareness in tuberculosis sufferers is influenced by discomfort and feeling tight when wearing masks, besides that there is stigma in the community who still stay away from and exclude tuberculosis patients even though counseling has been conducted to the community to increase their insight and awareness in preventing tuberculosis cases.

Counseling is a process of providing assistance that is carried out through counseling interviews by an expert (counselor) to individuals who are experiencing a problem (client) that leads to the overcoming of problems faced by clients (Prayitno, Erman Amti, 2003). Counseling is the "heart of his heart" a comprehensive guidance service. This means that if counseling services have been carried out, the counseling problem will be resolved effectively and other guidance efforts can only follow or act as a companion. In this case the role of nurses in improving the behavior of preventing tuberculosis is to provide counseling to clients and families about the importance of wearing masks

and disposing of phlegm which is not carelessly disposed of in a closed place that has been given disinfectant to prevent transmission.

Research Purposes

This study aims to determine the effect of counseling on improving the prevention behavior of pulmonary tuberculosis transmission.

Methodology

A quasy experiment study was conducted among all TB patients who recorded in working area of Pucang Sewu Health Center Surabaya which were recorded in 2017. Sample was selected by purposive sampling, inclusion criteria for patients with positive bta, ages 20 - 55 years, and TB patients without complications. Respondents were divided into 2 groups, tretament group and control group. As a control group that only received health education / counseling about TB and a group as tratment groups that were treated or given counseling. Researchers conducted counseling in groups according to agreement twice. Furthermore, observations were made by coming directly for 4 visits to assess whether there was a change in behavior.

Instruments used in data collection this study were interviewing and observational checlist. An interviewing questionnaire was development by researchers based on references from previous studies to collect data about a study subject's characteristics and patient knowledge about TB Disease. An observational checklist to observe respondent's practice to prevent tuberculosis transmission. The analysis in this study used the Wilcoxon Sign Rank test used on ordinal scale data to determine whether there was an effect of preventive behavior changes before and after counseling.

Discussion

According to studied sample knowledge related to tuberculosis improved after the counceling implementation. This agrees with the study conducted by Howyida, et al., who reported that the majority of TB patients knew most knowledge about tuberculosis (definition, causes, types, and mode of transmission, immunization, symptoms, tratment, complications, investigations, follow up nutrition pattern, drug contraindications, preventive methods and common helath symptom from disease).

Prayitno and Erman Amti (2004: 94), revealed that guidance was held in order to help individuals to better identify various information about themselves. Counseling is done which is giving knowledge and also prevention methods so that healthy behavior among respondents with pulmonary TB can change so that TB transmission can be minimized. For someone who provides counseling who has the task of resolving various obstacles in TB treatment and prevention methods during TB treatment that can be done by seeking health education through counseling methods to patients as well as providing health education media for example with leaflet charts and demonstrating how to transmit and prevention of TB. So there is an influence in terms of knowledge between before and after health education and counseling.

As regard to prevention transmission practice, the study result revealed that more than half of respondent wear masks, throw sputum in place, and take medicine on time. According WHO that what causes a person to act there reasons is facilities and infrastructure. The respondent's actions before giving less counseling were caused by the unavailability of facilities and infrastructure at home such as the availability of masks and sputum shelter, causing patients to throw phlegm carelessly and not wearing masks.. The purpose of counseling results in changes in behavior that

allow clients to live more productively. Efforts to facilitate the occurrence of behavior changes are done through interviews (although counseling is always done in interviews, but not all interviews can be interpreted as counseling) Patterson in Sofyan (2009). Counseling has a considerable impact, where respondents want to take TB prevention measures. Because counseling has been done twice, the results of the questionnaire show changes in the actions of pulmonary TB patients despite the gradual changes in the respondents' daily lives.

From the results above, there was an influence of counseling on improving behavior (knowledge, attitudes, actions) to prevent tuberculosis transmission in the work area of Pucang Sewu Health Center Surabaya. It means that counseling given for 2 meetings has a change in behavior for respondents in taking preventive measures for pulmonary TB.

Indicators that can be used in measuring the effectiveness of counseling are behavior change, positive mental health, problem solving, achieving personal effectiveness, and decision making (Shertz in Nurihsan, 2008). they already know that TB is a cough that usually has more than two weeks of symptoms. Which is mentioned that Mycobacterium tuberculosis is one of the lower respiratory tract diseases which most of the tuberculosis bacillus enter into the lung tissue through airbone infection and subsequently undergo a process known as the primary focus of the ghon (Wijaya, 2013). TB sufferers can actually recover completely, namely by doing routine treatment. In accordance with the theory that tuberculosis sufferers must be treated and treatment must be adequate. Tuberculosis treatment takes a minimum of 6 months. In eradicating tuberculosis, the state has guidelines in the treatment of tuberculosis called the Tuberculosis Program.

During the treatment period so as not to cause transmission to other family members, precautionary measures must be taken, namely by giving counseling by increasing knowledge and prevention methods so that the attitudes and actions of respondents at home can change to a better direction. The process of adopting new behaviors also requires more time and also has to be done giving repeated counseling so that behavior can change so that a good attitude is formed so as not to transmit it to others.

Conclusion

The impelemented counceling revealed significant improvements of patients knowledge about TB and practice to prevent transmission of TB. There were highly statistically significant relationship between counseling implementation and patient’s knowledge and practice of preventive tuberculosis.

Recommendation

Suggest conducting counseling to all patients and family, and continuous educational program during the follow up visits to upgrade their knowledge and practice

EFFECT SPIRITUAL SUPPORT AGAINST IMPROVEMENT COPING MECHANISMS ON THE ODHA IN BANYUWANGI COMMUNITY SUPPORT DISTRICT BANYUWANGI

A Yulianto
Master Student, Faculty Of Nursing, Universitas Airlangga, Surabaya
E-mail: agus.yulianto-2017@fkp.unair.ac.id

ABSTRACT

There is a wide-ranging impact on ODHA such as physical problems, psychosocial, emotional and spiritual. Indicated by changes in the character of ODHAsuch as living in stress, depression, feeling lack of spiritual support and changing coping mechanisms. The purpose of this study was to determine the effect of spiritual support to increase coping mechanisms to ODHA. This study used quasy experimental designdata collection. The population in this study all ODHA in Banyuwangi Regency. The sample size used a simple random sampling technique and obtained 88 respondents. Independent variables of spiritual support and dependent variable coping mechanism was measured by questionnaire. Data were analyzed using ordinal regression with $\alpha \leq 0.05$. The analysis of the data using Ordinal regression test obtained p value=0.000 and magnitude of spiritual support=17,422. It can be concluded that the value of p value 0.000<0.05 then H0 is rejected, which means there is the influence of spiritual support to increase coping mechanisms to ODHA in Banyuwangi district. The results of this study indicate that with spiritual support, it will directly improve the coping mechanism of ODHA and individuals will have good self-control in social communication, stimulate physiological functions, increase subjective awareness and defense mechanisms.

Keywords: Spiritual Support, Coping Mechanisms, ODHA

1. Introduction

HIV / AIDS emerged at the end of the 20th century, and spread very quickly throughout the world. An epidemic until 2011, HIV has infected more than 60 million adults and children. AIDS has approached 20 million infections in adults and children. The international community has responded to the HIV / AIDS pandemic, HIV continues to spread causing more than 14,000 new infections every day. Currently AIDS is the leading cause of death in Africa and a quarter of the world [1].

Since the discovery of the disease AIDS (Acquired Immune Deficiency Syndrome) and its causative virus HIV (Human Immunodeficiency Virus), there has been a wide-ranging impact on ODHA such as physical problems, psychosocial, emotional and spiritual. Indicated by changes in the character of ODHAsuch as living in stress, depression, feeling lack of spiritual support and changing coping mechanisms [2].

HIV cases were first reported in Indonesia in 1987. Until 2012, HIV / AIDS cases have spread in 345 of 497 (69.4%) districts / cities in all provinces of Indonesia. The number of new HIV cases each year has reached around 20,000 cases. In 2012 there were 21,511 new cases, of which 57.1% were 20-39 years old [3]. The total number of HIV / AIDS cases up to December 2013 was 1676 cases with 272 patients already dead and 769 in AIDS. Furthermore, when viewed from the highest risk factors for transmission through sex (81%) then the second is through syringes (10%), and from mother to child (2%). Additionally there are things that are not unexpected, namely the occurrence of HIV / AIDS in housewives which amounted to 392 cases and the incidence of under-fives was 36 cases [4].

Based on a preliminary study conducted on 8 ODHA in Banyuwangi Regency precisely in BCS on March 20, 2014, data was obtained showing that 5 out of 8 ODHA stated that they still refused to acknowledge what had happened to them, they often felt depressed, they also surrender in the face of the disease and still lack of spiritual support given by family, environment and other parties. So it can be concluded that the majority of ODHA in Banyuwangi District with a lack of spiritual support decreased the coping mechanism.

Spiritual plays an important role in the treatment of HIV / AIDS. Infected individuals HIV also experience changes in spiritual function, including behavior change and verbalizing distress. When experiencing stress, individuals will seek support from their religious beliefs. This support is very necessary to be able to accept the state of illness experienced, especially if the disease requires a long healing process with uncertain results. Praying or praying, reading scriptures and other religious practices often help meet spiritual needs which are also a protection for the body [5].

Depressed conditions or stress on ODHA will create coping mechanisms in an effort to overcome the problems that occur. Coping mechanisms are ways that individuals solve problems, adjust to changes, and respond to threatening situations. Coping mechanisms are very important to be used by individuals to solve problems, effective coping will help individuals free from prolonged stress. A study shows that coping mechanisms are related to individual responses to problems [6].

Spiritual influences a person's coping mechanism, so that one must hone spiritual intelligence skills to build a coprosive coping mechanism. A good development in the spiritual aspect can make a person more able to interpret life and have self-acceptance of his condition so that he gives a positive response to the changes that occur in him [7].

The above makes the researcher interested in conducting a study about "The Influence of Spiritual Support on Increasing the Coping Mechanism in ODHA in Banyuwangi Regency". In taking the title, the researchers were interested to find out whether there was a coping increase on PLHAs after being given spiritual support, and also as a further mission so that the number of HIV / AIDS cases especially in Banyuwangi Regency decreased.

2. Methods

This study researchers used quasi experimental research designs using cross sectional approaches. The population of this study was 113 people living with HIV in the BCS (Banyuwangi Community Support) Banyuwangi Regency. The sampling technique in this study was Purposive sampling. The number of respondents is 88 respondents. The instruments spiritual support using a questionnaire consisting of 28 item questions with 4 choices of answers namely always, often, sometimes, and never. The instrument for improving coping mechanisms using a questionnaire

consists of 25 questions with 4 choices of answers namely always, often, sometimes, and never. Data processing is done by editing by checking back from questionnaire data. Coding is done by coding each characteristic. Data obtained at the time of the study will be analyzed by quasi experimental analysis techniques systematically so that the research will find out the description of spiritual support and improvement of coping mechanisms using statistical tests using SPSS version 16.0 for Windows.

3. Results

Table 1 shows that of the 88 respondents, the majority of respondents were 31-40 years old, 59 respondents (67.0%). Most of the total 88 respondents were male, 63 respondents (71.6%). Nearly half of the total education of high school respondents is 32 (36.4%). Most of the 88 respondents, based on marital status with the number of unmarried at 49 respondents (55.7%). It can be seen that from 88 research respondents most of them were private employees, namely 46 respondents (52.3%).

Based on table 2, it is known that the spiritual support of ODHA in Banyuwangi Community Support (BCS) Banyuwangi District mostly has good spiritual support, at 74 respondents (84.1%). Whereas for the Koping Mechanism for ODHA in Banyuwangi Community Support (BCS) Banyuwangi Regency most of them have good coping mechanisms at 72 respondents (81.8%). Based on the results of table 3 shows respondents who have good spiritual support and have good coping techniques at 69 respondents, amounting to 78.4%.

On the results of the statistic test using Ordinal Regression test (Table 4) to 88 ODHA respondents in the Banyuwangi Regency BCS (Banyuwangi Community Support), get the value p = 0,000. Because the value of p 0,000 <0,05, Ho is rejected, so it can be concluded that there is an influence of spiritual support for improving coping mechanisms for ODHA in the Banyuwangi Regency BCS (Banyuwangi Community Support). The results of the Ordinal Regression statistical test (Table 5) to 88 respondents, it was found that there was an influence of spiritual support for the improvement of coping mechanisms in the Banyuwangi District of Banyuwangi (17.422).

4. Discussion

Based on the results of the study showed that spiritual support for ODHA in the Banyuwangi Regency BCS was as good as 74 respondents (84.1%) and coping mechanisms for ODHA in the Banyuwangi District BCS both at 72 respondents (81.8%).

The results of the statistic test using Ordinal Regression test to 88 ODHA respondents in the Banyuwangi Regency BCS (Banyuwangi Community Support), get the value p = 0,000. Because the value of p 0,000 <0,01, Ho is rejected, so it can be concluded that there is an influence of spiritual support for improving coping mechanisms for ODHA in the Banyuwangi Regency BCS (Banyuwangi Community Support). From the results of the Ordinal Regression statistical test to 88 respondents, it was found that there was an influence of spiritual support for the improvement of coping mechanisms in the Banyuwangi District of Banyuwangi (17.422).

This emphasizes how the spiritual dimension spreads across all other dimensions, whether identified or developed by individuals or not. Individuals are strengthened through their "spirit", which results in a transition towards prosperity. The influence of spirituality is especially important in the period of illness. When illness, loss, or pain affects a person, the person's energy is depleted, and the person's spirit is affected. How this affects a person's motivation to recover, participates in healing and the ability to change is often underestimated [8].

According to Nursalam and Ninuk Dian Kurniawati [9], it was revealed that coping effectively kept a central place on the body's resilience and the body's resistance to disorders and attacks of a disease both physical and psychological, social, spiritual. Not only limited to mild illness, but precisely the emphasis on the condition of the pain.

If individuals are in a position of stress humans will use various ways to overcome them, individuals can use one or more available coping resources. Someone who faces a serious illness and is considered a terminal illness will show a high awareness of his beliefs that appear in his daily behavior. Therefore individuals need every effort to overcome stress due to the conditions they experience [10].

Iyus Yosep [11], states that every change in every human beings can be a stressor that can influence the coping mechanism of the individual. The state of elongated emotional stressors that affect the entire personality of the individual and the functions of his life. This is related to emotions and has the same understanding with the state of feelings or emotions. Like other aspects of personality, emotions or mood play a role in the process of adaptation. There are four functions of emotional adaptation, namely as a form of social communication, stimulating physiological functions, subjective awareness and defense mechanisms.

Based on the results of cross tabulation between the two variables of spiritual support and coping mechanism, it shows that out of 88 respondents 69 respondents (78.4%) showed good spiritual support and coping mechanisms.

From the description above it can be concluded that spiritual support will both improve coping mechanisms for ODHA as evidenced by a total of 88 respondents who have 74 respondents who have good spiritual support and 72 respondents have good coping mechanisms. While respondents who had spiritual support and good coping mechanisms were 69 respondents. With good spiritual and spiritual support, ODHA will have faith and fulfill religious obligations, as well as the need to get forgiveness, love, establish a relationship full of trust with God and establish a relationship with someone, with others and with the environment. It will even strengthen the relationship with God or the Most High which guides one's life. Whereas the good coping mechanism on ODHA will affect the entire individual personality and function of life. Someone who faces a serious illness and is considered a terminal illness will show a high awareness of his beliefs that appear in his daily behavior. Coping mechanisms are closely related to one's emotions. This can be proven by a good coping mechanism that will shape the emotions of a person to be better, so that a better form of social communication can emerge, can stimulate physiological functions, subjective awareness and improve the defense mechanism of emerging stressors.

According to Khumsaen and Natawan [12], there is little data available regarding the influence of spiritual well-being on QOL among HIV-infected persons, particularly in rural health settings. These findings were also obtained in a quantitative study that assessed the quality of life of women with HIV/AIDS, where the domain of spirituality showed the best results. It covered aspects related to forgiveness and guilt and concern about the future and death. Spirituality was a positive strategy to confront HIV/AIDS, as well as to address biopsychosocial changes the disease causes in the lives of individuals.

Religion was a path to obtain support. For some people, having a religion that offered support for the difficulties experienced at that time in their life was more important than having a specific religion. This fact made the interviewees become members of a religious community, and change religion, church, or belief after they discovered the diagnosis, or even distance themselves from it after overcoming the main problems related to the disease. God represents a supreme being, who is the creator and ruler of everything. He could send suffering and pain, but could also provide relief and healing. The respondents believed that, if they were guilty and the disease was a punishment by God, they could expect healing, because God is infinite in all attributes. He is the source of life, truth, and love [13].

The most commonly used coping styles were acceptance and religion. The coping strategies intervention was found effective in significantly improving active coping, instrumental support, emotional support at post-test 1(after one month of intervention) and post-test 2 (after three months

of intervention) [14]. Research results Pinho *et al*., [15] show that religion has been associated with better conditions in which to deal with the problems developed by feelings of helplessness and denial experienced by ODHA. Individuals who reported having religion presented higher levels of satisfaction in life, leading to better adherence. Religiosity and spirituality have been shown as significant coping strategies among this specific population.

5. Conclusion

Spiritual support for ODHA in BCS, Banyuwangi Regency, namely 74 respondents (84.1%) had good spiritual support. The Koping Mechanism on ODHA in BCS Banyuwangi Regency, which is 72 respondents (81.8%) have good coping mechanisms. The results of the statistic test using Ordinal Regression test to 88 ODHA respondents in the Banyuwangi Regency BCS (Banyuwangi Community Support), get the value p = 0,000. Because the value of p 0,000 <0,01, H0 is rejected, so it can be concluded that there is an influence of spiritual support for improving coping mechanisms for ODHA in the Banyuwangi Regency BCS (Banyuwangi Community Support), which is 17.422.

ODHA is expected to have a more confident attitude and be active in spiritual activities around the environment and at the same time interact with the community, so that ODHA will have good coping mechanisms. It is hoped that the results of this study will be used as an illustration for BCS (Banyuwangi Community Support) to hold religious activities by bringing ulemas to help ODHA who have problems regarding spiritual support and can help improve coping mechanisms for ODHA. It is recommended to do further research with the theme of providing spiritual support to the OHDA and coping mechanisms and their development process before and after being given spiritual support.

FAMILY COUNSELLING ENHANCES ENVIRONMENTAL CONTROL OF ALLERGIC PATIENTS

S D Lestari1, L Nikmah1, and N D Kurniawati1
1 Faculty of Nursing Universitas Airlangga, Campus C UNAIR Mulyorejo, Surabaya
E-mail: ninuk.dk@fkp.unair.ac.id

ABSTRACT

Allergies can cause complications such as inadequate nutrition, impaired sleep quality, and inhibition of child growth and development. There were about 15% children who suffered from dust allergies in 2017 in Indonesia. Parents lacking of knowledge about environmental control can increase the prevalence of allergic relapse in children. Counselling is a method of health education that aims to improve knowledge, and practice. The purpose of this study was to investigate whether counselling has any influence on allergic related knowledge and environmental control measures skills. The design of study was a pre-experiment design. There were 14 respondents in this study who were recruited at a university hospital based on inclusion criteria with consecutive sampling. The independent variable was counselling, the dependent variable were knowledge and environmental control measures. Data were collected using a questionnaire and a check list. Data were analysed using Wilcoxon Sign Rank Test with significance level of $\alpha<0,05$. Based Wilcoxon Sign Rank Test there was an influence of counselling on knowledge and environmental control measures (knowledge level, p= 0,001; practice level p= 0,001). It is concluded that counselling is significantly increased knowledge and environmental control measures level.

Keywords: allergy, house dust mites, environmental control, counselling, knowledge, practice

Introduction

Despite its importance, the parents' knowledge and skills regarding house dust mites-environmental-control are still lacking [1]. Globally, a review concluded that awareness of this type of allergy remains low [2]. If left untreated, the environment full of house dust mites will cause allergy and asthma attack to sensitive individual [3–5]. Knowledge of parents with children allergic to house dust mites in the Allergy Outpatient Room at the Airlangga University Hospital regarding environmental control to reduce the house dust mite population is still inadequate. A survey conducted on March 5, 2018. showed that there were 3 out of 3 parents (100%) who were unable to provide the right answer when they were given questions about how to wash linen to reduce the population of house dust mites; and 2 out of 3 parents (66%) have not been able to provide appropriate answers on how to clean the environment to reduce the population of house dust mites. Existing studies on environmental controls that have been carried out shows that the knowledge of parents with house dust mite allergic children on environmental control is still low, even in 2003 after being given health education only 50% of parents had good knowledge regarding environmental control.

Allergy is a hypersensitivity reaction due to an induction by IgE that is specific to certain allergens, which binds to mast cells. Allergens are ingredients that are generally harmless and are found in many environments but can cause allergic reactions if in contact with allergic patients [3,4,6–8]. In sort, allergies to house dust mites are a hypersensitivity reaction to house dust mite allergens.

Dust and dust mites are the most common allergens in the room and most often cause allergies

[3,4,6,9–14]. House dust mites are the most common allergens found in rooms such as in the carpets and beds [2,15,16]. House dust mites are animals of the araknoidea class [3,17]. Stools and debris from house dust mites can cause allergies [18,19]. Home dust mite allergies can be reduced by environmental controls [11,20] however, parents' knowledge of environmental control is considered to be lacking.

The prevalence of allergies in the world has continued to increase for more than 50 years. The results of sensitization tests for one or more common allergens in 2016 among school children are close to 40% -50% worldwide. In 2012, 10.6% or 7.8 million children reported respiratory allergies [21]. The number of children with allergies in Indonesia is estimated at 15% [19]. The results of research by the University of Indonesia showed an increase in the percentage of children under 12 years of age with allergies to pollution and dust up to four times in the last 20 years, from 2% in 1980 and reaching 8% in 2000 [22]. Knowledge of parents who met the good category amounted to only 50% after being given health education in West Virginia in 2003.

Large number of accessible information about environmental controls to reduce the population of house dust mites, such as mass media, seminars and other health education does not necessarily improve parents' knowledge of environmental control. Lack of knowledge of parents about environmental control can increase the prevalence of allergic events in children. Allergies can cause other complications such as inadequate nutrition, disruption of the quality of sleep, inhibition of growth and development of children [23].

Counselling accompanied by a leaflet on how to properly control the environment can be given to parents who have kids suffering allergy to house dust mites to enhance the parents' knowledge regarding allergic environmental control. Counselling is chosen because it not only improves knowledge, but also provides ample time for parents with individual consultation; thus, it can help resolve individual obstacles in controlling the environment. Counselling is expected to be able to play a role in the process of behavior change, namely awareness, interest, evaluation, trial and adoption of the behavior; therefore, the parents' knowledge, attitude, skills and environmental control measures of house dust mites will increase, resulting in the suppression of the prevalence of allergies. The purpose of this study was to investigate whether counselling has any influence on allergic related knowledge and environmental control measures skills.

Materials and Methods

The research design used was pre-experiment with one-group pre-post-test design. The process of data collection was carried out in July, 2018 at an Outpatient Clinic of Allergy of a university hospital in East Java. The independent variable in this study was counselling regarding environmental control given to parents or children. The dependent variable in this study is the knowledge and actions of parents or children in environmental control to reduce the population of house dust mites.

The population of this study were parents and children with children allergic to house dust mites who were treated at Outpatient Clinic of Allergy Universitas Airlangga Hospital Surabaya in July 2018. Respondents of 14 people were obtained using consecutive sampling with inclusion criteria: 1) parents with children who were suffering allergies to house dust mites, 2) parents or children with children who were seeking treatment at Outpatient Clinic of Allergy Universitas Airlangga Hospital Surabaya 3) parents or children with at least elementary education 4) parents or children who underwent immunotherapy programs every 1 week and 3 weeks .

Data collection techniques were carried out using a knowledge questionnaire developed from Continuing Medical Education questions examinations sourced from The American Academy of Allergy, Asthma & Immunology (AAAAI) [24] and a check list instrument to determine parents' actions towards environmental controls to reduce house dust mite populations. right. Data analysis was conducted using SPSS 16.0 for Windows program and tested the Wilcoxon Signed Rank Test statistically, namely p 5 0.05. This research has passed the ethical review from the health research ethics commission at the Airlangga University Hospital in Surabaya and received the research

protocol approval with number 160 / KEH / 2018.

Results

Based on Table 2. the majority of respondents had never received other information regarding environmental control before counselling at 9 people (64%). A total of 4 respondents received information about environmental control more than 3 months ago or 28.5% of the total respondents. All respondents who had received information about environmental control came from other health education or 36% of the total respondents, and 1 respondent who accessed information about environmental control through the internet in addition to getting other health education or 7% of the total respondents.

Table 1. Respondents' characteristics of Family counselling improves environmental control of house-dust-mites.

Characteristics of respondents		n	%
Respondents' age (year old)	20-29	4	28.5
	30-39	7	50
	> 40	3	21.5
Kid's age (year old)	< 1	1	7
	1-3	4	28.5
	3-5	5	36
	5-6	1	7
	6-18	3	21.5
Education	Basic Education (grades 1-6)	1	7
	Basic Education (grades 7-9)	1	7
	Secondary Education (grades 10-12)	8	57
	Higher education	4	29

Table 2. Information regarding environmental control of house-dust-mites allergy.

Category		n	%
Have received information	Yes	5	36
	No	9	64
When was the last information received (in month)	< 3	1	7
	> 3	4	28.5
Source of information	Other health education sources	5	36
	The internet	1	7

Table 3**.** shows the Wilcoxon Signed Rank Test results. Wilcoxon Signed Rank Test is used to test for differences in pre-test and post-test results. The pre-test results revealed that the knowledge level of most of the 8 respondents scored less (57%) before being given counselling. An increase in the level of knowledge after being given counselling was 12 respondents (86%) had a good level of knowledge. The Wilcoxon Signed Rank Test results obtained $p = 0.001$ so that $p < 0.05$. This shows that there are differences between the results of the pre-test and post-test. It can be concluded that there is an effect of counselling on the knowledge of environmental control of parents with children

who are allergic to house dust mites.

Table 3. Parents' knowledge and skills regarding the environmental control of house-dust mites-allergy at pre and post intervention.

Level	Knowledge				Skills			
	Pre		Post		Pre		Post	
	n	%	n	%	n	%	n	%
Good	1	7	12	86	1	7	9	64
Average	5	36	1	7	6	43	5	36
Poor	8	57	1	7	7	50	0	0
Mean	4.79		8.64		2		3.64	
Standard Deviation	2.007		1.393		1.359		0.497	
p (Wilcoxon signed rank test)	0.001				0.001			

Based on Table 3, it is known that most of the 7 respondents (50%) were in the category of poor in skills of house-dust-mites-allergy environmental control before being given counselling. The level of skills had increased after counselling, which was 9 respondents (64%) in the good category. The Wilcoxon Signed Rank Test between pre and post intervention was p = 0.001, suggesting that there were differences between the results of the pre-test and post-test. It can be concluded that there was an effect of counselling on environmental control measures of parents with children allergic to house dust mites.

Discussion

Parents' knowledge after counselling has increased compared to before counselling. Before being given counselling the level of knowledge of the majority of respondents was in the less category while only one respondent was in the good category. After counselling, post-test results show that counselling can facilitate an increase in the level of knowledge of parents towards environmental controls for allergic children to be better. This is indicated by the majority of respondents in the good category, one respondent in the sufficient category and one respondent in the less category.

Research conducted by Lorensia shows that education is effective in increasing knowledge [25]. Health education controls the environment with counselling methods is the right method for parents with allergic children, because counselling can provide assistance to respondents to develop knowledge, and behavior [26].

This is consistent with the an existing knowledge developed by Lawrence Green which divides factors that influence health behavior into three, namely predisposing factors, supporting factors, and driving factors [27]. Predisposing factors consist of knowledge, attitude, age, and education [25,26]. Supporting factors consist of health service personnel and information [27]. The driving factor consists of family support, health workers, and community leaders. The existence of supporting factors in this case information can increase one's knowledge [27].

The level of knowledge is also influenced by the learning process [25]. The learning process is influenced by the conditions of the subject of learning, among others, capture power, intelligence, memory, motivation and so on. Rogers [28] argues that before accepting an object of learning a sequential process occurs: awareness (the subject is aware of the learning object), interest (the subject feels attracted to the object), evaluation (the subject evaluates the bad or bad object), trial (the subject starts trying to do something in accordance with the object or stimulus), adaption (the subject behaves new in accordance with the knowledge, awareness and attitudes obtained) 21).

Notoatmodjo argues, one of the factors that influence knowledge is education [26]. Knowledge is closely related to education [28]. It is expected that the higher the level of education of a person, the higher the knowledge he has. Besides education, there are many factors that can affect one's

knowledge, including age and experience. The thinking ability will be more mature as the person is getting older. Personal experience can also be used as a source of knowledge [24].

Some respondents who have a sufficient level of knowledge, and one respondent who has a good level of knowledge before being given counselling, can occur because respondents have previously obtained information on environmental control from other sources, namely health education received by respondents when children are allergic test respondents and respondents actively seek information through the internet.

The demographic data of respondents showed that the majority of respondents were in the category of 30-39 years so that most respondents were still classified as at a productive age who were still able to digest various information so that respondents could still be active and continue to learn so that the level of knowledge they possessed became better. Table 1.4 shows a change in knowledge from 57% of respondents in the category of knowledge level less than 86% of respondents are in the category of good knowledge level. In accordance with the theory of Notoatmodjo, the provision of information can facilitate the learning process of individuals to gain a new knowledge [29].

Counselling can be the best choice in providing health education because counselling implements two-way communication between clients and counsellors so that perceptual inequality can be reduced. Another advantage of counselling is the content of counselling based on the problems faced by the client so that the health problems experienced by the client can be solved. However, giving counselling cannot change the knowledge of all respondents. There is one respondent who has not experienced an increase in knowledge; this may be due to several factors including: the age of the respondents who are older than other respondents, and the lack of concentration of respondents during the counselling process takes place.

Knowledge or cognitive is a very important domain in shaping one's actions (covert behavior) [25]. The process of changing respondents' knowledge through counselling will result in changes in house-dust-mite environmental control measures for allergy prevention.

The parents' skills after counselling have increased compared to before counselling. Before being given counselling the majority of respondents' level of skills were in the poor category while only one respondent was in the good category. After counselling, the post-test results showed that counselling can facilitate an increase in the level of parents' skill for environmental control for allergic children. This is shown in Table 1.5 that the majority of respondents became showed good skills in environmental control and some showed sufficient skills.

This finding shows that the health education of environmental control with counselling method is the right method for parents with allergic children, because counselling can provide assistance to respondents to develop knowledge, and behavior [25]. Skinner argues that behavior is a certain order in terms of feelings (affections), thoughts (cognitions), and predisposing actions (conation) of someone to an aspect in the environment [26].

Action is the realization of a person's knowledge and attitudes in a real act [24]. Changes in actions can occur through processes or stages of change, namely knowledge, attitudes, and actions, which means that someone will only be able to perform well if the person already has a good knowledge and followed by a positive attitude. Nevertheless, some study found the different phenomenon: person can perform well even though they have poor knowledge and attitudes they have are still negative [14]. Anas [30] states that the actions of an individual can arise not necessarily based on knowledge and attitude. While Rogers [25] argue the sustainability of a skill or performance unsupported with a good knowledge; if a behavior is not based on knowledge and awareness then the behavior will not last long.

Comparison of respondent's actions before and after counselling can be seen in Table 1.5 before giving counselling the majority of respondents included in the category of poor skill and action in term of controlling the environment, while only one respondent in the category of good action level. The majority of respondent had not been able to choose the right linen and to choose the right temperature for environmental control. At post interventions, the level of action of the majority of

respondents increased to a good category, and some were in average category. These findings can best be explained with the Precede-Procede-Lawrence Green-theory which assert that the provision of health education can change predisposing factors, supporting factors, and driving factors. The current study targeting the predisposing factors to change the respondents' knowledge; knowledge acquisition was considered as the important factors formed new skills and actions of environmental control. The process of forming actions goes through stages, such as perceptions, guided responses, mechanisms, and adoption [25].

Counselling can be the best choice in providing health education because counselling implements two-way communication between clients and counsellors so that perceptual inequality can be reduced. Another advantage of counselling is the content of counselling based on the problems faced by the client so that the health problems experienced by the client can be solved.

Some respondents still cannot the right temperature of water used to clean the house for environmental control; this may be due to several factors, among others: lack of enthusiasm of respondents, lack of concentration of respondents and research rooms that use air conditioner so that it can cause respondent's body temperature to cool down.

Conclusion

An increase in the level of knowledge of parents regarding environmental control after counselling. Moreover, there was an increase in the level of parental action regarding environmental control after counselling.

The results of this study are expected to be the initial data for the next researcher in analyzing and examining parents' knowledge of environmental control. The next researcher is expected to be able to examine the attitude variables that have not been studied in this study, test the validity of the questionnaire used and choose another place for research data collection other than in poly, or can do door to door for research data collection.

MINDFULNESS-BASED THERAPEUTIC DEVELOPMENT ON PHYSICAL AND PSYCHOLOGICAL PROBLEMS : A SYSTEMATIC REVIEW

M Jufriyanto [1], W Holis [2] , A Syakura [3]
Faculty of Nursing Universitas Airlangga, Mulyorejo, Surabaya,
Indonesia E- mail: moh.jufriyanto-2018@fkp.unair.ac.id

ABSTRACT

Mindfulness is used as an effective nonpharmacological treatment to improve quality of life and to address various health problems. Until now, there have been many developments in mindfulness-based therapies. The literature review was employed for databases including Proquest, PubMed, and Scopus articles from 2009 to 2019. Search terms included mindfulness, therapeutic, development, physical, and psychological. Fifteen articles which include criteria for analysis. The results of this systematic review can show that mindfulness- based therapy can be given to patients with Rheumatoid arthritis, cancer, diabetes mellitus, and post-operative patients. The problems handled are mostly psychological problems and the physical problems only painful. Further research is needed for the development of mindfulness with technology for efficiency and convenience.

Keywords: mindfulness, therapeutic, development, physical, psychological

1. Introduction

Fatigue is a common symptom associated with a wide range of chronic illness [1]. Fatigue can refer to a subjective symptom of malaise and aversion to activity or to objectively impaired performance. It has subjective health complaint that entails emotional, cognitive, and behavioral components [2]. The symptom of fatigue is a poorly defined feeling, and careful inquiry is needed to clarify complaints of fatigue, tiredness, or exhaustion and to distinguish lack of energy from loss of motivation or sleepiness, which may be pointers to specific diagnoses [3]. Patients may complain of difficulty in carrying out normal activities of daily living, inability to work energetically or a feeling of tiredness even upon waking up [4].

Subjective fatigue is normally distributed in the population. The prevalence of clinically significant fatigue depends on the threshold chosen for severity (usually defined in terms of associated disability) and persistence. Surveys report that 5-20% of the general population suffer from such persistent and troublesome fatigue. Fatigue is twice as common in women as in men but is not strongly associated with age or occupation. It is one of the commonest presenting symptoms in primary care, being the main complaint of 5-10% of patients and an important subsidiary symptom in a further 5-10% [3].

Patients generally regard fatigue as important (because it is disabling), whereas doctors do not (because it is diagnostically non-specific). This discrepancy is a potent source of potential difficulty in the doctor-patient relationship. Fatigue may present in association with established medical and psychiatric conditions or be idiopathic. Irrespective of cause, it has a major impact on day to day functioning and quality of life. Without treatment, the prognosis of patients with idiopathic fatigue is surprisingly poor. Half those seen in general practice with fatigue use acupressure based on meridian theory. Acupressure is rapidly gaining acceptance as a safe, cost-effective, non-invasive, and non-pharmacological form of therapy. Proposals are that acupressure stimulates meridians, a network of energy path-ways throughout the body, to increase the flow of *Chi* (bioenergy), subsequently altering the symptom experience. Acupressure is applied to specific points by the use of finger, hand, elbow, foot, and/or acupressure band, an elastic band with a protruding plastic button for stimulation of these pathways to increase the flow of *Chi* [5]. Studies testing the efficacy of acupressure for symptom management have been a focus of research, particularly during the last decade. However, no reviews have been published reporting the efficacy of acupressure for relieving fatigue in various illness.

2. Methods

This systematic review using Fifteen journals from the databases such as Scopus, Science Direct, PubMed, and Pro-Quest were selected was performed using the search terms of acupressure and fatigue. Studies during which acupressure was applied as an intervention and assessed for its effectiveness on relieving fatigue were selected with the last ten year's time limitation. The study consist of Randomized Controlled Trials (RCTs) and Quasi Experiments from several database sources such as Scopus, ScienceDirect, PubMed and Pro-Quest with the last 10 years' time limitation (from 2009 to 2018).

The keywords acupressure, fatigue, acute, chronic, disease, health problem and complementary therapy. The inclusion criteria are set to limit the scope of the systematic review. The inclusion criteria of this systematic review include the research using acupressure intervention on adult age.

The first step in the preparation of this systematic review is the identification of 142 journals that have been collected from various databases based on the reviewer's defined keywords. The journals are selected according to predetermined inclusion criteria

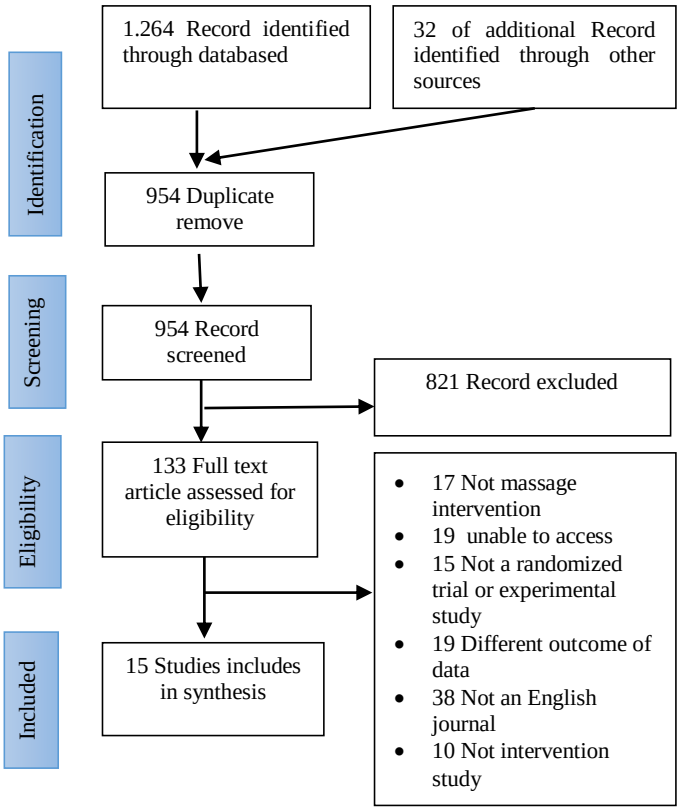

Figure 1. Flow of studies through the review

3. Result

Of the 15 research studies extracted, three covered the use of acupressure to diminish the patient with end stage renal disease , five studies persistent Cancer-Related Fatigue. and the other studies includes postpartum women, post-caesarean section, multiple sclerosis, chronic obstructive pulmonary disease, chronic back pain and migraine.

Table 1. Description of the interventions and protocols used in the selected studies.

No	Author	Method	Case	Acupressure point	∑ Sample	Time
1	[6]	QE	End stage renal disease	Combination St36, Sp6, K1, taixi	Acupressure (n = 28) Control (n = 28)	12 minutes 3 times a week For 4 weeks
2	[7]	RCT	End-stage renal Disease	Combination K1, St36, GB34, Sp6	Acupressure (n = 35) Placebo (n = 35) Control (n = 36)	15 minutes 3 times a week 1 week

No	Author	Method	Case	Acupressure point	∑ Sample	Time
3	[9]	RCT	Hemodialysis patients	Combination K1, GB 34, St36, Sp6, BL 23, and HT7	Acupressure (n = 32) Placebo (n = 32) Control (n = 32)	20 minutes 3 times a week For 4 week
4	[10]	QE	Hemodialysis patients	Combination St36, GB34, Sp6, K1	Acupressure (n = 52) Control (n = 66)	3 times a week For 4 week
5	[11]	RCT	Post-caesarean section women	Auricular	Acupressure (n = 40) Control (n = 40)	3 minutes (twice a day) For 5 days
6	[12]	QE	Postpartum women	The combination meridian Acupressure Abdomen, upper limbs, chest, abdomen, and lower limbs, side, back, back and lower limbs	Acupressure (n = 19) Control (n = 20)	90 min For 5 days
7	[13]	RCT	Cancer under chemotherapy	Combination L14, St36 and Sp6	Acupressure (n = 32) Placebo (n = 32) Control (n = 32)	1 day
8	[14]	QE	Hepatocellular Carcinoma Patients	auricular acupoints, including Yintang, Shenting, Cuanzhu, Taiyang, Jingming, Yangbai Fengchi and Baihui	Acupressure (n = 32) Control (n = 32)	4 minutes 2 times a day For 5 days

No	Author	Method	Case	Acupressure point	∑ Sample	Time
9	[15]	RCT	Persistent Cancer-Related Fatigue	Combination CV6, LI4, St36, K3, Ht7, Liv3, Anmian, and Yin Tang	Relaxation acupressure (*n* = 14) Low-intensity acupressure (*n* = 14) High-intensity acupressure (*n* = 15)	24 minutes For 12 weeks
10	[16]	RCT	Breast cancer receiving chemotherapy	Combination LI4, St36, Sp6	Acupressure (n = 24) Control (n = 24)	30 minutes 3 days A week For 12 weeks
11	[17]	RCT	Breast cancer survivors	The combination Relaxing acupressure *yin tang*, *anmian*, H7, Sp6, Liv3. *Du* 20, CV 6, LI4, St 36, Sp 6, K3.	relaxing acupressure (n=94), stimulating acupressure (n = 90) Control (n = 86).	3 minutes 10 weeks
12	[18]	QE	Chronic obstructive pulmonary disease	The combination P6, St 36, CV22, Bl3, Du 14, L1 & L10.	Acupressure (n = 20) Control (n = 20)	20 – 25 min For 4 weeks
13	[19]	RCT	Patients with migraine	The combination P6, Yin Tang	Acupressure (n = 38) Placebo (n = 38)	3 minutes 3 days For 4 weeks
14	[20]	RCT	Female nurses with chronic back pain	The combination GV20, H7 K1, BL60, BL32, GB30	Acupressure (n = 25) Placebo (n = 25)	14 minutes 3 times a week 3 weeks

No	Author	Method	Case	Acupressure point	∑ Sample	Time
15	[21]	RCT	Multiple sclerosis	The combination St36, Sp6, LI4	Acupressure (n = 50) Placebo (n = 50)	18 minutes 2 weeks (14 days)

*RCT : Randomized Controlled Trials
*QE : Quasi Experiments

3.1 The effectiveness of acupressure on fatigue in patient with end stage renal disease

Patients with the end-stage renal disease (ESRD) who require maintenance hemodialysis often reported symptoms of fatigue. Fatigue is viewed by health professionals as something that cannot be changed as it is part of the disease process [22]. In ESRD patients, untreated fatigue may highly affect the quality of life and lead to patients' increased dependency on others, weakness, loss of physical and psychological energy, social isolation, and depression. The elements that can affect the level of fatigue include depression, anemia, sleep disorders, and restless leg syndrome [23]

Four acupoints were used to decrease fatigue, such as Yungchuan (K1) in both feet, Zusanli (St36), Yanglingchuan (GB34) and Sanyingjao (Sp6) in both legs has found can reduced fatigue, depression and increase sleep quality [7].

3.2 The effectiveness of acupressure on fatigue in patients with cancer underwent chemotherapy

Cancer-related fatigue is the commonest symptom in cancer patients, with a high prevalence in most studies. Fatigue in cancer patients is multi-factorial and may be influenced by a variety of demographic, medical, psychosocial, behavioral, and biological factors [24]. Some conditions are commonly associated with fatigue, such as anemia, cachexia, fever, infection, and depression. Fatigue may occur as a part of a cluster of symptoms including pain, difficulty in sleeping, and perceived muscle weakness. The associations among these symptoms might encourage the development of effective integrated treatment strategies [25].

Patient reports suggest that cancer-related fatigue is more severe, more persistent, and more debilitating than "normal" fatigue caused by lack of sleep or overexertion and is not relieved by adequate sleep or rest [26]. Side effects of medications and non-suitable relief of fatigue with medications, shifts the patients to complementary and alternative medicine like acupressure medicine. Results of this investigation showed that acupressure in three points of L14, ST36 and SP6 has short-term effectiveness on the cancer-related fatigue of patients undergoing chemotherapy [27].

3.3 The effectiveness of acupressure on fatigue in patients during transcatheter arterial chemoembolization

Hepatocellular carcinoma (HCC) is the major cause of health problems in many developed

countries and varies according to geographic location [28]. Transcatheter arterial chemoembolization (TACE) can be palliative for unresectable HCC [29]. Fatigue and depression are reported as the most common problems for HCC patients treated with TACE [30]. Unrelieved fatigue and depression may cause patients to withdraw from treatment and can negatively impact quality of life. Some reports have shown that HCC patients have significant fatigue and depression which gradually increases during treatment.

The study explored the effects of acupressure on fatigue and depression during transcatheter arterial chemoembolization in HCC patients. Acupressure contains eight auricular acupoints, including Yintang, Shenting, Cuanzhu, Taiyang, Jingming, Yangbai, Fengchi, and Baihui. Stimulating the Yintang, Cuanzhu, Taiyang, Yangbai, Fengchi, and Baihui acupoints can alleviate headache symptoms. Stimulation of the Shenting acupoints can raise vitality and improve dizziness. Stimulation of the Jingming acupoint can diminish tired eyes. Stimulation of the Fengchi acupoint can improve stiff neck, headache, dizziness, and fatigue [14].

3.4 The effectiveness of acupressure on fatigue in postpartum and post-caesarean section women

In particular, early postpartum mothers reported that maternal fatigue was high in childbirth. If the physical and psychological stresses of the postpartum period persist, they can have a negative impact on the mother and impair her adjustment to daily life, and negative feelings about the maternal experience are likely to lead to postpartum depression. Acupressure massage, which promotes the circulation of blood and lymph, mental stability, and relaxation of muscles, is thought to be effective in decreasing maternal obesity, edema, stress, and fatigue. Postpartum healthcare is one of the major issues in women's lives. Many study find benefits of acupressure massage for postpartum women [31]. This finding strongly suggests that meridian acupressure massage was effective for relieving fatigue in postpartum women.

3.5 The effectiveness of acupressure on fatigue In patient with chronic obstructive pulmonary disease

Multiple factors might play a role in causing or maintaining moderate to severe fatigue in patients with COPD (figure). The amount of airflow limitation is poorly associated with fatigue, and optimal pulmonary pharmacological therapy does not seem to prevent deterioration of fatigue over time [32]. Moreover, COPD exacerbations (particularly those resulting in admission to hospital) were found to be important, precipitating factors of moderate to severe fatigue in patients with COPD.5 In addition to increased breathlessness, many patients report low energy as one of the foremost sensations associated with a COPD exacerbation The infection itself might enhance fatigue [33].

Acupressure was applied by pressing in circular movements on the acupoint with the thumb finger. Seven acupoints were used in the current study which were: P6 (neiguan), St36 (Zusanli), CV 22 (Tiantu), BL3 (Feishu), Du14 (Dazhui), L1 (Zhongfu) & L10 (Yuji). The duration of each session ranged between 20 – 25 min \ session, cosseting of 3 min of massage for neck and each shoulder to free the *Chi* and blood and 3 min for each acupoints to apply

acupressure [18]. The findings concluded that study group has statistically significant improvement in relation to dyspnea, respiratory rate and oxygen saturation than the control group [18].

3.6 The effectiveness of acupressure on fatigue in patient with chronic back pain

Lower back pain (LBP) is an extremely common health problem [34]. Lower back pain causes more global disability than any other condition. Disability-adjusted life years (DALYs) increased from 58.2 million in 1990 to 83 million in 2010 [35]. It is causing an enormous economic burden in both developed and developing countries [36].

LBP is defined as a nonspecific condition that refers to complaints of acute or chronic pain and discomfort in the area between the lower posterior margin of the ribcage and the horizontal gluteal fold [37]. LBP has a major negative impact on individuals' health-related quality of life, including poor general health, psychological distress, sleep disturbances, disability and fatigue [38]. Fatigue limits functionality and can lead to social and psychological impairments. Fatigue is a symptom that can be particularly problematic for LBP patients, can complicate and disrupt recovery and delays optimal return to daily life and work [39]. Chronic low back pain (CLBP) has been associated with altered trunk muscle responses as well as increased muscle fatigability This study showed the positive effect of GV20, H7, K1, BL60, BL32, GB30 acupressure combination on the improvement of fatigue among female nurses with chronic back pain, immediately, 2 weeks, and 4 weeks after the intervention [20].

3.7 The effectiveness of acupressure on fatigue in patient in women with multiple sclerosis

Multiple Sclerosis (MS) is the most prevalent neurological disease [40]. It is characterized by lesions and scarring of the protective myelin sheath of the central nervous system (CNS), leading to neuronal damage and axonal loss. It is more common in women than in men [41]. According to a study in MS is unpredictable and is one of the major diseases affecting patients quality of life [42].

The course of the disease is uncertain and the clients with MS may face physical problems including muscle weakness, bladder and bowel dysfunction, problems with speech, and vision [43] and also hidden difficulties such as fatigue [44]. Fatigue in MS patients may be cause multiple factor. In addition to immunologic abnormalities, multiple sclerosis is associated with an increased prevalence of other conditions including depression [45] and several sleep disorders [46]. For example, although sleep disorders are recognized for contributions to excessive daytime sleepiness, many patients with sleep disorders such as obstructive sleep apnea consider their problems with fatigue, tiredness, or lack of energy. Moreover, treatment of these disorders leads to robust improvement in patient-defined fatigue, tiredness, and lack of energy, as well as sleepiness [47] Acupressure at the acupoints ST36, SP6, LI4 showed significant improvement of the mean scores of fatigue compared to the placebo group at immediately, two, and four weeks after the intervention. Acupressure help to relieving fatigue by increasing chi energy and sleep quality[21].

4. Discussion

Acupressure has been practiced in China for more than 2000 years, but is only recently beginning to gain acceptance by Western medical practitioners as a legitimate means of treating symptoms of illness [48]. This therapy is a means of manipulating the same acupoints as used in acupuncture, but without the use of needles [49]. Acupressure is a noninvasive, safe and effective massage technique that employs pressure and massage to acupoints in order to stimulate the balance of life energy that in term promotes health and comfort [50]. The therapy can be easily taught to patients so that they can manage fatigue, and decrease adverse health outcomes to improve their quality of life [51].

The purposes of acupressure are to regulate and balance the body energy or *Chi*, and further to maintain health, prevent illness or enhance health [52]. This energy referred to as *Chi*. *Chi* flows through the 12 major energy pathways called meridians, each linked to specific internal organs system and 365 acupoints [53]. *Chi* energy also regulate spiritual, emotional, mental and physical health. Acupressure therapy is applied with the fingers on the acupoints and the stimulation lines or meridians of the body surface. The meridians start at the finger tips, connect to the brain and connect to the organ associated with the specific meridian [53]. These meridians can become blocked or slowed. Through applying pressure (acupressure) into one or more of these acupoints, imbalances can be corrected by stimulating or easing energy flow [54].

From the results of the fifteen studies, acupressure is shown to reduce various fatigue patient with end stage renal disease, persistent cancer-related fatigue. And the other studies includes postpartum women, post-caesarean section, multiple sclerosis, chronic obstructive pulmonary disease, chronic back pain and migraine. This study shows that there are various acupressure points in relieving fatigue. Further research using combination with one or more other acupoints or using other methods would be very important for accelerating the process of healing for patients. Some experts believe that stimulation of points in acupressure prevents the transfer of acute stimuli and increases the level of endorphins in the blood, and thus, causes pain relief [55], and could cause varying degrees of release and relaxation in the body, and consequently, affect the pain of muscle cramps [56].

A combination of many or all of the following point are typically used : PC6 to include sedation, GB20 to clear heat, LV3 to move and tonify blood, KD 3 to reduce heat, tonify blood and root the kidney, HT7 to calm the spirit , Sp6 to nourish blood and kidney chi and extra point yintang to calm the mind and spirit [57] included points to stimulate generation of *Chi* and blood (ST36), restore yang (LI4), *tonify Chi* /kidney/*yang* (CV6, K3) and raise yang (*Du* 20). Several of these points are commonly used to increase energy and endurance [58] .

This study only contains the effects of acupressure in various patients with limited literary sources. we need to add other literature to support the results of the review, more special reviews are needed as evidence that acupressure can objectively relieve fatigue, for example from the biochemical and neuroimmunological dynamics of the human body.

5. Clinical recommendation

The systematic review begins to establish a credible evidence base for the use of acupressure in relieving fatigue. An evidence-base of reliable and valid evaluation is crucial for clinicians. In terms of the implication for nursing education, practice, and research, the review provides important evidence that acupressure uses a non-invasive, timely, and effective way. In addition, acupressure should be included in the nursing education curriculum to help students learn about the effectiveness of complementary therapies. Health care providers should have begun to incorporate acupressure into their practice to help patients who experience fatigue. before giving therapy, health care providers must have an official practice permit to ensure patient safety. They must also practice based on practical guidelines for acupressure management, because the incorrect application of finger pressure, the inaccuracy acupressure points and the inaccuracy selection of acupoint combinations may give different results to the patient.

6. Conclusions

The results of the study reported the positive impact of acupressure in relieving fatigue level with several cases, especially on patient with end stage renal disease, persistent Cancer-Related Fatigue, postpartum women, post-caesarean section, multiple sclerosis, chronic obstructive pulmonary disease, chronic back pain and migraine. This review shows that acupressure is a noninvasive, timely, and effective action in reducing fatigue in patients with various diseases.

STIGMATIZATION PEOPLE LIVING WITH HIV AIDS (PLWHA) IN THE DISTRICT TULUNGAGUNG EAST JAVA - INDONESIA

Rio Ady Erwansyah[1], Nursalam[2], Ferry Efendy[2]
[1]Student of Faculty of Nursing, Universitas Airlangga Surabaya, Indonesia
[2]Lecturer of Faculty of Nursing, Universitas Airlangga Surabaya, Indonesia
Email: ppni.tulungagung2016@gmail.com

ABSTRACT

People with HIV AIDS (PLWHA) often experience stigma, the stigma that occurs among them is verbal statement and the act of keeping ODHA away from social activities, stigma can disrupt the social role of PLWHA.Stigma can come from anyone including health workers.PLWHA need actions to eliminate the stigma that occurs,so that PLWHA can live as other individuals without getting stigma.The purpose of the review literature is to identify the forms and sources of stigma that occur in PLWHA and efforts to eliminate stigma against PLWHA.The author finds journals that are relevant to the problem by using stigma keywords, health workers, HIV AIDS, and people with HIV AIDS.Journals were obtained from the Science Direct, Proquest, SagePub,and Scopus databases with 54 journals and 14 journals fulfilling the criteria for analysis.Journal analysis states that various efforts have been made to solve the problem of stigma against PLWHA,this effort includes the entry of HIV into health care work programs, the source of stigma from health workers requires special attention,because health workers should be promoters to eliminate stigma,necessary increasing the knowledge and expertise of health workers in handling and treating PLWHA.So that officers can become promoters in eliminating stigma against PLWHA

Keywords: stigma, HIV / AIDS, people with HIV AIDS (PLWHA)

1. Introduction

Stigma One of the problems faced in making efforts to control Human Immunodeficiency Virus (HIV) Acquired Immune Deficiency Syndrome (AIDS) in the community, this is due to the fear of being infected and the lack of knowledge about HIV AIDS. Unfair treatment (discrimination) and stigma are not only carried out by the community but also by health workers, stigmatization can be done intentionally or unintentionally. Various efforts have been made to solve the problem of stigma against people with HIV AIDS (PLWHA), these efforts include the inclusion of HIV programs in the Puskesmas work program, but with socialization and health counseling that have not been able to solve the existing problems [1]

Preventive efforts are very necessary because it can reduce the risk of HIV transmission, prevention efforts are considered most effective because they can prevent someone from being exposed to the risk of transmission , research on HIV treatment therapy has been carried out, one of which is Antiretroviral therapy (ART) can increase PLWHA life expectancy [2]

Handling HIV-AIDS problems is not enough only on health aspects, but also refers to social aspects. This is because, HIV-AIDS sufferers not only experience health problems, but also experience social problems. The social problem in question is the presence of stigma on PLWHA

and family members, the forms of stigma that are obtained vary among others in the form of verbal statements and discrimination [3]

Stigma occurs not only from people in the surrounding environment, but is also often carried out by health workers, who have an important role in advancing in the field of health services. Health workers should provide services to all people in need without distinguishing health and social status. For nurses in particular, they must also have value and self-confidence to provide services including PLWHA. Anxious feelings and worries that the nurse has can cause stigma without the nurse noticing [4]

The stigma can have an impact on many things starting from the onset of depression, psychological distress, and anxiety which will eventually lead to PLWHA being unable to achieve its independence. Other research shows that PLWHA is reluctant to open an identity because it cannot be accepted by its environment, so that most PLWHA has a disruption of social interaction with the surrounding community [5]. Disparities occur in several places that cause PLWHA to get worse with its health status, which is reflected in the treatment received by PLWHA in the work environment and living environment [6]

The purpose of this study was to conduct a systematic review related to PLWHA's perception of the stigma they experienced. This study is expected to provide ideas for further research related to PLWHA's perception of the stigma experienced and can be used as a reference in efforts to handle PLWHA.

2. Methods

Study search strategies that are relevant to the topic are carried out using the ScienceDirect, Proquest, and SagePub databases restricted from 2000 to 2018. The keywords used are "stigma", "HIV", "AIDS", full text articles and abstracts reviewed to choose studies which matches the criteria. The inclusion criteria in this review are stigma in people with HIV / AIDS. Journal searches using the above keywords get 54 journals and articles that match the inclusion criteria there are 14 journals.

3. Results

The journals reviewed in this study are qualitative research journals The number of articles obtained in this review are 14 journals and all of them use qualitative research. The method used to obtain information is using in-depth interviews and FGD (focus group discussion).

The period of research used in these studies varies from 1 month to 1 year, the longer the time the study and the frequency of interviews on average provide good results for the information obtained. The longer the study, the more information that can be extracted, this is indicated by the frequency of frequent interviews and frequently scheduled group meetings.

The sampling method used in the study was 14 studies which were carried out qualitatively. The sample in this study varied, for example age, In this study the age of the sample varied from teenagers to late adulthood. So that the data obtained is very diverse and covers all age ranges.

Based on the description of 14 studies, it is shown that the handling of HIV-AIDS problems is not enough only from the health aspect, but also refers to the social aspects [7]. This is because, HIV-AIDS sufferers not only experience health problems, but also experience social problems [8]. The social problem in question is the existence of stigma on PLWHA and family members, the forms of

stigma that are obtained vary among others in the form of verbal statements and discrimination [9]. Various efforts have been made to solve the problem of stigma against people with HIV AIDS (PLWHA), these efforts include the inclusion of HIV programs in health care work programs, an also include outreach and health counseling that has not been able to solve the existing problems [10]

4. Discussions

The results of the review indicate that stigma raises health problems and social activities, 1 in 4 people with HIV are unaware of their HIV diagnosis, and almost half present with a CD4 count <350 cells / microliter [11] 95% of informants reject their health status [12]. Stigma causes negative self-image and the occurrence of discrimination from the community causes interruption of social PLWHA [13]. Increasing understanding of social support mechanisms contributes to HIV treatment behaviors from PLWHA and can fill knowledge gaps [14]. Family support and peer group support can increase the level of psychological response [15].

Stigma and discrimination in health services carried out by health workers is one of the obstacles to the quality of providing health services to patients with HIV and AIDS, which in turn can reduce the health status of patients with HIV and AIDS, the stigma associated with HIV and AIDS is called a big problem and damages family life , social, and individual economics [16]. The stigma associated with HIV and AIDS is also considered a major barrier in the prevention, treatment and treatment of HIV and AIDS [17].

The stigma that occurs is influenced by several factors known as the power factor of the occurrence of stigma [18]. Power factors include four components including social, political, economic and spiritual factors. Social factors are influenced by weak communication and social contact between health workers and patients. Politically, stigma occurs because there is no policy that regulates the handling of HIV and AIDS patients, and the consequences of stigma and discrimination in patients related to HIV and AIDS. Economic factors, the emergence of stigma and discrimination due to a lack of provision of universal precaution facilities, the absence of rewards and reward services, and no health insurance if HIV and AIDS are contracted [19].

5. Conclusions

The results of a systematic review of research addressing the problem of HIV-AIDS is not enough simply from the health aspects, but also refers to social aspects. This is because HIV-AIDS sufferers not only experience health problems, but also experience social problems. The social problem in question is the existence of stigma on PLWHA and family members, the forms of stigma that are obtained vary among others in the form of verbal statements and discrimination. Various efforts have been made to solve the problem of stigma against people with HIV AIDS (PLWHA), these efforts include the inclusion of HIV programs in health care work programs, but with the outreach and health counseling that has not been able to solve the existing problems.

ABSTRACT

Shivering is one of complication that usually appear after spinal anaesthesia. It is correlation with hypothermia condition. Age, type of surgery, duration of exposure in operating room, operating room temperature, surgical procedure, type of anaesthesia, low body mass index, and temperature of intravenous fluid are risk factors of shivering incident. Applying hot-pack treatment could increase the body temperature. And it might reduce shivering grade of post- operative cesarean-section patients. The purpose of this study was to analyse effect of hot- pack treatment toward shivering grade among post-operative caesarean-section patients in recovery room. Pre-experimental design was performed. Twenty-five patients who post- operative caesarean section were willing to participation. Consecutive sampling was applied to collect the participants of this study. Hot-pack with 400C temperature were implement as accordance with the standard procedure operational that created by the researcher based on the literature review. Shivering grade was used to evaluate the participants shivering condition. Wilcoxon Signed Rank Test was used to analyse the data. There were significant effect of implementing hot-pack to decrease shivering grade among post-operative cesarean- section patients (0,000). In sum, skin receptors receive stimulations from administration of hot-packs. Next, hypothalamic as organ which control the body temperature will produce thermal. At the end, those process will reduction of shivering grade among post-operative cesarean-section patients.

Keywords: hot-pack, grade shivering, post-operative cesarean-section

1. Introduction

Surgical actions can cause various problems, one of the complications that may arise after surgery is a decrease in the patients's body temperature or postoperative hypothermia (Ignatavicious, 1999). The process of decreasing body temperature due to surgery will increase the body excess, improve vasoconstriction and changes in system thermoregulation in the hypothalamus. Hypothermic effects can also be corrected and affect postoperative length of stay (Goldberg, 2011). Repeat body temperature must be done immediately because the patients's subsequent effects will increase other discomforts such as chills and surgical injuries due to strain in the surgical wound (Goldberg, 2011).

The results of the Indonesian Basic Health Research (2013) showed births with the caesarean method amounted to 9.8% of the total 49,603 births throughout 2010 to 2013. The incidence of caesarean section in East Java in 2011 was 3,401 operations out of 170,000 deliveries or around 20% of all childbirth (East Java Province of Health Office, 2012). From the data recorded in the medical record of the Private Hospital in

Sidoarjo As long as 318 patients underwent caesarean section from December 2017 to May 2018. Sabiston (2011) reported about 78% of patients with elective abdominal surgery having experience of decreasing temperature body. In addition, from previous studies reported that 100% patients with kidney stone surgery were experienced hypothermia (35°C) in the operating room (Ninik, 2007). Shivering incidents are still often found in conscious recovery rooms. Ten patients reported experienced with shivering at one of the Private Hospital in Sidoarjo.

Post Anaesthetic Shivering is vascular to skeletal muscles on the face, jaw, head, body or extremities that last more than 15 seconds accompanied by hypothermia and vasodilation (Buggy & Crossley, 2008). The incidence of shivering after anaesthesia for patients undergoing spinal anaesthesia is around 40-60% (Nugroho et al., 2016). Shivering is caused by stimulation of the posterior hypothalamus from the dorsa medial portion near the third ventricular wall, called the primary motor center. Many factors can increase the risk of shivering after anaesthesia, including type of anaesthesia, age, temperature and type of intraoperative fluid treatment, operating room temperature and duration of operation (Alfan, Eddy & Arnaz, 2016). Before the patients experiences shivering, it is necessary to take action to warm up the body with heat therapy given to patients whose temperature is ≤ 36 0C (Altman, 1999). Hot packs are closed packages that contain a gel with a temperature of 40 °C (Rosdahl & Kowalski, 2014). Hot packs will be given in the right and left arm of the part in about 15 minutes (Rosdahl & Kowalski, 2014). However, applying hot packs was never given to patients who were experience with shivering in the Recovery Room in one of the private Hospital in Sidoarjo. Therefore, conducted this study was needed to determine the effect of hot-pack on shivering grade in post-operative caesarean section patients in the recovery room one of private hospital in Sidoarjo.

Methods

This research method was pre-experimental with one group pretest - posttest design. The respondents of the study were had pre-test and post-test before and after given an intervention The population in this study were all post-operative caesarean section patients in the Recovery Room (18-22 °C) one of private hospital in Sidoarjo. Consecutive sampling technique was performed. 25 of 30 population were met with inclusion and exclusion criteria during 2 weeks observation. Patients with spinal anaesthesia, body temperature less than 36°C, experiencing with shivering, around 20=45 years old, didn't received pethidine as medication, during stayed in recovery room was covered by blanket with the thickness 1 mm, and willing to participated were the inclusion criteria. Patients with General anaesthesia and experience with emergency condition were excluded from this study. Five patients which were exclude from this study were 3 patients with emergency operating criteria and 2 patients with general anaesthesia. Untoward event during study were found in this study. All of respondents participated until the study done. The instruments of this study were observation check list of shivering grade (Crossley & Mahajan, 2000) and SOP was made by researchers based in the study that conducted by Rosdahl and Kowalski in 2014. Hot compresses which was hot-pack brand resources and poly green brand digital thermometers were used as the tools of this study. Data was analysed by Wilcoxon Rank Test statistics.

Results & Discussion

This study was found that majority respondents were 26-35 years old (42%), senior high school many (64%), housewives (56%), over weight (76%), didn't had experience of caesarean (56%), the length of operation the results was mostly >60 minutes (60%), body temperature before being given hot-pack were 35°C-35.5°C (96%), body temperature in patients after being given hot-pack were 36.1°C-36.5°C (64%), the shivering grade before operation were the second shivering grade (80%), and the shivering grade after operation were the first shivering grade (80%).

Table 1 Characteristics of respondents

Characteristics	Frequency (n)	%
ges		
17-25 years	8	32
26-35 years	12	48
36-45 years	5	20
Education Background		
Junior High School	3	12
Senior High School	16	64
Diploma	5	20
Graduate	1	4
Occupations		
Private	10	40
Entrepreneur	1	4
Housewives	14	56

1	5	20
2	0	0

Table 2 Effect of hot-packs administration

Shivering grade Pre-Post	n	%
Negative ranks	25	100
Positive ranks	0	0
Ties	0	0
Amount	25	100
P = 0,000 < α =0,05		
Wilcoxon Signed Rank Test		

It can be concluded that the Wilcoxon test result showed the provision of hot-packs on shivering grades which was asymp significant (0,000 <α = 0.05). It means that there was an effect of giving hot-packs to shivering grade in postoperative caesarean section patients in the Recovery Room one of private hospital in Sidoarjo.

It was found that the shivering grade of 20 respondents before the Hot-Pack was given was obtained in the second shivering grade. The results of this study, many shivering occurred in respondents with early adulthood (26-35 years) as much as 48% and in late adulthood (36-45 years) as much as 20%. This is in accordance with the theory which states that ages of the patients can affect the body's metabolism due to hormonal metabolism, thus giving an indirect effect on body temperature (Tamsuri, 2006). The body's core temperature will decrease by 0.003 °C for each increase in ages (Frank, 2000). In the study of Nugroho et al (2016), it was showed that late adults experienced shivering more often than other ages. Age can affect the occurrence of shivering post anaesthesia, where the shivering threshold at old age is lower than 1 °C. In this study, researchers argue that the older the age of the body's core temperature decreases because at this age there has been a decline in metabolism so that the ability to maintain body temperature also begins to decrease.

The Body Mass Index is mostly in the category of overweight as many as 19 respondents (76%). In the study of Vanessa et al (2009) explaining the presence of morphometric influences, among others: body weight, height and body fat of patients to the incidence of hypothermia during surgery and people who are malnourished easily experience a decrease in body temperature (hypothermia). Body temperature is related to the high Body Mass Index, the greater the Body Mass Index, the greater the body temperature (Kogsayreepong et al 2000). Individuals with a thick layer of fat tend to not experience hypothermia because fat is a good enough insulator to channel heat at a speed of one third of the speed of other tissues (Tamsuri, 2006). From the theory above, the researcher argues that respondents who have large Body Mass Index increase body temperature, respondents are not easy to experience shivering because thick layers of fat can transmit heat.

All respondents who underwent surgery for > 60 minutes experienced shivering events (60%). The above results relate to the theory of Vanessa de Brito et al (2009) explaining that there is a relationship between the duration of anaesthesia and the onset of hypothermia. The longer the duration and operation, the body temperature can be lower so that it can trigger shivering. According to Putzu et al (2007) also explained that shivering is a response to hypothermia during surgery between the temperature of the blood and the skin with the core temperature of the body. Respondents who underwent surgery > 60 minutes experienced shivering quite a lot, this was in line with the research which stated that the incidence of shivering after spinal anaesthesia was most prevalent among respondents who underwent surgery with a duration of 61-120 minutes (Madjid et al., 2014).

The researchers argues that the longer an operation will cause a postoperative shivering because the skin is exposed to cold temperatures for too long. During spinal anaesthesia it also inhibits the release of the hormone catecholamine so that it will suppress heat production due to metabolism. In addition, the long duration of operation and the type of operation in caesarean section that carries out incisions in the abdominal wall and uterus causes an increase in heat output from the body to the external environment which increases the risk of hypothermia. This happened because the respondents were exposed to cold room temperatures

longer, not given blankets to cover their hands, shoulders and neck during surgery.

The temperature in the Recovery Room one of private hospital in Sidoarjo was 18°C, so it can increase the risk of shivering. This is in accordance with the theory which states that operating rooms with temperatures less than 200C can cause a decrease in body temperature (Frank, 2008). The researchers argue that cold temperatures or hypothermia in postoperative caesarean patients cause contractions of blood vessels that drain food and oxygen to the tissues until the intake is inadequate, a decrease in blood flow leads to the risk of blood clots forming, which further inhibits tissue oxygenation and causes resistance to the healing phase operation wound.

This study found that the shivering grade of 20 respondents after being given the Hot-pack was obtained in the first shivering grade and 5 respondents in the second shivering grade. The results showed that most experienced a decrease in shivering grade after hot packs were given. Most respondents experienced a rise in body temperature back to normal (36°C - 37°C) and a decrease in shivering grade to 0. This was supported by Rosdahl (2014) that the increase in body temperature returned to normal (36°C-37°C) after administration of hot-pack heat therapy caused by the effects of heat from hot packs that react to skin receptors that function as body temperature regulation both for heat and cold temperatures.

The skin receives heat from hot packs, the temperature of which is regulated according to the tolerance that the respondent can accept (40°C) until the heat can spread from the skin area to the blood vessels that cause vasodilation and re-repair the body temperature that experiences hypothermia and shivering so that the body temperature becomes normal. A total of 5 respondents did not experience a significant increase (second Grade of Shivering) in body temperature after giving a hot pack because they had a body mass that was above normal (obesity), age at the end of the adult and the length of time in the operating room. This is in accordance with Rosdahl's theory (2014) that body mass affects the return of normal body temperature.

Researchers argue that body mass affects the increase or decrease in body temperature. In people who have less or thin body mass, they will quickly experience a decrease in body temperature when exposed to cold or hot temperatures. Heat therapy using hot packs can restore body temperature quickly, sensations and effects of heat delivered through the skin and received by the dermal nerves resulting in dilation of the dilated dermal capillaries make the blood flow more flow to the surface of the skin so that it can spread and the body gets more blood flow flows to the surface of the skin to spread and the body gets adequate blood flow and causes the temperature around the skin to increase. Parts of the body that can have ease in absorbing and returning body heat are parts that are more sensitive to heat, namely the eyelids, neck and the inside of the arm or axilla (Rosdahl, 2014).

Based on the results of the above research, researchers argue that the reduction in shivering grade in postoperative caesarean section patients is influenced by several factors, namely the length of operation or the length of time the patient is exposed to cold air operating room, age, body mass index, nutrition, operating room temperature and blood loss during surgery . Repeated shivering when in the recovery room can occur because it is influenced by various factors including recovery room where the temperature is cooler than the operating room and cleaning the patient after the surgery ends. When in the Recovery room, the patient's post operation was not immediately replaced by his clothes and blankets. When the patient is taken by the clerk the new room will be cleaned and replaced.

Based on the results of the Wilcoxon test analysis obtained a significance value (p) value of 0,000 with a significance level of α 0,005, it means the value of p value <α can be concluded that there is an effect of giving hot-pack to grade shivering in patient post Caesarean surgery in the Recovery Room one of privet hospital in Sepanjang. Rosdahl (2014) argues that the increase in body temperature returns to normal (36°C-37°C) after the administration of hot-pack heat therapy caused by the heat effect of hot packs that react to skin receptors that function as body temperature regulation for both heat and cold temperatures. This is related to the theory (Guyton & Hall, 2014) The mechanism of increasing the temperature when the body is too cold where these 3 ways can increase heat. When the body is too cold, the temperature regulation system performs the exact opposite procedure namely the occurrence of skin vasoconstriction throughout the body caused by stimulation of the posterior hypothalamic sympathetic centre. Piloerection ie sympathetic stimulation causes

the arector pili muscles attached to the hair follicles to contract so that the hair stands upright and increase in thermogenesis (formation of heat) that is the formation of heat by an increased metabolic system that triggers the occurrence of shivering, sympathetic stimulation for the formation of heat and secretion of thyroxine.

Hypothalamic stimulation of the shivering is located in the dorsomedial part of the posterior hypothalamus near the third ventricular wall is an area called the primary motor center for shivering. Effect of hypothalamic temperature on body heat dissipation through evaporation and heat formation which is mainly caused by muscle activity and shivering (Guyton & Hall, 2014). If the body becomes too cold, signals from the skin and possibly also from the inner body receptors give off an uncomfortable cold feeling. Therefore, individuals will make adjustments to the right environment to be able to reach back to comfort such as moving into a hot room or by wearing clothes that have good insulation against cold air. This is a system of bodily regulation that is stronger than that found by physiologists in the past. Even this mechanism is truly an effective mechanism for maintaining body temperature in very cold environments (Guyton & Hall, 2014). This is supported by previous research by (Sutatia B, 2016) with the title of the effectiveness of Hot-Pack on decreasing body temperature in the first 10 minutes experiencing a normal temperature increase (360C-370C).

Based on the results of the above research, researchers argue that there is an effect of giving hot-pack to shivering grade through a mechanism to increase body temperature by giving heat therapy so that the effect of hypothalamic temperature on body heat dissipation through evaporation. Evaporation is a process that requires heat (evaporation heat) which is absorbed from the skin. This invisible evaporation of the skin or lung cannot be controlled for the purpose of regulating the temperature because the evaporation results from continuous diffusion of water molecules through the surface of the skin and respiratory system.

FAMILY AND SOCIAL SUPPORT NEEDS OF ELDERLY WITH DEPRESSION: A SYSTEMATIC REVIEW

Dhona Sutopo[1], Supia Ningsih Juita Sari[1], M. Elyas Arif Budiman[1], Winda Kusumawardani[1]
[1]Faculty of Nursing Airlangga University, Surabaya, Indonesia
E-mail : Dhona.sutopo22@gmail.com

ABSTRACT

Depressive symptoms were important public health issues and the study showed that the prevalence of depressive symptoms significantly differed between empty nest old adults and non-empty nesters (24.1% vs. 19.0%). The results of some study found that respondents had good family and social support did not have depression experience. Database search used an electronic database from Scopus with a range years from 2015– 2019. The keywords in the search were family support, social support, elderly and depression for available database. After getting the database through Scopus, then carried out a review to the stage of making a systematic review. The interactions and communications with the grandchildren, spouse, others family members and friends have an important and crucial in the process of preventing or reducing depressive symptoms in the elderly. Social connection with friends and family members is associated with reduced depressive symptoms in the elderly and further study should pay more attention to comparing factors associated depressive symptoms in the elderly

Keywords : family support, social support, elderly and depression

1. Introduction

The worldwide population is aging rapidly. The older population is predicted to reach 2.03 billion by 2050, and this number will account for 22% of the world's population [1]. The aging of population is accompanied with a series of problems, including depression, which is a remarkable public health problem that affects the mental health of the elderly (Luijendijk et al., 2008). The number of patients with depression increased by 18.4% between 2005 and 2015, and elderly patients suffer from one of the highest incidences of depression (World Health Organization, 2017)[2].

Depressive symptoms were important public health issues and the study showed that the prevalence of depressive symptoms significantly differed between empty nest old adults and non-empty nesters (24.1% vs. 19.0%)[3]. The elderly living alone had highest OR of depressive symptoms. Recent reviews confirm that few social relations and low social support – in particular low perceived emotional support – are risk factors for depression (Schwartzbach et al. 2014 ; Santini et al. 2015)[4]. Depression significantly lowers quality of life among older adults [5].

Social ties are important for a person's physical and mental well-being [6]. In old age, social support comes mainly from the family and friends. Social support is the existence or availability of people who care, appreciate and whom one can trust. The role of social withdrawal is predominantly striking among populations with greater predisposition to morbidity and mortality such as older adults. Depression is often linked to the risk or to the actual separation of emotional bonds and support[7].

2. Methods

2.1 Search strategy and study selection

This systematic review is a quantitative study using the PRISMA review (Figure 1). A literature search is carried out in four database such as Scopus, Sage Journal, Proquest, and PubMed with result limited to the last five years from 2015 to 2019. The keywords used in literature search are family, support, elderly and depression.

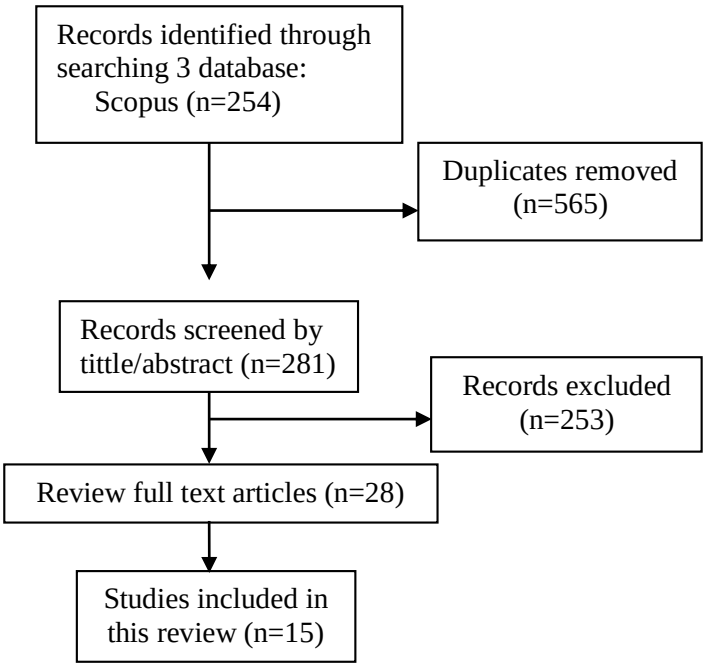

Figure 1. PRISMA flow diagram

2.2 Type of study

This systematic review was aimed to identify Family And Social Support Needs Of Elderly With Depression. A randomized controlled trial study (RCTs), which is in the top position of the evidence hierarchy, is qualified and suitable to answer this kind of question. Therefore, only RCTs were included in this review.

2.3 Inclusion and exclusion criteria

The inclusion criteria for the article are articles in English and which explain Family And Social Support Needs Of Elderly With Depression. Articles would be excluded if the study did not Family And Social Support Needs Of Elderly With Depression.

3. Results

Total articles collected numbered 16 articles. After reviewing the results, the interactions and communications with the grandchildren, spouse, others family members and friends have an important and crucial in the process of preventing or reducing depressive symptoms in the elderly.

3.1 Family Support dan Social Support

The research stated from the multivariate analyses showed that having no family members to

confide in increased the odds of the past year while having three or more family members to confide in decreased the odds of the past year MDD. And also, lower frequency of contact with friends was related to higher odds of the past year MDD. In terms of quality, having no friends to confide in increased the odds of the past year MDD. Similarly, having no friends to rely on increased the odds of the past year MDD while having three or more friends to rely on decreased the odds of the past year MDD [8].

The research stated in rural areas of Liuyang city, Hunan, China Significant differences were found between empty-nest and not-empty-nest older adults regarding loneliness (16.19±3.90 vs. 12.87±3.02, Cohen's d=0.97), depressive symptoms (8.50±6.26 vs. 6.92±5.19, Cohen's d=0.28) and the prevalence of major depressive episodes (10.1% vs. 4.6%) (all $p<0.05$) [9]

The study samples of NESDA and NESDO consisted of 1115 and 359 patients, respectively, with a major depressive disorder in the 6 months before baseline. At the 2-year follow-up assessment, 697 (59.0%) of the 1181 patients were in remission; they no longer fulfilled the criteria of a major depressive disorder in the preceding 6 months. The results produced are the social network characteristics of living in a larger household, the social support characteristic of few negative experiences with the support from a partner or close friend, and limited feelings of loneliness proved to have unique predictive value for a favorable course of depression [4]. Another research with Ordinary Least-Squares (OLS) Regression Analysis and SEM Analysis in China showed Social cohesion, associated with a lower rate of depression [10].

The other research stated from Australia with samples 160 Australian self-identified gay men aged from 65 to 92 years study showed that the relationship between living alone and depressive symptoms weakened with increasing levels of belonging with gay friends [11].

4. Discussion

The results of this study were consistent with the hypothesis that the qualitative of social relationships within ones network is related to depression. Specifically, having three or more family members and friends to confide in or rely on was associated with lower levels of depression in the past year, while not having any family members from whom to seek emotional support was associated with an increased likelihood of having had a depressive episode within the last year [8].

In several studies a higher number of elders with symptoms of depression presented lower perception of affective-consistency, adaptation, and family autonomy factors than those without depressive symptoms; family adaptation was the factor most affected for elders with depressive symptoms. From this result, family becomes essential to the elderly and lack of family support or perceived lack of family support constitutes a relevant factor for the occurrence of depression in the elderly[12].

The evaluation of the influence of family function on depression in a sample of elderly Chinese, with and without depression, found that elderly patients with depression showed worse family functioning and lower social support than elders without depression[13]. According to a Brazilian study, familial dysfunction was higher among elders with depressive symptoms and, therefore, that family abandonment is a risk factor for depression[14]. The family has a fundamental role for the elder, and may aid in treatments and strengthen ties. Thus, the family must be inserted in the daily life of elders[15].

5. Conclusion

The family support and social support have a very important role in the process of prevention or severity in cases of depression in the elderly. The higher social connection quality was more closely and consistently associated with lower odds of the past year depression [8]. Also, another result showed that the presence of depressive symptoms was higher among the elderly with family dysfunction [14].

Tittle	Population And Sample	Aims and Design Method	Outcome And Conclusion
The relationship between depressive symptoms and family functioning in institutionalized elderly (Simone camargo de oliveira1, Ariene Angelini dos Santos2, Sofa cristina iost Pavarini, 2014)	A total of 225 elderly residents were found in the six institutions studied. Among these, 118 were excluded for not meeting the inclusion criteria of the study. The subjects of this study were 107 elderly in total; 42 men and 65 women	The present study aimed to investigate the relationship between family functioning and depressive symptoms among institutionalized elderly. This is a descriptive, cross-sectional study of quantitative character	In this study, it was found that the majority of elderly had high family dysfunction (57%), followed by good family functioning (22%) and moderate family dysfunction (21%). The presence of depressive symptoms was higher among the elderly with family dysfunction. The results also showed that there was significant correlation between the Family APGAR and depressive symptoms. In multiple logistic regression analysis we concluded that the institutionalized elderly with dysfunctional families were more likely to have depressive symptoms
Quality of Life, Family Support, and Comorbidities in Institutionalized Elders With and Without Symptoms of Depression (Aurigena Antunes de Arau ´jo1, Rosa Ange ´lica Silveira Rebouc ¸as Barbosa2, Marı ´lia Stefani Souza de Menezes, Ingrid Iana Fernandes de Medeiros, Raimundo Fernandes de Arau ´jo Jr, Caroline Addison Carvalho Xavier de Medeiros. 2015)	138 institutionalized elders in the State of Rio Grande do Norte, Brazil. Inclusion criteria include: age ≥60 years, residence in a philanthropic Institution of Long Permanence for Elders, and cognitive ability	Cross-sectional study with institutionalized elders . The aim of this study was to analyze the socio-demographic, quality of life, family support, and comorbidities variables in institutionalized elders with and without symptoms of depression.	Showed that depressive symptoms are closely related to low quality of life in institutionalized elders. Other factors that also negatively influenced the quality of life in this population include: low socioeconomic conditions, unsatisfactory family assistance, and occurrence of comorbidities.
Family Relationships and Depressive Symptoms Among Chinese Older Immigrants in the United States (Jinyu Liu, XinQi Dong, Duy Nguyen, and Daniel W. L. Lai. 2016)	the Population Study of Chinese Elderly in Chicago, a community-engaged, population-based epidemiological study and using a sample of 3,159 Chinese older immigrants	Multivariate negative binomial regression Analysis. This study examines how supportive and negative relationships with family members (children and spouse) influence depressive symptom severity among this population	This study sheds light on the importance of both supportive and negative family relationships for the mental well-being among older Chinese immigrants. The fndings suggest that aiding relationships with children were more important for women than men. This study builds on socioemotional selectivity theory by providing evidence of the significant association between family relationships and wellbeing among older Chinese immigrants. Further, this study extends the knowledge base about older adults' experience of international migration by depicting a nuanced picture of the interactions between positive and negative intergenerational and

			spousal interactions, culture of origin, and gender roles.
Loneliness and depression among rural empty-nest elderly adults in Liuyang, China: a cross-sectional study (Guojun Wang, Mi Hu, Shui-yuan Xiao, Liang Zhou. 2017)	A total of 839 rural older residents aged 60 or above completed the survey (response rate 97.6%). In line with the definition of empty nest, 25 participants who had no children were excluded from the study, while the remaining 814 elderly adults with at least one child were included for analysis.	A cross-sectional multi-stage random cluster survey was conducted from November 2011 to April 2012 in Liuyang, China. To compare loneliness, depressive symptoms and major depressive episodes between empty-nest and not-empty-nest older adults in rural areas of Liuyang city, Hunan, China.	Significant differences were found between empty-nest and not-empty-nest older adults regarding loneliness (16.19±3.90 vs. 12.87±3.02, Cohen's d=0.97), depressive symptoms (8.50±6.26 vs. 6.92±5.19, Cohen's d=0.28) and the prevalence of major depressive episodes (10.1% vs. 4.6%) (all $p<0.05$). Loneliness and depression are more severe among empty-nest than not-empty-nest rural elderly adults. Loneliness was a mediating variable between empty-nest syndrome and depression.
The relationship between social support networks and depression in the 2007 National Survey of Mental Health and Well-being (Aliza Werner-Seidler, Mohammad H. Afzali, Cath Chapman, Matthew Sunderland, Tim Slade. 2017)	A national survey of 8841 participants aged 16–85 years was conducted. A sample divided to be three age groups: younger adults (16–34 years), middle-aged adults (35–54 years), and older adults (55+ years)..	Logistic regression was used to investigate the relationship between social connectivity factors and 12-month prevalence of Major Depressive Disorder in the whole sample	higher social connection quality was more closely and consistently associated with lower odds of the past year depression, relative to frequency of social interaction. The exception to this was for the older group in which fewer than a single friendship interaction each month was associated with a two-fold increased likelihood of the past year depression (OR 2.19, 95% CI 1.14–4.25). Friendship networks were important throughout life, although in middle adulthood, family support was also critically important—those who did not have any family support had more than a three-fold increased odds of the past year depression (OR 3.47, 95% CI 2.07–5.85) High-quality social connection with friends and family members is associated with reduced likelihood of the past year depression
Prognostic significance of social network, social support and loneliness for course of major depressive disorder in adulthood and old age (R. H. S. van den Brink, N. Schutter, D. J. C. Hanssen, B. M. Elzinga, I. M. Rabeling-Keus,M. L. Stek, H. C. Comijs, B. W. J. H. Penninx and R. C. Oude Voshaar. 2017)	sample of 1474 patients with a major depressive disorder, of whom 1181 (80.1%) could be studied over a 2-year period.	to examine the differential predictive values of social network characteristics, social support and loneliness for the course of depressive disorder, and to test whether these predictive associations are modified by gender or age. Two naturalistic cohort studies with the same	Multiple aspects of the social network, social support and loneliness were related to depression course, independent of potential confounders – including depression severity – but when combined, their predictive values were found to overlap to a large extent. Only the social network characteristic of living in a larger household, the social support characteristic of

		design and overlapping instruments.	few negative experiences with the support from a partner or close friend, and limited feelings of loneliness proved to have unique predictive value for a favorable course of depression. If depressed persons experience difficulties in their social relationships, this may impede their recovery. Special attention for interpersonal problems, social isolation and feelings of loneliness seems warranted in depression treatment and relapse prevention
The factors associated with geriatric depression in rural China: stratified by household structure (Fengfeng Gong, Dongdong Zhao, Yuanyuan Zhao, Shanshan Lu, Zhenzhong, Qian & Yehuan Sun. 2017)	The population according to data from the Sixth National Census conducted in China, this county (Dangtu) has a population of 655,534, of which 55% live in the rural areas. And sample was 3182 eligible subjects and gathered data by face-to-face interview	This study aimed to estimate the prevalence of depressive symptoms and related factors of the empty nest elderly in rural China with method Multivariate logistic regression models. The method used Multivariate logistic regression models	The present study showed that the prevalence of depressive symptoms significantly differed between empty nest old adults and non-empty nesters (24.1% vs. 19.0%). The elderly living alone had highest OR of depressive symptoms. Depressive symptoms of empty nest elderly was associated with sleep quality, economic status, pain, social support and ADL. Depressive symptoms obviously prevail among empty nest elderly than non-empty nesters. It reminded us that complementary social support from family and society is essential.
Assessment of Depression and Social Support in Elderly Subjects Residing in an Old Age Home: A Pilot Study (Gowthamapura Venkatappa Kavana, Eregodu Manjunath Sparshadeep, Mohammed A Shiyas, Damodar KP Sheeba. 2016)	The population were an old age home in Taliparamba in the northern district of Kerala, India and sample were 60 elderly subjects of either gender aged >60 years in a selected old age home in northern Kerala, India	To assess the depression status and satisfaction with social support in elderly subjects residing in old age home and then investigate the possible association between depression and social support in them. The methods used The cross-divisional, questionnaire-based pilot study	GDS scores indicated that the percentage of subjects with depression (25%) was significantly low {t (59)=4.47, p=0.001} as compared to normal subjects (75%). GDS scores showed significant negative Pearson's correlation with MSPSS scores (r=-0.268, p=0.038). MSPSS scores indicated that a significantly higher percentage of subjects (63.3%) showed low satisfaction with family support {t(59)=2.85, p=0.006}. General satisfaction with social support was perceived only as moderate by majority (45%) of subjects. Although the depression status is low, it certainly varies inversely as the satisfaction with social support. However the satisfaction with family support perceived in the old age home is poor. Thus, the need for improvement of family relationships of inmates

			with modification of social support system arises at institutional level.
The social network index and its relation to later life depression among the elderly aged ≥80 years in northern Thailand (Myo nyein Aung, saiyud Moolphate, Thin nyein nyein Aung, Chitima Katonyoo, songyos Khamchai, Pongsak Wannakrairot. 2016)	The population were community residents in Chiang Mai Province, Northern Thailand. The representative sample of 435 community residents, aged ≥80 years, were included in a multistage sample.	This study explored the social networks belonging to the elderly aged $80 years and assessed the relation of social network and geriatric depression. This study was a community-based cross-sectional survey	The median age of the sample was 83 years, with females comprising of 54.94% of the sample. The participants' children, their neighbors, and members of Buddhist temples were reported as the most frequent contacts of the study participants. Among the 435 participants, 25% were at risk of social isolation due to having a "limited" social network group (SNI 0–3), whereas 37% had a "medium" social network (SNI 4–5), and 38% had a "diverse" social network (SNI ≥6). Regular and frequent contact with various social contacts may safeguard common geriatric depression among persons aged ≥80 years
Mental health of the elderly: perceptions related to aging (Lais Soares Vello, Maria Alice Ornellas Pereira, Regina Célia Popim. 2014)	The choice of subjects was conducted through a contact made by the researcher with the professionals working at the Family Health Strategy. Thirteen subjects were interviewed, aged 70 years or over, assisted at the service, with a diagnosis related to mental health and who, at the time of the interview, had conditions to answer the proposed questions.	Study undertaken in 2012 using the qualitative method of Minayo and the thematic analysis according to Bardin's suggestions. Data were collected through semi structured interviews that took place in the homes of the elderly people. The guiding question was: At this point in your life, how do you feel? Tell me	The elderly who were satisfied stated that this was due to the good relationship with their family, spouse, to the fact of having autonomy and respect from the society. Those who were shown to be dissatisfied reported lack of family support, physical limitations imposed by age and the presence of illnesses as the main causes.

ABSTRACT

The problem that frequently occurs in the older adult is anxiety. Anxiety may lead to depression and other emotional illnesses if it continuosly occurs on someone, even it may cause physical illnesses. One technique to improve of anxiety is Auditory Stimulation Care (ASC) and Spiritual Emotional Freedom Technique (SEFT). The researcher combines the two techniques into Auditory Stimulation Spiritual Emotional Freedom-Technique Care (ASSEF-TC). The study was aimed to analyze the influence of ASSEF-TC on the anxiety of the elderly in nursing home at Surabaya. The study was used as a pre-experiment method with one group pre-post design. Population in the study was 36 people and 17 of them were used as a sample by using purposive sampling. ASSEF-TC technique used as an independent variable, the dependent variable was a degree of anxiety. The result of the study shows that the level of the anxiety was decrease after 15 days of ASSEF-TC technique. The result of the Wilcoxon signed rank test shows that there was a significant effect of ASSEF-TC. It can conclude that there was a significant influence of ASSEF-TC techniques on decreasing the level of anxiety.

Keywords: elderly, anxiety, auditory stimulation care, stimulation emotional freedom technique

1. Introduction

The elderly is the age group with the highest anxiety rate in developing countries like Indonesia, comprising up-to 50% of the case in the general population[1]. One of the contributors was psychological changes, including: feeling alienated, experiencing post-power syndrome, contracting with chronic diseases and depleting financial independence [2]. Particularly in the city of Surabaya within which the second-largest city of the country was the most populated area with older adults who experienced anxiety at about 60.7%.

The nursing theory of Roy's adaptation describes humans as an interconnected system with input, control, and output [4] . This theory can explain and can be applied in this study, namely the elderly can adjust to anxiety because of the treatment and procedure effective coping mechanism by building positive perceptions and discard negative perceptions so that the anxiety of the elderly decreases.

The Spiritual Emotional Freedom Technique (SEFT) was proposed as an effective approach that affect the decrease amygdala activity in the limbic system of the brain, which regulates emotional including anxiety [6]. SEFT was suggested to have an advantage in facilitating the flow of energy and tuning in to stimulate individuals' spiritual submission (to God). According to Vink, Aartsen and

Schoevers [7] the beat used in SEFT smoothens the flow of energy and raises positive perceptions and eliminates negative perceptions. On the other hand, the Auditory Stimulation Care (ASC) was proposed as a stimulation to the auditory sense to send signals to the brain positive suggestions. Previous research suggests that stimulating auditory organs would decrease anxiety [8]. The combination of SEFT and ASC is proposed in this study as a nursing intervention to reduce anxiety in older adults.

The general aim of this study was to evaluate the influence of the combination of SEFT and ASC (later called as ASSEF-TC) on the level of anxiety in older adults. The ASSEF-TC was designed as a non-pharmacological intervention that can be delivered by nurses.

2. Method

This study was a pre-experimental research design. Seventeen residents of a nursing home in Surabaya were purposively involved as respondents following informed consent. The intervention was conducted daily for 15 days. This action was carried out by the inventor of SEFT and was followed every day by a trained-certified nurse. The level of anxiety was evaluated pre- and post-15-day intervention. This study's ethical approval was obtained from the Universitas Airlangga HREC under the 281 - KEPK on 11th January 2017.

The evaluation instrument used in this study was the Geriatric Anxiety Inventory (GAI) questionnaire that is specifically developed to assess anxiety level for older adult. The data gathered from the study was collected for analysis using Wilcoxon Signed Rank Test statistical test with a significance level of $p \leq 0.05$.

3. Results

Most of the respondents' ages are over 70 years old, where the highest level of education was diploma, indicating higher education level. The majority of the respondents have lived in nursing homes for between 1-5 years, previously working as self-employed and currently having a sedentary lifestyle (see Table 1).

Table 1. Respondents Demographic

No	Characteristic	Percentage	%
1	Age		
	a. 60-70	7	41%
	b. >70	10	59%
2	Last Education		
	a. ES	-	
	b. JHS	1	6%
	c. SHS	7	41%
	d. College	9	53%
3	Duration of Stay in Private Nursing Home	5	29%
	a. <1 year	12	71%
	b. 1-5 year		
4	Last Job		
	a. Civil servant	5	29%
	b. Private	10	59%
	c. Doesn't work	2	12%
5	Leisure time activities		
	a. Chatting with other	5	29%
	b. Sit/stay in the room	10	59%
	c. making crafts	2	12%

ASSEF-TC techniques that were tested out daily informed the level of anxiety (see Table 2). At the time of the pre-intervention, the respondents were mostly severely anxious, (41%) and least of them had either mild anxiety or at a panic level (12%). When the post test was obtained almost all respondents experienced mild anxiety (82%).

Table 2. Anxiety level before and after treatment

nxiety level of	e test		ost Test	
Non anxious				3%
Mild		?%	1	?%
Moderate		5%		
Severe		1%		
Panic		?%		
Total	7	)0%	7	)0%

The difference in the level of anxiety was evaluated after 15 consecutive days. A significant decrease in the 17-scale anxiety level occurred in 6% of the respondents. The statistical tests showed the p value of 0.00, suggesting that the ASSEF-TC technique was significantly improved the level of anxiety in the respondents (see Table 3).

3. Discussion

3.1. Identify elderly anxiety before being the treatment of Auditory Stimulation Spiritual Emotional Freedom - Technique Care

All respondents had mild, moderate, severe, and panic anxiety. These results were identified following the initial interview with pre-test based on the GAI. Twenty-one respondents were worried, 12 found it difficult to make decisions, 10 were often nervous, 14 found it difficult to relax, 14 were unable to enjoy something because of fear, 11 felt there were some things that bothered him, 9 were often tense , 9 could not resist their worries, 13 were often nervous, sometimes his worries affected his stomach which resulted in abdominal pain and this was experienced by 5 respondents. There were 10 respondents who thought they were someone who was easily agitated, 10 felt there was something bad that would happen to him, 7 often trembled, 14 often worried and it interfered with his life, 7 sometimes missed something because he was too worried and 9 was often annoyed.

Before being given treatment, some respondents had severe anxiety, some even panicked. The

highest score was 20. This is because the elderly who have severe anxiety and panic are mostly elderly who are> 70 years old so that many of their body functions are getting weaker and causing anxiety. In accordance with the opinion of [2] that the elderly are getting older with weakening physiological functions such as alienation and worry.

[9] say several factors related to causes that affect a person's anxiety are factors in the level of education of the elderly, previous employment history, and lack of family support. In this study most of the graduates were academics and colleges, namely 10 people, others were high school graduates, and 1 junior high school graduate. The results showed that respondents who graduated from academies or tertiary institutions tended to be at a mild and moderate level of anxiety, while those for junior and senior high school graduates tended to have severe anxiety and panic. In theory, it is said that the level of education influences the ability to think, the higher the level of education of a person, the easier it is to think rationally and capture new information, including describing problems [10]. Researchers argue that the level of education is one of the factors that influence the level of anxiety because the higher the level of education, the better coping in dealing with anxiety.

The second factor is the previous job of the elderly. In this study because the elderly who previously became civil servants had mild anxiety and the elderly who previously worked as private employees or did not work tended to experience severe anxiety and panic. In this study there were 5 elderly people who previously worked as public servants or became wives of high-ranking officials, 10 self-employed people, and 2 people did not work. This is in accordance with the theory of [11] the status of current and past employment is one of the factors that influence one's anxiety.

Low / low income, precarious work or even no work causes a person to have an inadequate source of coping in the face of life stressors. [12] state that the loss of the role of social function and work causes anxiety for the elderly because friendship communication networks are reduced, resulting in declining identity and elderly self-esteem. So the researchers argue that there is a relationship between work history and anxiety of the elderly. Previous employment history is something that can affect the anxiety of the elderly who live in the institution because it relates to the condition of the disease due to their work and receipt of pensioners' money each month for those who worked as civil servants, and those who are self-employed or not, those who have money and have to wait for the visiting family to give money to the respondent.

Elderly in nursing homes experience exposure to the environment and new friends that require the elderly to adapt both positively and negatively. In this study there was no significant difference in the elderly living in homes <1 year and between 1-5 years because there were elderly people who experienced anxiety because they lived in homes <1 year and there were elderly people who panicked and had severe anxiety even though they had lived in the orphanage for 1-5 years. This is in accordance with the statement by [13], that the failure of adaptive responses is characterized by failure to interact, care less, and assets and savings that do not meet needs cause concern and decentration in the elderly. Excessive anxiety is a psychological symptom of anxiety. Anxiety is out of control and lasts a long time and disrupts daily activities. Elderly people at the home can experience seclusion from family members for various reasons and this exile is very painful for the elderly. Along with the time the elderly want to develop family ties again [14]. The loss of various things is the originator of the anxiety of the elderly who can then have an impact on physical and mental illness in old age [15].

At the time of observation based on the aspects of the most GAI questionnaire, 15 respondents

said they often felt worried, some experienced tension, were unable to relax, and often felt nervous. This was stated by [16] that a person who experiences anxiety and tension for those who live in a home will especially feel fear and anxiety for most of the time and tend to overreact with even mild anxiety, are unable to relax, experience sleep disturbances, fatigue, head or stomach pain, and other physical complaints.

When interviewing the cause of anxiety with ASC, some respondents revealed the cause of their anxiety was due to physical illnesses or complaints due to their illness, sometimes feeling dizzy because of their high rates, feeling their own pain due to osteoporosis, and feeling sore from diabetes mellitus. [7]state that anxiety is also influenced by health status, medical disorders, or drug use. The progress of the disease process threatens independence and quality of life by overloading the ability to carry out personal care and daily tasks.

Another respondent said that being anxious about separating from his family [spouse, child and grandchildren]], became increasingly anxious when a few weeks awaited the family did not visit the orphanage. This is also explained by [9] that the factors that cause anxiety to the elderly are family, which is the main support system in maintaining their lost health. The role of families in the care of the elderly includes maintaining and caring for, maintaining and improving mental status, anticipating socio-economic changes, and providing motivation and facilitating spiritual needs.

4.2. Identify elderly anxiety after being given an Auditory Stimulation Spiritual Emotional Freedom - Technique Care

After being given an auditory Stimulation Spiritual Emotional Freedom - Technique Care, technique for 10-15 minutes every day for 15 days, there was a change in anxiety level in the elderly with anxiety in Surabaya Hargo Dedali Nursing Home for all respondents. This is evidenced by all respondents who initially experienced mild, moderate, severe, even panic changes or decreased scores in the GAI questionnaire to mild anxiety and no anxiety at all. Obtained 3 (18%) respondents who did not have anxiety at all and 14 (82%) respondents who had mild anxiety. The mild anxiety that this research makes respondents more calm in facing the rules in the institution, are more tolerant with fellow elderly people in the institution, and accept all conditions that cause anxiety. According to [17] mild anxiety is related to everyday life that causes a person to be alert and improve perception. The symptoms are fatigue, high awareness, being able to learn, and behavior according to the situation.

In the post test there were no respondents who were worried at all times, 2 respondents found it difficult to make decisions, 2 could not enjoy something because, 1 considered small things everyday disturbing, 3 sometimes felt tense, 1 felt easily worried, all respondents can withstand worries, no one is often nervous, 1 respondent feels his mind makes him worry, 2 has stomach ache because when he is worried it increases his stomach tension, 2 is easily agitated, no one feels there will be anything bad, 5 respondents feel that his concern disturbs his life , no respondent often feels worried, 1 feels sometimes something is blocking his stomach, 3 respondents sometimes miss something, and 2 respondents still feel upset.

In the GAI questionnaire the most felt points before and after were statements about concerns which occurred to the respondents who were disturbed in life. Based on the posttest results table data, most of the decline was very significant so that it can be interpreted that ASSF-TC is very influential on decreasing anxiety levels in the elderly.

Respondent number 15 had a very significant difference, namely a decrease in the score of 17 points from 20 during the pre-intervention to 3 points at the time of intervention. The respondent claimed he felt comfortable and calmed down when given this ASSEF-TC technique. Anxious, anxious, and worrying complaints gradually disappear because all the problems have been divulged and passed on to Allah SWT. Respondents claimed that they were increasingly comfortable living in a home where they had been 3 years because their feelings of dislike of the system in the home and their feelings of dislike for their fellow elderly people began to disappear, because they emphasized the interests of others above their own interests, were more tolerant and did not feel irritated or revenge for anyone. Interventions given to respondents were able to have a positive impact on adaptation in the home and in eliminating anxiety. The theory that supports this change was revealed by [18], namely the elderly who have lived in orphanages for more than 1 or 2 years have the ability to adjust better than the elderly who have just entered as new residents. According to [14] anxiety in elderly people is related to the ability of the elderly to adapt to the new environment. The researcher argues that older people who live longer in homes have better coping and adaptation abilities than new residents and affect their anxiety.

The lowest decrease in score was experienced by respondents number 2 and 6, namely 5 points because previously respondents experienced mild anxiety, after this ASSEF-TC technique was conducted the respondents claimed to have no anxiety and good social attitudes and behavior as evidenced by a score of 0 in the post test. The researcher argues that the decline in anxiety levels in the elderly at Hargo Dedali Nursing Home is influenced by ASSEF-TC techniques as a way to reduce anxiety that has never existed and needs to be studied. Characteristics of respondents such as age, education history, past employment history, length of stay in the orphanage, and the habit of filling in free time did not significantly affect changes in decreased anxiety levels.

The results of the components in the GAI questionnaire that did not undergo much change both before and after the intervention were item number 16, namely that the respondents felt that the concerns in their minds disturbed their lives. Most complaints are found in point number 16 because every respondent who feels anxious must feel that these feelings interfere with daily activities in his life. This study shows that older people can decrease their anxiety level with ASSEF-TC intervention.

The old leisure time and activities which still cause anxiety comes from their own mind. Elderly people at the institution are the highest anxiety group for various reasons. Some ways that are done is to do auditory stimulation care or stimulation of verbal communication to stimulate the auditory system. [19] revealed that to overcome feelings of anxiety hearing distraction techniques can be used because it reduces emotional tension. It can also be done by the Spiritual Emotional Freedom Technique (SEFT) technique that has been proven by previous studies that SEFT can reduce anxiety. SEFT is used to streamline healing on anxiety, panic, anger, stress & disturbances of mind, anxiety, depression and sadness, self-image, fear and phobia, loss, guilt, insomnia, bad memory, pain, physical healing, performance improvement (exercise, public speaking), trauma, and sexual abuse [20].

Then the researchers combined these two techniques into one, namely Auditory Stimulation Spiritual Emotional Freedom Technique Care (ASSEF-TC) to reduce the anxiety of the elderly in order to be more optimal. ASSEF-TC provides a distracting effect that increases endorphins in the control system and makes relaxation, the vibrations of verbal communication from the source reach the ears, then spread throughout the body. Cells affected by sound vibrations respond by changing

their own vibrations. Brain cells vibrate and send magnetic and electromagnetic waves that represent brain activity. Brain cells are affected by vibrations of whatever type and source. In this central voice therapy is applied to reduce anxiety and depression also reduce pain due to increased protein in the body and reduce infection [21] . SEFT is done by tapping two fingertips to balance the energy of meridians in the body when symptoms of disturbing physical and emotional deterioration occur. Memory remains the same, but symptoms of the disease disappear and generally last a long time [20]

All respondents experienced a decrease in GAI scores and felt happier. After being given the ASSEF-TC technique the respondent looks calm and does not easily feel irritated, and can neutralize his own anxiety. Another positive impact is the reduction of the elderly who often fight because of trivial problems and small things, the elderly can relax, and also resist anxiety and their own worries. ASSEF-TC was first performed by Dr. H. Syarif Thayib, M.Sc, he is a Lecturer at the Da'wah and Communication Faculty of UIN Sunan Ampel Surabaya, Commissioner of PT. Madina Utama, Co. SEFTER SEFT Founder (Spiritual Emotional Freedom Technique) and speakers at seminars, workshops, and SEFT training, FunTastic Family in Hong Kong, Macao, China, Singapore, Malaysia, and Saudi Arabia, Doctor of Human Resource Management at Airlangga University with the title "very satisfying" . Then the researchers conducted the ASSEF-TC accompanied by him and applied to all respondents. At the next meeting the researchers conducted ASSEF-TC independently to the respondents.

4.3. Effect of Auditory Stimulation Spiritual Emotional Freedom - Technique Care on reducing anxiety in the elderly

Based on the results of the study, it was found that there was a decrease in the anxiety level of the elderly in Surabaya Dedali Hargo Nursing Home. This proves that there is an ASSEF-TC influence on reducing anxiety in the elderly. The results of the statistical test with the Wilcoxon Sign Rank Test can be seen in Table 5.3 and were obtained by decreasing the anxiety level scores of the elderly before and after the ASSEF-TC intervention with a value of $p = 0.00$.

The results of this study are in accordance with the results of previous studies by [22] regarding the influence of verbal communication on anxiety in the face of pre-retirement retirement. . However, the combination of ASC and SEFT is a new technique that needs to be studied further and in this study it has been proven that there is an effect of a combination of ASC and SEFT or can be abbreviated as ASSEF-TC for elderly anxiety in private nursing home.

This research refers to Roy's conceptual framework of adaptation theory. Starting from the input process in this study is a vocal stimulus namely ASSEF-TC. Stimulus vocal is a stimulus that directly adapts to someone and has a strong influence on individuals [5]. Then the process of adaptation continues to the regulator and cognator subsystem. Regulators are coping processes that include the body's subsystems, namely nerves, chemical processes, and endocrine. Cognator is the process of coping with someone who includes four systems, namely knowledge, processing perceptions of information, learning, consideration, and emotions [23]. Someone can have a coping mechanism to solve problems, adjust to changes, and respond to threatening situations [22]. There are two kinds of mechanisms, namely adaptive that supports growth in achieving goals, and maladaptive responses, namely mechanisms that hinder function in achieving goals [4].

Stimulus with ASSEF-TC affects the elderly with anxiety in Surabaya Dedali Hargo Nursing Home. This has an effect on the cognator which consists of processing perceptions and information

from negative to positive, then learning from the techniques provided by the researcher to the respondent, as well as considerations and emotions from respondents' anxieties. The regulator that plays a role here is inadequate GABA and eventually endorphins can be released when given ASSEF-TC interventions. The effect of the study is that the physiological aspects of the elderly are improving, the self-concept (psychic) shows that initially many experienced a decrease in self-esteem because some factors become more confident, in social terms the respondents' social functions increase because respondents become more tolerant and are not easily upset with others in the nursing homes and administrators in the orphanage. Interdependent respondents are increasing because their interpersonal relationships are getting better at the individual level in the elderly and at the group level.

All respondents in this study had an adaptive response because they were able to achieve the expected goal of decreasing anxiety levels. Adaptive response is a response where humans can achieve the goals or balance of the body system, a maladaptive response is that humans cannot control the balance of the body or cannot achieve the expected goals [4]. A maladaptive response in this study is if there are respondents whose anxiety levels remain or increase after being given ASSEF-TC techniques and this is not found in this study.

There is a significant change from the influence of ASSEF-TC on the anxiety of the elderly in Surabaya Hargo Dedali Nursing Home, based on Roy's adaptation theory which states that everyone always uses coping both positive and negative [4] ASSEF-TC changes negative suggestions to be positive with ASC auditory stimulation and positive tapping of SEFT so that anxiety decreases due to loss of negative perception.

This ASSEF-TC technique causes respondents to process perceptions and information from researchers from positive negatives and constructs, discard negative emotions and foster spiritual emotions that make sure of themselves that anxiety and resentment are lost because they are dispensed and justified. This is in accordance with Roy's theory that a person's coping process includes knowledge and emotions, processing perceptions and information, and emotions

Physiologically, the elderly will experience anxiety. Anxiety disorders experienced include physical health, loneliness, feeling useless, alienation from the environment, economic, psychological, and social problems [24]. There are 2 types of therapy to overcome anxiety, namely pharmacology or drugs and non-pharmacological. For non-pharmacology, distraction, relaxation, imagination, mental therapy, environmental modification, therapeutic communication, and the spiritual emotional freedom technique (SEFT) can be performed.

ASSEF-TC is a non-pharmacological and non-invasive therapy that can be used to reduce anxiety levels in the elderly and is a combination of ASC and SEFT. Human voice is a powerful healing instrument because human voice energizes and perfectly balances the brain in an instant. This is called Auditory Stimulating Care [19] Brain cells vibrate because stimuli from humans send magnetic and electromagnetic waves that represent brain activity [8]. SEFT is done by tapping two fingertips at several locations in the body. The beat is to balance the energy of the meridians in the body when symptoms of physical and emotional decline occur. Actual memory is the same, but symptoms of the disease disappear and last long [25] The benefits of SEFT have been felt since the first technique was carried out and activated electrical energy in the body [21]

The ASSEF-TC technique was carried out with several approaches, the method was carried out uttering positive sentences from the 10 pillars of caring from J. Watson's caring theory because the

concept of caring and researchers adopted and made positive sentences in accordance with J. Watson's concept to reduce optimal anxiety. Then tapping at several points of the body on the meridian energy. Respondents who received this intervention felt more comfortable, relaxed, and calm after being given therapy so that they felt the impact gradually. His feelings are calmer and there are rarely anxious feelings.

Scientifically ASSEF-TC works by stimulating the auditory senses of the respondent, stimulating the brain and providing calm that can release endorphins so that the respondent feels happy and relaxed. In addition, light beats at several body meridian points aim to balance the energy of meridians in the body when symptoms of physical and emotional deterioration occur. There is a relationship between the anxiety of the elderly with quality of life, namely the higher the anxiety of the elderly, the lower the quality of life [26]. With the decline in the level of anxiety of the elderly indicates that the quality of life of the elderly is getting higher and the elderly can undergo their daily activities and activities comfortably and calmly without any anxiety.

5. Conclusion and recommendations

Before the ASSEF-TC was given, most of the anxiety levels of the elderly were on a moderate, severe, and panic scale due to various factors such as physical illness, longing for family, and not adapting to the institution. After ASSEF-TC all respondents decreased their anxiety to be mild and there was no anxiety at all because respondents accepted ASSEF-TC techniques for 15 times to adapt and improve individual coping.

Auditory Stimulation Spiritual Emotional Freedom - Technique Care (ASSEF-TC) can reduce anxiety levels in the elderly because it can cause the elderly to be comfortable, relaxed, and sincere for the conditions that cause anxiety.

For nurses, nursing home staff or other health practitioners, can provide this ASSEF-TC technique to the elderly regularly to reduce anxiety. For the next researcher, it is hoped that they can carry out research with a larger number of samples and more treatment variables that can be combined, but also can conduct research by comparing the effectiveness between giving ASSEF-TC and other techniques that can be used to reduce anxiety in the elderly.

ABSTRACT

HIV / AIDS is a disease that cannot be cured yet. Maintaining the optimum quality of life is a goal treatment people living with HIV/AIDS (PLWHA). Adherence to taking anti-retroviral therapy (ART) is one of the keys to success in achieving optimal Quality of Life for PLWHA. Nationally, the prevalence Adherence to taking anti-retroviral therapy was low, as well as in Southwest Sumba. The factors that influence the low prevalence of taking ART adherence in Southwest Sumba, Indonesia are not known yet. The aim of this study was to analyse the factors that influence adherence to taking ART in people living with HIV/AIDS in Southwest Sumba. An analytical cross sectional design was used in this study. 45 out of 68 PLWHA were willing to become respondents. Snow ball sampling was performed to recruit the respondents. Data were obtained using a questionnaire that had achieved validity and reliability tests. Ordinal regression tests have been used to analyse data. The results of the analysis found that knowledge (0.010), attitudes (0.018), motivation (0.023) and characteristics of comorbidities (0.043) were factors that influenced adherence to taking ART. Whereas, health workers and health services did not affect adherence of taking ART. The AIDS prevention commission in the health department of Southwest Sumba province is expected to be able to prepare a strategy to increase the knowledge, attitudes, and motivation of PLWHA so that they can improve the adherence to taking ART. In addition, strategies for taking ART is needed to be created for PLWHA who have co-morbiditi.

Keywords: adherence, anti- retroviral therapy, people living with HIV/AIDS
.

1. Introduction

HIV/AIDS is one of disease which can't cure yet. One of the treatment goal for PLWHA is maintaining their quality of life (QoL) PLWHA. Taking ARVs as accordance with the physician order is needed to achieve better QoL among PLWHA especially physical domain. However, some countries facing problem about adherence to taking medication for PLWHA which taking ARVs (WHO, Progress Report, 2016). PLWH who have good adherence in taking ARV (above 95%) will not become AIDS. While, PLWHA who have good adherence in taking ARV will experience more stable condition and a longer life span. In the other hand, PLWHA who have poor adherence of ARV (below 95%), their viral load will increase and it will have negative impact to their physical health. While people with AIDS will accelerate the progress of the disease and aggravate the situation, experience faster death (Ministry of Health, 2007).

In 2016, according to estimated data from The Joint United Nations Program on AIDS (UNAIDS) in the world of people with HIV & AIDS (PLWHA) totaling 38.8 million people, deaths caused by this disease from 2010 to 2015 have reached 35.1 million people, and in 2015 the number of deaths reached 1.1 million (UNAIDS, 2016). Among those PLWHA only 17,025,900 people (44.8%) taking ARVs. In Indonesia with the number of HIV & AIDS cases 295,689 people, with details of HIV cases totaling 208,909 and AIDS totaling 86. 780 people. sufferers who drank ARV amounted to 127,128 people (42.99%), while Nusa Tengggara Timur was ranked 19th most people with HIV with 4,206 cases (487 new cases in 2016). The number of people receiving ARV therapy is 1.851 people (Directorate General of P2P Ministry of Health RI, 2017). Sumba Barat Daya (SBD) number of people with HIV & AIDS since 2009 until December 2017 the number of cases is 277 people (Sahabat VCT Clinic SBD, 2017). PLWHA who had undergone treatment since January 2016 until December 2017 were 68 people (24, 5%) and those who were active numbered 43 - 48 people / year (63.2 - 70, 6%) and who often negligent or discontinued medication amounting to 20-25 people / year with an absent or discontinued frequency of drugs up to 40 times / year (29.4 - 36.8%). The data shows that there are still very high rates of non-compliance with taking ARV drugs for people with HIV & AIDS. (Data from January 2016 to December 2017). From the results of interviews with health workers at Health Officer of Sumba Barat Daya Regency on September 29, 2017 by telephone, said that of the 68 sufferers who were undergoing treatment, people who had missed or dropped out had taken approaches and visits as well as interviews about what were the obstacles (January to December 2017).

Djauzi (2002) found that compliance with taking medication for HIV & AIDS patients includes accuracy in time, number, dosage, as well as the individual's way of taking personal medicine. Non-adherence to therapy will reduce the effectiveness of antiretroviral drugs and even increase viral resistance in the body (Dessy in 2016). According to the Ministry of Health (2011), states that there are 5 factors that can affect adherence to ART / ARV, namely the first characteristics of patients; includes socio-demographic factors (age, gender, race / ethnicity, income, education, blind / literacy, health insurance, and the origin of groups in the community, eg transvestites or commercial sex workers) and psychosocial factors (mental health, drug use, environment and social support, knowledge and behaviour towards HIV) and its treatment. The second factor is the characteristic of comorbidities; includes the clinical stage and length of time since being diagnosed with HIV, the types of accompanying opportunistic infections and symptoms associated with HIV. The presence of opportunistic infections or other diseases causes an increase in the number of drugs that must be taken. The third factor is health care facilities; convoluted service systems, expensive, unclear and bureaucratic health financing systems are obstacles that play a very significant role in compliance, because this causes patients to be unable to access health services easily. These include comfortable rooms, guaranteed confidentiality and good scheduling, friendly and helpful officers. However, the factors that influence adherence ARVs among PLWHA di Sumba barat isn’t investigation yet (HIV/ AIDS)

2. Methods

The design used in this study is a cross sectional analytic survey. The population of all PLHIV who received ARV treatment was 68 people. The sample of some people living with HIV with ARV treatment was 45 people. The sampling is convenience sampling. Data was obtained using questionnaires and medical records in the VCT clinic of in the Sumba Barat Daya. The questionnaires used consisted of 52 statements and 6 topics, namely the database consisting of 6 items. Special data consists of 5 items, namely 1.) patient characteristics, which include knowledge consisting of 10 statements with scoring for true statements of value 2 and incorrect values of 1; attitude consists of 6 statements with scoring system positive statement strongly agree (SS) value 4, agree (S) value 3,

disagree (TS) with value 2, and strongly disagree (STS) with a value of 1; motivation consists of 10 statements with scoring strongly agree (SS) given a value of 4, Setuju (S) given a value of 3, strongly disagree (STS) given value 1 (one) 2.) Characteristics of comorbidities, with 22 types of comorbidities, with choice exists and does not exist. 3.) Combination of ARV drug therapy, consisting of 5 true and false statements. 4.) Officers who serve PLWHA, consist of 4 statements yes and no. 5.) Health services, consisting of 4 questions with choices a, b, c, or d. 6.) Compliance, consisting of 6 statements yes and no. The questionnaire model for points 1 to 5 was adopted from the research questionnaire Dessy (2016) and Sindi (2017), while compliance was adopted from the Version questionnaire model of the 8-item Morisky Medication Adherence Scale (MMAS) developed by Sakthong, et al (2014) ".

3. Results

Based on table 1.1 the results of the majority of respondents with early adulthood (26-35 years) as many as 33 respondents (73.3%), a small percentage of late teen respondents (36-45 years) as many as 3 respondents (6.7%). the results of the majority of respondents with male sex as many as 27 respondents (60.0%), and some respondents with female gender as many as 18 respondents (40.0%). it is found that almost half of the respondents with education in almost half the respondents with high school education were 17 respondents (37.8%), a small proportion of respondents with PT education were 3 respondents (6.7%). the results of the majority of respondents with the work of farmers (respondents had worked outside the area> 1 year) as many as 32 respondents (71.1%), a small proportion of respondents did not work as much as 1 respondent (2.2%). Based on table 2.1 the results of a small percentage of respondents with less knowledge as much as 11 respondents (24.4%), some respondents with enough knowledge as much as 12 respondents (26.7%), and almost half of respondents with good knowledge as many as 22 respondents (48.9 %). Based on 8 table, the results of almost half the respondents with a pretty good attitude as many as 19 respondents (42.2%), most of the respondents with a good attitude as many as 26 respondents (57.8%), and no respondent has a good attitude (0%). Based on table 9 the results of almost the majority of respondents with strong motivation were 32 respondents (71.1%), a small proportion of respondents with moderate motivation as much as 4 respondents (8.9%), and some respondents who had weak motivation as many as 9 respondents (20 , 0%).

Comorbidities with adherence to antiretroviral (ARV)		
Absent	7	15.6
Present	38	84.4

4. Discussion

Based on the results of the ordinal regression statistical test the results of the significance value of p-value 0.010 are smaller than the alpha value (0.05) so that H0 is rejected and H1 is accepted which means there is a respondent's cognitive influence on knowledge in adhering to antiretroviral drugs for people with HIV & AIDS (PLWHA) (Table 1). Good knowledge will also produce good compliance. The better knowledge of respondents, the better adherence to ARV treatment. According to researchers' observations before the commencement of ARV therapy, PLWHA were given counselling before being tested for HIV and after HIV testing. Counselling is also given to couples and families if ODHA are willing to notify their status. Counselling includes information about HIV, nutrition for PLWHA and information about ARV therapy. The purpose of these activities is to increase knowledge about ARV therapy. According to Notoatmodjo (2010) knowledge is needed by someone, so that it will facilitate the occurrence of healthy behaviour in the person. Knowledge is also intended to provide an understanding of wrong understanding and is not conducive to healthy behaviour that can make a bad effect on one's health. This study is in accordance with the research conducted by Martoni, et al. (2013) which examined the most powerful factors affecting patients with HIV & AIDS on ARV therapy. The results obtained indicate that knowledge is the most powerful factor in influencing adherence to ARV therapy

Based on the results of the ordinal regression statistical test, the significance value of p-value 0.018 is smaller than the alpha value (0.05) so that H0 is rejected and H1 is accepted, which means there is a positive influence on the attitude of adherents to taking antiretroviral drugs for people with HIV & AIDS (PLWHA) (Table 1). This study was also conducted by Rudi (2013) conducted at Padang Panjang Hospital, stating that there was a significant or significant relationship between the compliance of PLWHA and the success of taking ARV drugs with p-value (0.001). Attitude is an evaluative statement both pleasant and unpleasant towards objects, individuals, or events. This reflects how someone feels about something to do an action (Robbins, 2008). Mubarak & Chayatin (2009), attitudes are predisposing to actions or behaviours and have not been an action or activity. The results of this study are also in line with the research conducted by Surya (2014) which showed that there was a significant relationship between the attitudes of PLHIV patients and their adherence to taking antiretroviral drugs at the Serunai Polyclinic in the Regional General Hospital Dr. Achmad Mochtar Bukit tinggi in 2014 was p value 0.013 ($p < 0.05$).

Based on the results of the ordinal regression statistical test, the results of the significance value of p-value 0.023 are smaller than the alpha value (0.05) so that H0 rejected and H1 accepted, which means that there is a characteristic influence of motivational respondents by adhering to taking antiretroviral drugs (ARVs) of people with HIV & AIDS (PLWHA) (Table 1). This research was also conducted by Anggipita (2010) conducted at the NGO Graha Mitra Semarang, stating that there was a significant or significant relationship between the motivation of PLWHA and adherence to taking ARV drugs with p-value (0.007). Motivation is a human psychological characteristic that contributes to the level of one's commitment. This research is in accordance with the theory discussed by Nursalam & Ninuk (2007) in the journal Public Health, motivation is the drive to do positive things for himself and others. Motivation is the driver of behaviour toward a goal based on the existence of a need that can arise from within the individual, or can be obtained from outside and other people / families.

Based on the results of the ordinal regression statistical test the results of the significance value p-value 0.043 are smaller than the alpha value (0.05) so that H0 is rejected and H1 is accepted which means there is an influence of comorbidities with adherence to taking antiretroviral drugs (PLWHA) (Table 1). Some researchers have looked at the effect of the disease itself on adherence to treatment regimens. However, there is enough evidence to show that the condition and duration of the disease, and the severity of the symptoms, can have an influence. For example, in a study of accessibility to

treatment, it was found that low CD4 lymphocyte counts and proliferation of clinical symptoms were strongly associated with treatment utilization. They reported that CD 4 cell levels were negatively correlated with attendance when meeting health workers. Seropositive people who have no symptoms are more likely to lose appointments than people who feel sick.

Based on the theory and results of the study, the researchers argued that the characteristic factors of comorbidities with adherence to antiretroviral (ARV) medication that occurred in the Southwest Sumba VCT clinic were caused by knowledge factors indicated by the frequency of 25 elementary and junior high school respondents (55.55%) so that the introduction of PLWHA to the characteristics of the comorbidities itself is lacking, which results in the onset of symptoms of PLWHA not yet coming to the clinic, after the symptoms become more severe they make treatment to the clinic which results in more additional treatment, which can lead to burnout ODHA in undergoing ARV treatment can lead to disobedience of PLWHA in undergoing ARV therapy itself.

Based on the results of the ordinal regression statistical test the results of the p-value of 0.286 are greater than the alpha value (0.05) so that H0 is accepted and H1 is rejected, which means there is no influence of health service factors by adhering to antiretroviral drugs AIDS (PLWHA) in Southwest Sumba (Table 1).

Someone who is infected with HIV, will experience an infection for life and is at risk of transmitting the virus to other people. Therefore, a strategy is needed to prevent transmission. Since the discovery of antiretroviral drugs and combination ART, there has been a change in the reduction of HIV & AIDS morbidity and mortality from 60% to 90% and improvement in quality of life and life expectancy for PLWHA (WHO, 2003, MOH, 2006). Although ARV therapy is not able to cure disease, ARV therapy has been able to reduce new HIV infection cases, such as experience in developing countries in South Africa, Nepal, Cambodia and others (UNAIDS, 2012). Therefore, the government has sought to improve the care, support and treatment of PLWHA, through the implementation of comprehensive and sustainable HIV & AIDS services (LKB). With LKB, it is expected that ODHA services in treatment will be more optimal, along with improving quality of life and decreasing transmission to the wider community.

HIV & AIDS services in LKB are services that involve health workers and across sectors, as well as stakeholders widely, which are based on basic principles including: human rights, equality of access to services, implementation of quality HIV & AIDS services, prioritizing the needs of PLWHA and his family, paying attention to the needs of key population groups and other vulnerable populations, involvement of families and PLWHA, application of chronic care, ARV therapy services with a public health approach, reducing barriers to accessing services, creating a supportive environment to reduce stigma and discrimination, and prioritizing gender (Indonesia Ministry of Health, 2012).

Based on the results of the ordinal regression statistical test, the significance value of p-value 0.102 is greater than the alpha value (0.05) so that H0 is accepted and H1 is rejected which means there is no effect of alloying therapy with adherence to taking antiretroviral drugs (ARVs) (PLWHA) in Sumba Barat Daya (Table 1). The combination of therapies included types of drugs used in alloys, alloy forms (FDC or not FDC), number of pills to drink, complex of alloys (frequency of drinking and influence with food), drug characteristics and side effects, and easy access to ARVs (Ministry of Health, 2014).

Based on the results of interviews of researchers with officers who deal with PLWHA, it was known that before the treatment was carried out the officers had counselled the PLWHA also explained about the treatment process to be carried out and about the type and method of taking the drug. And based on the results of the study, it is known that the combination of treatment for all people living with HIV / AIDS is good and right, but there are still people who are not adherent to undergoing ARV therapy, so the researchers concluded that the combination therapy had no effect on the compliance of PLWHA in all treatment procedures by officers properly and correctly. But

returning to ODHA itself is whether they want to undergo treatment properly or not in order to get maximum results from treatment.

Based on the results of the ordinal regression statistical test, the significance value of p-value 0.297 is greater than the alpha value (0.05) so that H0 is accepted and H1 is rejected, which means there is no influence of health care workers by adhering to antiretroviral drugs for people with HIV & AIDS (PLWHA) (Table 1).

Garcia P. Ramirez (2003) one of the factors that influence adherence to taking ARV drugs for HIV & AIDS (PLWHA) is the relationship between health workers and patients. Several studies have examined the effect of relationships between health workers and seropositive individuals. In those who have, both the quality of this interaction and the client's attitude towards health workers have been cited as factors that can affect the level of compliance. This factor includes, the first is the relationship of patients and health workers. In qualitative studies, patients have recognized the influence of professional relationships on their level of acceptance and compliance. This influence was also shown in one of the early studies regarding factors that determined higher compliance with the protocol for experimental treatment. The authors note that individuals with high levels of adherence had fewer difficulties in relationships with their health care workers and that the level of positive support they considered was higher than among patients who were less diligent in their care.

The second factor is communication. Similar results were reported in a study of adherence to secondary prevention recommendations among homosexual and bisexual men. They concluded that efforts to promote this awareness should not only concentrate on the problem of risk but also on the way the message is delivered professionally and assimilated by the patient. The factors of expertise of health workers with character and individual characteristics, such as the level of experience with antiretroviral treatment or their attitude towards clients, are also influenced. This incidence is higher among doctors who are less experienced than doctors who are experienced with this situation. This is an example of the overall strength of doctors, not only in encouraging adherence to regimens but also limiting information about care and access to these drugs. The final factor in the relationship between health workers and patients is program monitoring, although no study has shown a relationship between monitoring treatment regimens and adherence to them, some authors have suggested that flexible schedules and comfortable environments will contribute to higher adherence to treatment regimens.

The results of the study show that there is no significant effect between the relationship between health workers and patients, where in West Sumba Regency health workers have made various efforts so that PLWHA can undergo ARV treatment properly such as conducting counselling, often making contact and visiting ODHA to see and monitor the development and treatment of PLWHA. But back again to the intention of people with HIV & AIDS (PLWHA) in undergoing treatment, if the sufferer has less intention because he feels that the treatment is just in vain, because ODHA feel that the disease will not be able to cease again, ODHA will not undergo treatment with good and right.

5. Conclusion

The AIDS prevention commission in the health department of Southwest Sumba province is expected to be able to prepare a strategy to increase the knowledge, attitudes, and motivation of PLWHA so that they can improve the adherence to taking ART. In addition, strategies for taking ART is needed to be created for PLWHA who have co-morbidities.

THE EFFECT OF PROGRESSIVE MUSCLE RELAXATION INTERVENTIONS ON DEPRESSION, STRESS, ANXIETY, AND QUALITY OF LIFE: A SYSTEMATIC REVIEW

Sholihin[1], T A Firmanti[1], W P Sudarmaji[1], N T Septiana[1]
[1] Faculty of Nursing, UniversitasAirlangga, Surabaya, East Java, Indonesia
E-mail: sholihin-2018@fkp.unair.ac.id

ABSTRACT

Progressive muscle relaxation intervention is the technique including continuous and systematic stretching and relaxing of the muscles until the whole body becomes relaxed. It has effects in improving depression, stress, anxiety and quality of life via mental and physical relaxation. Literature search focused on thirty four published studies, undertaken in the past six years until now. Searches were made on seven databases, to identify relevant publications on progressive muscle relaxation. The impact of progressive muscle relaxation interventions remained in effect for between seven days and six month after the interventions. This systematic review identified progressive muscle relaxation interventions program had different called, Applied Progressive Muscle Relaxation Training (APMRT) Program, Progressive Muscle Relaxation Therapy (PMRT), Progressive Muscle Relaxation Training (PMRT), Progressive Muscle Relaxation Technique (PMRT), Progressive Muscle Relaxation (PMR), and there are studies compare Guided Imagery (GI), music therapy, and deep diaphragmatic breathing. Anxiety, depression, stress are some factors that affect patients' quality of life which can be improved by Progressive Muscle Relaxation Therapy (PMR)

Keywords: depression, stress, anxiety, quality of life, progressive muscle relaxation

1. Introduction

Cancer is one of the health problems which is growing rapidly in the world [1]. And it is the number two cause of death in the world. Cancer and its treatment are the main factors that cause anxiety and depression [2–4]. Patients with cancer experience emotional distress which are characterized by psychological symptoms such as anxiety or depression, psychological symptoms that arise and complex cancer processes have a negative impact on their quality of life [5]. A negative impact on the function and patient quality are not only caused by the cancer process but also the complications, side effects of treatment, and the duration of cancer that is suffered [6]. Some studies showed that cancer and its treatment can cause physical, emotional and social problems that lead to decreased function, impaired sexual function, and body image changes, followed by structural changes and reduced self-confidence. Family problems, emotional, economic problems, the anxiety are the impact of psychological problems due to the decrease of psychological and physical functions which can affect individuals' quality of life and their families [7]. Anxiety affects all biological, psychological, and social aspects and how human needs are met [8–11]. Depression and anxiety can cause behavioral changes and affect treatment by attacking awareness, weakness, motivation, and reducing coping abilities and quality of life [12]

Depression and anxiety are cancer symptoms that can last for several years [13], which can cause negative effects on patients' quality of life, appropriate medical care, recurrence, survival and recovery from surgery during hospital care [14–16]. The negative impact of cancer diagnosis and the sequelae of cancer treatment, 20% -30% of breast cancer patients suffered depression and anxiety,

which is significantly higher than the prevalence of appropriate depression and anxiety (6% -8%) in healthy women (Bj orneklett , HG, Lindemalm, C., Rosenblad, A., Ojutkangas, ML, Letocha & Strang, P., 2012). In China, the prevalence of anxiety, depression, or anxiety and depression in breast cancer patients were 21.1%, 34.4% and 15.6% [14]. Based on WHO predictions, the incidence of cancer in Iran will reach 85,000 cases from all populations with a mortality rate of 62,000 in 2020 [17]. Based on an increase of the elderly population in the world (with an increase from 605 million in 2000 to 2 billion in 2050), the number of cancer patients is estimated to increase [18]. In the US, there were almost 60% elderly of 11 million cancer patients. In Iran, cancer is the third cause of death, and WHO reports 12% of deaths annually [19].

Hormones such as adrenaline, glucagon, epinephrine, norepinephrine, and cortisol are correlated with stress. Particularly, cortisol is an important indicator of changing physiological conditions in stress response. Sensitivity to cortisol is greater than other hormones and seen in physical, mental and cognitive stress. There are several objective indicators of physiological responses, including blood pressure, heart rate, body temperature, and breathing [20]. According to P. J. Oh and Choi (2012), many cancer patients met stress, anxiety, depression, insomnia, and post-traumatic stress disorder. This stress can affect the nervous systems, endocrine, immune and interfere with recovery through delayed wound healing, metabolic reactions, and changes in body composition after surgery or treatment [21,22].

Several studies have confirmed that proper care and intervention in cancer patients, such as complementary therapy that can help relieve physical and psychological discomfort [23]. Relaxation has a significant psychological impact, by relaxation we can improve specific aspects of our personality, strengthen positive quality of life and change unwanted habits and attitudes [24]. Relaxation techniques have been used as effective supplementary therapies for anxiety and depression, adding the patient's ability in coping and self-care skills to reduce anxiety symptoms [25,26]. Edmund Jacobson has found Progressive Muscle Relaxation Techniques (PMRT) in the 1920s as an intervention to help patients deal with anxiety and ensure that muscle relaxation can calm the mind [27]. Progressive Muscle Relaxation (PMR) is a systematic technique used to achieve full relaxation and has been shown to improve quality of life related to health in medical and psychiatric diseases [28]. Progressive Muscle Relaxation Therapy (PMRT) is easy to learn, has no side effects, and can be done in all locations. The purpose of our systematic review was to review the evidence regarding the use of PMR intervention for cancer patients to improve depression, stress, anxiety, and quality of life via physical relaxation.

Research Methods

2.1 Research Literature

There were four researchers who participated in searching the research literature. The English literature and publications over the past six years (2013 to 2019) with data bases in Scopus, Proquest, Google Scholar, Oxford, and Science direct journals were used. Keywords used in searching the literature were "Progressive Muscle Relaxation", AND "Cancer" AND "Anxiety", AND "Depression", AND "Stress", AND "Quality of Life". The literatures found with these keywords were thirty-four literatures.

2.2 Article Selection

The selected articles criteria in this systematic review were first, they might be original articles and they were not in the form of systematic reviews. Second, the articles discussed about Progressive Muscle Relaxation interventions and their combinations. Third, participants were people who were suffering from cancer which were not specific to certain cancers or treatments. The Fourth was

interventions about progressive muscle relaxation in cancer patients. All authors on systematic review selected the appropriate article.

2.3 Data Extracted

Data taken in the found literature were themes, authors, population, intervention, combination, time needed to give intervention, results, follow-up, and the methods used (PICOT).

3. Result

There were thirty-four literatures obtained, four were systematic reviews, three had the same titles, eighteen gave Progressive Muscle Relaxation (PMR) interventions not in cancer patients. One article discussed the effect of PMR on nurse students, one article discussed the effect of PMR on retirees, and one more article discussed the effect of PMR on patient's parents, and another article discussed about instruments to evaluate the effect of PMR.

There were ten articles selected for systematic review [29–39]. Seven literatures used Randomize Control Trial (RCT) method [29,32,33,36–38,40], One literatures used quasi-experimental method[35], two literatures used pre-post design[31,39]

The total research population in all literatures was 60-222 people, after randomly selected; the final number of research respondents who were willing and qualified in all the literature was from 46 to 170 people. The intervention given in the literature is Progressive Muscle Relaxation (PMR) and several interventions combined with other interventions which are also complementary or non-medical alternative therapies. Three literatures provided PMR interventions without combination of other interventions [31,35,39], Three literatures combined PMR and Guide Image (GI) [32,36,38], two literatures combined PMR and music [29,33], one literature combined PMR and one literature used three combinations of PMR, GI, and deep breath [40]

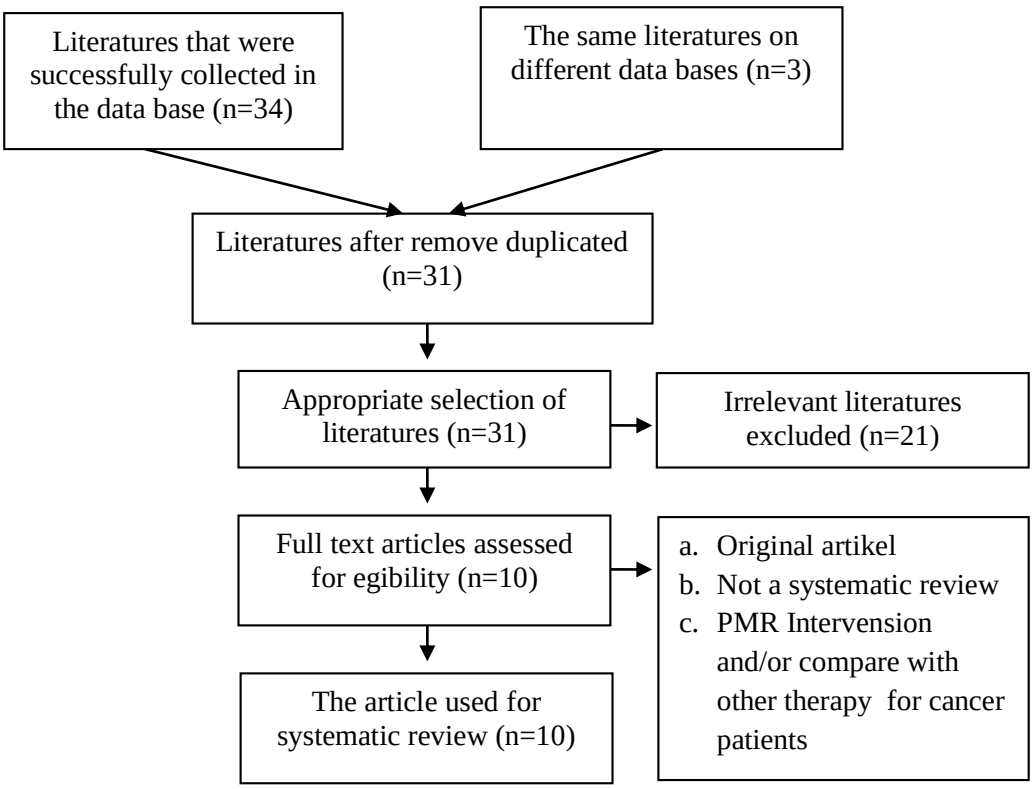

Figure. 1.Information flow chart

3.1 Summaries of Included Studies

The first study [36] combination of PMR and GI sessions for cancer patients. The intervention session was carried out in the respondent's house to minimize stress which is related to factors from the hospital medical environment. After being randomly selected, the control group received standard care (meeting weekly with a central psychologist) and the intervention group received 4 PMR and GI sessions which were monitored every day and unattended sessions for three weeks. Daily reminders (text messages) were given to the intervention group to remind them to practice PMR and GI every day at the same time.

The second study [39]PMRT program was conducted by the experimental group before and after surgery for 5 days. The researcher instructed participants to take a twice a day program (7: 00-8: 00am and 7: 00-8: 00pm) for 5 days. The experimental group practiced PMRT with the researchers, who provided MP3 players and earphones, the PMRT Program was only done by listening to MP3s. All participants were trained individually. Participants dressed loosely and were in a comfortable position and did PMRT according to MP3 recordings. The researchers instructed to lower the curtains and keep the surrounding environment calm before listening. Each participant could adjust the MP3 volume, there was also a replay button. MP3 officers remained with each participant until they were finished and MP3 was returned. Participants in the control group received standard post-operative intervention and education. In addition to care and education, the experimental group received the PMRT program.

The third study [33] patients were randomly divided into two intervention groups with 20 minutes PMRT and 20 minutes CM five elements of music and 20 minutes of peaceful rest for each treatment and control group. The intervention was given at 10 am or 3pm for 8 weeks.

The fourth study [32] initial research protocol required that patients only experienced 3 sessions of GI and PMR and be monitored. Interventions included: 2 minute breathing exercises, followed by 10 minutes progressive muscle relaxation exercises and 15 minute picture sessions with a pleasant guide. The control group only received regular care (standard) It was explained in international guidelines.

The fifth study [29] intervention group was given progressive muscle training and music therapy second day (48 hours) after mastectomy, while the control group was given standard treatment. Interventions were carried out in the morning (06.00-08.00) and evening (21.00-23.00), the exercise was carried out for 30 minutes for each session until the patient was planned to go home.

The sixth study [40] respondents were asked to come to the right place in the hospital with a nurse. The presence of nurses was required due to the old age and the fact that they needed a lot of training. Respondents were divided into 2 groups, a group consisted of 8 people, and the second group consisted of 7 people. Education and practice sessions were different in each group, groups of 8 people got 45 minutes for 4 consecutive times after a month of education and practice. This technique was carried out for 6 months under the direct supervision of the researcher. The researcher followed up on the truth of the administration and technical over the telephone and obtained information from the patient's nurses. The control group was given three usual sessions on lifestyle and life experience

The seventh study [31] all participants received guidance sessions to learn progressive muscle relaxation exercises following Bernstein and Borkovec. This technique consisted of subsequent contractions and relaxation in all groups, interventions were sequential. The initial position with eyes closed, the participants were instructed to contract and relax the muscles of the hands, arms, face, neck, shoulders, abdomen, and lower limbs. During the implementation of the technique, patients were suggested to do normal breathing.

The eighth study [34] intervention is Applied Progressive Muscle Relaxation Training Program (APMRT), two hours therapy consisting of six modules. The total of three therapies was carried out by the principal researcher for six weeks. The APMRT program involved quality of life discussion

in prostate cancer, rational, description and therapy demonstration. In addition, abdominal breathing techniques were taught to improve relaxation through demonstrations by the principal researcher. Patients were encouraged to practice their own therapy every day for a period of six months.

The ninth study [38] involved 4 phases: T0, T1, T2, and T3. T0 (patient registration): all patients admitted to the hospital at least 48 hours before screening by the research nurse for inclusion / exclusion criteria. Group A patients were scheduled for individual PMR sessions - IGI. Group B received regular care. Furthermore, to avoid losing patient control (group B) from potentially favorable interventions, they were also offered PMR individual session, an IGI Session at the end of the study. T1 (24 hours from T0): GI practitioners interviewed patients who met the requirements, told them about the purpose of the study, and explained the method. T2 (in 1 hour from T1): every PMR session - IGI had duration of 20 minutes due to the patient's weak condition and difficulty concentrating for a longer period of time. T3 (within 2 hours of intervention).

The tenth study [37], all interventions were performed in a private room with sufficient light and warmth to make the patients feel relaxed during the study. No other individuals were allowed to enter the room during the sessions. While performing exercises, the patients were asked to wear casual and comfortable clothes. Exercises, as with reflexology, were individually performed as 16 home visits for each patient twice a week as two sessions, each for 20 minutes, for 8 weeks under the supervision of the researcher. The study design and intervention techniques were explained to each patient, who then signed an informed consent. If the patients took analgesics either orally 60 minutes or intravenously 30 minutes earlier than the intervention, the intervention was delayed to distinguish between the effects of intervention and those of the analgesic. Therefore, for the home visits, the patients were called by the researcher to evaluate the condition, and the visits were then performed according to the following arrangements. A reflexology session usually lasts for 30 minutes; therefore, two sessions were performed for a total of 60 minutes at each of the 16 home visits within an 8-week period.

4. Discussion

The main purpose of this systematic review is to strengthen the evidence that Progressive Muscle Relaxation interventions (PMR) can improve cancer patients 'psychology, namely anxiety, stress, and depression to improve patients' quality of life. Two items of the literature found that there was an improvement in the patient's level of anxiety and depression as indicated by the decrease in cortisol [36,39]. Cortisol is an important indicator of changing physiological conditions in stress response [20]. Other literature result showed improvements in anxiety, stress and depression, and quality of life. Another literature showed the result of improvements in physical conditions such as decreased pain, nausea, headache and prosperity level. Five studies showed improvements in psychological and physical conditions[31,36,38,40]. Three studies showed psychological improvement and quality of life without any information related to the patient's physical improvement [29,33,41]. Progressive muscle relaxation is one of the complementary and alternative therapies (CAM) applied in quality of life (QOL) management [42]. PMR was not the only therapy that can reduce depression, stress, anxiety and increase quality of life, but also the combination of PMR with other complementary therapies can also improve depression, stress, anxiety and quality of life for patients with cancer. Intervention group receiving music therapy and progressive muscle relaxation training plus routine nursing care had significant improvement in depression and anxiety [29]. Progressive muscle relaxation, guided imagery, and deep diaphragmatic breathing significant improvement in QoL and physical functioning [40]

The weaknesses of this systematic review were the intervention of Progressive Muscle Relaxation (PMR) was done by the combination of other complementary therapies such as music, Guide Image (GI), and deep breathing. Seven literatures provided PMR therapy with combination of complementary therapies[29,33,36,38], even one of the six therapies used three therapies, ten

literatures did not show disease, and the same treatment, even though the case is cancer but different treatment can cause different physical and psychological effects. Four cancer literatures in general [31,33,36,38], a literature on colorectal cancer [39], five studies of breast cancer [29], prostate cancer [41], and combination of both [36,40]. One literatures obtained chemotherapy treatments [36], one literature obtained an operating plan [29]. This systematic review were less homogeneous literatures between treatments and interventions, so the results cannot be ensured whether PMR plays full role in reducing anxiety, depression, stress and improving patients' quality of life or it was not yet clear which therapy was more effective.

5. Conclusion

The systematic review provide empirical evidence to support the proportion that Progressive Muscle in combination or without combination other complementary therapies can reduce depression, anxiety, stress and also increase quality of life in cancer patients.

E-mail: eko.shipanglipuring74@gmail.com

ABSTRACT

The implementation of health services that prioritize the quality and sustaining patient safety by giving high caution to the risk of fall patients. To support the implementation is the fall risk assessment format or instrument that complies with the standard. This systematic review aimed to evaluate the implementation of the fall risk assessment for predicting the incidence of patients falls in the hospital. Systematic review used the main database and related websites to complete the literature. Thirteen papers were included in the criteria. The results of the review showed that fall risk assessment on elderly patients including Hendrich II Fall Risk Model Scale (HIIFRMS), Stratify, the Morse Fall Scale (MFS) and FRATs (Fall Risk Assessment Tools) had high effectiveness in preventing the occurrence patient falls. Hendrich II Fall Risk Model Scale (HIIFRMS) has the highest predictive value than other instruments. Based on the results and literature, the Hendrich II Fall Risk Model Scale (HIIFRMS) was found to be a good predictor to assess the elderly patients in the hospital. Hendrich II Fall Risk Model Scale (HIIFRMS) has high accessibility and clearly evaluation in predicting the risk of fall for the elderly.

Keyword: fall risk assessment, elderly, fall

1. Introduction

Sustaining patient safety in the hospital has become an obligation for all health workers who serve patients, from when the patient comes to the hospital to when they are discharged. The implementation of health services that prioritizes the quality and patient safety by giving high caution to the risk of fall patients. Support for this implementation is the fall risk assessment format or instrument that complies with the standard.

Falls are a serious problem for hospitalized patients. The major cause of hospital injuries are accidental falls [1]. Falls often result in psychological trauma and physical injury. Grenier-Sennelier et al. found that physical injury occur in 70% of falls and 10% of injuries cause of fractures. 4 of 5 fall patients will taking longer of stay in hospital and experience psychological effects. Some of more serious injuries were caused by fractures and head injury [2].

The effect from falls can be complications of fracture, such as restricted movement and long term of care and even death. Complications of fracture becomes the major cause of deaths from falls as these elderly are more likely to become bedfast and complication to be pneumonia. Statistics showed that more than 75% of deaths from falls occurred in elderly patients [2].

Cause of increasing aging population, the elderly has high risk in fall and almost half of the elder people have falling experience. About 5% of them after fall have fracture, about 11% of cases cause severe injury, and fall is a main cause of death in the elderly [3]. The increase in falls in this population is loss of coordination and strength, primarily due to paralysis caused by the stroke. Falls

are not attributed to age but more likely attributed to illness or other issues however age often considered in the incidence of falls.

There are several scales that used to assess the fall risk, so this review focusing on scale which are commonly used in hospital. To evaluate the implementation of the tools, in this study we use Stratify, Hendrich II Fall Risk Model, FRATs (Fall Risk Assessment Tools) and Morse Fall Scale. Support for this implementation is the fall risk assessment format or instrument that complies with the standard. The purpose of this review was to evaluate the instruments for assessing the risk of falls by hospitalized patients, and their effectiveness on preventing falls when implemented in the clinical setting.

2. Method

A literature search was conducted in some major databases such as ProQuest, Medline, Google Scholar, Science Direct, and Elsevier. Keywords used were fall risk assessment, elderly, and fall. The search languages were English and Indonesian. Year limitation used was from 2013 to 2018. From 957 articles obtained, the article's inclusion criteria were: 1) fall risk assessment tools using stratify, Henrich II fall risk, MFS and FRATs; 2) in hospital setting. Papers were critically reviewed and relevant data were extracted and synthesized using an approach based on Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA).

The parameters used to determine the fall risk assessment tools were Stratify, MFS, FRATs, and Hendrich II fall risk model. Stratify scale has five items. The five items including anxiety, instability, history of falls, bad vision affects life, frequent urination and defection. The patient belongs to the high risk groups of falling who minimum have two falling risk factors mentioned above.

Hendrich II fall risk model scale includes three items, such as depression, disorientation, and dizziness. The patients can be identified into the high risk group of falling if the total score of the scale is ≥ 5. MFS has six items which includes ambulatory aid, having history of falling, diseases, mental status, IV or IV heparin, and gait instability [3]. The purpose of fall risk assessment tools (FRATs) is to prevent falls and identify risk factors also the level of fall risk[4].

3. Results

The results from the study by Palumbo et.al suggest that FRAT-up is a suitable screening tool to use in populations of community-dwelling older people and FRAT-up risk score was predictive for future falls [5][6].

The evaluation of Stratify Scale for assessing the risk of falls in acute hospitalized patients was conducted by Aranda et.al. In was found to be the best tool for assessing the risk of falls by being hospitalized adult patients. However, the behavior of these instruments varies greatly depending on the population and environment, so the operation must be tested before implementation [1].

Hendrich II Fall Risk Model has been the most effective and predictive tool for the assessment of elderly falls [7]. Hendrich II Fall Risk Model has a higher sensibility in assessing the risk of falling patients by testing the elderly balance function [8][2]. The results showed that Stratify, Hendrich II Fall Risk Model and Morse Fall Scale had better consistency in the possibility of evaluating falls because the three scales were closely correlated in assessing the risk of falls in elderly patients. In addition, they have a higher sensitivity in evaluating the risk of falling patients, but their emphasis on specialization is different. Nurses in the clinic area must adopt it based on the characteristics of elderly patients [4][9].

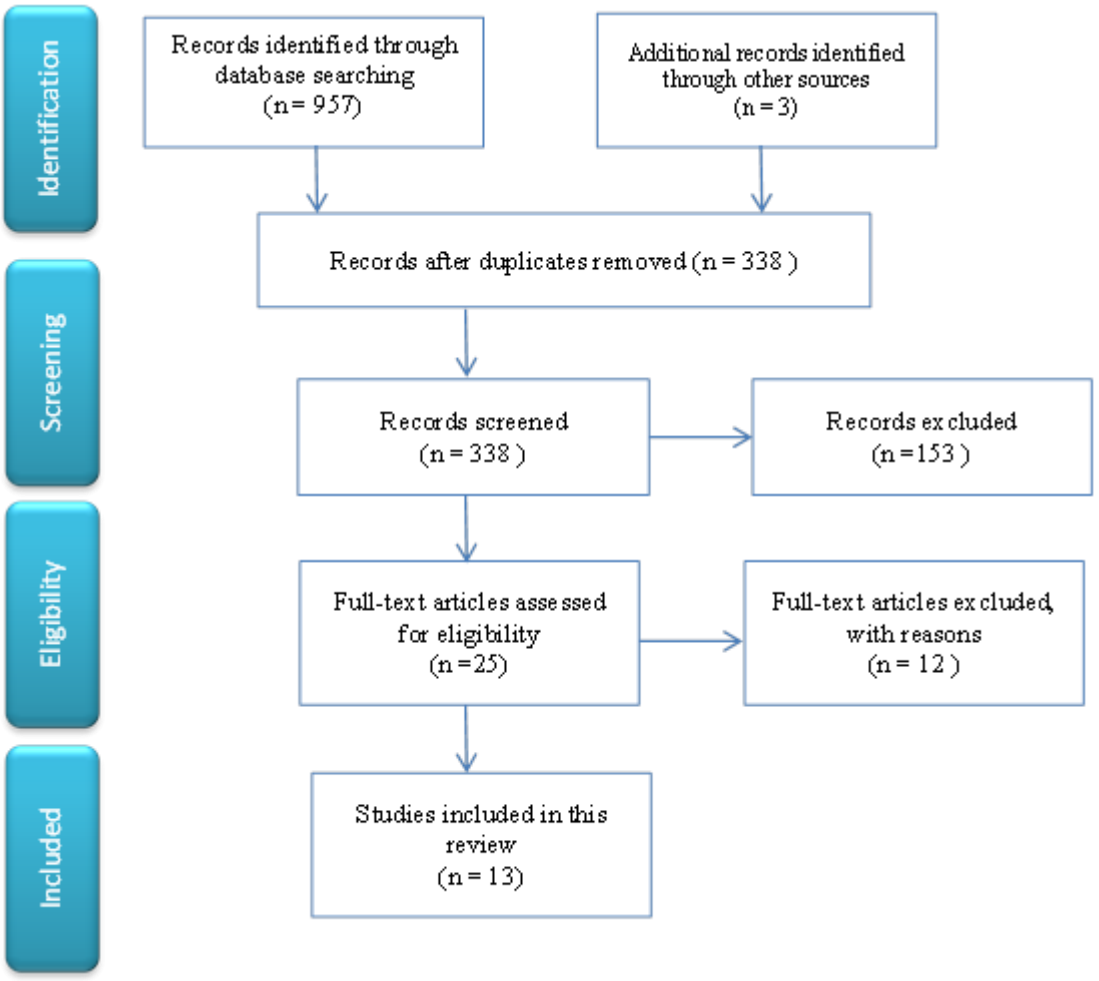

Figure1. PRISMA flow chart

4. Discussion

The evaluation for fall risk factors is important to prevent and predict the risk falls. A few of the studies in the world showed that assessing the risk factors were related and implementing the preventive steps for elderly [4]. This is particularly useful in clinical area for identifying the behavior of the instruments currently used exclusively in the hospital settings, where falls are the most frequent adverse events, and thus are directly relevant to the development and implementation of safety policies in long term care hospitals.

5. Conclusion

The Hendrich II Fall Risk Scale is the most inclusive and reliable tool surveyed from others. This tool is simple, reliable, and easily used in clinical settings to prevent the risk of falls. As long as this tool is used, it still can't control the patients who fall. Skill improvement was conducted to check whether health care givers are using this tool correctly.

Table 1. Selected study

Title /Author / Year	Study Design / Participants	Tool Name	Result
Stratify, Hendrich II fall risk model and Morse fall scale used in predicting the risk of falling for elderly in-patients [4](Han, Jialin *et.al*, 2017)	Nonrandomized studies N = elderly	• Stratify • Hendrich II Fall Risk • Model Morse Fall Scale	There was statistical significance in the score differences of the three rating scales for both groups (P<0.05). And the correlativity among the rating scales was 0.680~0.888.
Fall Risk Assessment Tools for Elderly Living in the Community: Can We Do Better?[10] (Palumbo et.al, 2015)	Nonrandomized studies N = elderly	FRATs	The proposed model and FRAT-up both attained the same discriminative ability.
Fall risk assessment tools for use among older adults in long-term care settings: A systematic review of the literature [6](Nunan, 2017)	Systematic Review N= older adult	FRATs	Several FRATs showed moderate-to-good predictive validity and reliability, with the Modified Fall Assessment Tool and the Peninsula Health Falls Risk Assessment Tool (PHFRAT) also demonstrating good feasibility.
Evaluation of Reliability and Validity of the Hendrich II Fall Risk Model in a Chinese Hospital Population [8](Zhang, 2015)	RCT N= elderly	Hendrich II Fall Risk Model	The Chinese version of the HFRM showed good reliability and validity in assessing the risk of fall in Chinese elderly inpatients.
Fall Risk Assessment for Older Adults: The Hendrich II Fall Risk Model[7] (Hendrich, 2016)	RCT N= adults at risk for falls	Hendrich II Fall Risk Model	Model has been used successfully in multiple international studies.
Falls Risk Assessment	Literature Review N= elderly	Hendrich II Fall Risk Model	The results of this literature found that the Hendrich II Fall Risk Scale is the most inclusive and reliable tool surveyed.
Feasibility and predictive performance of the Hendrich Fall Risk Model II in a rehabilitation department: a prospective study [2](Campanini, 2018)	Prospective study N= elderly	Hendrich Fall Risk Model II	The HIIFRM showed satisfactory feasibility and predictive performances in rehabilitation wards.

Baseline Prevalence Study of Hendrich II Fall-Risk Assessment Tool at a Local Community Hospital[11] (Pontual, 2017)	RCT N = elderly	Hendrich Fall Risk Model II	The HFRM II's effectiveness was in line with that of other fall tools.
Instruments for assessing the risk of falls in acute hospitalized patients: a systematic review and meta-analysis [1](Aranda-Gallardo, 2013)	Meta-analysis N= adult	• Stratify • Hendrich II Fall Risk • Model Morse Fall Scale	The STRATIFY scale was found to be the best tool for assessing the risk of falls by hospitalized acutely-ill adults.
Risk assessment and incidence of falls in adult hospitalized patients[9] (Pasa, 2017)	Cohort Study N = Adult	Morse Fall Scale	The largest group of hospitalized patients was classified as at high risk for falls according to the MFS. The incidence rate of falls corresponded to 1.68% and it was verified at a higher percentage of patients who fell were classified in the category at high risk for falls.
Development of a New Fall Risk Assessment Index for Older Adults [3](Yamada, 2012)	RCT N = Adult	• Stratify • Hendrich II Fall Risk • Model Morse Fall Scale	We have demonstrated that the new index is a reliable indicator for falls in elderly people who have higher levels of functional capacity. Our data suggest that a score of more than 1 indicated by the new index can predict falls in robust elderly people.

THE EFFECT OF SOAKING FEET WITH WARM WATER TO INSOMNIA FOR OLDER ADULT AT NURSING HOME

Nur Chamidiyah[1], Rodiyah[1], Iswanto[1]
[1]Nursing Bachelor Program of STIKES Pemkab Jombang
E-mail: ners_ody@yahoo.com

ABSTRACT

The older adult have more health problem than adult such as sleep disorders especially insomnia. One intervention to solve the problem is soaking feet with warm water. The purpose of study is to know the effect of soaking feet with warm water to insomnia for older adults at Nursing Home in Jombang, Indonesia. The design of srtudy used pre experiment with one group pre test and post test design. The independent variables of this study was a soaking feet with warm water and the dependent variable was insomnia. The population of this study were all older adult who experienced insomnia at Nursing Home at Jombang as many as 38 people. The samples were 16 people that were taken by using quota sampling. Instruments used insomnia rating scale. The analysis data used Wilcoxon statistical test. From the result of study was showed that from 10 respondents (62,5%) experienced moderate insomnia before intervention and 8 respondent (50%) experienced mild insomnia after intervention. The intervention of soaking feet with warm water was done for 7 days with 15 minutes each day. The data analyzed using Wilcoxon sign rank test with p value 0,001. It is expected that nursing service doesn't focus on pharmacological therapy, but also non pharmacological therapy such as relaxation therapy, soaking feet with warm water to overcome insomnia to older Adult.

Keywords: soaking feet with warm water, insomnia, older Adult

2. Introduction

Age is an important factor for sleep quality. It is a physiological process that occurs in every human being, in the aging process it increases.. Sleep disorders or insomnia are disorders that occur in older adults. This condition is the most common sleep problem, and can be persistent. The short period of insomnia is most often associated with challenges [1].

In Indonesia, the number of older adults reached 20.89 million at 2015, an equivalent to 8.04% of the total population in Indonesia [2]. In Indonesia, in the 40-years age group, 7% of cases were related to sleep problems. The same thing was found in 22% of cases in group 60 years and over who experienced sleep disorders at night [3].

Based on a preliminary study conducted by researchers on March 2, 2017 at the Tresna Nursing Home in Jombang used interviews of insomnia sufferers and a questionnaire rating scale of 10 respondents obtained 2 older adults without insomnia, 2 older adults with mild insomnia, 4 older adult with moderate insomnia and 2 older adults had severe insomnia.

Sleep disorders that often occur in the older adult consist of difficulty sleeping, frequent awakeness at night and difficulty starting to sleep again, reducing night time sleep, etc. The total amount of normal time for sleep requirements was 6 hours/ day. Insomnia in the older adult had a significant impact during the day, impaired attention and memory, mood, depression, high risk of falls and decreased sleep quality [4].

The right cure for insomnia was to find out the cause of insomnia first. Healing could be done by changing habits and environment or by pharmacological and non-pharmacological therapy. Often actions were generally carried out with pharmacological therapy. Pharmacological therapy was used by providing hypnotic sedatives such as Golan nan benzodiazepine. However, in the event of changes in pharmacodynamics, pharmacokinetics and also the effects of drugs in the body of older adults which caused pharmacological management which was very risky for the elderly. Thus, non-pharmacology was a safer alternative choice, namely stimulus control, doing moderate exercise, walking in the morning, gymnastics or muscle relaxation and relaxation therapy [4].

Water with a temperature of 39 °C was given for 15 minutes. Soaking feet with warm water was a cheap and easy way to relieve stress, insomnia, difficulty, overcome and muscle strain by lifting acupuncture points located at the bottom of each leg. The nerve from flexus venosus from this nervous system stimulation was passed to the posterior corn and then proceeded to the spinal cord, to the dorsal root, then to the basal ventral thalamus and into the functioning brain in the rave area [5].

From previous studies that had been conducted on disorders of insomnia namely the Effectiveness of Foot Bath with Hot Water on Fatigue Levels among Elderly Patients. in India, where could be found about feet with warm water that effective for relieving stress, insomnia, coping, and coping with older adult [6]. The study was carried out, among others, regarding feet soaked in water toward the quality of sleep in the Mangiran Trimurti village of Yogyakarta, published by, the results of sleep quality findings, significantly in both studies, was related to the older adult who did not need to consider warm water foot soak [3].

Based on these problems, researchers want to discuss about soaking the feet with warm water against insomnia in the older adult, according to the explanation above was to understand the level of insomnia before the soaking warm water process was given to older adults, knowing the level of insomnia after the process of soaking warm water, and analysis of the effect of soaking warm water in older adults.

3. Research Methods

The design of study was a Pre-experimental Design with a One Group Pre-Post Test Design approach, which was a pre-experimental design by involving one group of subjects. The subject group was observed before intervention, then observed again after intervention [7]. The independent variable of this study was warm water foot soak and the dependent variable of this study was insomnia. The population in this study were all older adult who experienced insomnia in the Nursing Home of Jombang as many as 38 people. The sample of this study was 16 older adults. This study technique used quota sampling. The inclusion criteria were: all the insomnia elderly and cooperative elderly. On the other hand, exclusion criteria were: elderly with total bed rest, elderly with infectious disease. The intervention of soaking feet warm water was done for 7 days with 15 minutes each day. This study was conducted on 12 to 28 April 2014 in the Social Services Unit of Tresna Werdha Jombang. This study used the *Wilcoxon signed Rank Test statistic*.

4. Results

Table 1. The characteristic of respondent (n=16)

Characteristic	N	%
Gender		
Female	16	100
Male	0	0
Age		
60-74 Years	5	31,3
>75 years	11	68,8
The way to reduce		
Taking sleeping pills	4	25
Not sleeping during the day	2	12,5
Rest	10	62,5
Drug therapy		
Yes	0	0
No	16	100
Total	16	100,0

T**able 2.** The level of insomnia after and before treatment

Insomnia Level	Pre-Test		Post-Test	
	Frequency	Percentage (%)	Frequency	Percentage (%)
No insomnia	0	0	4	25
Mild Insomnia	5	31,3	8	50
Moderate Insomnia	10	62,5	4	25
severe insomnia	1	6,3	0	0
Total	16	100	16	100
Wilcoxon sign test ($\alpha = 0.05$)				,001

From table 2 it is shown that most (62.5%) of the elderly respondents before warm water foot soak therapy were experiencing moderate insomnia and a half (50%) from older adult of respondent had mild insomnia. From the results of data analysis used the Wilcoxon sign test with a significant level of $\alpha = 0.05$, the calculation results obtained $p = 0.001 < \alpha = 0.05$, thus H_0 was rejected and H_1 was accepted. This means that there was the influence of warm water foot soak on insomnia in the older adult at the Nursing home, Jombang.

5. Discussion

From table 2, the results of the study showed that respondents who experienced insomnia in the older adult before warm water foot soaking was found that most (62.5%) of the respondents experienced moderate insomnia, as many as 10 people.

Among the factors that were considered to influence the incidence of insomnia in the older adult were: female sex, age, marital status, income, education level [8]. There were also several factors that can affect sleep disorder both in terms of quantity and quality, namely: health status, environment, diet, medicine and lifestyle. In one study it was shown that most events were stressful and experienced insomnia. However, women were considered more stressful than men. Increasing negative emotional reactivity in women could cause gender differences in insomnia. Feelings of women were very sensitive and sensitive to things that interfere with their thinking caused a woman

to experience more sleep disorders (insomnia) than men. The risk of depression increases in women, especially when there is a history of depression, just losing, living alone, weak social support, staying in the institution, decreasing health, and functional limitations. The high rate of depression in women was more related to the transition of reproductive and hormonal functions or menopause [9]. As humans age, there will be an aging process that was followed by various degenerative health problems, especially those that affect human changes from physical, cognitive, emotional, social and sexual changes. These changes could cause various kinds of disorders, such as disorder of insomnia [9]. By increasing age, the elderly was no longer productive, decline in physical and mental abilities, unable to carry out more strenuous work, enter retirement, left behind by partners, stress to face death, depression, increase various kinds of disease and insomnia. This is the same as when this study of the number of respondents who experienced insomnia was aged > 75 years.

Relaxation therapy with warm foot soak was the right intervention to overcome insomnia in the older adult because it had no side effects, is safe, of low cost and is a simple intervention. Soaking the feet with warm water could also relieve stress, fatigue and tired muscles that often occur in the elderly [6]. Insomnia can be overcome by non-pharmacological methods including by soaking feet in warm water that can help the older adult become relaxed and affect the elderly to want to sleep (sofaritic effects).

Based on the data obtained above, there was compatibility with the theory of relaxation therapy with warm water foot soak that can affect sleep needs because soaking feet with warm water can stimulate nerves/acupuncture points on the soles of the feet [5]. Scientifically, warm water had a physiological impact on the body such as reducing the burden on the supporting joints of the body. These effects had various effects on blood vessels where the warmth of water makes blood circulation smooth so that it can cause a relaxing effect [10]. Based on the physiology that the foot area there are skin nerves namely flexus venosus from this nerve sequence stimulation was passed to the posterior corn and then proceed from spinal cord to the dorsal root, then to the basal ventral thalamus and into the brain stem which was precisely the bottom of the pons and medulla in which the sofarific effected (want to sleep) [5]. Warm water foot soak could reduce insomnia. Soaking the feet with warm water could make blood circulation smooth so that it provided a relaxing effect and can stimulate the acupuncture points on the soles of the feet which can cause sofaritic effects (want to sleep). So this can be used for one way to reduce the level of insomnia in the elderly. The other factors which affect the insomnia could not control (anxiety, depression, the death of life partner, uncomfortable society)

6. Conclusion

Based on the study above there was an influence of warm water foot soak on insomnia in the older adult in the nursing home at Jombang, Indonesia. It is used since it is not expensive and can be implemented into daily activities. It is expected that the older adult can continue the interventions that have been carried out by themselves and cam carry them out routinely.

SUPPORTIVE CARE NEEDS OF CANCER PATIENTS UNDERGOING CHEMOTHERAPY IN UMMC

Athirah Binti Mohd Aziz
Faculty of Medicine University of Malaya Kuala Lumpur

CHAPTER 1: INTRODUCTION

1.0 Introduction

This chapter will covered on background of this study about the supportive care needs for cancer patients undergoing chemotherapy and problem statement which are issues that need to be addressed in this study. Other than that, this chapter also will explain on the significance of this study to cancer patients and among nurses and healthcare provider. Objectives also will be listed in general and specific. Research questions also had been explained briefly that need to be observed had influenced patients the most. Lastly, some importance operational definition about this study also will be given.

1.1 Background of the study

Cancer is a major cause of morbidity and mortality in this entire the world, with 9 million people newly diagnosed each year and 5 million people dying from the disease. Based on American Cancer Society of Cancer 2017, nearly 13% of all cancers diagnosed in adults ages 20 and older will be cancers in year 2017, in which fewer than 6 cases per 100000 people per year.

In 2017, it is estimated that almost 1.7 million new cases of cancer will be diagnosed, in which prostate cancer will be the leading common cancer among males (19%), followed by lung cancer (14%) and colorectal cancer (9%). On the other side, breast cancer is the most common among female with the percentage of 30, followed by lung cancer (12%) and colorectal cancer (8%) (Cancer Facts & Figures, 2017).

A diagnosis of cancer can affect a person's physical, psychological, spiritual and social well-being. Some of these effect will resolve over time as some of individual had enough personal coping resources, social and professional support and some need to take a longer time in order to cope with the new health status they received. Therefore, early identification and referral of individuals with unmet supportive care needs can improved ones self-management, as this can be associated with morbidity and distress.

Thus, the aimed of this is to determine the supportive care needs of cancer patients undergoing chemotherapy in University Malaya Medical Centre (UMMC).

1.2 Problem statement

According to study done by Carlson et al. (2004) on high level of untreated distress and fatigue in cancer patient, 37.8% of 2776 representative cancer patients met criteria for general distress in the

clinical range in which results show most men has high proportion for somatisation whereas women for depression. However, both gender have no differences in anxiety or severity in distress. In addition, almost half of all patients who met distress criteria had not sought professional psychosocial support. This shows that distress is very common in cancer patients across diagnoses and disease but those who are reported having high level of distress are not taking advantage of available supportive resources. However, further exploration need to be done in order to collect more information on factors predicting distress among cancer patients and use of psychological care in order to meet their needs in surviving with the disease.

Differences in demographic characteristics and psychosocial among each cancer patients may influence supportive care needs. Therefore, the first step that should be taken part in order to provide correct supportive care is by identifying the significant relationship between demographic characteristics and level of supportive care need as this is essential in order to provide high-quality care and patients' satisfaction.

However, previous studies on supportive care needs for cancer patient shows lack of exploration in Malaysia where most studies had done in overseas such as in Australia and United Kingdom. This make the researcher to do this study in Malaysia which will be conducted in University Malaya Medical Centre (UMMC).

Thus, in response to this problem, this study is done to identify the highest needs of patients with cancer across five factors of domains which are psychological, health system and information, physical and daily living, patient care support and sexuality needs. Other than that, this study will also determine the significant relationship between demographic characteristics and level of supportive care need of cancer patient.

1.3 Significance of study

The current study is significant as it offers insight into the unmet supportive care needs of cancer patients at different stages of cancer experienced. This study is important as its findings will benefit patients, nursing practices and organizations.

1.3.1 Patient

Significance of this study to patients are they can provide information on their unmet needs that they require in surviving cancer. The survey done by using the 34- item Supportive Care Needs Survey (SCNS-SF34), patient will indicate their level of need for help that they need the most which include five factors; psychological needs, health system and information needs, physical and daily living needs, patient care and support needs and sexuality needs . This study may improves one's life in surviving cancer and undergoing treatment in supportive care that they need the most once their unmet needs had been addressed.

1.3.2 Nursing

Significance of this study to health care provider especially nurses are they can filled the gap of the treatment given to the cancer patient with the information gathered in this study. As there are different approaches in order to fully understanding survivors' cancer experiences and quantifying their outcomes which including assessment of their quality of life, satisfaction in

health care and needs assessments which is not only identifying their needs and importance, but also the extent to which the needs they are met. They can acknowledge in depth the common supportive care needed by cancer patient. Furthermore, this study also can enable the healthcare provider to be more focused on the issues that their patients expressed to be addressed in order to achieve an optimal wellbeing. With better understanding this group of patients, the health care provider can tailor their care to the specific needs identified by their patient and results in the development of a number of valid and reliable cancer- specific treatment.

1.3.3 Organisation

The findings of this study will bring benefit to organization considering the unmet needs of cancer patients had been addressed through this study as they will be guided on what should be emphasized by their healthcare worker such as doctors and nurses in their area. This can improve patients' perception on treatment provided in the hospital. As this study done, it is also hope that the information gathered may help the organization in future planning to address specific priorities and unmet needs of cancer patients in the management of healthcare.

1.4 Objectives

1.4.1 General objective

- To determine the supportive care needs of patients with cancer undergoing chemotherapy in UMMC.

1.4.2 Specific objectives

- To determine the level of supportive care needs of patients with cancer undergoing chemotherapy.
- To identify the domains of needs among patients with cancer.

- To identify the useful sources of supportive care as perceived by patient during treatment of cancer
- To determine the significant association between demographic characteristics and level of supportive care need.

1.5 Research questions

Based on the problem statement, the following research questions were identified:

- What are the type supportive care needs of patients with cancer undergoing chemotherapy?
- What are the level of supportive care needs of patients with cancer undergoing chemotherapy?
- What are the domains of needs among patients with cancer?

- What are the of usefulness sources of supportive care as perceived by patients?

- What are the significant association between demographic characteristics and level of supportive care needs?

1.6 Operational definition

The following definitions are provided to ensure uniformity and understanding of these terms throughout the study:

1.6.1 Supportive care need

According to NCI Dictionary of Cancer Terms (n.d), supportive care refers to care that are given in order to improve ones' quality of life of patients who have a serious or life-threatening disease. The aim of this care is to prevent or treat as early as possibly the symptoms of the disease, the side effects occurs that caused when undergoing treatment for the disease. Other than that, the psychological, social and spiritual problems that arouse related to a disease or its treatment. In this study, supportive care is care that focuses on relieving symptoms caused by cancer. It can be given at any

time when patients feel ill thus can help them feel more comfortable and can easier to cope with the disease and treatment received.

In this study, supportive care needs refer to the unmet needs from cancer patients that need to be addressed in order to cope with the both the physical and psychological effects of cancer and its treatment. Thus, the assessment will be done by using 34-item Supportive Care Needs Survey (SCNS-SF34) questionnaire which consist of five need domains such as physical and daily living, psychological, health system and information, patient care and support and sexuality.

1.6.2 Patient with cancer

According to Collins English Dictionary (n.d), patient with cancer refers to a person who is receiving medical treatment for a malignant growth or tumour. In this study, cancer patients are patient who had been diagnosed with all type of cancer such as breast, colorectal and prostate cancer who undergoing chemotherapy in UMMC.

1.6.3 Chemotherapy

According to National Cancer Institute (NCI) Dictionary of Cancer Terms (n.d), chemotherapy is a treatment that uses drugs to stop the growth of cancer cells. It was done either by killing the cells or by stopping them from dividing. Chemotherapy treatment may be given through mouth, injection, or infusion or on the skin depending on the type and stage of the cancer that is being treated. The treatment may be given alone or with other treatments such as surgery, radiation therapy or biology therapy.

In this study, patients in UMMC were being recruited as respondents to answer the questionnaire.

1.7 Summary

This chapter had covered background of this study about the supportive care needs for cancer patients undergoing chemotherapy and problem statement which are issues that need to be addressed in this study. Other than that, this chapter also had explain on the significance of this study to cancer patients and among nurses and healthcare provider. Objectives also had been listed in general and specific. Research questions also had been explained briefly which consists of five domain factors that need to be observed influenced patients the most. Lastly, some importance operational definition about this study also had been given.

CHAPTER 2: LITERATURE REVIEW

2.0 Introduction

Literature review is a key step in research process. It is a text from a scholarly paper which include current knowledge including substantive findings, as well as theoretical and methodological contributions to a particular topic. The reviews are secondary sources, in which need not any new report or experimental work and more often associated with academic-oriented literature which are found most in academic journals. Therefore, this should be done by reviewing previous studies and experiences that related to the proposed studies before starting any research. Hence, this literature review of past studies can contribute to new study ideas, insight and knowledge.

In order to search for literature review, a systemic way should be imply to get the most related literature which related to the current studies. Therefore, search engine for the literature review will be done. It is a systemic search of electronic bibliographic databases that was conducted during before conducting a research study. As for my study, a review of literature review in the area of supportive care needs of cancer patients that had been published over the past 10 years was conducted.

2.1 Search strategies

A systemic search of electronic bibliographic databases was conducted during the third week of September 2017. A review of literature in the area of supportive care needs of cancer patients had been published over the past 10 years was conducted.

2.1.1 Criteria

In order to search for the precise literatures, relevant keywords had been keyed to filter out articles that are irrelevant. The inclusion and exclusion criteria were establish to guide the search for related articles to the study. Some inclusion criteria that had been used were:

- Articles published within year 2000-2017
- Full-text only

- English language articles

2.1.2 Sources

The electronic search was performed on the following databases that has been subscribed by University of Malaya digital library: CiNaHL@EBSCO, PubMed, Science Direct and Medline. Other than that, the used of Google Scholar to search articles and journals related to the topic study also had been done.

2.1.3 Keywords

cancer, cancer patients, perceived needs, unmet needs, supportive care, supportive care needs.

The Boolean operators such as AND, OR and Not were also used in order to combine or exclude keywords during the literature search. These help to connect search words together to either narrow or broaden the set of results.

2.2 Results of key studies

The search on electronic databases and reference minimally covered 754530 of all articles applicable to supportive care needs of cancer patients. Of these, duplicated articles were removed, and of 369378 articles screened by title and abstract, only 342 articles had met the inclusion criteria for further critical review. Subsequently, there were a total of 36 original articles relevant to this study and 10 had been used as literature review.

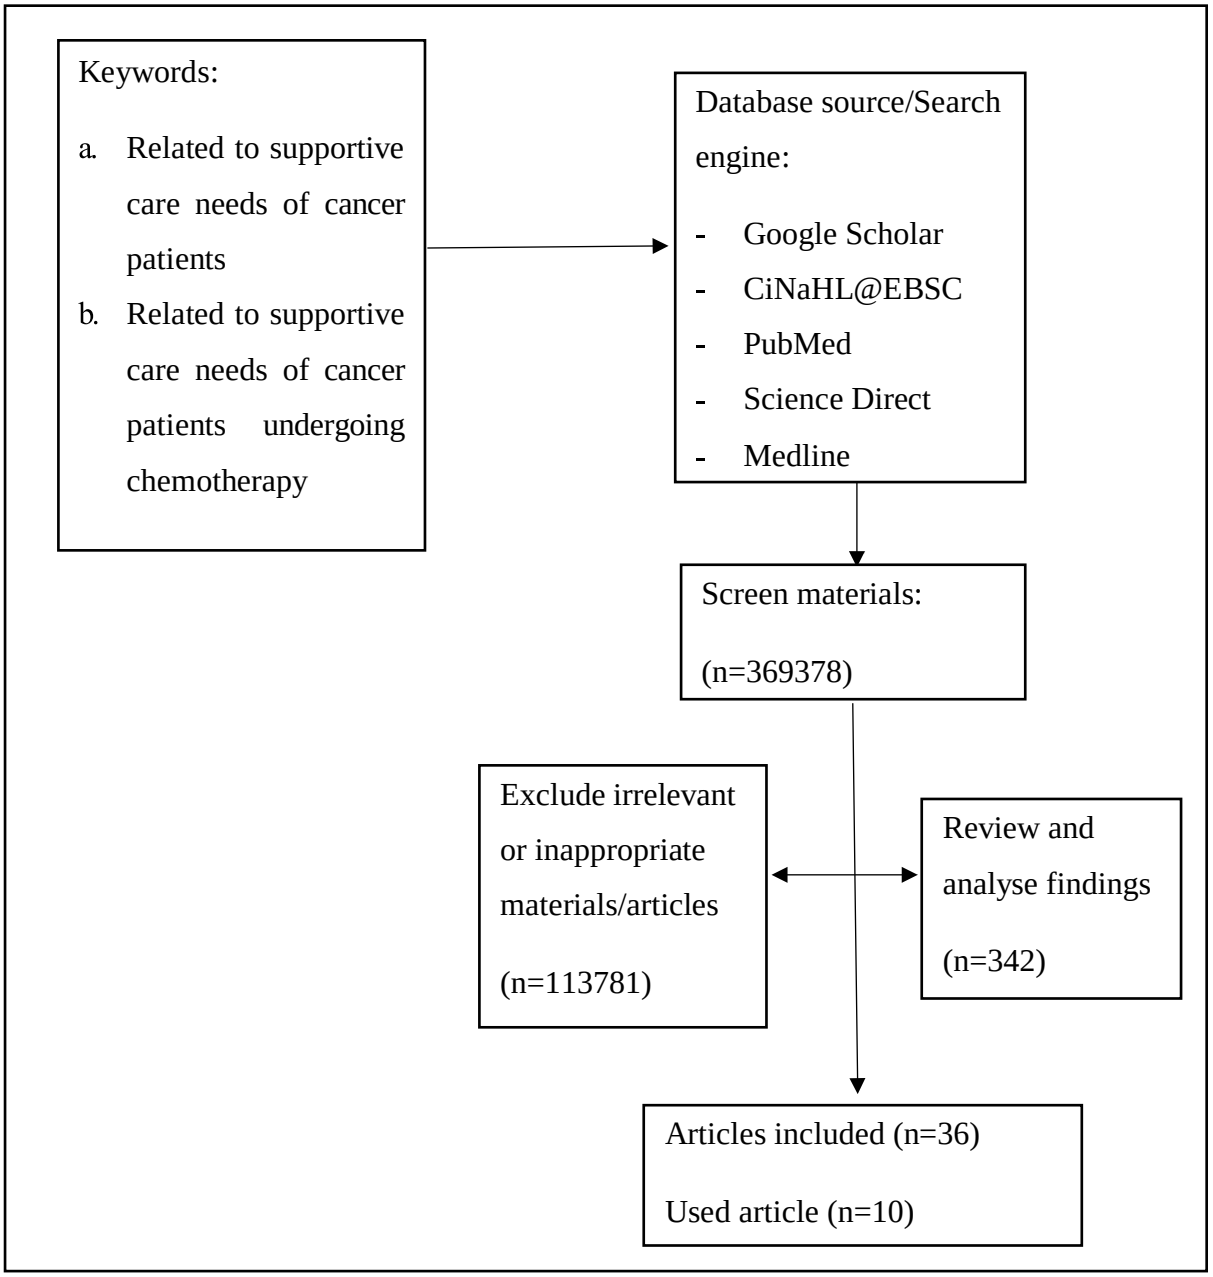

Figure 1 shows search outcomes from databases and keyword used

2.3 The supportive care needs of cancer patients

Numerous studies have been attempted to explain the effect of supportive care needs towards cancer patients.

According to studies done by Boyes et al. (2012), about one-third (37%) of survivors reported one or more items of moderate or high level unmet need, six months after a cancer had been diagnosed. Meanwhile, almost two-thirds (63%) had been reported with either no or low level of unmet needs. The most commonly reported as moderate to high level unmet needs results from the psychological and physical and daily living domains.

The prevalence of unmet need reported by the survivors in this study is clearly lower than previous reported studies that used the same validated instrument and classification of unmet need as the researcher used two largest state –based cancer registries in Australia to assemble a population-based sample of survivors in the early stages of cancer survivorship. The researchers are confident in their findings that most survivors' supportive care needs as measured by the SCNS-SF34 are relatively well met given that the study sample is generally representative of the source population.

As due to the size and composition of the study sample, the researches were also able to directly compare the prevalence of supportive care needs between seven common cancer types in Australia at that time, which consist of colorectal, breast, blood, lung, head neck, prostate and melanoma cancer. A significant variation had revealed across cancer types with 65% of whom reported no items of unmet need reported by survivors of melanoma. On the other side, 60% of survivors of lung cancer were reporting at least one item of moderate or high level need. This might be due to

high level of burden that associated with lung cancer in terms of poor prognosis, side effects of the treatment and declining in physical health.

Other than that, cancer type was found to be significantly associated with moderate to high level unmet physical and daily living and sexuality needs, after adjusting for a comprehensive range of sociodemographic status. Survivors of lung cancer had the highest odds of reporting unmet physical and daily living needs, whereas survivors of prostate cancer had extremely high odds of reporting unmet sexuality needs. Thus, these findings had suggest that type of unmet need experienced by survivors does not routinely differ between cancer types.

A number of associations had been established for the first time on account of the range of study factors that had been examined in this study. Results showed low level of social support and maladaptive coping styles were associated with multiple domains of unmet need.

Therefore, this study had directly inform health care professionals and organisation involves in providing supporting care needs to the patients. They have also suggest that coping support interventions may have the potential to contribute to the prevention or reduction of survivors' unmet needs across all domains.

A literature review on supportive care needs of cancer patients has been done by Smith et al in 2014 which result shows one major that need identified was the requirement of informational support other than emotional, spiritual and financial support. This study review of the literature

results all studies done reveal cancer patients' needs for emotional, spiritual, informational, and financial support during all phases of treatment. There are also needs for support that are not being met through current treatment programs especially in vulnerable populations. Therefore,

recognizing many aspects of patients' lives that may affected by a cancer diagnosis is an important component of adequate care. Identifying the unique stressors experienced by different populations provides insight into the supportive care needs such patients may have throughout treatment and survivorship.

There are various ways to deliver supportive care to those in need such as by religious communities or caregivers as well as providers. However, healthcare providers must first recognize the supportive care needs of their patients and incorporate effective resources and interventions into treatment plans. Therefore, by understand the support care needs and challenges experienced in relation to a cancer diagnosis can help healthcare providers to tailor treatment plans more effectively for different population. However, more research is needed on population-specific interventions and ways of connecting patients with resources.

A studies done in Nagoya City University Hospital and Saitama Medical University International Medical Centre in Japan to assess the accuracy of oncology nurses' recognition of supportive care needs and symptoms of their patients undergoing chemotherapy revealed that the nurses' recognition may not accurately reflect their patients' supportive care needs and symptoms in routine practice. In clinical practice. It may be beneficial to conduct routine screening of patients' perceived needs and symptoms comprehensively using-administered questionnaires.

The most prevalence needs of patients in this study were in the psychological domain which contributed 77.0%, followed by the health system and information domain (64.2%) and the physical domain (59.9%). The prevalence of the health system and information domain perceived by the oncology nurses is 73.8% was the highest, and the sensitivity and the specificity for this domain were the highest which is 79.2%

and the lowest is 35.8%, respectively, in the needs domain. Positive predictive value and negative predictive value for psychological needs were the greatest which 80.4% and lowest is 28.3%, respectively, among the needs of domain.

The accurate assessment of supportive care needs and the physical and psychological symptoms of cancer patients represent the first step toward appropriate intervention in relation to these problem. However, this study has reveal that nurses may not reliably recognize such needs or symptoms of their patients in routine care, particularly psychological symptoms and support needs where the result shows markedly under-recognized. Other than that, nurses' awareness of their patients' supportive care needs also were less than optimal among all domains, even though the researchers believed that needs assessment may offers an opportunity to better understand cancer patients' problems under treatment, the subjectivity of patients' supportive care needs mean that it may not be easy to recognize them simply by superficial communication.

In addition, the low negative predictive value for the psychological domain may also indicate that cancer patients often have psychological needs that are not recognized by nurses. The association between psychological and/or emotional problems and supportive care needs is slight, which emotional functioning was said in previous study by Snyder et al to be associated not only with psychological needs but also information needs and care and support needs.

Physical symptoms associated with chemotherapy, such as hair loss, appetite loss and fatigue were better be recognized than symptoms not specific to chemotherapy such as constipation, insomnia, dyspnoea and pain. As the results showed the

prevalence of physical symptoms that are not specific to chemotherapy was high in this population, nurses should pay adequate attention to these symptoms.

This study also showed that nurses have difficulty identifying both clinical depression and anxiety. According to previous study done by Hegel et al (2008) and Akizuki et al (2005) on distress thermometer for depression in cancer patients, it would be beneficial for nurses to implement distress screening among cancer patients in clinical settings.

However, there were some limitations that can be found in this study where bias in selection due to rejection of some potential subjects to participate. Other than that, the use of different assessment measures for bot patients and nurses might have influenced the results and factors relating to nurses' workload pressure and rapport with patients were not investigated comprehensively which also might have impacted on accuracy of needs or symptoms recognition. Lastly, caution should also have been exercised before applying the results to patients with other characteristics.

2.4 Associated of sociodemographic with supportive care needs

According to the studies done by the Boyes et al (2000) on the unmet supportive care needs of patients with cancer in Australia, results had suggested that cancer patients continue to experience high levels of unmet needs across a range of domain.

In this study, age had been associated with higher levels of unmet need in psychological, patient care and support, health system and information and sexuality domains. This is proven as results showed cancer patients ages between 31-60 years consistently displayed higher levels of unmet need compared to those age of 70 years and above. This finding was said to be consistent with other research in which

conclude that cancer and its treatment has a greater impact of psychosocial of younger patients than older patients. Therefore, this can be conclude that younger people might be more amenable to disclosing the psychosocial needs compared to older adults who believed that they should be able to cope and keeps their needs in private.

A significant predictor of reporting some unmet need in the psychologic, patient care and support, and physical and daily living domains. The differences in the prevalence of unmet needs that been observed compared with other studies is had been expected as the patient samples that they have obtained mainly from only one treatment centre. This had reinforcing the importance of sampling across different groups.

Furthermore, the type of treatment received in the last month also was associated with some needs in both the health system and information domain and the sexuality domain. The finding in this study had shown that patients who receiving immunotherapy, chemotherapy or hormone therapy were likely to report higher sexuality needs compared to those receiving other treatments. This may be due to the physical side effects of the treatments received.

The duration of time of cancer site currently receiving treatment from the diagnosis were also found to affect the needs in the patients care and support domain. This study shows patients with multiple cancer sites such as at lung, colon, rectal carcinoma or a brain tumour had higher levels of unmet need as compared to the breast carcinoma patients. Other than that, the duration since the last admission for treatment was also found to predict some needs in the physical and daily living domain. Finding shows patients who had last attended the clinic more than a year ago were less likely to report the needs in physical and daily living compared to patients who had attended

in the last month. This finding might had reflect a familiarity of patients with the treatment process and its side effects. Other than that, the likelihood that those who last attended to the clinic more than a year ago may not having in an intensive phase of active treatment.

According to study done by Carlson et al. (2004) on high level of untreated distress and fatigue in cancer patient, 37.8% of 2776 representative cancer patients met criteria for general distress in the clinical range in which results show most men has high proportion for somatisation whereas women for depression. However, both gender have no differences in anxiety or severity in distress. In addition, almost half of all patients who met distress criteria had not sought professional psychosocial support. This shows that distress is very common in cancer patients across diagnoses and disease but those who are reported having high level of distress are not taking advantage of available supportive resources. However, further exploration need to be done in order to collect more information on factors predicting distress among cancer patients and use of psychological care in order to meet their needs in surviving with the disease.

Differences in demographic characteristics and psychosocial among each cancer patients may influence supportive care needs. Therefore, the first step that should be taken part in order to provide correct supportive care is by identifying the significant relationship between demographic characteristics and level of supportive care need as this is essential in order to provide high-quality care and patients' satisfaction.

A systemic review study had been done by James et al in 2008 on the unmet supportive care needs of people with cancer. Of 94 articles or report that have

documented the unmet needs of patients with cancer during their illness, 57 of these had quantified unmet need. The highlight of these study were people that affected by cancer have a range of unmet needs. However, quantifications of these needs presents considerable challenges as does obtaining a clear idea of the prevalence of need within each supportive care domain.

Across all time points and varied within and between studies, the prevalence of need was highly variable in all domains which ranging from 1% to 93%, where those in the activities daily living domain shows the most frequently reported unmet needs which ranging from 1-73%. These results were followed by psychological domain which ranging from 12-85%, information domain (6-93%), psychosocial domain (1- 89%) and physical domain (7-89%). However, communications and sexuality domains were least frequently investigated which both ranging from 2-57% and 33- 63% respectively.

However, according to this study, unmet needs in all domains varied at all time points as given that needs were ascertained using a variety of different type of methods and there was only one study prospectively measured needs over time. Therefore, it is not possible to assess the degree to which needs change along the cancer illness trajectory. However, there were some trends emerged

from the data, for example, the highest levels of unmet need for most domains were identified during treatment. Other than that, the prevalence of unmet need for each domain had the largest variation during treatment phase as compared to any other time point of cancer illness. For most domains, however, the lowest prevalence of unmet need was found to be the highest for patient that had complete the treatment. This results had proven that unmet needs are more likely to be found in a larger proportion of people at this time point. However, these trends are likely due to the fact a greater number of studies have been conducted

at bot treatment and post-treatment for people at that time points compared to other stages of cancer illness. Therefore, a lack of evidence had been highlighted in this study review regarding the unmet needs of people newly diagnosed with cancer with only three studies identified.

Anxiety and fears about the cancer spreading or returning were identified as the most commonly psychosocial issues among patients, which particularly during the treatment and post-treatment phases. They were concerned about how those closest to them were coping with their disease. Adequate information about managing the side effects of treatment were also one of the important areas where information provision was found to be inadequate where practical assistance within the home were also regularly noted as areas where improvements could be made at the treatment and post- treatment stage. This suggest that ongoing support when patients are not in direct contact with health system or living in the community, receiving treatment or post- treatment are currently areas where supportive care needs is lack. There is also evidence to suggest people with more advanced stages of disease or with poor health status are more likely to have unmet needs.

This study had also proves that heterogeneous samples in terms of cancer patients' site and stages used within most studies had causes difficulty in making interpretation since broad and heterogeneous sample often utilised for pragmatic reason which provide a valuable picture of the challenges facing cancer patients in general but may overlook disease and stage specific issues. In facts, studies that investigated cancer specific site unmet needs during the treatment and post-treatment phase generally reported higher levels of unmet need compared to studies that used mixed cohort of patients. Therefore, these results had suggests that assessment should be conducted

with a homogenous sample of patients and could provide a more detailed analysis of tumour-specific unmet needs.

In conclusion, this systemic review study had proved that prevalence of unmet need, their trends and predictors are highly variable in all domains at all time points of the cancer illness which suggests that relying on data from elsewhere to plan cancer services or interventions in order to reduce unmet need may not appropriate. The results of highest unmet needs appeared during treatment and post-treatment phase however is likely due to the fact that this is where current efforts to identify unmet needs have been directed. The focus of studies at a single time point during illness trajectory also does not take into account on how unmet needs may change over time. Other than that, methodological inconsistencies had further compound the issues.

Therefore, in order to improve understanding of the unmet needs, context- specific, well-designed, prospective studies are needed as such studies can investigate the impact of early assessment and management of the unmet needs on subsequent patient outcomes. Other than that, standardisation of measures and reporting methods used would also benefit future interventional

research in order to identify on how best to address the unmet supportive care needs of people with cancer.

A qualitative study done by Salarvand et al in 2016 on priorities in supportive care needs for non-metastatic cancer patients undergoing chemotherapy in Iran according to oncologist' perception shows that it is essential to have education and consultation for cancer patients undergoing chemotherapy. This is due to the necessity for increased self-management capabilities of patients in controlling chemotherapy side effects, increasing their compliance with the disease and increasing their adherence to the treatment. Moreover, education empowers families to care for their

patients. This results is similar with previous studies done in 2004 by Epping-Jordan JE on improving the quality of health care for chronic conditions which also confirmed that issues that included the provision of information, patient support and empowering patients and their families to take better care of their diseases and self-management supports are important for improving care and outcome.

In addition, oncologists in this study also noted the need to provide social and treatment supports for the patients in the form of support groups and importance of support from families, friends and health care provider in addition to the consideration of family support. This study has emphasized the importance of support provided by family caregivers, which is consistent with other study which also reveals that each family members, friends and health care providers play an important role in supporting the newly diagnosed cancer patients undergoing chemotherapy as this can encourages patients to cope with their disease and its treatment (McCarthy et al, 2015).

This study also have shown that it is necessary to address cultural conditions for these patients is areas that include cultural change, attempts to reduce cultural cancer-related stigma in the society and taking into account cancer-related stigma of cancer. Other than that, this study also emphasized the importance of psychological support for patients as this factors have been reported as major determinants that specify supportive care needs of cancer patients, has been revealed by previous study done by Armes et al in 2009 on patients' supportive care needs beyond the end of cancer treatment.

In term of financial support, participants have noted that the role of financial support by charitable organizations and donors is undeniable in patient support and can reducing the financial burden of the treatment. Regarding the need for

multidisciplinary care teams, there is no such approach in Iran's health care culture, as revealed in this study. Oncologists noted the need for development and improvement of the physical environment of health care settings in order to provide services to those undergoing chemotherapy. However, this study did not find any other study that addressed this issue.

The limitation of this study was none of the oncologist had explained sexual care for patients which should be necessitated a multidisciplinary team in caring for these patients. They also did not consider spiritual care for these patients to be a priority since most likely because the Iranian community is predominantly an Islamic, a religious society and they have spiritual care available.

According to studies done by Whye et al (2016), on the supportive care needs of prostate cancer patients in Sarawak, the findings indicated that no significant difference between older and

younger age groups in all five domains of supportive care needs except for psychology and sexuality needs, younger patients had higher needs in sexuality compared to older patients.

In terms of psychological needs, those who were in the older age experienced lower distress level as compared to younger age group. This may be because of less work and families responsible as they grew older.

Higher educational level patients also had showed that they have the highest needs in all domain except physical and daily living. They are more likely to employ active information in order to satisfy their information needs. As they knew about their cancer stages, patients showed greater level of needs in the health and information as compared to those who did not know what stage of cancer they are having. This finding could be due to the nature of patients' information needs that associated with their

stage in the cancer journey as different information needed during different period of stages.

Thus, in response to previous studies, this study will be conducted using homogenous sample of patients which only take those who are treated as outpatient in order to address a more detailed analysis of tumour-specific unmet needs. This include those with advanced stages of disease and poor health status that currently undergoing chemotherapy in UMMC which are more likely to have unmet needs other than those who had newly been diagnosed with cancer.

2.5 Summary

This chapter had explained the search strategies and discussion of relevant literature review as this literature review is to guide the researcher to have better understanding on the current research topic that will be conducted. Other than that, by literature review also will helps to plans future study methodology by referring the previous studies that had been done.

CHAPTER 3: METHODOLOGY

3.0 Introduction

Research methodology is the process used to collect information and data for the purpose of making decisions. It deals with a range of ways to make the most out solving key research problems which composite of philosophies, ideas, and foundations that drive the actions, the methods that will be used. Therefore, this chapter describes the study design and provides a rationale for the selection of population and sampling setting, instrumentation, and method of data collection. Other than that, the formulation of a research design and methodology also will be described and explained.

3.1 Study design

This is a cross sectional design study to collect data on supportive care needs on patient undergoing chemotherapy in UMMC. Quantitative research is a present- oriented research that seeks to accurately describe what is and to analyse the facts obtained in relation to the problem

under study. This type of research may lead to theories or hypotheses to be tested experimentally.

3.2 Study setting

The study was conducted in University Malaya Medical Centre (UMMC). UMMC is a renowned premier teaching hospital with 980 beds under the Ministry of Education in Malaysia (University Malaya Medical Centre, 2013)

The study setting was restricted to clinic that consist of cancer patients who undergoing chemotherapy at Infusion Room, Day-Care Medical in University Malaya Medical Centre (UMMC). This is done in order to obtain a homogenous sample.

3.3 Population and sampling

3.3.1 Target population

Target population which are accessible were all cancer patients undergoing chemotherapy in UMMC. UMMC is a referral centres recorded an average of 1250 new cancer cases in 2016.

A number of 150 cancer patients a day, have been diagnosed with cancer, being physically and mentally willing and able to complete the questionnaire and currently undergoing chemotherapy for the following cancers were recruited; respiratory, haematology, gynaecology, orthopaedic, breast, prostate and colorectal. This included only out-patients who are undergoing chemotherapy in UMMC.

3.3.2 Sampling method

Sampling is the process of selecting a number of individuals for a study in such a way that the individuals represent the larger group from which they were selected. The purpose is to gather data about the population in order to make an inference that can be generalized to the population. Therefore, a sample, then, is a subject of population elements. A representative sample is one whose key characteristics closely approximate those of the population. In this study, researcher used simple random sampling method, a type of probability sampling that ensures that each element of the population has an equal and independent chance of being chosen as the population is small, homogenous and readily available in the setting area, which consists of only out-patients cancer who are undergoing chemotherapy in Infusion Room, Day-Care Medical in UMMC.

3.3.3 Sample calculation

The sample size was calculated using Raosoft Sample Size Calculator (2004) calculator. The calculation was based on an estimated total average population size of 1250 new cancer cases treated at the UMMC annually in 2016, with margin for error of 5% confident interval of 95%, respondent distribution of 50% and the minimum recommended sample size was 295. From the sample size calculation, to avoid drop outs and missing data, 20% was added. Thus, total sample size is 354 of cancer patients will be recruited.

3.3.4 Inclusion and exclusion criteria

Participant selection was based on the following criteria:

1. More than 18 years old
2. Undergoing chemotherapy at outpatient chemotherapy day care in UMMC
3. Able to read and understand English and Bahasa Malaysia
4. Being physically and mentally willing and able to complete the questionnaire

3.4 Research instrument

Research instrument is device used in order to collect data. In this study, the research instrument used to collect data is by using questionnaire. The questionnaire consisted of two main parts. Part I comprised questions that solicited the demographic characteristics of the patients. Part II consisted of questions related to Supportive Care Needs Survey Short Form 34 (SCNS-SF34) that has been modified and validated by 3 experts. Part III consisted of self-construct questions on usefulness of sources supportive care.

3.4.1 Questionnaire

The questionnaire were developed with permission from the previous study of Allison Boyes in 2012 and from the Short-form Supportive Care Needs Survey (SCNS-SF34) designed by Centre for Health Research and Psycho-oncology (CHeRP), Cancer Council, New South Wal. The language used in this questionnaire is English and Bahasa Malaysia.

Part A Sociodemographic Background

Part A consisted of 10 open and closed-ended format items. The items include questions that were design to determine basic sociodemographic and clinical characteristic related to disease such as age, gender, ethnicity, religions, educational level, marital status, employment status, household income, diagnosis, cancer stage at time of diagnosis, and staging of cancer. Each questions were using nominal scale.

Part B Short-form Supportive Care Needs Survey (SCNS-SF34)

Part B encompassed a modified and validated questionnaire (34 items) adopted from Short-form Supportive Care Needs Survey (SCNS-SF34). It is a valid instrument for measuring cancer patients' perceived needs across a range of five domains which are psychological needs (10 items), health system and information needs (11 items), physical and daily living needs (5 items), patient care and support needs (5 items)and sexuality needs (3 items).

- The psychological domain assesses needs related to emotions and coping.

This domain consists of 10 items.

- The health system and information domain assesses needs related to the treatment centre and for information about the disease, diagnosis, treatment and follow-up. This domain will be presented by 11 items.
- The physical and daily living domain assesses needs related to coping with physical symptoms, side effects of treatment and performing usual tasks and activities. In this domain, 5 items will be presented.
- The patient care and support domain assesses need related to health care providers showing sensitivity to physical and emotional needs, privacy and choice. This domain will be represented with 8 items.
- The sexuality domain assesses needs related to sexual relationships. This domain is represented by only three items in which will be questioned about the changes in sexual feelings and relationship other than in need to be given information on sexual relationship while undergoing treatment on cancer.

Participants were presented with a 5-point Likert-type response format (1 - not applicable; 2 - satisfied; 3 - low need; 4 – moderate need; 5 – high need). Separate analyses using SPSS software were done for each of the five domain.

Section C Usefulness of Source Supportive Care Needs

Section C consists of 14 items that assessed participants' sources of supportive care needs presented with a 5-point Likert-type response format (1 - not useful at all; 2 – not useful; 3 – not sure; 4 – useful; 5 – very useful).

3.4.2 Reliability and validity

Validation studies have shown that the Cronbach's alpha of the English version was 0.86-0.96 (Boyes et al, 2009). The factor structure of this short-form survey explained more than 70% of the variance with the internal reliability of items within each factor was assessed with the coefficient criteria set of 0.7 and exceeded 0.8 in all domains. This demonstrating good construct of validity to be used as an instrument for this research. It provides brief and valid information about cancers' patient needs in which enable the health care professionals to improve their care to specific needs identified by their patients. In addition, this 34-item SCNS questionnaires will takes up approximately 10 minutes for the respondents to complete.

In order to makes sure that the study is warranted and feasible to the cancer patients in UMMC, a pilot study was conducted. This was done once the researcher has get the ethic approval from UMMC and validation by experts done which consist of a lecturer from Department of Nursing Science, one sister from Department of Clinical

Oncology who is specialised and in charged in Chemotherapy Day-Care clinic UMMC and a lecturer from Department of Oncology.

3.5 Data collection method

On the date of the data collection, the researcher asked the patient if they were keen to participate in the study. Not all patients were compulsory to participate in this study. They may refuse if they do not want to. Those who were agree to take part in the study were thanked. Each respondents were given clear and detail information regarding the purpose and benefits of the study. Time estimated to complete the questionnaire are within 20 minutes. Respondent had right to withdraw from the study any time without any reasons and punishment from the researcher.

Other than that, all the respondents were assured that all data that has been collected will be kept as confidential and will be only for academic purpose. The researcher then distributed the questionnaire to the patients who are agree to participate and they were asked to sign the consent form which will be attached to the questionnaire. Since most of the respondents were undergoing chemotherapy during this study was held, therefore, they were having difficulty in answering by themselves. For that, an interview were done as to make things easier. Furthermore, the researcher encouraged the respondents for any unclear statement. The researcher was available throughout the data collection time.

After the data has been collected, the researcher checked the returned questionnaire one by one. This was to make sure that all items has been answered and to avoid any missing data. The returned questionnaire then were numbered to make sure the amount of sample achieved. All the patients will be thanked for the participation in the study.

3.6 Data analysis

The questionnaire was processed and numbered. All the response were filled up according to variables and analyse by using SPSS. Sociodemographic data in Part A will be analyse and presented with frequency and percentage in Chapter 4 later. For part B, for each item, respondents were asked to indicate their level of need for help over the last month as a result of having cancer by using the five point Likert Scale. The five response options are described as follows: **1=No need, Not applicable** (This was not a problem for me as a result of having cancer.), **2=No need, Satisfied** (I did need help with this, but my need for help was satisfied at the time.), **3=Some need, Low need for help (**This item caused me little concern or discomfort, I had little need for additional help.), **4=Some need, Moderate need for help (**This item caused me some concern or discomfort. I had some need for additional help.), and **5=Some need, High need for help (**This item caused me a lot of concern or discomfort. I had a strong need for additional help.)

In the Supportive Care Needs Survey Short For 34 (SCN-SF34), separate analyses using SPSS software were done for each of the five domain. The domain score, the average score for all items in the domain was calculated for those respondents who answered all items within domain. Domain scores were calculated by summing up the responses to each of the needs items within each domain and dividing the total by the number of items in the domain. The domain score was the dichotomized, with a score one correspond to “no need” and a score two correspond to “some need”.

The data was being analysed by using Pearson Chi Square test and Cross tabulation in order to identify the significance relationship between demographic characteristics and level of supportive care need of cancer patients undergoing chemotherapy in UMMC.

For part C, for each item, respondents were asked to indicate the usefulness of source supportive care from sources as listed using the five point Likert Scale. The five response options are described as follows: 1= Not useful at all, 2=Not useful, 3= Not sure, 4= Useful and 5= very useful.

3.7 Ethical consideration

The researcher had looked into all ethical issues for this study. Before starting the survey, an approval letter with ethic consideration was sent to the UMMC in order to get permission to do this survey to the patients undergoing treatments there. Once the permission had been approved, only then the survey will be conducted.

The respondents were given assurance of confidentiality of this research. A brief and well-explained instruction was given to the respondents before they started answering the survey. This was done by stating the information on the cover letter of the questionnaire. Not to mention, the cover letter that include the researcher's identification and purpose of the study will enclosed the questionnaire. This wasdone in order to instruct and inform the respondents on how to answer the questionnaire correctly. Consent also had been given before answering the questionnaire. Moreover, target samples have their right to not participate in the research or withdraw any time. In order to ensure that the feedback received from the questionnaire remains confidential, at the same time protecting all respondents' identity, all the answered questionnaire that has been returned back will be kept properly in a covered box and be kept.

3.8 Pilot study

According to Collins English Dictionary, pilot study is a small-scale experiment or set of observations undertaken to decide how and whether to launch a full-scale project. To simplify, it is a trial run before the actual research study is done. The study will be done to a group of people that have similar condition to the subjects that should be tested. This pilot study is conducted whenever a new instrument is being develop or when a pre-existing instrument is being used with people that have different characteristics from those for which the instrument was originally developed. The purpose is to help the researcher to determine whether a more substantial study is warranted and the researcher will be able to take a pragmatic view on the main study's potentialities and feasibility.

As the instruments was being modified from Australia, thus, in order to make sure the reliability and validity of the instruments to cancer patients in Malaysia especially in UMMC, pilot study was done from June to September 2018. 36 cancer patients who undergoing chemotherapy in UMMC were chosen to participate in this pilot study. They were identified in order to prevent any repetition of sample answering the same questionnaire during the actual survey later.

The results from the pilot study were analysed by using reliability test Cronbach's alpha in IBM SPSS Statistics 23. The Cronbach's alpha of the overall questionnaire was 0.906, Section B was

0.863 and Section C was 0.899. Participants who had answered the questionnaire were not be taken into consideration again for the actual survey participation. Since the questionnaire was reliable, there was no major changes made on questionnaire before collecting data for actual study. Only that a dropped out of an item (no. 13) in section C; the usefulness of source supportive care (mobile apps for cancer patients) were since the item were not exposed to the patients yet as proved by during the pilot study.

3.9 Summary

This chapter had been organized to include introduction, study design, study setting, population and sampling, research instrument, data collection method, data analysis, ethical consideration, pilot study and summary. It explains the study design which answer the objective that has been constructed. Furthermore, the purpose of planning methodology is as to make sure this study is in the proper track. Therefore, correct methodology will enhances the data collection in which will later be interpreted in the chapter 4.

Population and sampling enables the researcher to study the population based on the subset that has been choose as targeted sample. Online software named Raosoft has been used to calculate the sample size. Furthermore, it is important to make sure research instrument to be reliable and valid. Thus, pilot study and validation from experts had been explained. Data collection was done systematically in order to make sure all items in the questionnaire will be answered truthfully along with the consent for the participants.

Chapter 4 DATA ANALYSIS

4.1 Introduction

This chapter describes the analysis of data that had been collected. The researcher entered the data and performed analysis by using Statistical Package Social Science (SPSS) version 23.0. The findings relate to research objectives that guided this study. The descriptive statistics and inferential statistics were included according to specific objectives as stated in Chapter 1. Data were analysed to determine supportive care needs of patients with cancer undergoing chemotherapy in UMMC. Researcher had used the descriptive statistics in analysing the demographic data of the respondents, as well as the supportive care needs and usefulness of source supportive care among the cancer patients undergoing chemotherapy in UMMC. Other than that, Pearson Chi- Square test also was used in order to analyse the association between respondents' demographic characteristics data and knowledge. All the results that has been analysed were written in narrative explanation and displayed in form of table. Several aspects has been included in this chapter:

- Data screening and data management
- Response rate during data collection
- Description of demographic data, supportive care needs and usefulness of source supportive care among respondents
- Description of association between supportive care needs of cancer patients and demographic variables of the patients with cancer undergoing chemotherapy in UMMC.

4.2 Data screening and data management

Data were collected and screened in order to be processed for the data analysis. Data were screened for any missing data, 2 responses when only 1 was represented and mark between 2 answers. Any of these data would be discarded. This is in order to produce better quality of data. Thus, in the initial stage of data analysis, all the data collected were entered based on the identification numbers tagged to the questionnaire with accordance to the respondents' identification to avoid double entry. All the data were then screened and no missing values detected. Next, all the screened data was entered into SPSS to be analysed as well back up for documentation. All the hardcopy of the data that has been collected was stored in a bag for storage purpose.

Data was managed and checked for distribution by using normality tests in order to determine the type of analysis test used to analyse data. In this study, the dependent variables were supportive care needs and usefulness sources of supportive care. Normality tests show normality distributed for supportive care needs scores as both kurtosis and skewness were less than ±1.96 (.816 for skewness and 1.319 for kurtosis). Kolmogorov-Smirnov test of normality for supportive care needs results also show normally distributed as the p value shows $p<.05$. For usefulness sources of supportive care, the results shows normally distributed as evidenced by skewness .368 and kurtosis -1.097 with Kolmogorov- Smirnov test shows $p<.05$. All the results can be refer in table 4.1. Therefore, non-parametric test: Pearson Chi-square will be used to analyse the data as it is unaffected by distribution of data.

Table 4.1 Normality test

	Kolmogorov-Smirnov		**Skewness**		**Kurtosis**	
	Statistic	**p-value**	**Statistic**	**Std. Error**	**Statistic**	**Std. Error**
Supportive care needs	.153	.001	.816	.141	1.319	.281
Usefulness of source supportive care	.146	.001	.368	.141	-1.097	.281

4.3 Respond rate

A total of 354 questionnaire were distributed by researcher through face to face with the respondents and collected back on the same day. However, out of 354 patients, only 300 patients completed and returned the questionnaires (n=354), whereas the remaining were discarded as some of the respondents were not able to complete the questionnaire. This represented a response rate of 84.75%. Researcher's personal approach to the respondents had ensured the 84.75% respond rate. The flow of distributed questionnaire was displayed as shown on figure 4.3.1 below:

Calculation for response rate:

$$\text{Response rate} = \frac{\text{Total completed questionnaire}}{\text{Total distributed questionnaire}} \times 100\%$$

$$= \frac{300}{354} \times 100\%$$

$$= 100\%$$

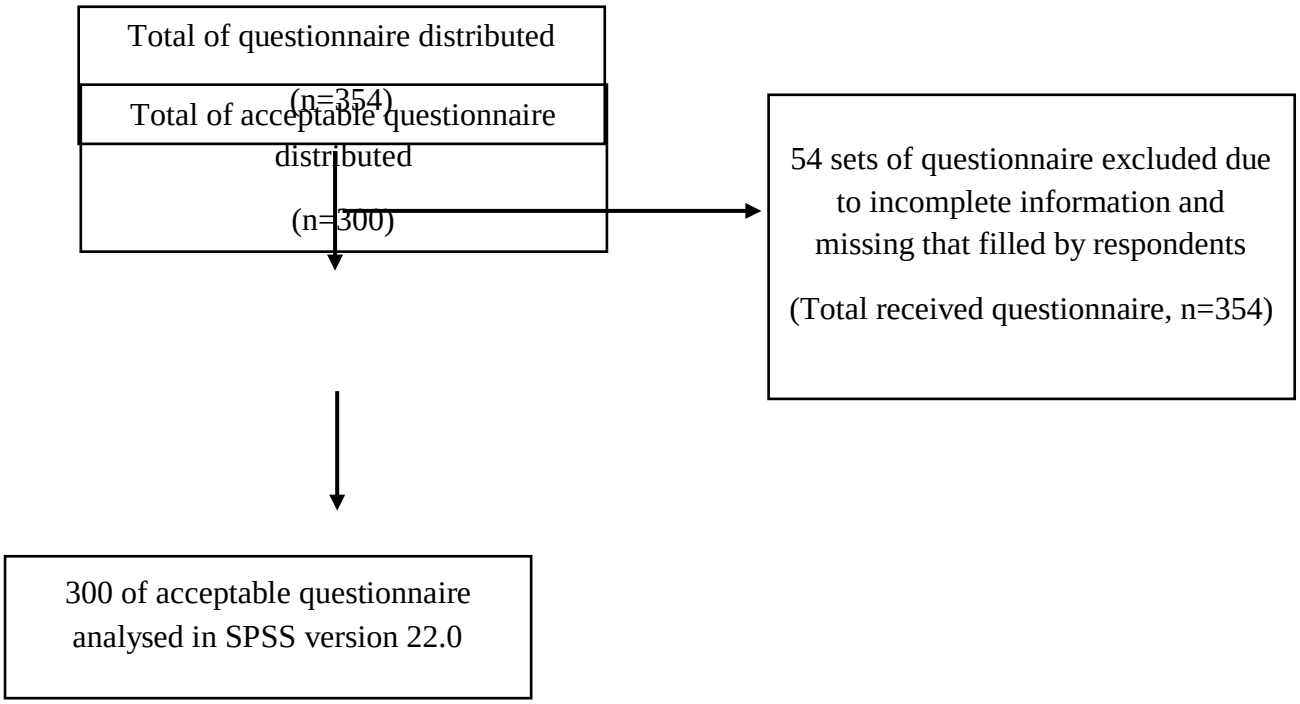

Figure 2 Flow of selected distributed questionnaire

4.4 Description of demographic of the respondents

In this study, the demographic characteristics data included age group, gender, ethnicity, religion, marital status, formal education, employment status, household income, type of cancer and cancer stage at time of diagnosis. Table 4.2 displays the details of demographic characteristics of the respondents. This study recruited a total of 300 respondents. From the table, it shows that age group of more than 56 occupied highest percentage that is 40.7% (n=122) while age group of 18 to 36 had the lowest percentage in this study that is 23.3% (n=70). In term of gender, female contributed a total of 163 out of 300 in this study which accounts about 54.3% compared to male which was only 137 that accounts about 45.7%.

In term of ethnicity, there were four ethnicity that were put in to account, which were Malays, Chinese, Indians and others. From the table, it shows that 125 of respondents from Malays ethnicity contributed the highest percentage (41.7%) in this study, whereas 5 of respondents from other ethnicity contributed the lowest percentage (1.7%). Besides that, for religion aspect, there were 128 (42.7%) of respondents from Islam which contributed the highest percentage, while there were only 38 (12.7%) respondents from Christianity which contributed the lowest percentage of the respondents. This result shows that the majority of the respondents were from Islam religion.

There were 46.3% (n=139) respondents were married which has contributed the highest percentage among respondents, while only 17.3% (n=52) respondents were widowed, which contributed the lowest percentage of the respondents. Other than that, in term of employment status, there were 153 respondents who are employed which contributed highest percentage (51.0%), whereas 59 respondents were unemployed which contributed the lowest percentage (19.7%). There were 208 (69.3%) respondents had average monthly income above RM3000 which contributed the highest percentage among the respondents, while only 9 (3.0%) had average monthly income above RM5000 which contributed the lowest percentage of the respondents. This shows that the majority of the respondents were having monthly income above RM3000.

In term of type of cancer, there were four type of cancer that were put in to account, which were breast, colorectal, haematological and other. As shown in table 4.2, it shows that 96 of respondents from breast cancer type contributed the highest percentage (32.0%) in this study, whereas 55 of the respondents from haematological cancer type contributed the lowest percentage (18.3%). Besides that, there were 125 (41.7%) of respondents were at late stage (III and IV) of cancer at time of diagnosis from which contributed the highest percentage, while there were 66 (22.0%) respondents do not know their cancer stage at time of diagnosis which contributed the lowest percentage of the respondents. This result shows that the majority of the respondents were at their late stage of cancer at time of diagnosis.

Table 4.2 Sociodemographic and medical characteristics of respondents (N=300)

Sociodemographic and medical characteristics	**n**	**%**	**Mean (SD)**
Age (years)			48.82 (13.17)
18-36	70	23.3	
37-55	108	36.0	
56 and above	122	40.7	
Gender			
Female Male	163	54.3	
	137	45.7	
Ethnicity Malay Chinese Indian

	125	41.7	
	66	22.0	

4.5 Level of supportive care needs of patients with cancer undergoing chemotherapy

In the Supportive Care Needs Survey Short For 34 (SCN-SF34), separate analyses using SPSS software were done for each of the five domain. As been mentioned before, the domain score, the average score for all items in the domain was calculated for those respondents who answered all items within domain. Domain scores were calculated by summing up the responses to each of the needs items within each domain and dividing the total by the number of items in the domain. The domain score was the dichotomized, with a score one correspond to "no need" and a score two correspond to "some need". In this study, the minimum and maximum score were 34 and 121. Table 4.3 shows the list items of patients' level of supportive care and information and patient care and support. The highest mean score for the item of needs and its representative mean score and standard deviation (SD). The items were grouped into five domains which are psychological, physical and daily living, sexuality, and health system and information domain. The highest level of supportive care needs is item in psychological domain, "Uncertainty about the future" where the mean score is 1.84 with standard deviation of .37. Meanwhile, the lowest mean score for the item on patient's level of supportive care needs is item in health system and information domain, "Being given information (written, diagrams, drawings) about aspects of managing illness and side-effects at home" where the mean score is 1.07 with standard deviation of .25.

As shown in the table, in psychological domain, for the item "Anxiety", there are 76% of the respondents chose no need and 24.0% of the respondents chose some need. More than half of the respondents chose no need for the item "Feeling down or depressed" which are 88.3% whereas another 11.7% respondents chose some need.

Next, there are 235 of them response no need for the item "Feelings of sadness" whereas another 65 of them chose some need. For the item "Fears about cancer spreading", all of the respondents response no need of supportive care needs. There are only 95 respondent out of 300 respondents response no need for the item "Worry about the results of treatment are beyond your control", whereas 205 of the respondents chose some need. Next, for the item "Uncertainty about the future", only 16.0% of the respondents' response no need whereas most of them chose some need where the results shows 84.0% of respondents. For the item "Learning to feel in control of your situation", more than half of the respondents chose no need (65.7%) and 34.3% of the respondents chose some need. Out of 300 respondents, 222 of them chose no need for the item "Keeping a positive outlook" and only 78 respondents chose some need. There are only 91 out of 300 respondents had response no some need whereas most of the respondents (n=209) chose some need for the item "Feelings about death and dying". For the last item in this domain, 185 of respondents chose no need for the item "Concerns about the worries of those close to you" and 115 respondents chose some need.

In physical and daily living domain, for item "Pain", 205 out of 300 respondents chose no need and the other 95 respondents chose some need. For the item "Lack of energy/tiredness", half of the respondents chose no need (n=153) and 147 of respondents chose some need. Next, among 300 respondents, there are 237 respondents chose no need for the item "Feeling unwell a lot of time" whereas 63 of the respondents chose some need. For the item "Work around home", more than half of the respondents chose no need (82.0%) whereas 18.0% of the respondents chose some need on this item. Lastly, 84.0% of the respondents chose no need and 16.0 %

of the respondents chose some need for the item "Not being able to do things that used to be".

In sexuality domain, among 300 respondents, more than half of the respondents had choose no need for the item "Changes in sexual feelings" whereas another 61 respondents chose some need for the item. For the item "Changes in sexual relationship", there are 243 of the respondents chose no need for the item and 57 respondents chose some need. Lastly, most of the respondents chose no need for the item "Being given information about sexual relationship" which contributed 85.0% of the results whereas 15.0% of them chose some need.

In health system and information domain, majority of the respondents had chosen no need for the item "Being given written information about important aspects of care" which results in a total of 270 of respondents whereas another 30 respondents chose some need for the item. Majority of the respondents also had chosen no need for the item "Being given information (written, diagrams, drawings) about aspects of managing illness and side-effects at home" which results in a total 93.3% of respondents whereas another 6.7% of the respondents chose some need. Other than that, out of 300 respondents, a total 275 of the respondents chose no need for the item "Being given explanations of those tests for which you would like explanations" and another 25 respondents chose some need. Only 27 of the respondents had choose some need for the item "Being adequately informed about the benefits and side effects of treatments before choosing to have them" whereas 273 of the respondents chose no need. There are 87.0% of respondents had response no need and 13.0% of the respondents had response some need for the item "Being informed about test results as soon as possible". Of 300 respondents, 80.0% of respondents had choose no need for the item "Being informed about cancer which is under control or diminishing (that is, remission)' whereas another 20.0% chose some need for this item. There are 76.7% of the respondents chose no need for the item "Being informed about things you can do to help yourself to get well and 23.3% of the respondents chose some need. Next, Out of 300 respondents, there are 254 of the respondents chose no need for the item "Having access to professional counselling (eg; psychologist, social worker, counsellor, nurse specialist) if you, family or friends need it" and 46 of them chose some need. There are 277 of the respondents chose no need for the item "Being treated like a person not just another case" and another 23 respondents chose some need for this item. For item "Being treated in a hospital or clinic that is as physically pleasant as possible", majority of the respondents chose no need and only 8 respondents chose some need. Lastly, for the item "Having one member of hospital staff with whom you can talk to about all aspects of condition, treatment and follow-up", there are 271 of the respondents had response no need whereas only 29 respondents chose some need for this item.

For the last domain which is patient care and support domain, out of 300 respondents, there are 192 of respondents chose no need for the item "More choice about which cancer specialists to see" whereas 108 of the respondents chose some need for this item. For the item "More choice about which hospital to attend", more than half of the respondents had response no need which results in a total of 266 of the respondents and another 34 of the respondents response some need for this item. Majority of the respondents had chosen no need for the item "Reassurance by medical staff that the way you feel is normal" which results in a total of 91.0% whereas another 9.0% respondents chose some need. Next, 87.3% of respondents had choose no need for the item "Hospital staff attending promptly to your physical needs" whereas another 12.7% of them chose some need on this item. Lastly, more than half of the

respondents had response no need for the item “Hospital staff acknowledging and showing sensitivity to your feelings and emotional needs” which is 69.3% and 30.7% of the respondents had response some need on this item.

Table 4.3 Patients’ response for level of supportive care needs (n=300)

Total domain level	**No need n(%)**	**Some need n(%)**	**Mean**	**SD**
Psychological			2.39	.60
Anxiety	228 (76.0)	72 (24.0)	1.24	.43
Feeling down or depressed	265 (88.3)	35 (11.7)	1.12	.32
Feelings of sadness	235 (78.3)	65 (21.7)	1.22	.41
Fears about cancer spreading	98 (32.7)	202 (67.3)	1.67	.47
Worry about the results of treatment are beyond control	95 (31.7)	205 (68.3)	1.68	.47
Uncertainty about the future	48 (16.0)	252 (84.0)	1.84	.37
Learning to feel in control of your situation	197 (65.7)	103 (34.3)	1.34	.48
Keeping a positive outlook	222 (74.0)	78 (26.0)	1.26	.44
Feelings about death and dying	91 (30.3)	209 (69.7)	1.70	.46
Concerns about the worries of those close to you	185 (61.7)	115 (38.3)	1.38	.49
Physical and daily living			1.95	.48
Pain	205 (68.3)	95 (31.7)	1.32	.47
Lack of energy/tiredness	153 (51.0)	147 (49.7)	1.49	.50
Feeling unwell a lot of time	237 (79.0)	63 (21.0)	1.21	.41
Work around home	246 (82.0)	54 (18.0)	1.18	.39.
Not being able to do things that used to be	252 (84.0)	48 (16.0)	1.16	.37
Sexuality			1.60	.73
Changes in sexual feelings	239 (79.7)	61 (20.3)	1.20	.40
Changes in sexual relationship	243 (81.0)	57 (19.0)	1.19	.39
Being given information about sexual relationship	255 (85.0)	45 (15.0)	1.15	.36

Table 4.3 continued

Total domain level	**No need n(%)**	**Some need n(%)**	**Mean**	**SD**
Health system and information			1.95	.47
Important aspects of care	270 (90.0)	30 (10.0)	1.10	.30
Information about aspects of managing illness and side-effects at home	280 (93.3)	20 (6.7)	1.07	.25
Explanations of those tests need explanations	275 (91.7)	25 (8.3)	1.08	.28
Informed about the benefits and side effects of treatments before choosing to have them	273 (91.0)	27 (9.0)	1.09	.29
Test results as soon as possible	261 (87.0)	39 (13.0)	1.13	.34
Cancer which is under control or diminishing	240 (80.0)	60 (20.0)	1.20	.40
Things can do to help to get well	230 (76.7)	70 (23.3)	1.23	.42
Having access to professional if needed	254 (84.7)	46 (15.3)	1.15	.36
Treated like a person not just another case	277 (92.3)	23 (7.7)	1.08	.27
Treated in a hospital or clinic that is as physically pleasant as possible	292 (97.3)	8 (2.7)	1.03	.16
Having one member of hospital staff whom can talk to about all aspects	271 (90.3)	29 (9.7)	1.10	.30
Patient care and support			2.01	.58
More choice about which cancer specialists to see	192 (64.0)	108 (36.0)	1.36	.48
More choice about which hospital to attend	266 (88.7)	34 (11.3)	1.11	.32
Reassurance by medical staff that the way you feel is normal	273 (91.0)	27 (9.0)	1.09	.29
Hospital staff attending promptly to your physical needs	262 (87.3)	38 (12.7)	1.13	.33
Hospital staff acknowledging and showing sensitivity to your feelings and emotional needs	208 (69.3)	92 (30.7)	1.31	.46

4.6 Domains of needs among patients with cancer

Table 4.4 shows domain mean score that were identified by summing up responses of each items within domain and dividing the sum by the number of item in the domain. A higher score (maximum 4, minimum 1) would indicate higher level of needs in the domain. As shown in the table 4.3, psychological domain was found to have highest mean score which is 2.39 with standard deviation of .60, followed by patient care and support which is 2.01 with standard deviation of .58, physical and daily living which is 1.95 with standard deviation of .48 and health system and information which is also shows mean of 1.95 with standard deviation of .47. Meanwhile, the sexuality domain has the lowest mean score which is 1.60 with standard deviation of .73.

Table 4.5 Top ten highest need reported in the last month among respondents

Rank	Item	% of sample reporting some need	Domain
1	Uncertainty about the future	84.0	Psychological
2	Feelings about death and dying	69.7	Psychological
3	Worry about the results of treatment are beyond your control	68.3	Psychological
4	Fears about cancer spreading	67.3	Psychological
5	Lack of energy/tiredness	49.7	Physical and daily living
6	Concerns about the worries of those close to you	38.3	Psychological
7	More choice about which cancer specialists to see	36.0	Patient care and support
8	Learning to feel in control of your situation	34.4	Psychological
9	Pain	31.7	Physical and daily living
10	Hospital staff acknowledging and showing sensitivity to your feelings and emotional needs	30.7	Patient care and support

Table 4.5 shows the top 10 items that respondents have indicated some need for help. Overall, 6 out of 10 items of supportive care needs were from psychological domain, 2 items from physical and daily living domain and one item from patient care and support domain.

The highest ranked item were "Uncertainty about the future" (84.0%), followed by "Feelings about death and dying" (69.7%) , "Worry about the results of treatment are beyond your control" (68.3%), "Fears about cancer spreading" (67.3%), "Lack of energy/tiredness" (49.7%), "Concerns about the worries of those close to you" (38.3%), "More choice about which cancer specialists to see" (36.0%), "Learning to feel in control of your situation" (34.4%), "Pain" (31.7%) and "Hospital staff acknowledging and showing sensitivity to your feelings and emotional needs" (30.7%).

4.7 Usefulness of source supportive care

Table 4.6 also shows the details of item analysis of patients' level of usefulness of supportive care. For item "Doctor", none of the respondents had choose not useful at all, not useful and not sure. However, 93 out of 300 respondents had choose useful and 207 of the respondents had choose very useful.

For the item "Nurses", none of the respondents had choose not useful at all and not useful. However, 16 of them chose not sure, 164 of them chose useful and 120 of the respondents chose very useful.

Next, among 300 respondents, there are 12 respondents chose not useful at all for the item "Family member" whereas 5 of the respondents chose not useful. Other

than that, there are 60 of the respondents chose not sure, 190 of them chose useful and 33 of the respondents chose very useful.

For the item "Friend", 17.7% of the respondents chose not useful at all, 12.3% of them chose not useful and 31.7% of respondents chose not sure. Meanwhile, 30.7% of the respondents chose useful and 7.7% of them chose very useful for this item.

There are 98 of the respondents had response not useful at all, 35 of them response not useful, 46 of them had response not sure, 111 of them had response useful and about 10 of the respondents had response very useful for the item "Religion body".

There are only 141 respondent out of 300 respondents' response not useful at all for the item "Website/Internet", whereas 54 of them chose not useful, 26 of them chose not sure, 74 of them chose useful and 5 of them chose very useful.

Out of 300, 164 respondents chose not useful at all for the item "Patient's guide book/ leaflet", 40 of the respondents chose not useful and 19 of the respondents chose not sure. Meanwhile, 75 of the respondents chose useful and only 2 of the respondents very useful.

Of 300 respondents, 167 respondents had choose not useful at all for the item "YouTube", 59 of them had choose not useful, 29 of the respondents had choose not sure, 40 of them chose useful and 5 of the respondents chose very useful for the item.

There are half of the respondents chose not useful at all and 11.0 % of the respondents chose not useful for the item "Social worker". Other than that, 29.0% of the respondents chose not sure, 4.3% of the respondents chose useful and none of the respondents very useful for this item.

Table 4.6 Respondents' response for level of usefulness of source supportive care (n=300)

	Not useful at all n (%)	**Not useful n (%)**	**Not sure n (%)**	**Useful n (%)**	**Very useful n (%)**	**Mean**	**SD**
Doctor	0 (0.0)	0 (0.0)	0 (0.0)	93 (31.0)	207 (69.0)	4.69	.46
Nurses	0 (0.0)	0 (0.0)	16 (5.3)	164 (54.7)	120 (40.0)	4.35	.58
Family member	12 (4.0)	5 (1.7)	60 (20.0)	190 (63.3)	33 (11.0)	3.76	.82
Friend	53 (17.7)	37 (12.3)	95 (31.7)	92 (30.7)	23 (7.7)	2.98	1.20
Religion body	98 (32.7)	35 (11,7)	46 (15.3)	111 (37.0)	10 (3.3)	2.67	1.35
Website/Internet	141 (47.0)	54 (18.0)	26 (8.7)	74 (24.7)	5 (1.7)	2.16	1.30
Patient's guide book/ leaflet	164 (54.7)	40 (13.3)	19 (6.3)	75 (25.0)	2 (0.7)	2.04	1.30
YouTube	167 (56.7)	59 (19.7)	29 (9.7)	40 (13.3)	5 (1.7)	1.86	1.15
Social worker	167 (55.7)	33 (11.0)	87 (29.0)	13 (4.3)	0 (0.0)	1.82	1.00
Medical book and journal	172 (57.3)	59 (19.7)	24 (8.0)	43 (14.3)	2 (0.7)	1.81	1.12
Cancer support group/volunteer	171 (57.0)	39 (13.0)	69 (23.0)	21 (7.0)	0 (0.0)	1.80	1.02
Newspaper or magazine	173 (57.7)	53 (17.7)	44 (14.7)	28 (9.3)	2 (0.7)	1.78	1.05
Television/Radio	168 (56.0)	67 (22.3)	41 (13.7)	24 (8.0)	0 (0.0)	1.74	.98

For the item "Medical book and journal", 172 respondents out of 300 respondents response not useful at all, 59 of them chose not useful, 24 of them chose not sure, 43 of them chose useful and only 2 of the respondents chose very useful.

For the item "Cancer support group/volunteer", there are 57.0% of the respondents chose not useful at all, 13.0% of the respondents chose not useful and

23.0% chose not sure. However, none of the respondents chose very useful for this item.

Next, among 300 respondents, there are 173 respondents chose not useful at all for the item "Newspaper or magazine", 53 of the respondents chose not useful and 44 of the respondents chose not sure. Meanwhile, 28 of the respondents chose useful and only 2 of the respondents very useful.

Lastly, for the item "Television/Radio", 56% of the respondents response not useful at all, 22.3% of them response not useful and 13.7% of them chose not sure. Other than that, 8.7% of the respondents chose useful and none of them chose very useful.

4.8 Association between levels of supportive care needs with demographic characteristics

In determining the association between demographic characteristics data and level of supportive care needs, researcher used Pearson Chi-Square test to evaluate the likely it is that any observed difference between the data sets arouse by chance. The demographic data included were age, gender, ethnicity, religion, marital status, formal education, employment status, household income, cancer type and cancer stage at time of diagnosis. The association between demographic data and level of supportive care needs were displayed in table below.

Table 4.7 shows the summary results of Chi-square test of independence between demographic characteristics and level of supportive care needs. The Pearson's Chi-square test independence suggests that level of supportive care needs was found to have statistically significant association with all demographic characteristic accept religion and formal education of respondents.

None (0.0%) from the age group 18-36, 19 (17.6%) from age group 37 to 55 and 17 (13.9%) from age group 56 and above had no need of supportive care needs. This is indicates that the respondents from age group 37-55 has lowest level of supportive care needs among respondents. The chi-square analyses reveal a significant association between levels of supportive care needs and age group, $X^2(2, N=300) = 13.18$, $p<.05$. Meanwhile, 70 (100.0%) from the age group 18-36, 89
(82.4%) from age group 37 to 55 and 105 (86.1%) from age group 56 and above had some need of supportive care needs. This is indicates respondents from age group 56 and above has highest level of supportive care needs among respondents.
6 (3.7%) from female respondents and 30 (21.9%) from male respondents had no need of supportive care needs. This is indicates that the male respondents hadlowest level of supportive care needs among respondents. The chi-square analyses reveal a significantly association between satisfaction level and gender, $X^2(1, N=300) = 23.39$, $p<.05$. Meanwhile, 157 (96.3%) from female respondents and 107 (78.1%) from male respondents had some need of supportive care needs. This indicates that respondents from female gender has highest level of supportive care needs among respondents.
19 (15.2%) from Malay respondents, 7 (6.0%) from Chinese respondents, 5 (9.3%) from Indian respondents and 5 (100.0%) from other ethnicity had no need of supportive care needs. This is indicates that respondents from Malay ethnicity had lowest level of supportive care needs among respondents. The chi-square analyses reveal a significantly association between satisfaction level and ethnicity, $X^2(3, N=300) = 42.17$, $p<.05$. Meanwhile, 106 (84.8%) from Malay respondents,

109 (94.0%) from Chinese respondents, 49 (90.7%) from Indian respondents and none from other ethnicity had some need of supportive care needs. This indicates respondents from Chinese ethnicity has highest level of supportive care needs among respondents.

19 (14.8%) from Islam religion, 5 (6.3%) from Buddhism religion, 5 (9.3%) from Hindu religion and 7 (18.4%) from Christianity religion had no need of supportive care needs. This is indicates that respondents from Islam religion had lowest level of supportive care needs among respondents. The chi-square analyses reveal not significantly association between satisfaction level and religion, X^2 (3, N=300) = 5.35, p>.05. Meanwhile, 109 (85.2%) from Islam religion, 75 (93.8%) from

Buddhism religion, 49 (90.7%) from Hindu religion and 31 (81.6%) from Christianity religion had some need of supportive care needs. This is indicates that respondents from Malay religion had highest level of supportive care needs among respondents. 5 (4.6%) of single respondents, 23 (16.5%) of married respondents and 8 (15.4%) of widowed respondents had no need of supportive care needs. This is indicates that respondents from married respondents had lowest level of supportive care needs among respondents. The chi-square analyses reveal a significantly association between satisfaction level and marital status, X^2 (2, N=300) = 8.96, p<.05. Meanwhile, 104 (95.4%) of single respondents, 116 (83.5%) of married respondents and 44 (84.6%) of widowed respondents had some need of supportive care needs. This is indicates that respondents from married respondents had highest level of supportive care needs among respondents.

4 (9.3%) from primary education respondents, 27 (15.8%) from secondary education respondents and 5 (5.8%) of tertiary education respondents had no need of supportive care needs. This is indicates that respondents from secondary education respondents had lowest level of supportive care needs among respondents. The chi- square analyses reveal not significantly association between satisfaction level and formal education, X^2 (2, N=300) = 5.74, p>.05. Meanwhile, 39 (90.7%) from primary education respondents, 144 (84.2%) from secondary education respondents and 81 (94.2%) of tertiary education respondents had some need of supportive care needs. This is indicates that respondents from secondary education respondents had highest level of supportive care needs among respondents.

23 (15.0%) from employed respondents, none from unemployed respondents and 13 (14.8%) from retired respondents had no need of supportive care needs. This is indicates that respondents from employed respondents had lowest level of supportive care needs among respondents. The chi-square analyses reveal a significantly association between satisfaction level and formal education, X^2 (2, N=300) = 10.02, p<.05. Meanwhile, 130 (85.0%) from employed respondents, 59 (100.0%) from unemployed respondents and 75 (85.2%) from retired respondents had some need of supportive care needs. This is indicates that respondents from employed respondents had highest level of supportive care needs among respondents.

17 (8.2%) from income less than RM3001, 19 (22.9%) from income between RM3001-RM5000 and none from income more than RM5000 had no need of supportive care needs. This is indicates that respondents from income between RM3001-RM5000 had lowest level of supportive care needs among respondents. The chi-square analyses reveal a significantly association between satisfaction level and household income, X^2 (2, N=300) = 13.44, p<.05. Meanwhile, 191 (91.8%) from income less than RM3000, 64 (77.1%) from income between RM3001-RM5000 and 9 (100.0%) from had some need of supportive care needs. This is indicates that

respondents from income less than RM3000 had highest level of supportive care needs among respondents.

(8.3%) from breast type cancer, 21 (30.9%) from colorectal type cancer, 2 (3.6%) from haematological type cancer and 5 (6.2%) from other type cancer had no need of supportive care needs. This is indicates that respondents from colorectal type cancer had lowest level of supportive care needs among respondents. The chi-square analyses reveal a significantly association between satisfaction level and type of cancer, X^2 (3, N=300) = 30.43, p<.05. Meanwhile, 88 (91.7%) from breast type

cancer, 47 (69.1%) from colorectal type cancer, 53 (96.4%) from haematological type cancer and 76 (93.8%) from other type cancer had some need of supportive care needs. This is indicates that respondents from breast type cancer had highest level of supportive care needs among respondents.

4(3.7%) from early stage, 25 (20.0%) from late stage and 7 (10.6%) from do not know cancer stage had no need of supportive care needs. This is indicates that respondents from late stage had lowest level of supportive care needs among respondents. The chi- square analyses reveal a significantly association between satisfaction level and cancer stage at time of diagnosis, X^2 (2, N=300) = 14.86, p<.05. Meanwhile, 105 (96.3%) from early stage, 100 (80.0%) from late stage and 59 (89.4%) from do not know cancer stage had some need of supportive care needs. This is indicates that respondents from early stage had highest level of supportive care needs among respondents. Table 4.7 Association between levels of supportive care needs with demographic characteristics

4.9 Summary

There were a total of 300 data used in this data analysis. SPSS version 23.0 was used to analyse the result. The results were tabulated in the table as shown above. Psychological domain was found to have highest mean score which is 2.39 with standard deviation of .60. The chi square test and descriptive statistic were used. . There had been proved to have significantly associated between level of supportive care needs and demographic characteristics. There was not significantly associated between level of supportive care needs and religion and formal education.

Chapter 5

DISCUSSION, RECOMMENDATION AND CONCLUSION

5.0 Introduction

This chapter reviews the research that has been carried out. A brief review of the research is presented. In this part, all issues such as the research objectives, framework and research methodology will be briefly discussed. Then, the major findings of this study will later be discussed. Other than that, in this section, the findings from the test derived from data analysis in previous chapter also will be discussed. The implications of current study also are discussed. Next, the contributions of this study also will be presented. Finally, discussion on the limitation and direction for future research also are presented.

5.1 Discussion

The present study is a cross-sectional analysis of the supportive care needs of cancer patient undergoing chemotherapy in UMMC. The respondents recruited were generally more than 60 years old, mainly Malay, Islam, were married, received at least secondary level education, were employed and with household income less than RM3001 (Table 4.2).

As mentioned in Chapter 1, the main objective of the present study is to determine the supportive care needs of patients with cancer undergoing chemotherapy in UMMC. The descriptive method is used in this study and random sampling method was used for gathering data. The questionnaire served as the instrument for collecting data. All out-patients cancer that undergoing chemotherapy in Infusion Room, Day-

Care Medical in UMMC were the respondents. This study was conducted from June 2018 to September 2018.

Discussion of the following were based on the objective of the study as below:

- To determine the level of supportive care needs of patients with cancer undergoing chemotherapy.
- To identify the domains of needs among patients with cancer.
- To identify the useful sources of supportive care as perceived by patient during treatment of cancer
- To determine the significant association between demographic characteristics and level of supportive care need.

5.1.1 Supportive care needs level of patients with cancer undergoing chemotherapy

The first objective of this study is to determine the level of supportive care needs of patients with cancer undergoing chemotherapy. The supportive care needs level were grouped into five main domains. Domain scores were calculated by summing up the responses to each of the needs items within each domain and dividing the total by the number of items in the domain. The domain score was the dichotomized, with a score one correspond to "no need" and a score two correspond to "some need". In psychological domain, most respondents reports on needs for the item "fears about cancer spreading", " worry about the results of treatment are beyond your control", " uncertainty about future" and " feeling about death and dying".

In physical and daily living, respondents were reported to have low level of needs in this domain as most of the respondents chose "no need" for the items in this domain.

In sexuality domain, the findings of this study reported that most respondents have low level of needs for this domain most of them chose "no need" for the items in these domain.

In health system and information, the finding of this study proved that the respondents have low needs in this domain as most of the respondents chose "no need" for each item in this domain.

In patient care and support domain, this findings of this study reported that most of the respondents has low level of need for this domain as majority of them chose "no need" for the items in this domain.

The highest level of supportive care needs is item in psychological domain, "Uncertainty about the future" where the mean score is 1.84 with standard deviation of .37. Meanwhile, the lowest mean score for the item on patient's level of supportive care needs is item in health system and information domain, "Being given information (written, diagrams, drawings) about aspects of managing illness and side-effects at home" where the mean score is 1.07 with standard deviation of .25.

5.1.2 Domains of needs among patients with cancer

The second objective of the study aimed to identify domains of needs among patients with cancer.

From the results of the current study (Table 4.6) revealed that respondents indicated a higher mean score (by means representing a higher level of supportive care

needs in the domain, range 1-4) in the *psychological* domain with mean score is 2.39 and standard deviation of .60, followed by *patient care and support* domain which is
2.01 with standard deviation of .58, *physical and daily living* domain which is 1.95 with standard deviation of .48, *health system and information* domain which is also shows mean of 1.95 with standard deviation of .47 and the *sexuality* domain which has the lowest mean score which is 1.60 with standard deviation of .73. However, this findings is in contrast with previous research among breast cancer survivors done in Kuching, Sarawak (W. L. Cheah, 2016) which ranked the *health system and information* domain with the highest mean score.

Based on the individual item ranking (Table 4.7), there is a greater need expressed within *psychological* domain compared to other domains such as *health system and information* domain. This finding is consistent with previous study in Australia (Sanson-Fisher et al, 2001) which ranked *psychological* domain with the highest mean score. However, these findings were in contrast with previous research among breast cancer survivors done in Kuching, Sarawak (W. L. Cheah, 2016) which ranked *health system and information* domain as a greater need expressed. This difference may be due to underlying cross-continental cultural difference between respondents of in Sarawak and compared to respondents in Kuala Lumpur.

5.1.3 Useful sources of supportive care as perceived by patient during treatment of cancer

The third objective aimed to identify the useful sources of supportive care as perceived by patient during treatment of cancer. From the results of the current study, a total of 207 respondents reported to choose "doctor" as the most useful source of supportive

care perceived which are the highest source of supportive care perceived by respondents with mean shows 4.69 with standard deviation of .46 , followed by "nurses" (4.35, SD: .58), "family member" (3.76, SD: .82), "friends" (2.98, SD: 1.20),
"religion body" (2.67, SD: 1.35), "website/internet" (2.16, SD: 1.30), "patient's guide

book/leaflet" (2.04, SD: 1.30), "YouTube" (1.86, SD: 1.15), "social worker" (1.82, SD: 1.00), "medical book and journal" (1.81, SD: 1.12), "cancer support group/volunteer" (1.80, SD: 1.02), "newspaper/ magazine" (1.78, SD: 1.05) and lastly
"television/ radio" (1.74, SD: .98).

5.1.4 Supportive care needs level with demographic characteristics

The forth objective aimed to determine the significant association between demographic characteristics and level of supportive care need. In this study, age has been associated with higher levels of supportive care needs among cancer patients. This is proven as results had shown that cancer patients more than 56 years old displayed higher levels of supportive care needs compared to those who is aged below than 56 years old. This finding was said to be in contrast with research from Australia in which results showed cancer patients' ages between 31-60 years consistently displayed higher levels of supportive care needs compared to those aged 70 years and above.

Gender was associated with reporting needs with female gender has highest level of supportive care needs among respondents as compared to male respondents. This findings is said to be similar with previous research from Australia (Sanson- Fisher et al, 2000). Even though the results may be influenced by the number of female

respondents which were larger sample than male respondents (54.3%), it is consistence with other research.

Marital status was associated with reporting needs with respondents who were married has highest level of supportive care needs among respondents as compared to single and widowed respondents. This was consistent with previous research from Australia (Sanson-Fisher et al, 2000) whereby married patients ($p<0.001$) were significantly more likely to indicate the need of help. Moreover, this finding make intuitive sense in which given that married respondents have spouse whom they need to confront their needs especially sexuality needs more frequently, therefore increase the needs.

Formal education was not associated with level of supportive care needs among respondents with mean being not significant ($p>.05$). This finding was found consistent with previous study from Australia (Sanson-Fisher et al, 2001). This can be said that respondents with higher level of education are more likely to be aware of their condition, leading them to actively seek ways to improve their state of health and barriers they would face.

Current study had reported that respondents who are employed had highest level of supportive care needs among respondents. This findings proved that employment status was associated with level of supportive care needs among respondents as compared to unemployed and retired respondents. This finding was found in contrast with previous research from Australia (Sanson-Fisher et al, 2001) in which resulted in unemployed respondents to report a higher domain mean score compared to those who were unemployed. There may be underlying factors which

influence this outcome such as due to complications from treatment of chemotherapy they undergoing resulted reduce in ability to work.

Household income level show significant associated with level of supportive care needs among respondents. This study proved that respondents from income less than RM3000 had highest level of supportive care needs among respondents. This findings was found in contrast with previous study done in Kuching, Sarawak (W. L. Cheah, 2016) in which the results did not show any significant difference in any of the domain scores. It was suggested that having less income can leads to financial barriers in terms of ability to satisfy one's daily care and needs.

Cancer stage at time of diagnosis show significant associated with level of supportive care needs among respondents in this current study where it proved that respondents from early stage had highest level of supportive care needs among respondents. However, this findings was found to be in contrast with previous research done in Kuching, Sarawak (W. L. Cheah, 2016) which resulted not significance different in mean scores across all domain in relation to cancer stage at time of diagnosis. However, this study suggests that there are still supportive care needs that needed to be addressed, despite of any of cancer staging at time of diagnosis.

5.2 Limitation of the study

The first limitation of the study is that the random sampling method had contributed to a higher chance of biases which can lead to not reliable data. Every study may have biases in approaching sample during data collection. As for this study, the researcher may tend to approach Malay respondents compared to other ethnicity as it was much easier to give cooperation to the same ethnicity compared to difference ethnicity.

Besides that, the study setting is also one of the limitation of this study as the data was collected at Infusion Room, Day-Care Medical UMMC only. Other than that, respondents who were not proficient in English, unable to read and too ill were excluded to take part in this study which may have resulted in an underestimate of the prevalence of supportive care needs given that language barriers have been associated with poorer access to health care services. Lastly, the limitation of being a cross- sectional study means that cause-effect relationship could not be assessed and any changes in the supportive care needs cannot be evaluate over time.

5.3 Recommendation

Based on the findings presented, the following recommendations are suggested:

1. The researcher recommend to change the sampling method as to avoid bias in sampling.
2. The researcher recommend that to expand the collection setting to few area such including inpatient cancer so that the more data can be analyse on supportive care needs of cancer patients
3. The researcher recommend to include health care provider especially nurses' perspective on supportive care needs given to patients so that the unmet needs and any lack of supportive care given during treatment can be addressed.

5.4 Summary

In summary, this study had provided valuable insights into demographic characteristics of cancer patients undergoing chemotherapy in UMMC and their associated supportive care needs with gaps of physical domain is emphasized. There should be effort including the delivery of supportive care needs in psychological domain that should be targeted, culturally sensitive, with appropriate linguistically, especially to mid-age cancer patients, had secondary education attainment, and were employed with low household income and those in early stage of diagnosis.

THE CORRELATION OF MOTHER'S ROLE WITH TOILET TRAINING ABILITY FOR CHILDREN AS OLD AS 18-36 MONTHS AT BARENG VILLAGE, BARENG SUB DISTRICT, IN JOMBANG DISTRICT

Monika Sawitri P; Mamik Ratnawati; Mumpuni Dwiningtyas
STIKES PEMKAB JOMBANG, Jombang, Indonesia
Mamik.perawat@gmail.com

ABSTRACT

Toilet Training for children is an effort to train children in order to be able to control in urinating and defecating .Parents who are less to play an active role and they are less to understand the readiness of children because they have activities with their work or they are lazy to do toilet training will affect many children as old as 18-36 months to get bed wetting. Defecating (BAB) and urinating (BAK) at everywhere, even until school age were caused because of toilet training failure. This research aimed to determine the correlation of mother's role with toilet training ability for children as old as 18 – 36 months at Bareng Village, Bareng Sub District, in Jombang District. The design of research used correlation analytic with cross sectional approach . Population in this research was all mothers who had children as old as 18 – 36 months at Bareng Village, Bareng Sub District, In Jombang District as many as 325 people. The total of samples was 65 respondents. Sampling technique used cluster random sampling. Research variable consisted of Independent variable was mother's role by using questionnaire. and toilet training ability for children as old as 18 – 36 months by using questionnaire, furthermore it was analyzed by using the statistical test of chi square with $\alpha = 0,05$. The result of this research showed that the most mother's role were positive as many as 39 respondents (60 %) , the most of toilet training capability for children as old as 19 – 36 months were capable as many as 44 respondents { I 67, 7 }. The result of Chi square test was obtained 0'000 , 005. This research concluded that there were the correlation of mother's role with toilet training ability for children as old as 18 – 36 months at Bareng Village, Bareng Sub District, in Jombang District. it is expected that mothers had better practice toilet training to children and avoid using the practical way such as wearing diapers frequently.

Keywords: mother's role, toilet training, children as old as 36 months

1. Introduction

Family in relation to children is identified as a place or institution of care that can give love. Meeting emotional and loving needs can be started as early as possible. Emotional bonding and close affection between parents and children will be useful to determine children's behavior in the future. Families have duties in child development, such as giving examples of good behavior, upholding discipline, giving affection, fulfilling educational needs and maintaining children [1]. When children are 18-36 months old parents must begin to exercise their children's ability to urinate and defecate into the toilet. Parents must be patient and understand the child's readiness to start teaching toilet use. Parents also have to have positive support, one example is parents must be ready to take children to the toilet when they want to defecate or urinate [2].

Parents do not play an active role and do not understand children's readiness, because some parents are busy with their work or are lazy in doing toilet training. This busyness makes parents not want to bother in taking care of their children. Parents use more practical methods with the use of diapers so that the mother does not have difficulties when the child wants to defecate. Busy parents

also do not pay attention to the environment in their house that looks dirty, so children are less comfortable with facilities for defecation as well as parents who do not provide bathroom facilities that are easily accessible to children [3].

A survey conducted in Indonesia by the Nakita tabloid (2014) states that half a million children aged 6-16 years still bed wet. It consisted of: 17% of children aged 5 years, 14% of children aged 7 years, 9% of children aged 9 year, and 1-2% of children aged 15 years, while about 30% of children are 4 years old, 10% of children are 6 years old, 3% of children are 12 years old and 1% of children are 18 years old still wet their bed. There are also around 20% of children under five not doing toilet training and 75% of parents do not view such conditions as a problem.

Based on preliminary studies conducted by researchers on March 9, 2017 using a questionnaire in Bareng Village, Bareng District, Jombang Regency of 10 respondents who had children aged 18-36 months, it was found that 6 children were still wet because their role in toilet training was lacking, 2 children have enough toilet training and 2 children can do toilet training or are already good.

Toilet training in children is an attempt to train children to be able to control urination and defecation. This toilet training can take place at the stage of a child's life at the age of 18 - 36 months. The problem arising from the above incident is that many children aged 18-36 months who wet their bed, defecation and bladder were banned, even to school age due to the failure of toilet training. This will adversely affect the future development of children. The impact caused by parents who do not implement toilet training among children is that children become stubborn and unruly. In addition, children are not independent and still carry the habit of wetting the bed. Toilet training that is not taught early will make it more difficult for parents to teach children when children get older (Firdaus, 2014).

Children generally have not learned to use the toilet until they are 3 years old. Boys usually learn to use the toilet for 6 months and take longer than girls. Most health experts suggest that toilet training should be done when children begin to show interest in learning toilet training (Karen, 2010). Children who use diapers will usually experience delays in toilet training. The delay is due to the child feeling that there is no need to go to the toilet because when using a diaper they still feel comfortable despite having done BAK. Generally, children who use diapers are starting to be interested in toilet training at the age of 4 years, even in some cases children begin learning toilet training at the age of 7 years. (Frank & Theresa, 2010). Many things that cause toilet training failures include the use of diapers, starting toilet training at the wrong time, forcing children and punishing children. The use of diapers should be stopped when the child is 2 years old because with the use of diapers the child will not be trained to control when it is time to defecate and bladder. In children aged 18-36 months, if toilet training is carried out properly, children should not wet their bed during the day. Parents should not punish and scold children in applying toilet training because almost no child does remember to wet his bed (Hendi, 2010).

The benefit of applying children's training toilets is to train children to live in discipline, be responsible, foster self-confidence and shape children to master themselves. All the benefits of applying toilet training are conducted simultaneously to train motor skills and sharpen independence (Rahadiasih, 2010). Parents should play a more active role in seeking information through the media. The media include books and the internet that contain the importance of toilet training education in children aged 18-36 months. Parents can train toilet training as early as possible for their children, so that they will not increase their bedwetting and defecation and defecation.

Based on the background above, the researcher was interested in conducting research on the relationship of the role of mothers with toilet training abilities in children aged 18-36 months in Bareng Village, Bareng District, Jombang Regency.

2. Methods

The design of the research in this study is analytic correlation with across sectional approach. The population in this study were all mothers who had children aged 18-36 months in Bareng Village, Bareng District, Jombang Regency, amounting to 325 people. The sample used was 65 respondents with cluster random sampling.

3. Measure

The variable of this study consisted of independent variables, namely the role of the mother using a questionnaire and the ability of toilet training in children aged 18-36 months using a questionnaire and which were then analyzed using the chi square test.

4. Results

The results of the research obtained in the study of the Relationship between the Role of Mothers and Toilet Training Ability in Children 18-36 Months in Bareng Village, Bareng District, Jombang Regency on April 13-21 2018 are as follows: Table 1 shows that the majority of respondents aged 20-35 years were 40 respondents (61.5%). Most of the respondents had basic education (elementary, junior high), which was 41 respondents (63.1%). Most of the respondents did not work namely 44 respondents (67.7%). Almost all respondents had received information about toilet training, namely 54 respondents (83.1%). Most of them get information from health workers, namely 31 respondents (57.4%). Most of the children aged 18-24 months were 35 respondents (53.8%). And most of the sex of boys is 33 respondents (50.8%). Table 2 shows that the majority of maternal roles are positive, namely 39 respondents (60%). Table 3 shows that the majority of toilet training capabilities in children aged 18-36 months are capable of a number of 44 respondents (67.7%). Table 4 that of the 39 respondents the role of positive mothers was almost entirely the ability of toilet training in the category of capable of 34 people (87.2%)

5. Discussion

From the results of the chi square statistical test obtained significant numbers or probability values (0,000) far lower significant standard 0.05 or (r <a), due to r <a, which means there is a relationship of the role of mothers with toilet training abilities in children aged 18- 36 months in Bareng Village, Bareng District, Jombang Regency. From the results of the Contingency Coefficient statistical test, it obtained significant numbers with a value of 0.455 which means it is in the medium category. The role is a behavior associated with someone who holds a certain position, a position identifying a person's status or place in a social system [4]. According to Rahayu [3] affection and mother's role influence the implementation of early toilet training, where the attention of the mother will monitor the development of children aged 18-36 months, it will have a faster effect in training children aged 18-36 months to do toilet training early. With the role of mother, the child will be more courageous or motivated to try because they get attention and guidance. According to the researchers, this study has a conformity with the facts above where mothers who have a positive role in implementing toilet training almost all have children who are able to do toilet training. Through training toilets, children will be taught by parents to be responsible for doing BAB or BAK activities in their place and avoid defecating or urinating in places. But the results of the study also found a slight gap where there were still mothers who had a negative role but their children were able to do toilet training at 10 respondents (38.5%). This could be because parents do not wear diapers on their children so that children are not used to defecating and smacking their pants. In addition, physical, mental and cognitive readiness in children aged 18-36 months so naturally children are able to not wet their bed for 2 hours, imitate parents while in the bathroom and curiosity about the toilet habits of their older siblings or parents. That way even though the role of parents is not optimal or has a negative role, the child is able to do toilet training.

6. Conclusion

The role of mothers in Bareng Village, Bareng Sub-District, Jombang Regency is mostly 39 respondents (60%). The ability of toilet training in children aged 18-36 months in Bareng Village, Bareng District, Jombang Regency is mostly capable of 44 respondents (67.7%). There is a relationship between mother's role and toilet training ability in children aged 18-36 months in Bareng Village, Bareng District, Jombang Regency in the medium category (0.455).

THE RELATION BETWEEN FAMILY SUPPORT AND PATIENTS' SELF-ESTEEM IN LEPROSY HOSPITAL AT KEDIRI

H S Anggi[1], L S Martha[1]
[1] Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
E-mail: anggi.hanafiah.syanif-2018@fkp.unair.ac.id

ABSTRACT

The high incidence of leprosy will give a great impact on the lifes of leprosy patients, families and communities. As a result, the leporsy patients lose their role in society. it makes them feel no self-esteem. The purpose of this research is therefore to find out the relation between family support and self-esteem of leprosy patients in the Leprosy Hospital at Kediri. This research method used was descriptive analytic with cross sectional approach. The research population was 48 respondents, taken by purposive sampling, there were 43 respondents and the data collection technique used was questioner. Data were analyzed with Spearman's rho.The results of this research indicate that family support of leprosy patients in the Leprosy Hospital at Kediri is mostly "good" (79.07%) and self-esteem of leprosy patients at the Leporsy Hospital at Kediri is mostly "fair" (67.44%). From Spearman's rho test, the results obtained was value of p = 0.000, because the p-value less than 0.05, it means that there is a significant relation between family support and self-esteem of leprosy patients at the leporsy Hospital at Kediri The researcher concludes that the support of family is found closely related to leprosy patients in Leporsy Hospital at Kediri..

Keywords: family support, self-esteem

1. Introduction

Family in relation to children is identified as a place or institution of care that can give love. Meeting emotional and loving needs can be started as early as possible. Emotional bonding and close affection between parents and children will be useful to determine children's behavior in the future. Families have duties in child development, such as giving examples of good behavior, upholding discipline, giving affection, fulfilling educational needs and maintaining children [1]. When children are 18-36 months old parents must begin to exercise their children's ability to urinate and defecate into the toilet. Parents must be patient and understand the child's readiness to start teaching toilet use. Parents also have to have positive support, one example is parents must be ready to take children to the toilet when they want to defecate or urinate [2].

Parents do not play an active role and do not understand children's readiness, because some parents are busy with their work or are lazy in doing toilet training. This busyness makes parents not want to bother in taking care of their children. Parents use more practical methods with the use of diapers so that the mother does not have difficulties when the child wants to defecate. Busy parents also do not pay attention to the environment in their house that looks dirty, so children are less comfortable with facilities for defecation as well as parents who do not provide bathroom facilities that are easily accessible to children [3].

A survey conducted in Indonesia by the Nakita tabloid (2014) states that half a million children aged 6-16 years still bed wet. According to the researchers, this study has a conformity with the facts above where mothers who have a positive role in implementing toilet training almost all have children who are able to do toilet training. Through training toilets, children will be taught by parents to be responsible for doing BAB or BAK activities in their place and avoid defecating or urinating in places. But the results of the study also found a slight gap where there were still mothers who had a negative role but their children were able to do toilet training at 10 respondents (38.5%). This could be because parents do not wear diapers on their children so that children are not used to defecating and smacking their pants. In addition, physical, mental and cognitive readiness in children aged 18-36 months so naturally children are able to not wet their bed for 2 hours, imitate parents while in the bathroom and curiosity about the toilet habits of their older siblings or parents. That way even though the role of parents is not optimal or has a negative role, the child is able to do toilet training.

6. Conclusion

The role of mothers in Bareng Village, Bareng Sub-District, Jombang Regency is mostly 39 respondents (60%). The ability of toilet training in children aged 18-36 months in Bareng Village, Bareng District, Jombang Regency is mostly capable of 44 respondents (67.7%). There is a

relationship between mother's role and toilet training ability in children aged 18-36 months in Bareng Village, Bareng District, Jombang Regency in the medium category (0.455).

ADJUSMENT DURING THE TRANSITION TO RETIREMENT: A SYSTEMATIC REVIEW

Siswati[1], Merryana Adriani[2], Retno Indarwati[1]
[1]Faculty of Nursing, Airlangga University, Surabaya, Indonesia
[2]Faculty of Public Health, Airlangga University, Surabaya, Indonesia
E-mail: siswati-2017@fkp.unair.ac.id

ABSTRACT

The transition to retirement is a simple event that happens to those who work, this can be a fun thing for some people, but it can cause problems for others. The purpose of this review is to find out how retirement experiences during the transition to retirement, especially changes and difficulties in adjusting for retirement. A systematic search was performed via Scopus, Google Scholar, and Pubmed, and a reference list of retrieved longitudinal study and cohort studies in English that studied adaptation in the transition to retirement and the factors that influenced it. A total of 10 studies, the study explained psychosocial factors, 2 others added socioeconomic aspects that influence retirement adjustments. The findings show that retirement perceptions, retirement self-efficacy, mental resources, psychosocial factors can help retirees adapt during the transition period. Adaptation during retirement transition is strongly influenced by individual psychosocial factors. Every individual who is in a transition period needs to be given training to improve psychosocial skills in order to maintain their health in general.

Keywords: adjusment, trantition to retirement

1. Introduction

Transition from work to retirement is a major life event in most people's lives [1] which may influence health behaviors and use of time [2], and is a source of major changes in the organization of daily life and societal status [3]. About 70% of retirees experienced minimum psychological well-being changes; about 25% of retirees experienced negative changes in psychological wellbeing during the initial transition stage, but showed improvements afterwards; and about 5% of retirees experienced positive changes in psychological well-being [4].

Retirement is a key moment in the existence of each individual, and its impact on an individual's lifestyle changes is consequential [3]. The quality of retirement adjustment varies by the amount of retirement resources and overall changes in total resources during the retirement transition [5], quality of retirement adjustment is strongly dependent on the amount of total resources possessed by the retired person, upon experiences earlier in life [6], who experience loneliness, the transition to retirement could result in depression and health problems earlier in life might experience more difficulties adjusting to the social dimensions of the retirement transition as well [6]. Therefore, the purpose of this systematic review to find out how retirement experiences during the transition to retirement, especially changes and difficulties in adjusting for retirement.

2. Material and methods

This systematic review was reported in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews) Statement.

2.1 Data Sources, searches, and data selection

A systematic literature search was performed from December 2013 to April 2018 of Scopus, Proquest, Science Direct, and Google Scholar. The literature review was conducted using adaptation or adjustment, transition to retirement keywords. The selection of articles is determined by the following inclusion criteria: (1) full text published; (2) articles published between to 2013-2018; (3) articles published in English; (4) articles focusing on factors that influence adaptation in the transition to retirement

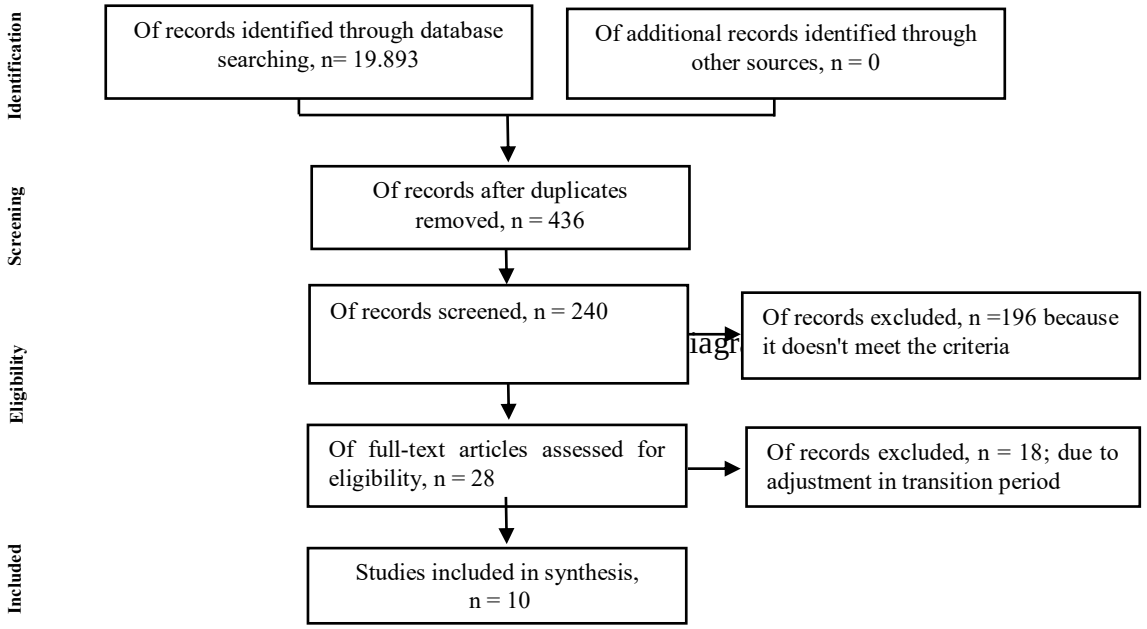
2.2 Data extraction and quality assessment

All quotes taken from electronic databases are imported into the Mendeley Program. Analysis of the title and abstract of each study taken from the literature search to identify studies that have the potential to meet the requirements of the first reviewer. The full text of the remaining research is obtained for further examination. The last review was conducted by reviewers of two reviewer. Data of included studies were independently extracted by the same two reviewers by including first author's name, year of publication, study design, general characteristics of participants, research measurement tool and the main outcome of interest. Descriptive analysis was carried out on data obtained from papers reviewed to analyze adjustments during the pension and life transition period after retirement. Our hypothesis is that retirement adjustments are influenced by the resources possessed by employees

3. Results

3.1 Study Design

As many as articles were found, the results came from four database: 713 articles in Scopus, 1.012 articles in Science Direct, 768 articles in ProQuest, and 17.400 articles in Google Scholar. The result of article selection according to the inclusion criteria of 10 articles, then given the serial number and done article analysis to facilitate the review process. There are several kinds of inclusion criteria in this study namely adjusting leisure time usage, resource use, satisfaction after retirement, symptoms of depression in the transition period. This study used Prospective cohort study or longitudinal study.



3.2 Characteristics of Participant

In this systematic review of 10 studies all the population are retirees, with a varied sample of ages 50-80, research carried out in various parts of the world including Asia, Europe, Australia, and the Americas.

3.3 Findings

The incidence of difficulty adjustments varies between dimensions. Some studies suggest difficulties in adjustment are less in financial terms but more difficulty adjusting to loss of status [6]. Another study related the dimensions of work conditions with an understanding of the retirement process, found that strong job identification was associated with more difficulties in the transition to retirement. Some longitudinal studies report heterogeneity in retirement effects and show that many older workers may have problems adjusting to retirement [7]. In line with other studies that state that older workers who are lonely are at increased risk for adaptability [8]. This is supported by other findings about pensions that show an increase in symptoms of depression among older Japanese adults, especially men from lower occupational class backgrounds [1].

4. Discussion

Adjustments to retirement can be determined by the type of transition and individual resources, capability influences changes in life satisfaction variously depending on each other [7]. Changing life course experiences might have important implications for retirement quality. [6] With sufficient retirement planning and adequate retirement resources, the retirees can experience a smooth adjustment to this important life event [5].

The heterogeneity as working conditions, timing of retirement, social participation influence on individual emotions in the transition to retirement [3]. Resources such as self-esteem, autonomy, social support, self-rated physical health, self-rated cognitive ability, basic finances are related to changes in life satisfaction, that is self-esteem, social support, and self-rated physical health, while autonomy, self-rated cognitive ability, or basic financial not significant effects [7]. This is different from other research that shows that among various types of personal resources, cognitive resources, such as perceived autonomy and cognitive functioning abilities, could reliably predict the quality of adjustment to retirement, which were reflected in the changes in physical functioning, life satisfaction, psychological well-being, and psychological distress before and after retirement [5]. Resources predicted retirement adjustment and retirement satisfaction in the following order: finances and health, followed by social resources, and lastly emotional, cognitive, and motivational resources [9].

The transition to retirement entails many lifestyle changes [8], this is due to some changes in income, activity, social status, etc., but, retirees who are still working are more likely to engage in social activities such as recreation, because they still have greater financial resources [10]. During the pension transition period, also found the use of leisure time with increased sedentary behavior such as non-occupational sitting time and watching television, computer use and other sitting times [2]. The more retirees consider retirement as a positive event, the better they adapt to the new temporality of their retirement life and the more they feel satisfied with their current life, healthy and less depressed [11].

5. Conclusion

In this review, Individual resources before retirement have a stronger influence on changes in life satisfaction. Every individual who is in a transition period needs to be given training to improve psychosocial skills in order to maintain their health in general. important to keep up the level of

available resources for retirees in order to maintain their well-being in late life. Further research is recommended to identify the role of policy makers towards retirees.

ABSTRACT

Cases of hypertension include disease with a high incidence rate. Hypertensive sufferers need to do a blood pressure check regularly at least once a month, then trying to reduce salt consumption, fat and do regular exercise, family support is needed to prevent and control hypertension. The purpose of this article is review evidence of an intervention on the family support for hypertension. In this article, the authors conducted a relevant literature review in various data using the keywords hypertension, family support, and social support. This review conducted database in Scopus, Science Direct, and Sage Journal with inclusions are randomized trial study determined from 2014 to 2019 and related to hypertension that assessed using the PRISMA (Preferred Reporting Items for Systematic reviews and Meta- Analyses) Statement. There are studies included inclusion criteria, consist of seven studies. Seven eligible studies were included with outcome was the blood pressure measurement. A main theme which often appear from each study identified as: Understanding of hypertension, family support, and social support. The result introduction of timely family support is has shown that can be stabilize blood pressure, positively associated with medication adherence and blood pressure monitoring.

Keywords: intervention, family support, hypertension

1. Introduction

Hypertension is one of the key risk factors for cardiovascular disease leading to heart attacks and strokes. Researchers have estimated that hypertension affects about 40% of the population and is the cause of about 9 million deaths every year worldwide [1]. Currently, one-quarter of the world's adult population has hypertension, and modelled projections indicate an increase to 1.15 billion hypertensive patients by 2025 in developing countries [2]. In spite of progress in the prevention and treatment of elevated blood pressure, hypertension remains a major health challenge worldwide. Most hypertensive patients need two or more drugs to control their blood pressure and concomitant statin treatment to reduce cardiovascular risk factors. Despite the availability of various effective and safe antihypertensive drugs, hypertension and its concomitant risk factors remain uncontrolled in most patient [3].

Social support, which is the assistance and protection provided to an individual has been conceptualized in both cognitive and behavioral terms. The cognitive aspect refers to perceived support, whereas the behavioral aspect refers to received support [4]. Several studies have examined the factors influencing compliance behaviors with hypertensive treatment. Among these studies, Marin-Reyes and Rodriguez-Moran found that compliance with hypertensive treatment was directly linked to the support of family members [5]. The aim this study for knowing effectiveness support system for hypertension.

2. Methods

This systematic review was reported in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) Statement. Of records identified through database searching, n = 654, then Exclusion Literature review, editorial, critical synthesis, paper discussions, comment, mini-review, and study protocol fond 210 articles. Which corresponds the topic there are 8 articles.

2.15Data Sources and Searches

Databased searched from Scopus, PubMed and Science Direct provide studies related to family support for hypertension determined from 2014 to 2019.

2.16Study Selection

A systematic search of electronic databases begin on December 23, 2018. The first step: we search the electronic database Scopus, PubMed, and Science Direct to identify key articles and identify keywords by adjusting the main concepts: 1. Hypertension, 2. Family support 3. Social support. Our keywords search for both quotes and full articles, including title, abstract, text, and references information. The second step, translating keywords in English to search relevant articles in electronic databases.

2.17Data extraction and quality assessment

All citations retrieves from electronic databases were imported to Mendeley Program. Two reviewers (JH, PA) independently analyzed the titles and abstracts of every studies retrieved from the literature search to identify potentially eligible studies. The full text of the remaining studies was obtained for further examination. The last review conducted by a first reviewer (IPA).

Data of included studies were independently extracted by the same two reviewers by including first author's name, year of publication, sample size, study design, duration of trial, and general characteristics of participants (age, hypertension or high blood pressure, gender)

The reviewed data are continued to see family support for hypertension. Each study has been read at least 3 times before data extraction ensure a thorough understanding of the content. The following steps:

1) Identify studies using relevant databases by using additional characteristics of keyword studies: authors, publication year, study design, study types and sample characteristics
2) Use the terms of inclusion and exclusion criteria to filter the study and narrow the focus
3) Independently extract data on research characteristics (reference details, population, determination, objectives or study objectives, methodologies, methods of data collection and analysis)
4) The reported findings include major themes and subthemes, including author descriptions and labels, and all illustrated excerpts

Data extraction protocol in the final stages by collecting data extraction results from 2 reviewers (JH and PA) to compare data extraction and discuss if there is a difference. The differences appear in the review together by using the full article.

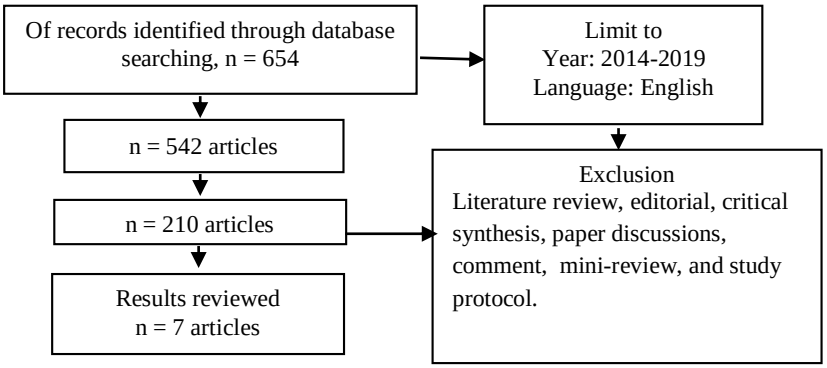
3. Results

3.13Literature Search

The year of this research has started from 2014 to 2019. These reviews come from various countries; China, Nigeria, Turkey, and USA. Sources of this review used Scopus, PubMed, and Science Direct. Inclusion criteria were 5 year publication (2014-2019), respondents with hypertension either home nursing or hospitalization. Exclusion criteria were literature review, editorial, critical synthesis, paper discussions, comment, mini-review, and study protocol. Articles selection started on January 9st, 2019.

The title of article there are family member-based supervision of patients with hypertension: a cluster randomized trial, blood pressure control and perceived family support in patients with essential hypertension seen at a primary care clinic, social support and management of hypertension in south west Nigeria, the association of family social support, depression, anxiety and self-efficacy with specific hypertension self-care behaviors in Chinese local community, effect of social support on the treatment adherence of hypertension patients, social and community factors associated with hypertension awareness and control among older adults in Tirana, Albania, self-care behavior and related factors in older patients with uncontrolled hypertension.

Figure 6. Flow diagram of the literature search to identify randomized trial evaluating interventions that successfully lowering blood pressure of hypertensive Asian elderly.



3.14Study Characteristics

Research by Shen et.,al. revealed that the family member-based supervised therapy have positive effects on patients' adherence to blood monitoring and hypertensive medications. The role of a patient's family members on the management of hypertension. Findings from this study suggest that family member based supervision can be a way to promote medication adherence and better outcomes [3].

Research by Olowaseun et.,al showed positive association between BP control and perceived family support emphasizes the need for medical workers to reflect on the available family support when managing hypertensive patients. Other research, strong perceived family support will improve their self-worth and motivation. Social support from friends can also control blood pressure [4]. Research in Nigeria, support from friends or family members (concerned about their illness, giving reminders about medication) showed better treatment compliance than those who did not [5]. It is essential that health care providers carry families of patients with hypertension along in their management to improve hypertensive patients' function and treatment outcome [4].

Research from Chinese aimed to examine the relationships of family social support, depression, anxiety and self-efficacy with a wide variety of self-care behaviors in sample of hypertensive patients. In all three adjusted models, family social support was positively associated with taking medication and monitoring BP, and self-efficacy was positively associated with performing physical exercise[6]. Study at Turkey too have the same result, treatment adherence and social support from family, friends

or both levels of the patients were found to be substantially good; besides, adherence to drug treatment was found to increase positively as the social support of patients with hypertension increase [7]. Besides that family support, social and community factors influence stabilize blood pressure too [8]. Family support can affected self-care behavior hypertensive patients [9].

4. Discussion

This systematic review study shows family support for hypertensive patients can improve their daily lives with controlled blood pressure. All based on studies and research are included in the review. This research is needed to improve the quality of services offered by health professionals to promote the importance of family roles. The critical assessment applied in this study was published by the limitations of the existing literature, specifically referring to the saturation of theory and detailed details about the small themes of each study. This research provides clear and important data from the analysis and the results obtained are important in a small theme (code). The life experience of individuals with hypertension provides a different perspective, requiring a different method with family support. It needs a more thorough and deep assessment, then in understanding needs a good understanding between health professionals, family and hypertensive clients. Therefore, not only physical complaints but are also able to answer other problems. The synthesis of evidence can identify all the objectives of the review identifying the importance of individual understanding of hypertension, what happens from physical aspects, fulfillment of health, psychological dynamics experienced, stigma dynamics that occur, relationships and social roles, economic recovery, and daily activities that is lived. Social family support is strongly associated with hypertension treatment compliance in patient [6]. Systolic or diastolic blood pressure was significantly decreased with A family member-based supervision [3]. Family social support was positively associated with medication adherence and regular BP measurement. Strategies to improve family social support should be developed for hypertension control, yet further prospective studies are needed to understand the effects of family social support, depression, anxiety and self-efficacy on self-care behaviors [6].

5. Conclusion

Family support has an important role in controlling blood pressure. The family provides motivation support for taking medication, controls blood pressure regularly and regulates the lifestyle of hypertensive patients. Besides family support, friend and community social support is also needed so that motivation to control blood pressure is strongly. Social support provided by the family influences the patient's motivation to control blood pressure.

STIKes Pemkab Jombang
Email: fitri.firranda2626@gmail.com

ABSTRACT

Physical activity that is less able to cause obesity and increases the risk of hypertension, decreases motivation and creativity and can subsequently affect the quality of life. This study aims to determine the correlation of physical activity with stability in blood pressure and quality of life in patients with hypertension. The population of this study was hypertensive patients in the Rejoagung Village. The sample was 30 respondents with hypertension and still abel to activity. The sampling technique used purposive sampling. The Data on physical activity and quality of life were obtained through interview used questionnaire, while blood pressure data was obtained through documentation in Posyandu cadres in last three months. Most of the samples were 45- 80 years old, 76.7% women, 43.3% had elementary education, 73.3% were farmers. Chi square statistical test of physical activity and blood pressure stability showed a significant value (p) = 0.035, while physical activity and quality of life were obtained (p) = 0.001. Daily physical activity which was classified as moderate activity and carried out routinely could get a positive impact on the stability in blood pressure and quality of life.

Keywords: physical activity, blood pressure, quality of life

1. Introduction

Hypertension is one of the chronic diseases that until now remained a concern of health workers. Hypertension sufferers in Indonesia are estimated to number 15 million people, but only 4% are have their hypertension controlled. The prevalence of hypertension tends to be higher in the low education group and the group does not work [1].

Work is physical activity, mild, moderate and severe, depending on the type of work. A lack of activity can increase the risk of being overweight which can increase the risk of hypertension. Poor physical activity can also cause fat buildup, decreased interest, people tend to be more lazy, but not everyone can do regular physical activity to maintain health.

Physical activity that is less able to reduce physical health in general, can further reduce motivation, and creativity which in turn will affect a person's quality of life. Physical activity is very beneficial [2], to improve quality of life in general and physical health [3].

One effort to control hypertension can be done by doing physical activity. Doing physical activity from moderate activities can prevent hypertension [4]. Regular physical activity is also useful to regulate body weight and strengthen the heart and blood vessel system [1]. Based on this, the researchers were interested in seeing how the relationship between physical activity and blood pressure stability and quality of life in hypertensive patients.

2. Methods

The population of this study was hypertensive patients in Rejoagung Village, Ploso District, Jombang Regency. The samples used in the study were 30 people with the criteria of hypertensive patients without complications and were still able to carry out physical activity.

The data collection tool used in this study was a questionnaire and a posyandu documentation book. Physical activity questionnaire using the Elderly Physical Activity questionnaire Physical Activities Scale for the Elderly (PASE) which has been modified and translated into Indonesian. The quality of life questionnaire uses a standard questionnaire made by the World Health Organization (WHO). Blood pressure measurement by looking at the documentation on the Posyandu book in the last 1 month. To prove the hypothesis of this study using the chi square test with alpha 0.001.

3. Results

Table 1. Characteristics of respondents in Posyandu Lansia RW 5 Rejoagung Village Ploso District, Jombang Regency in September 2018

Characteristic of respondents	Frequency	Percentage (%)
Age 45-59 years	16	53,3
60-74 years	11	36,7
>74 years	3	10
total	30	100
gender		
male	7	23,3
female	23	76,7
total	30	100
education		
primary school	13	43,3
junior high school	11	36,7
senior high school	6	20
total	30	100
work		
farmer	22	73,3
housewife	5	16,7
private	3	10
total	30	100

Table 2. Relation of Physical Activity to Stability of Blood Pressure

		Blood pressure		Total
		Stable	unstable	
Physical activity	less	0	3	3
	enough	13	7	20
	well	6	1	7
Asymp sig 0,035				

Table 3. Relationship between Physical Activity and Quality of Life

		Kualitas hidup		
		less	enough	well
Physical activity	less	0	3	0
	enough	0	19	1
	well	0	2	5
		0	24	6
Asymp. Sig 0,001				

Chi square statistical test results of physical activity and quality of life showed a significant value (p) = 0.001 <0.05 which means that H1 was accepted. Thus, there is a relationship between physical activity and the quality of life of patients with hypertension in Rejoagung Village, Ploso District.

4. Discussion

According to the results of the modified PASE questionnaire, the activities most often carried out by respondents were at home activities such as cooking, sweeping, mopping, while questions about sports activities found that many did not do it routinely. Based on the characteristics of respondents about work, most of the respondents work as farmers. Despite the age characteristics of many who are elderly, respondents are still quite active in carrying out home and rice field activities.

Respondents with stable blood pressure on average were found in respondents who did enough physical activity.

Research shows a low value in the environmental domain, where this domain examines the quality of life of respondents regarding the satisfaction felt by respondents about spatial governance in the surrounding environment, comfort, ease of access to transportation, and opportunities for recreation. Characteristics of respondents based on age were mostly in the age range of 45-59 years. This age is an age with a relatively high level of work, so it is most likely that at this age they do not have time to do recreation and this is supported by environmental management that is less supportive.

Analysis of the relationship between physical activity and blood pressure stability p <0.05 (0.035) shows that there is a relationship between physical activity and blood pressure stability. Regular physical exercise prevents and treats hypertension and dyslipidemia. Physical activity greatly influences the stability of blood pressure [5]. Carrying out moderate intensity physical activities for at least 30 minutes 5 days a week or high intensity for a minimum of 20 minutes 3 days a week increases functional capacity and is associated with a reduction in the incidence of cardiovascular disease and mortality. Physical exercise induces physiological cardiovascular adaptations that improve physical performance. By doing physical activity regularly can increase the work of the heart so that it can control the stability of blood pressure in a person.

The results of the analysis of the relationship between physical activity and quality of life in patients with hypertension in Rejoagung Village, Ploso Subdistrict, Jombang Regency obtained p value <0.05 (0.001) which means that there is a relationship between physical activity and quality of life in hypertensive patients.

Physical activity carried out routinely and happily will improve general physical health, and reduce psychological problems. As we know that physical and psychological health are aspects of quality of life.

5. Conclusion

There is a relationship between physical activity and the quality of life of patients with hypertension in Rejoagung Village, Ploso District.

ABSTRACT

Women living with HIV/AIDS have complex problems in living by a stigma from the community and reducing motivation to live. This causes helplessness that occurs in women with HIV. They need an effort that can evoke a better spirit of life. They are need empowerment with the benefits of giving hope, dreams, courage and encouraging them to be filled with the power to continue a better life. The purpose study literature review is to identify the empowerment needs in the women living with HIV/AIDS. The authors found article accordance with the conduct that relevant literature review in various data using the keywords "empowerment, women, HIV/AIDS". Data based on SCOPUS, SAGE, Science Direct, Proquest and Pubmed. The criteria consisted as 4.106 articles found, five years limit journal (2013-2018) and selected 17 article that suitable with criteria. In the process of the analysis of the articles showed that women living with HIV/AIDS need empowerment to consists of family, financial, community and life style. The functions of empowerment to increase ability and motivation in life. It has an important role to continue a better life in women living with HIV/AIDS.

Keywords: empowerment, women, HIV/AIDS

1. Introduction

Empowerment is a key approach for addressing HIV-related issues that focuses on addressing the broader context [1]. Empowered people have freedom to make their own choices and the ability to act. The level of empowerment consists of the empowerment of an individual, group and society. This, in turn, enables them to better influence the course of their lives and the decisions that affect them [2]. This is one of the most important steps for the empowerment of women. Women living with HIV, by living a longer life and with the occurrence of HIV, can have an impact on reducing the health system and changing transitions across broad sectors including psychology, society and economy [3]. There are concrete problems with the emergence of women living with HIV / AIDS, namely social and structural factors such as financial discomfort, stigma, and discrimination, violence, and comfort in the form of a legal and policy environment that is associated with an increased risk of HIV transmission especially for female sex workers [4]. This is what underlies self-health assessment as a reference and what is used to assess the role of non-biomedical conditions in mediating HIV status that have an impact on improving health [3]. Economic empowerment programs are often heralded as a key means to addressing gender inequality and poverty to mollify the impact of AIDS-related stigma [5]. All of the women reported that HIV had devastated their household finances and that their family finances decreased as the couple became too weak to work. The fact is that the households ended up facing extreme poverty and hunger as the parents had to spend everything on treatment [6]. The efforts are made in the form of empowerment, where

empowerment is one way to improve the ability and independence of the community to allow them to improve their standard of living. This process is carried out in order to allow them to have a better life fought for with their own strength [7]. Empowerment can be done by providing interventions in the form of empowering counseling, which makes it an important step in carrying out life guidance to improve the health of mothers living with HIV and their children [8]. The methods include empowerment in terms of economic independence, and physical, mental and social health by changing the lifestyle better [9]. The purpose of this systematic review is to summarize some of the empowerment needed by the women living with HIV. This is done as a measure of the empowerment needed by the women living with HIV as they continue to struggle to continue on to reach the point of having a better life. The results obtained can be passed on to the AIDS watchdog and researchers.

2. Methods

2.1. Design

The design of this study was a systematic review of a mixed method study approach (qualitative and quantitative) formulated to review the relevant research studies and the correlated comprehensive analysis. The systematic reporting structure used PRISMA *(Preferred Reporting Items for Systematic Reviews and Meta-Analysis)[1]*.

2.2. Inclusion and Exclusion Criteria

This systematic review established both inclusion and exclusion criteria that focused on quantitative, mixed method studies. Some of the research designs used an RCT (*Randomize Control Trial*). Feasibility studies to describe the experiences and needs for empowerment were needed by the mothers living with HIV with language eligibility criteria, with minimal abstracts using English. The year of publication was limited to the last 5 years (2013 – 2018). Further inclusion criteria are studies with female respondents living with HIV.

2.3. Search Strategy

The first step is that we searched on electronic databases - SCOPUS, SAGE, Science Direct, Proquest and Pubmed - to identify the key articles and to identify the keywords by adjusting the main concepts. The main concepts were empowerment, women and HIV. Our keywords were used to look for quotes and articles done in full; this included the titles, abstracts, texts, and references. The second step was to translate the keywords into English to find the relevant articles accordingly in the electronic databases. Next, for the third step, a filter was used – PRISMA - to determine which articles passed to be further reviewed according to the research topic. The search strategy had a search limit, which was the last 5 years between 2013 – 2018.

3. Result

The total articles collected consisted of 17 articles. The population that the respondents' research used was women living with HIV. From the results of the systematic review carried out, there is empowerment, which can benefit the women living with HIV in the form of education empowerment, and by combining empowerment, intervention empowerment and community empowerment. A total of 17 studies reviewed in 2013 - 2018 were conducted in several major countries, namely Iran, the USA, and Kazakhstan. Most of the literature founds was focused on empowering women living with HIV in the USA.

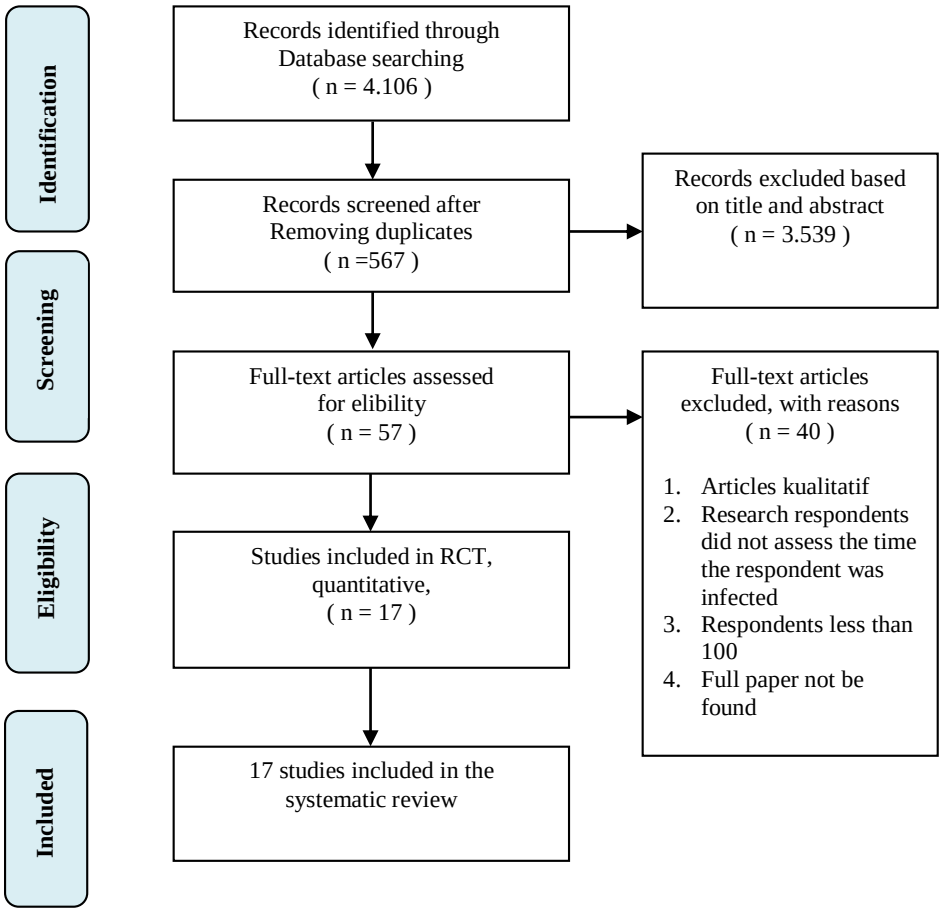

Figure 1. PRISMA flow diagram

3.1. Education Empowerment

Empowerment education includes several factors, namely the provision of education in psychology, spirituality and the quality of life. Economic empowerment programs actively counter women's vulnerability by directly addressing the mutual influences of the axes of inequality within which the women were embedded [5]. In empowerment counseling interventions, this benefits the respondents in reducing partner violence and the secondary outcomes include improvements in women's mental health, safety and self-efficacy [8]. Through the policies and programs that build women's capabilities, improving their general access to social and political opportunity, and guaranteeing their safety is the goal [11]

3.2. Combining empowerment

Combining empowerment, family communication and positive cultural identity can increase the knowledge of HIV prevention, ESSA and the ability to discuss HIV [2]. The empowerment combination is used to combine more than one empowerment type needed by women living with HIV. For example, in training the independence and knowledge of women living with HIV, the goal

is for the respondents to carry out activities that improve in terms of independence that is both knowledge and financial.

3.3. Intervention empowerment

The healthcare empowerment model posits that to maintain patient engagement in care, the patient should feel involved, committed, collaborative and engaged in health care, as well as tolerant of uncertainty regarding the outcomes and complications associated with disease management [3]. The interventions provided varied, among others, including the provision of the Emotional Empowerment Technique (EET). This provides benefits and manifestations in the development of the psychotherapy experienced by the respondents [4].

3.4. Community empowerment

A community empowerment approach to HIV prevention and access to universal ART for female sex workers is a promising human rights-based solution to overcome the persistent burden of HIV among female sex workers across epidemic settings [15]. Community empowerment has an expending comprehensive impact on the HIV epidemic. In community empowerment, the families play an important role in the program's implementation because they are the closest person to the respondent [12]

4. Discussion

The aim of this is a systematic review to explore the empowerment needed by women living with HIV AIDS. The review revealed the limited available research in this field of study, identifying only 17 relevant studies.

Empowerment, as mentioned above, is the capability to make choices and to transform the choices into desired actions. There is a need to enable the women to access the means of empowerment. One of the primary ways in which this access can be guaranteed is through education. Education here is not just about literacy, but it is also about the awareness of the social injustices and discriminations that women face. It is about a critical understanding of the links between the women's own lives and the larger socio-political structures that they are a part of [2]. Education is regarded at the national level as an important catalyst for the development of the country. Several initiatives have been undertaken by the GOI for girls' education in order to empower women and girls alike.

Women living with HIV who received the individual intervention had lower scores for decision-making ability, concealment self-efficacy and perceived psychological health. They also had a higher weight of secrecy. Thus, these women were more in need of an intervention regarding disclosure issues. This can be explained in different ways. First, for these women, the social and family environment might have been more difficult, and finding the time and excuses to come to the collective sessions every week may have been hard for them. Second, discussing disclosure issues implies being ready to talk about it. If these women experienced traumatic experiences in relation to their HIV infection and/or specific disclosure events, then it might have been too frightening for them to share this with other WLHIV during the intervention[5]. The victims blaming themselves for the violence perpetrated against them only encourages the abuser and this continues a vicious circle of violence. Therefore, it may be advisable to initiate counseling and training programs along with women's empowerment initiatives to change the belief systems of the victims.

One way to improve the women's empowerment when it came to living with HIV/AIDS is to microfinance her training to have an impact in terms of fixing the knowledge economy [16]. One of the primary ways in which women can be citizens is through education. Education here is not just about literacy but it is about an awareness of the social injustices and discriminations that women face [2]. We also learned how economic empowerment programs have impacted on the women's role within their husband's household, which directly addresses the intersection of these axes of inequality. Consequently, economic empowerment programs allowed the women to (re)gain a sense of legitimacy within their households and communities, thereby reducing their marginalization and ultimately alleviating their own experiences with AIDS-related stigma. [6].

Life Skills is a peer-led and peer-delivered intervention, which may be a key characteristic for success in this population. We believe that the intervention was effective because of this combination of characteristics. It was grounded in the participant's social realities, focused on empowerment and practical needs, delivered by their peers. The high level of participant-rated satisfaction with the intervention reflects the salience of this approach [7].

While we found support among our study participants, as previously mentioned, it is necessary to conduct follow-up research with the mothers who left the program. It is also imperative to explore further complexities of the threshold of women's empowerment [6].

This systematic review has provided evidence, based on the effectiveness of empowerment for women living with HIV, that such methods can increase motivation to allow them to continue their lives better; education empowerment combines an intervention and the community, and seems to work best. This can provide a better life expectancy for women living with HIV.

5. Limitation

There are several potential limitations associated with this systematic review. The majority of the woman living with HIV AIDS in this research did not work so an effort should be made to fix empowerment in the education sector. Some had skills that were inclined to making them unable to provide a good response.

6. Conclusion

The intervention from empowerment resulted in a wide range of impacts epidemiologically, politically and socially across the heterogeneous countries. Around the world, the United Nations Program gives HIV/AIDS support to organizations that provide health-care services to patients with HIV to ensure that all have equal access to these services. For instance, there are adherence clubs where patients are given medicines and where basic medical check-ups are performed. There are also self-formed community antiretroviral therapy groups in which the members distribute medicine to their neighbors and appointment visits where medical visits take place less often and where the medicines are dispensed for a longer period of time. The provision of education by health-care professionals to people with HIV can be effective at improving the quality of life of women living with HIV in society.

	Women's Marginalization in West Nile Uganda [6]		countered women's vulnerability by directly addressing the mutual influences of the axes of inequality within which women were embedded. Consequently, HIV-positive women were able to (re)gain a sense of legitimacy in their households and communities, ultimately mitigating their experiences with AIDS-related stigma.
10.	Social self-value intervention for the empowerment of HIV infected people using antiretroviral treatment: a randomized controlled trial [14]	Randomized controlled trial	Social self-value interventions provided to HIV infected people during ART increased their empowerment. This intervention can be expanded to be utilized in routine services.
11.	A community empowerment approach to the HIV response among sex workers: effectiveness, challenges, and considerations for implementation and scale-up [15]	Quantitative	Community empowerment-based approaches to addressing HIV among sex workers were significantly associated with reductions in HIV and other sexually transmitted infections, and with increases in consistent condom use with all clients.
12.	Marital Rape and HIV Risk in Uganda: The Impact of Women's Empowerment Factors [16]	Quantitative	Significant differences were revealed for marital rape, women's empowerment variables and reducing the HIV risk according to their socio-demographic characteristics.
13.	Community mobilization, empowerment and HIV prevention among female sex workers in south India [17]	Quantitative	Community mobilization has benefits related to empowering women living with HIV both individually and collectively
14.	Epidemic Impacts of a Community Empowerment Intervention for HIV Prevention among Female Sex Workers in	Quantitative	A community empowerment approach to HIV prevention and access to universal ART for female sex workers is a promising human rights-based solution

No	Title, Authors, & Time	Design	Main Result
	Generalized and Concentrated Epidemics [18]		to overcoming the persistent burden of HIV among female sex workers across epidemic settings.
15.	Empowerment and Condom Use Among Mexican and Mexican American Women in Illinois [19]	Quantitative	Sociocultural and political forms of empowerment were significantly correlated with condom use.
16.	Marriage Age, Fertility Behavior, and Women's Empowerment in Nigeria [20]	Quantitative	Age at first marriage has a significant relationship with women's fertility behavior and empowerment. The enactment and enforcement of legislation to eliminate early marriage will impact positively on fertility reduction and women's empowerment in the country.
17.	Violence and Economic Empowerment of Women in Pakistan: An Empirical Investigation [21]	Quantitative	The women who earn cash and/or in-kind face greater violence. Education can reduce the violence against women and a family history of violence contributes positively toward greater violence. The results also confirm the existence of a regional disparity in this regard. Based on findings of this study, we have provided policy suggestions to mitigate the issue of spousal violence against women.

ABSTRACT

Scabies is a skin disease due to mite investment Sarcoptes scabiei and is one of the neglected skin disease. Scabies can easily spread to children and adolescents with poor hygiene and dense environment. The purpose of this article is to identify the incidence of scabies at schools in children and adolescents. The authors conducted of a relevant literature review in various data using the keywords "scabies, children, adolescents and schools". Data based on SCOPUS, Science Direct, Proquest and Pubmed. The criteria consisted of full text published in criteria were five years limit journal (2013-2018) and article using English. The results as much as 1.149 articles found, and selected 15 articles that suitable with criteria. Children and adolescents in schools can easily experience scabies and transmit to other friends because of poor personal hygiene and dense environment at the school.

Keywords: scabies, children, adolescents and school

6. Introduction

Scabies is a common contagious parasitic skin disease and a public health problem, mainly in tropical and subtropical countries. Scabies is a common parasitic infection caused by the mite *sarcoptes scabiei*. Scabies affects about 300 million people worldwide yearly[1]. Epidemiological studies have indicated that the prevalence rate of scabies is not affected by sex, race, or age, and that the primary contributing factors in contracting scabies seem to be poverty and overcrowded living conditions. Infectious skin diseases and infestations like pediculosis and scabies are a common problem in schoolchildren owing to the close contact between classmates [2].

Scabies transmission occurs through direct and prolonged contact, and possibly through sharing contaminated clothing or bedding. Infestation causes intense pruritus, particularly at night, often causing sleep disruption. The excoriation of lesions can lead to secondary bacterial superinfections, therefore treating an infestation early during the disease process may prevent bacterial superinfection and scabies transmission to close contacts. Treating scabies in a community leads to a concurrent reduction in rates or pyoderma [3].

Scabies has recently been adopted as a Category A World Health Organisation (WHO) Neglected Tropical Disease (NTD), highlighting the priority of this condition in developing countries. Scabies is a skin infestation caused by the parasite (*sarcoptes scabiei*). Scabies presents

with an intensely pruritic rash with a characteristic distribution pattern. Clinical manifestations include papules, burrows and pruritus. Distribution varies with age and often includes the involvement of the webs of the fingers, the flexor aspect of the wrist, feet and torso. Transmission is predominantly through direct contact with infected skin, but fomites including bedding and clothing can also play a role. Secondary infection by group A Streptococcus (GAS) and/or Staphylococcus aureus causing impetigo is common and may lead to complications including cellulitis, abscess, septic arthritis, osteomyelitis and septicaemia [4]. Scabies is endemic in tropical regions globally, with prevalence rates between 5–10% commonly reported in children [4]). The purpose of this review was to make sure that the children had good personal hygiene and a good environment, and to decrease the incidence rate of scabies in the children and adolescents.

7. Material and methods

This systematic review reporting was in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews) Statement.

2.18Data Sources and Searches

The databases searched were Scopus, Science Direct, Proquest and Pubmed, which provided the studies related to scabies, children, adolescents and schools from 2013 through to 2019.

2.19Study Selection

The literature review was conducted using scabies, children, adolescents and school as the keywords. The selection of the articles was determined by the following inclusion criteria: the full text was published, the articles were published between 2013-2019, the articles were published in English, they looked at the incidence rate of scabies, and the articles focused on scabies, children, adolescents and schools.

2.20Data extraction and quality assessment

All citations retrieved from the electronic databases were imported into the Mendeley Program. Two reviewers independently analyzed the titles and abstracts of every study retrieved from the literature search to identify potentially eligible studies. The full text of the remaining studies was obtained for further examination. The last review was conducted by the first reviewer. The data of the included studies were independently extracted by the same two reviewers by including the first author's name, the year of publication, the study design, the sample size, the general characteristics of the participants, the research measurement tool used and the main outcome of interest. A descriptive analysis was conducted of the data obtained from the reviewed papers to include and focus on the incidence rate of scabies in the children and adolescents.

8. Results

3.1 Study Design

As many as 1,185 articles were found, and the results came from four databases: 154 articles in Scopus, 150 articles in Science Direct, 284 articles in Proquest and 597 articles in Pubmed. The results of the article selection were according to the inclusion criteria of 15 articles. They were then given a serial number and article analysis was conducted to facilitate the review process.

There were a set of inclusion criteria, such that the articles used were cross-sectional, prospective, epidemiological and cohort in nature.

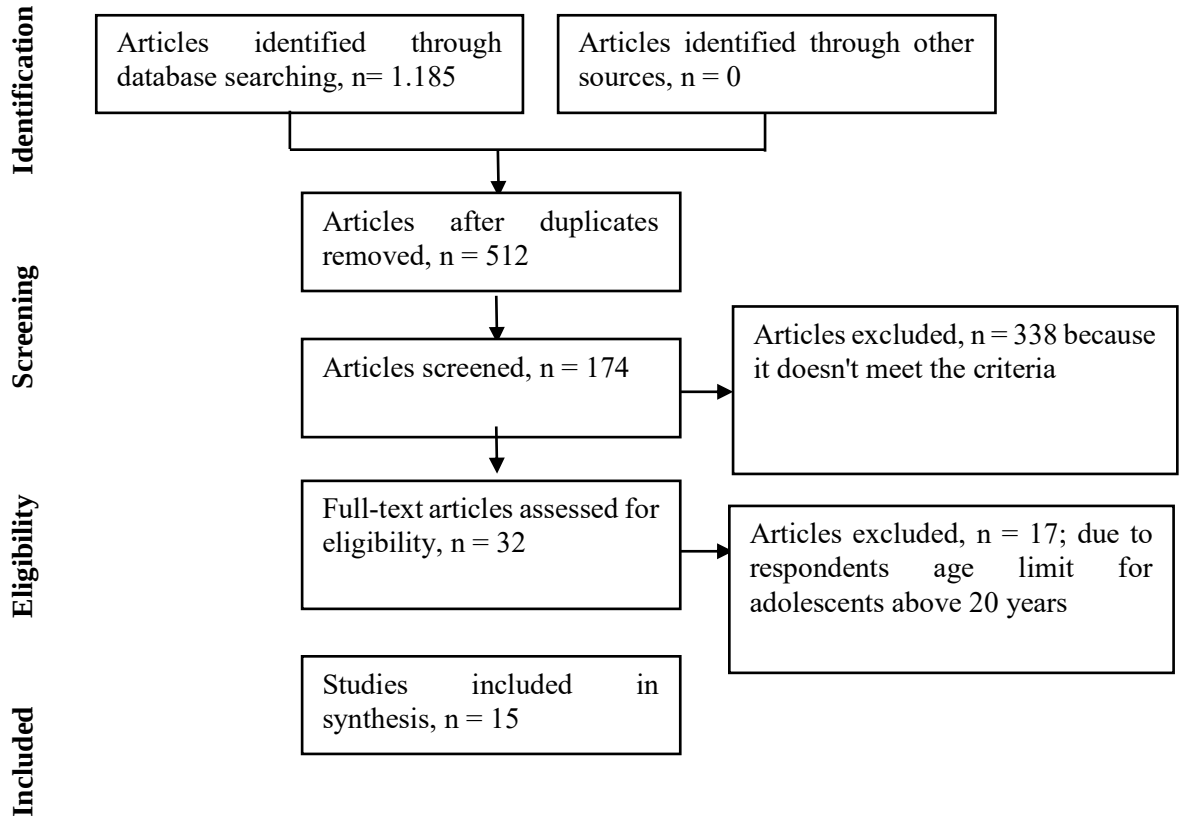

Figure 1: PRISMA flow diagram

3.2 Characteristics of Participant

In this systematic review from 15 articles, the population was made up of children and adolescents in school with a sample variant 2-4.532 participants ranging from 1-20 years old. The studies included were in East Asia, the Arabic region, Europe, Australia and America.

3.3 Incidence scabies in the children and adolescents

The present study determined the frequency of SSD in a sample of 1894 schoolchildren with skin disorders from Kisenso semi-rural county in Kinshasa, DRC [5]. The majority of the affected children were boys. The most affected schoolchildren were of a younger age (5–7 years). The interdigital spaces were found to be the location with the higher proportion of SSD skin lesions (93.8%) and vesicles were the most frequent form of skin lesion (95.3%) [5]. Personal hygiene was defective in 80% of schoolchildren, and more than half of SSD schoolchildren were not on any anti-scabies medication at the time of this study. Skin sores were recorded at least once for 307 (84%) out of the 365 children and scabies was recorded for 260 (71%) of the children. Of these, 251 (69%) child health records reported at least one episode of scabies and at least one episode of skin sores previous [5]. The most frequent

age at the point of first infection for the skin sores and scabies was similar at 3–4 months with no new first infections reported after the age of 32 months. The male sex was a risk factor for scabies infestation, which is a finding differing from Hegab et al's report in Egypt where there was no difference between males and females [6] . Sleeping with others had already been identified as a risk factor for scabies infestation [2], as well as the sharing of clothes with others. In fact, the high contagiousness of human scabies is transmitted by contact with an infected skin[7]. If the students are infected and they have no access to the infirmary to consult and/or to be treated, then they can spread the disease to others. Moreover and unsurprisingly, students complaining of pruritus had a 93.4-fold increased risk of being diagnosed with scabies. The itching can become very intense and uncomfortable, so that may affect the quality of life of the individual[8]. The epidemiological data about scabies infestation in students has provided valuable information about the risk factors and this suggests a basis for prevention and therapy methods. In the current study, the difference in the prevalence of scabies between males and females was not statistically significant[9]. This result corresponds with the results of other studies in Nigeria and Turkey. However, male predominance was observed in other Indian studies and this might be related to the social factors in society and in the country [10].

9. Discussion

The present study showed that the prevalence of scabies was higher among children from rural schools than among those from urban schools. Many studies from other countries also support this finding in a population of children aged 13-15 years old. This finding could be explained by a larger family size in rural areas, leading to overcrowding, in addition to a decreased level of health education, poverty and bad behavioral habits such as sharing clothes and bed linen with others, and dealing with animals [17]. The prevalence of scabies in the present study was higher among children whose fathers were illiterate or who were only primary level educated. Among those were fathers who were unemployed or manual workers. These results are in line with those of the previous studies, which have also demonstrated that the illiteracy of the adult household members were a very good predictor of the presence of scabies in developing and industrialized countries. In the present study, it was found that sleeping with others, having animals in the house, dealing with animals outside the house, living in houses made of soft brick, having a family history of itchy skin lesions and sharing clothes with others were all significant risk factors for scabies infestation. Many studies in our country and in other countries also support these findings [6]. This is supported by the previous prevalence studies, which have reported a high prevalence of scabies in hot, tropical areas where overcrowding facilitates the rapid spread of the scabies mite. The burden of scabies over the human lifespan has differing patterns in regions with a high or low scabies burden. Scabies and impetigo contribute to a significant burden of disease for children and adults in low resource countries [10]. Scabies infection can predispose an individual to secondary bacterial infection with GAS and *S. aureus*. GAS is also implicated in the etiology of glomerulonephritis, ARF and RHD, which can develop in the context of mild infections or carriage. High rates of skin infection in school students are suggestive of high rates community wide, including among vulnerable groups such as infants, preschool children and the elderly. Whilst improving access to clinical treatment is important, consideration should also be given to implementing programs targeted at limiting or eradicating endemic scabies and impetigo. Possible strategies can include community education, water, sanitation and hygiene programs and community treatment with mass drug administration [2].

10. Conclusion

In conclusion, the findings of the current study confirm that scabies is still an important health problem affecting schoolchildren in our community, especially in rural areas. Poor living conditions (inadequate housing, sleeping with others, illiteracy, having animals in the house, dealing with animals outside the house, and sharing clothes with others) are important risk factors involved in the transmission of scabies.

EDUCATION AND SELF MANAGEMENT INTERVENTION PROGRAMS FOR PATIENTS WITH COPD : A SYSTEMATIC REVIEW

N T Septiana[1], T A Firmanti[1], A Mufidah[1], N Fajriyah[1]
[1]Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
Email: nita.tri.septiana-2018@fkp.unair.ac.id

ABSTRACT

Self management is very important to increase patients skills and confidence, empowering the individual to take an active part in their disease management and increase the quality of life of patients with Chronic Obstructive Pulmonary Disease (COPD). The increasing incidence of COPD because of most patients fail to engage in adequate self management. This systematic review is to identify effectiveness education and self management intervention programs for patients with COPD. A randomized control trial (RCT) study using the PRISMA approach from: Scopus, SageJournal, Proquest, and Pubmed limited to the last 6 years; from 2014 to 2019 and obtained 12 articles that selected from 168 articles was found. This systematic review found five programs, they are self-management education programs and behavior modivication, Self-Management Programme of Activity Coping and Education (SPACE), individual self management plan and support intervention, the health coaching Programme, and self management supported by telehealth. The results of studies was collected mostly for 6 months. The most of the result from the studies show the impact of self management intervention programs to improve HRQoL and physical exercise capacity, self efficacy, self-care behaviours, self management skills and reduce the incidence of exacerbation.

Keywords: education, self management, intervention program, COPD

1. Introduction

This systematic review aimed to identify self management intervention programs for patients with COPD. Chronic Obstructive Pulmonary Disease (COPD) is a chronic lung disease that is common in the community, which cannot be cured but it can be controlled with long-term treatment. An increase in the prevalence and mortality of COPD occurs because most patients fail to carry out self-management properly. About 90% of deaths from COPD occur in countries with a middle or low income, where strategies for treatment, prevention, and the control of the disease do not go well. The WHO estimates an increase in mortality from COPD of more than 30% in 10 years, if the intervention to control risk factors is not done well[1].

COPD is a major cause of chronic morbidity and mortality throughout the world. More than 3 million people died because of COPD in 2012, which accounted for 6% of all deaths globally and currently, COPD is the number fourth most common cause of death in the world [2]. The WHO data globally shows that the prevalence of COPD in the world is 251 million cases and that an estimated 3.17 million have died. The WHO also estimates that in 2030, COPD will be the third cause of death in the world [1]. Basic Health Research records that 3.7% of the total population of Indonesia suffers from COPD, where the prevalence is higher for men [3].

The treatment of COPD requires a long process, so the patients need a good self management strategy for managing the disease. COPD self-management is the active participation of the patients in the treatment of the diseases based on adequate coping behavior, compliance with drug use,

attention to changes in severity and breathing techniques. Patients who have good self management can reduce their respiratory-related and all-cause hospital admissions and improve their health-related quality of life (HRQOL)[4]. Poor self management can cause many COPD patients to be repeatedly hospitalized because of the complaint of the recurrence of shortness of breath or the occurrence of exacerbations [5].

Many interventions can be done to improve the self management of patients with COPD. A COPD self-management intervention program is an educational program for patients with COPD with the goal of motivating, engaging, and supporting the patients to positively adapt their health behaviors and to develop skills to better manage the disease[6]. Self-management interventions exert positive effects in patients with COPD on respiratory-related and all-cause hospitalizations and they have a modest effect on 12-month health-related quality of life, thus supporting the implementation of self-management strategies in clinical practice [7]. Self management interventions in patients with COPD were associated with a better quality of life, fewer hospital admissions and improved symptoms [4]. Self management intervention programs are very important to improve the skills and confidence of the patients, to empower the individuals to take an active part in their disease management and to improve the quality of life of patients with COPD. This systematic review has identified the importance of self management programs for patients with COPD.

2. Methods

2.1. Search strategy and study selection

This systematic review only gathered RCT articles using the PRISMA[Figure 1]. A literature search was carried out in four databases - Scopus, SageJournal, Proquest and Pubmed - with the results limited to the last five years from 2014 to 2018. The keywords used in the literature search were education, self management program, telehealth and Chronic Obstructive Pulmonary Disease (COPD).

2.2. Type of study

This systematic review aimed to identify self management intervention programs for patients with COPD. A randomized controlled trial study (RCTs), which is in the top position of the evidence hierarchy, is qualified and suitable to answer this kind of question. Therefore, only RCTs were included in this review.

2.3. Inclusion and exclusion criteria

The inclusion criteria of the articles were that they all had to contain a self management intervention program for patients with COPD. All articles using the English language were included. Articles were excluded if the study did not utilize a randomized control trial (RCTs).

2.4. Participants, Interventions, Comparators, Outcomes and Study design (PICOS)

The feasibility of the study was assessed using the PICOT approach: the participants were patients with COPD, interventions were the type of self management education, there was no comparison and the outcomes were to improve HRQoL, physical exercise capacity, self efficacy, self-care behaviors, self management skills and knowledge. The intention was to reduce the incidence of exacerbation. The study design was a randomized controlled trial study (RCTs).

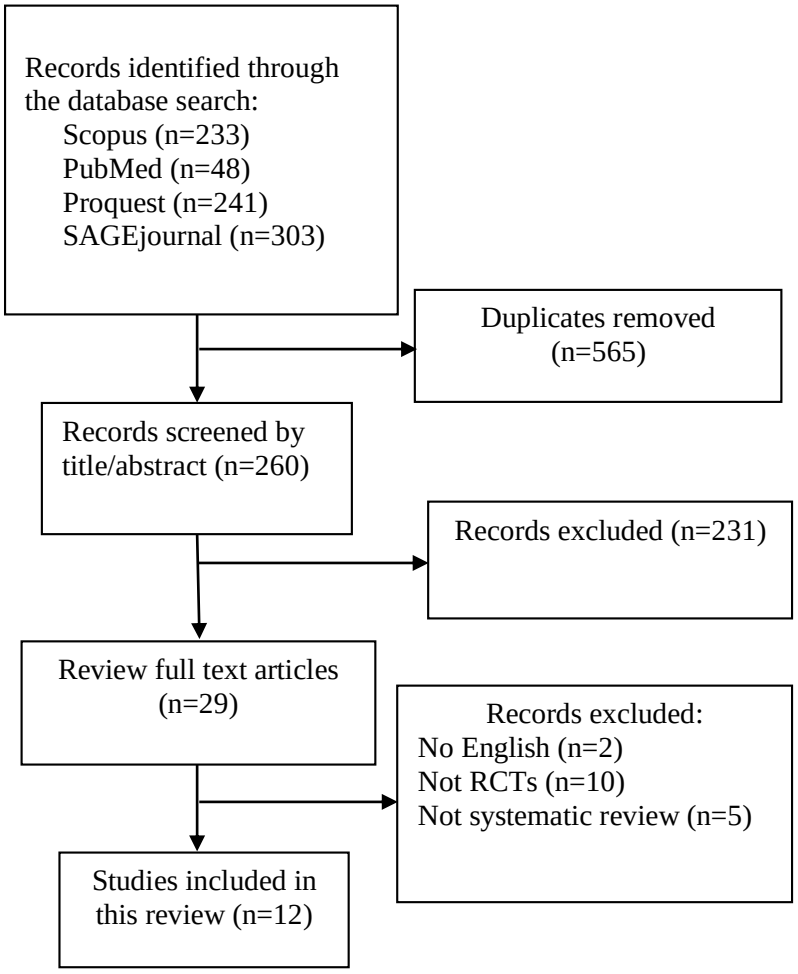

Figure 1. PRISMA flow diagram

Table 1. Summary of the studies included in the review

Author	Type of study	Participants and country	Interventions and Times	Outcomes
[13]	RCTs (Qualitative)	36 patients of adults with COPD. UK	SPACE program (Self-management Program of Activity, Coping and Education): Time: intervention in 6 weeks, follow up in 6 months.	1) Perceptions of the program (participants were very satisfied with the breadth of the content and the education that it provided). 2) Lifestyle changes (increased physical activity and exercise behavior as well as altered medication use and the use of breathing control and chest clearance techniques, decreased breathlessness, increased participation in valued activities, increased knowledge and understanding of COPD, improved energy levels and improvement in walking times).
[5]	RCTs (Quantitative)	250 patients with COPD. Spain	Self-management education program. Time: 1 year.	The rate of COPD exacerbations with visits to A&E or hospitalization had decreased (reduced exacerbations).
[14]	RCTs (Qualitative)	20 COPD patients. China	The health coaching program. Time: 6 months.	Improved lung function, physical activity, quality of life, and self management skills, as well psychological status in short and long-term.
[9]	RCTs (Quantitative)	51 COPD patients (25 control group, 26 intervention group). China	Self-management education programs (SMEPs) Time: 6 months.	Significant improvement in self-efficacy.
[11]	RCTs (Quantitative)	184 people with COPD (92 people in control group, and 92 people	The Self-Management Program of Activity, Coping and Education	At 6 weeks, there were significant differences between the groups in the CRQ-SR dyspnoea, fatigue and emotion scores, exercise performance, anxiety, and for disease knowledge.

		in interventions group). Europe.	(SPACE) for COPD. Duration: 6 weeks and a follow up in 6 months.	At 6 months, there was no between-group difference in relation to changes in CRQ-SR dyspnoea. Exercise performance, anxiety and smoking status were significantly different between the groups at 6 months.
[16]	RCTs (Quantitative)	577 patients COPD (289 patients intervention group, 288 patients control group) in England.	Telephone health coaching intervention delivered by nurses. Time: intervention 6 months, follow up in 12 months.	Changes in self management activities, but this did not improve health related quality of life (no difference in SGRQ-C total score at 12 months). At six months, there was an improvement in physical activity, and they had received a care plan, rescue packs of antibiotics, and an inhaler use technique check.
[8]	RCTs (Quantitative)	131 COPD patients in primary and secondary care. UK	Clinician-led Self Management Education Program. Time: 6 months.	Improvements in important outcomes such as activation, mastery and self-management abilities.
[10]	RCTs (Quantitative)	54 patients diagnosed with COPD. Canada	Self management education program with the coaching of a case manager. Time: 6 months	Improved the patients' quality of life, self management skills and knowledge.
[12]	RCTs (Quantitative)	78 patients (39 patients in both groups). UK	Self-management Program of Activity, Coping, and Education for COPD (SPACE for COPD). Time: 3 months	No reduction in the readmission rates at 3 months, but SPACE worked for COPD when it came to preventing readmission within 30 days.
[17]	RCTs	29 COPD patients.	Telehealth program.	No significant results on the number of hospitalizations, length

	(Quantitative)	The Netherlands	Time: 9 months	of stay, and emergency department visits, but significant clinical measures (decreased dyspnea level).
[18]	RCTs (Quantitative)	1,325 participants. The Netherlands	A web-based, computer-tailored COPD self-management intervention. Time: 6 months	No significant results regarding physical activity and smoking cessation.
[15]	RCTs (Quantitative)	215 participants. USA	Health coaching plus a written action plan for exacerbations and brief exercise advice. Time: 12 months	Improved quality of life and reduced COPD readmissions.

3. Results

In total, 2950 patients were involved in 12 different studies. There were four articles in 2014 (33,3%), one article in 2015 (8,3%), three articles in 2016 (25%), one article in 2017 (8,3%), and three articles in 2018 (25%). After reviewing the results, the self management intervention programs were classified as education programs (58,3%), coaching programs (33,3%) and web-based programs (8,3%). There were four types of intervention program, namely the self-management education program (SMEP), the Self-Management Program of Activity Coping and Education (SPACE), the health coaching program and telehealth coaching intervention, and web-based computer-tailored self-management intervention [Table 1]. The duration of the follow-up to the self-management intervention programs in this review were 3 months in one study (8,3%), 6 months in seven studies (58,3%), 9 months in one study (8,3%), and 12 months in three studies (25%). The media of the self management intervention programs used in this review consisted of slides using Powerpoint, modules, video, telephone calls, an app and a website.

3.1 Self management education programs

There were four articles that used a self management education program (SMEP) in this review. The research conducted by Sanchez et al (2016) used a self management program for 1 year in two pre-post-test groups. The intervention group accepted the SMP-COPD program individually[5]. Comparative groups, or control groups, received routine care and had regular visits. The interventions were conducted in 3 sessions. The first session was where they received educational material consisting of a PowerPoint presentation with 20 slides about the main characteristics of the disease, the symptoms of exacerbation and inhaled medicines. In the second session, there was an opportunity for questions and a physiotherapist showed them how to do a series of basic physical exercises. The

third session used sheet paper education and instructions for the patients that consisted of four sheet types: the first sheet contained instructions about physical care and exercise for a stable period (green), the second sheet consisted of care sheets for exacerbation (orange), the third sheet contained instructions to follow in case their condition became serious or emergency (red sheets), and the fourth sheet contained instructions for the technique of inhalation that contained a systematic and protocol-based process to train all of the patients in intervention group on the correct administration technique for each prescribed inhaler, with a particular emphasis on both avoiding critical errors and compliance[5]. After the 1 year follow up, the results showed that a reduction of exacerbation incidences.

Research conducted by Turner et al (2014) used SMEP for seven weekly sessions that were three hours each. The SMEP included weekly COPD-specific content including managing breathlessness, COPD medication and managing COPD exacerbations[8]. After the 6-month follow up, the results of the study showed that there were improvements in patient activation, improvements in COPD mastery, a range of self-management abilities (self-monitoring and insight), a constructive attitude shift, and new skills and technique acquisition.

SMEP was used in study by Ng Wai I & Smith GD (2017) conducted on a group basis with five to eight participants in each section[9]. The SMEP workshops in this study comprised of an overview of the definition of COPD, the natural course of the disease, information on how to manage a stable condition, advice on how to prevent complications and a self-treatment guideline (or action plan) for managing exacerbations. They were delivered to the experimental group by the principal researcher over three 1.5-hour nurse-led sections that ran over 3 consecutive weeks at a demonstration room in the clinical setting. After 6 months, the study evaluated the self efficacy of the patients with the CSES tools from Bandura's Self-Efficacy theoretical framework that consist of 34 items exploring the five dimensions of self-efficacy[9]. The results of the study showed that there was an improvement of general self-efficacy in the intervention group, especially for physical exertion, weather/environment effects, and intense emotions. Three themes that emerged from the focus groups were greater disease control, improved psychosocial well-being and perceived incapability and individuality.

The research conducted by Bourbeau et al (2018) used a self management education program with the coaching of a case manager who focused on treatment adherence, inhaler technique, smoking cessation, and the use of an action plan for exacerbations[10]. The intervention program consisted of an initial visit and three follow-ups at 4–6 weeks, 4–6months and 1 year. The initial visit lasted for around 90 minutes and consisted of an assessment of their educational needs, a spirometry and a 1-hour encounter with the educator (respiratory therapist). During the encounter, the following topics were covered: COPD etiology and pathophysiology, COPD control, smoking cessation, the use of a written action plans for acute exacerbations, adequate inhaler technique, and medication adherence. The follow-up visits lasted for around 60 minutes in which pre-bronchodilator spirometries were performed and their educational needs were assessed. Based on the individual patient needs, specific self-management skills were addressed (exacerbation recognition, action plan use, inhaler technique among others). The results of the study showed that there were improvements in HRQoL, treatment adherence, adequate inhaler technique, and COPD knowledge, that they increased their prescription for long-acting bronchodilators with/without inhaled corticosteroid, kept up with their flu immunizations, and had COPD action plans in the event that the patient had an exacerbation.

3.2 Self Management Program of Activity Coping and Education (SPACE)

There were three articles that used the Self-management Program of Activity, Coping, and Education (SPACE). The article by Mitchell et al (2014) used the SPACE for COPD manual for at least 6

months, which is a 176-page workbook that individuals can follow independently at home[11]. The manual, divided into four discreet sections, contains educational material and a home exercise program. The intervention was carried out by a physiotherapist during a 30–45-min consultation. The participants needs were discussed and goal setting strategies were introduced. The participants were advised on how to use the manual at home and the exercise regime was described by the physiotherapist in detail. It was anticipated that the participants would work through the manual in approximately 6 weeks. However, the participants were advised the manual was theirs to keep, as it could be used as a resource for the future and that the lifestyle changes it suggested should be lifelong. The participants then received two telephone calls from the physiotherapist 2 and 4 weeks into the program to reinforce their skills and providing them with the encouragement to progress. There was no further contact between the physiotherapist and the participant after the telephone call at 4 weeks[11]. The result of the study was evaluated at 6 weeks and 6 months. The results of the 6 weeks evaluation showed that there were significant differences between the groups in the CRQ-SR dyspnoea, fatigue and emotion scores, and for the exercise performance, anxiety, and disease knowledge. The results of the 6 month evaluation showed that that there no difference in the changes of CRQ-SR dyspnoea between the groups. Exercise performance, anxiety and smoking status were significantly different in the intervention group.

The research conducted by Johnson et al (2016) was the intervention of SPACE introduced to the manual exercises conducted by a trained physiotherapist (VJ-W) in a one-to-one session lasting 30–45 minutes using motivational interviewing techniques to facilitate behavior change, goal setting, and problem solving[12]. The participants were advised how to progress and they were informed that the manual could be valuable for the future to reinforce any life-long lifestyle changes. They then received structured phone calls within 72 hours and at 2 weeks, 4 weeks, 6 weeks, 8 weeks, and 10 weeks post-hospital discharge with the aim of reinforcing their skills, helping them to identify and manage exacerbations, promoting an active lifestyle, and providing encouragement, while tailoring them to the patient's needs. After the 3 month follow up, SPACE for COPD did not reduce the readmission rate above that of usual care, but it did help prevent readmission within 30 days. The results of the study explained that the patients receiving the intervention reported feeling better able to arrange their life to cope with COPD, that they knew when to seek help about feeling unwell, and that they more often took their medications as prescribed.

The research conducted by Apps et al (2017) used SPACE with an interview according to the following four themes: perceptions of the program, lifestyle changes, social support and disrupting the factors and barriers to maintaining routine. The intervention followed a 6-week assessment and it was then followed up after 6 months[13]. After the follow up after 6 months, the results of the study showed that there were lifestyle changes, increased physical activity and exercise behavior as well as altered medication use and the use of breathing control and chest clearance techniques, decreased breathlessness, increased participation in valued activities, increased knowledge and an understanding of COPD, improved energy levels and an improvement in walking times.

3.3 The health coaching program and telehealth coaching intervention.

There were four articles that used the health coaching program and telehealth coaching intervention The research conducted by L Wang et al (2018) used a combination of 1 face-to-face coaching session (in the hospital) and monthly telephone coaching (after discharge). The intervention used a 3-step nurse led program[14]. Step 1: an individual face-to-face health coaching session at the hospital provided by the coach assessing the patients' self-management level, exercise capacity, medical adherence, and psychological status. A face-to-face consultation between the patient and nurse-coach

was conducted focusing on patients needs with an interviewing experience that lasted 25–71 minutes. Step 2: making a plan to improve the patient's self-management skills based on the baseline subjective and objective findings as in Step 1. A self-management booklet and a health diary to record their health behaviors were given to the patients and they were also encouraged to use a pedometer. Step 3: monthly telephone support to provide the patients with the resources to reduce the barriers in the implementation of the plan. There was an evaluation of their improvements by the coach and the patient in the telephone follow-up. Monthly telephone coaching was performed to support and motivate the patient implementing the plan, to evaluate improvements in the program, to adapt the contents of the program, and to make changes according to the patient's symptoms and individual needs. After 6 months of follow up, the results of the study showed that there were improvements lung function, physical activity, quality of life, and self management skills, as well as ther psychological status in both the short and long-term.

The research conducted by Benzo et al (2016) used the health coaching program[15]. The program included providing the patient with a written Emergency Plan to be activated in the event of an exacerbation, discussing the concept of self management, goal setting, action planning, and the mechanics of the telephone session to come. The result of study showed that it improved their quality of life and reduced COPD readmission.

The research conducted by Jolly et al (2014) used a telephone health coaching intervention delivered by the nurses. The intervention promoted accessing smoking cessation services, increasing physical activity, medication management and action planning (4 sessions over 11weeks; postal information at weeks 16 and 24). The nurses received two days of training[16]. The results included changes in the self management activities, but it did not improve health related quality of life. There was no difference in the SGRQ-C total score after 12 months. After the six month follow-up, the results showed that the intervention group reported greater physical activity, more had received a care plan, they had rescue packs of antibiotics, and an improved inhaler use technique

Another research conducted by Tabak et al (2014) used a telehealth program called "The Condition Coach"[17]. The program consisted of four modules: an activity coach (for ambulant activity monitoring and for the real-time coaching of daily activity behavior), a web-based exercise program (for home exercising), the self-management of COPD exacerbations via a triage diary on the web portal (including the self-treatment of exacerbations) and a teleconsultation (for comments and asking questions of the patient's primary care physiotherapist and vice versa via the web portal). After the 9 months follow-up period, no significant results were found in the number of hospitalizations, the length of stay, and emergency department visits but there was a significant clinical measure in terms of the decreased dyspnea level.

3.4 Web-based computer-tailored self-management intervention

The research conducted byVoncken-Brewster (2015) used the "MasterYourBreath" application. The intervention was designed to change the participants' health behavior through a web-based application providing computer-generated tailored feedback[18]. The application had a modular design, including two behavior-change modules, smoking cessation and physical activity, divided into six intervention components. The participants assigned to the experimental group were asked by email to access the application with a personalized account and to use the application for 6 months. The computer-tailored application was embedded in a website.

The website contained general information about the MasterYourBreath project, COPD/being at risk of COPD, smoking, and physical activity. Online self-management resources, such as videos

with home exercises (seven exercises focusing on strength and balance) and hyperlinks to other informative websites, were also included. The tailored feedback and prompts referred the participants to the home exercises and other resources. Application use was monitored by the research team and email prompts were sent to encourage application use, mostly within a 2-week time interval addressing new content on the website, as this could increase the number of follow-up visits. The results of the study showed that there was no significant impact on the primary outcome measures (physical activity and smoking) or on the secondary outcome measures (intention to change behavior and dyspnea).The only significant effect found was on clinical disease control, but the improvement was too small to have clinical relevance and it was not significant after correcting for the relevant baseline characteristics.

4. Discussion

This systematic review aimed to identify the self management intervention programs for patients with COPD. The reason for conducting this systematic review is related to COPD as a major cause of chronic morbidity and mortality throughout the world. The treatment of COPD is long term, so the patients need a good self management strategy to manage the disease. Self-management interventions are defined as structured interventions for individuals aimed at an improvement in self-health behaviors and self-management skills[19]. We need to know what kind of self management intervention programs we can use to manage the disease. From reviewing the results of the twelve RCT articles, all of them showed that self management intervention programs had a positive impact on the COPD patients. Most of the results from the study showed that the impact of self-management intervention programs was related to improving their lifestyle changes (increased physical activity and exercise performance), bolstering their quality of life, self-efficacy, self-management skills and knowledge, thus reducing the incidence of exacerbations and re-admission. Four articles related to improving quality of life. There were three articles that explained that improving self management skills and knowledge. There were two articles that explained the impact on changes in lifestyle (increased physical activity and sports performance). Three articles were related to the decrease in the publication of exacerbations and readmission to the hospital. One article showed that it increased self efficacy. Two articles showed that no significance in the results related to readmission and hospitalization, length of stay, emergency department visits, and regarding physical activity and evaluating smoking cessation. The follow up duration that the self management intervention program used was 6 months which had a positive effect on COPD. The main effect from all of the articles in this review was an improved quality of life. This improvements of the quality of life of COPD was found in the studies conducted by L Wang et al (2014), Benzo et al (2016), Jolly et al (2018) and Bourbeau et al (2018).

This systematic review showed that there are four types of intervention programs used, namely the Self Management Education Program (SMEP), the Self Coping and Activity Education (SPACE) Program, the health coaching program and telehealth coaching intervention, and a web-based computer-tailored self-management intervention. The Self Management Education Programs (SMEP) was more widely used in this review (four articles). SMEP can reduce exacerbation[5], increase self efficacy[9], improve the patient's self management skill and abilities[8], and improve their quality of life[10]. Education is centre stage but while COPD self management interventions programs often include education and action plans, the intervention is considered to be more than just the sum of these two components[6]. Improvements in the activity levels, energy and overall quality of life represent important clinical outcomes for chronic illness populations, especially for patients with COPD[20]. The self management intervention programs are very important for patients with COPD to improve their lifestyle changes (increased physical activity and exercise performance), quality of life, self efficacy, self management skills and knowledge, thus reducing the incidence rate of exacerbation and readmission.

This systematic review had several limitations. First, the systematic review only gathered RCT articles using the PRISMA approach, and we did not use a meta-analysis approach to analyze the studies. Second, the authors limited the language of the articles to English. Third, most of the studies in the review came from Europe (consisting of eight studies); only two studies came from Asia and only two studies came from America.

5. Conclusion

Self management intervention programs can be used as an effort to improve the self management skills and quality of life of patients with COPD. SMEP is the intervention that was mostly used in this review with a duration of 6 months. The self management intervention program was effective for patients with COPD, with the main effect of improving their quality of life. The role of the nurses in the self management intervention program was as educators and facilitators in implementing the self management interventions. Nurses are expected to be able to provide good education about self management in COPD patients including the treatment of the disease based on adequate coping behavior, compliance with drug use, attention to changes in severity and breathing techniques. This is so then the patients actively participate in implementing self management of the disease.

ABSTRACT

Non-compliance with treatment for tuberculosis (TB) clients is a serious problem that must be addressed immediately. Treatment failure, disease transmission, and drug resistance are problems that occur due to non-compliance with treatment. Intervention strategies have been developed to improve adherence and treatment success rates. The purpose of this systematic review is to describe various intervention strategies that can be used to improve TB client medication adherence. Literature search uses pre-determined keywords through several electronic databases such as SCOPUS, PROQUEST, Springer Link, SAGE JOURNAL and Science Direct from 2008 to 2018. Qualitative and quantitative studies are included. There are 19 studies reviewed. The results showed that there were various categories of interventions that could be used to improve medication adherence to TB clients, namely the Directly Observed Treatment Short Course (DOTS) which is a government program, health education, psychological counseling, Use of science and information technology, incentives and support (family, peers and professionals). The results of this systematic review showed that various intervention strategies are needed to improve treatment compliance for TB clients. The intervention strategy will be more effective and provide benefits if applied with a combination system, not a single intervention.

Keywords: intervention, medication adherence, patients pulmonary tuberculosis

1. Introduction

Tuberculosis (TB) is a significant health threat that causes around two million deaths per year[1]. The government has implemented the Directly Observe Treatment Short Course (DOTS) strategy that has been observed globally since 1995. However, dissatisfaction is still a difficult problem to overcome in the management of TB patient treatment[2]. The factors affecting the non-compliance of TB patients in treatment includes the knowledge of TB and treatment, the distance to the nearest health facility, stigma, the perceptions of disease and malady, psychological stress, changes in residence and economic status[3]. Inadvertence in treatment is an important thing to observe because inappropriate treatment can cause the transmission of disease, the prevention of treatment and the immunity of the TB bacteria against Anti-Tuberculosis (OAT) drugs called MDR-TB[4].

TB has a huge impact on the lives of the sufferers, physically, mentally and socially. Physically, TB that is not treated properly will lead to increasingly long-term treatment and complications, such as the spread of infections to other organs, malnutrition, severe coughing up of blood, drug resistance

and even death[5]. Mentally and socially, the problems that are often experienced by the TB patients include stigma, shame, worry, disbelief, and fear of death[6]. Prolonged psychological problems and not getting serious treatment are one of the factors that cause non-compliance which in turn will lead to failure in terms of the treatment[7]. Intervention strategies to reduce patient non-compliance have been developed by the international community, government, community, health workers and fellow sufferers community (peer group support) [8].

The purpose of this systematic review was to summarize the various intervention strategies that can be used to improve the TB patients' compliance with treatment by synthesizing the previous studies. We hope that this systematic review can be used as information for TB program facilitators and clinical research.

2. Methods

A systematic goal was developed based on the PICO (Patient, Intervention, Comparison, and Outcome) framework model[9]. This systematic review was performed in line with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) statement and checklist[10,11]

Search strategy data sources

The systematic search of the PICO base electronic data framework was carried out according to the PICO framework[9]. For the first step, the researchers searched the SCOPUS, PROQUEST and Springer Link electronic database, with SAGE JOURNAL and Science Direct also being used to identify the key articles and to identify the keywords by adjusting the key concepts: Patient TB "AND" intervention "AND" Improve "OR" increase "AND" Compliance "OR" adherence. Our keywords were used to search for quotes and full articles including the title, abstract, text and reference information. The second step was translating keywords in English to find the relevant articles in the electronic databases. The third step was to filter using the PICO framework to determine which articles passed for further review according to the topic. The complete search strategies were limited to the last 10 years between 2008 – 2018.

Inclusion criteria

This systematic review establishes the inclusion criteria with a focus on quantitative studies, qualitative studies and mixed method studies. This is a feasibility study to describe the various types of intervention strategies that can be used to improve the compliance of TB patients in line with treatment according to a language eligibility criteria where a minimal number of abstracts using English. The year of publication was limited to the last 10 years from 2008 - 2018. Further criteria for the inclusion group were studies with adult TB patients (>18 years).

Exclusion criteria

Non-English, reviews and non-research articles.

Screening

The protocol standard for selecting the research studies was suggested in the PRISMA method for the systematic review followed by screening by removing duplicates. Three reviewers then selected the titles, abstracts, and keywords before deleting any irrelevant quotes according to the selection criteria. The reviewers noted the reasons for choosing the research studies including the selection of the inclusion data. The selection of the research studies was recorded by two reviewers and then they were compared to one another to adjust the feasibility according to the criteria set. Secondly, to minimize the risk of an incorrect study entry in the selection, there were several research studies that were applicable or that could be applied in a review by one or two reviewers to allow it to be

potentially included in the next review stage. The full text of the articles was obtained if the title and abstract met the inclusion criteria or if the feasibility study was clearly resolved by a joint discussion between the reviewers.

Data extraction
The following data was extracted: author, year, journal, country, the setting of the study, the aim of the study, the research questions, the type of study, the sampling method, the key findings and if there were any relevant secondary outcomes. Two authors (ADA and RI) were involved in the data extraction and after organizing the results in a table, the findings were discussed and reviewed again.

Quality assessment
The assessment of the quality of the articles to be reviewed used the quantitative study tool known as the Critical Appraisal Skills Program (CASP). There were 10 different questions that considered the results of the quantitative studies, the validity of the studies, and their uses[12]. CASP is a tool used for evaluating the quality and utility of the research reports[13]. The 10 questions in CASP were answered by selecting "yes", "no" or "not now" for each question. The allocation of the scores was on a scale of 10 for each article reviewed based on how many "yes" answers there were. A score of yes that was above 7 or more refers to a quality of article that is very good. The purpose of this quality assessment was not to distinguish between the articles in terms of quality but in a systematic process and standard process, we can use this to provide high-quality reviews based on the existing topics.

Analysis
Due to the methodological diversity of the studies included and the limited number of studies that specifically addressing the objectives set for this review, descriptive synthesis is considered to be the most appropriate analytical method[14].

3. Result

Study result
The search strategy was carried out by generating a total of 12,118 citations; 11,996 items of the existing literature were deleted during the first screening because the title and / or abstract did not match the specified eligibility criteria, which included the year published being < 2008, it not being an item of original research or where the TB was in children. In total, 122 full articles came from the second stage of the screening and the final 13 articles obtained were retained for review. In addition to this, 6 additional articles were obtained from the reference screening stage and thus the last session included 19 articles on the interventions used to improve treatment compliance for TB patients (see Figure 1).

Study Characteristics

Types of study. A total of 19 studies reviewed in 2008-2018 were conducted in 9 countries: Nepal, South Africa, Vietnam, Bangladesh, Ethiopia, South Korea, China, Pakistan and Spain. Quantitative, qualitative and mix methodology research methods include Randomized Control Trial (RCT), prospective observational study, cross-sectional survey, prospective cohort study, retrospective study, qualitative research with grounded theory approach and research using mix methods (see Table 1).

Types of participant. The number of samples in this study varied. For quantitative research, the number of patients ranged from 68 – 46581. For the qualitative research, the number of patients was between 20-110 and for research with a quantitative and qualitative mixed methodology, the number of patients was between 10-49. The studies in Indonesia show that the prevalence of tuberculosis in men was 3 times higher than the prevalence in women[15]. Around 49% (almost half of the sample) experienced mild to severe psychological disorders and this will ultimately be a factor causing the client's non-compliance in treatment[3].

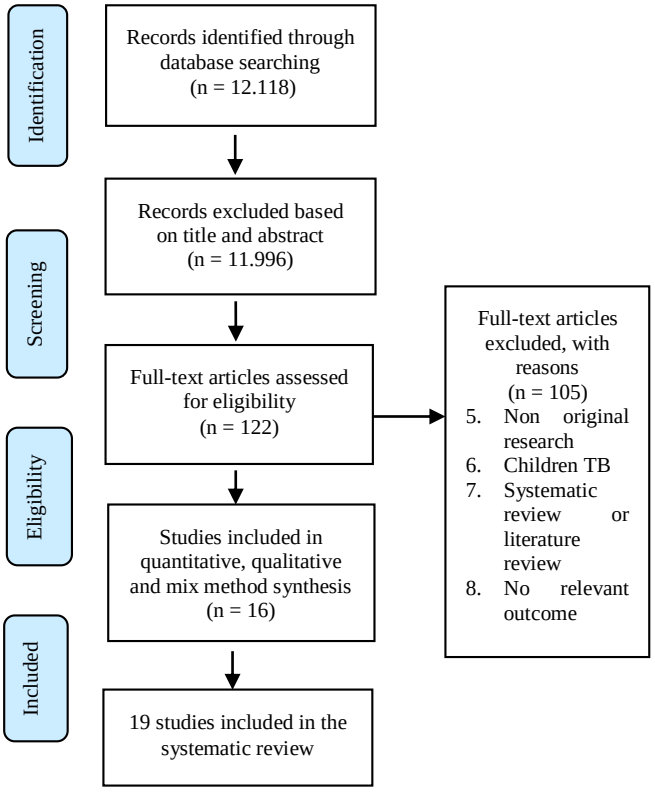

Figure 1. Flow Diagram

Summary of studies

The literature search identified 19 journals that describe the interventions that can be used to improve medication adherence in TB patients. From the articles found, five categories of intervention were obtained and found to improve the treatment compliance of TB patients, namely the Directly Observed Treatment Short Course (DOTS) which is a government program, health education,

psychological counseling, the utilization of science and technology, and giving incentives and support (family, peers and professional).

Directly Observed Treatment Short Course (DOTS). The World Health Organization (WHO) and the International Union Against Tuberculosis and Lung Disease (IUATLD) developed a TB control strategy known as the DOTS strategy since the early 1990s. It has been proven to be a cost-effective control strategy. The main focus of DOTS is the discovery and healing of patients, especially those with infectious type TB. This strategy breaks the chain of TB transmission and reduces TB incidence in the community. The finding and healing of TB patients is the best way to prevent TB transmission. The DOTS strategy was recommended as a global strategy in TB control since 1995[16].

Nineteen articles reviewed as DOTS were the main programs intended to regulate TB. In its implementation, DOT must be supported or combined with other support to improve patient support in the treatment[17,18]. Interventions that can be done to support the DOTS program include financial support[19,20], support for psychological counseling[20,21], DOTS combined with mobile phone reminders/ Short Messages Sent (SMS)[22,23], the combination of DOTS with various support around the patient such as family support, peer group support, surrounding community support, community cadres and support from health workers[24,25], combination DOTS with structured education to improve on the knowledge, attitudes and actions that can support patient support in medicine[26], arranged in regional languages[27] or based on existing theories[3]. The DOTS implementation program was also conducted through home visits to provide direct education to the patients and their families about clean and healthy lifestyles[28]. With the development of science and technology, the implementation of the DOTS program in developed countries such as the United States and Vietnam used a method called the Shortly Observed Treatment Short Course (VDOT). This method proved to be effective, easy to understand and accepted as increasing TB patient compliance with costs that were more efficient and limited resources[29].

Health education. The articles reviewed mentioned that health education for TB patients undergoing treatment is very important in order to increase the knowledge, attitudes and practice of patients in medication compliance [26] and to increase the psychosocial support of the patients [7,8]. They should also increase the family participation to support the patients to complete the treatment[27]. Health education about the disease, treatment, nutrition, the prevention of transmission and other supporting factors needs to be conveyed to the patient diagnosed with TB until the final treatment[24]. Patients who do not receive information and who cannot argue incorrectly can be one of the factors that cause non-compliance in treatment which ultimately leads to treatment failure, the transmission of disease and drug resistance[30]. Health education designed using the local language can improve the patients' understanding of the TB disease. The good understanding of the patients and their families can improve patient compliance to treatment and increase the role and family support of the patients in completing their treatment[31]. Health education guided by behavioral theories such as HBM can be more effective and significant when it comes to improving the medication adherence to TB patients. This is because the theory can predict and explain a person's beliefs about patient health including the adherence to treatment [3].

Psychological counseling. The articles reviewed illustrated that psychological counseling is needed for the TB patients [3,21], especially for those newly diagnosed with TB[7]. The diagnosis of TB is generally seen of as something surprising, demoralizing and able to cause various social and psychological problems. The psychological responses experienced by the TB patients at the time of the initial diagnosis of TB include worry, disbelief, shame, fear of death, fate and relief[6]. Patients at a high risk of noncompliance must be identified at the beginning of the treatment and offered services by a psychologist[32]. The health workers must be specially trained in competent psychological communication with patients to improve their compliance[7]. TB is associated with serious emotional and social consequences. When the coherence of the disease increases, the negative emotional and social consequences of the disease can be reduced. A preparation and development program is needed to identify and overcome the emotional responses, including stigma, related to TB[1]. Psychological counseling, when given to the TB patients and well understood, can improve the quality of life of the patients[28]. Patient confidence can improve medication adherence and improve the cure rate[20].

Use of science and information technology. The articles reviewed show that the use of science and technology can support the success of the DOTS program because it can produce high levels of compliance with limited resources[33]. The goal of sustainable development and the global drive for universal health coverage is to explore new ways to improve medication adherence. Health information delivered through Mobile Health (mHealth) is very promising when it comes to improving the quality and efficiency of health care / treatment. In addition, mHealth can discuss important aspects of treatment noncompliance in terms of the patients by facilitating new and sophisticated ways of providing financial and non-financial incentives. The types of mHealth that can increase compliance in the TB patients come in 5 categories, namely Video Observation of Therapy (VOT); Indirect technology monitoring - Patient facilitated (IP); Indirect monitoring technology - Device facilitated (ID); Direct monitoring technology -Embedded sensors (DE) and Direct monitoring technology - Metabolite testing (DM)[34].

The DOTS strategy with an audio-visual method is known as the Video Directly Observed Treatment Short Course (VDOT). This method has been proven to be effective, easy to understand and accepted to improve TB patient compliance with more efficient costs and limited resources[29]. The management of pulmonary TB patients through Short Message Service (SMS) reminders can effectively strengthen the complete level of treatment of pulmonary TB patients[23], reduce missed dose levels and discontinued treatment levels, and further increase the patient's awareness of performing phlegm re-examination [22]. Besides that, SMS reminders help them to overcome obstacles such as stigma, loss of privacy, limited transportation and the burdens associated with traditional interventions. This makes the participants feel "cared for" and the patients feel that the health workers are "responsible for their care". Compared with the participants without cellphone-based interventions, SMS interventions have significantly improved the adherence to TB treatment[35]. SMS reminders compiled based on the behavior theory of Information Motivation Behavioral Skills (IMB) with a collaborative approach can produce interventions that are more responsive, culturally appropriate, and comprehensive, but its preparation requires a relatively longer time. The development steps include 1. building intervention components, including justification, consideration, time and frequency of components; 2. developing message education, including cultural adaptation, text formatting or short message services (SMS) and prioritizing message delivery orders; and 3. determining the implementation protocol[33].

Incentives and social support (family, peers, health workers and society). The articles reviewed said that the provision of support for TB patients in treatment is very useful to support the compliance to successful treatment[7]. TB patients need support from various parties, especially family support (economic / financial, emotional, information and instrumental), social support to avoid stigma and support from professional health workers (about TB disease, medication and drug side effects and treatments)[25]. Social support and incentive programs must be universally available for all patients from the start of treatment (intensive phase) through to the advanced phase of treatment, especially for patients who are considered to be at risk of failing to complete the treatment programs[19]. Providing incentives can also reduce the default rate[17]. Professional support can be realized by home visits. Face to face education is very useful and recommended[20]. TB control programs must maintain close monitoring and provide greater socio-economic support to patients at high risk of being disobedient and failing treatment[18]. Family and peer support (fellow TB patients) is very instrumental at improving patient compliance to treatment[24]. Funding for treatment or drug provision must be established to eliminate the lack of access to treatment as a potential reason for the failure of the intervention. Continuous efforts in the field of TB control are needed to achieve the key unmet targets, especially for low-income populations in disadvantaged areas[36].

4. Discussion

The results of the review indicate that treatment non-compliance is a problem that is a challenge that must be addressed in the management of TB patients. DOTS has been a world-recommended strategy in TB control since 1995, where the main focus was finding and healing patients, especially infectious-type TB, breaking the chain of TB transmission and reducing the TB incidence rate in the community. Finding and treating TB patients is the best way to prevent transmission TB[16]. In the management of treatment for TB patients, DOTS will be more effective if done together or in combination with other interventions such as health education, psychological counseling, the use / utilization of science and technology and the provision of incentives and support (family, peer and professional)[8].

Health education about the disease, treatment, nutrition, prevention of transmission and other supporting factors needs to be conveyed to the patient diagnosed with TB until the end of their treatment. Patients who do not receive information and who do not understand it well can be one of the factors that cause non-compliance in treatment, which ultimately leads to treatment failure, the transmission of disease and drug resistance[18,28]. Psychological counseling and educational interventions, guided by HBM, significantly decrease the rate of medication non-compliance among the intervention group. The provision of psychological counseling and health education for TB patients who undergo routine treatment is recommended. This can be achieved if the interventions are guided by theoretical behavior and incorporated into routine TB treatment strategies[3].

MDR-TB patients are very vulnerable to extreme stigma and financial difficulties. Providing counseling and financial support may not only reduce their vulnerability but it may also increase their cure rate. The National Tuberculosis Program should consider including financial support and counseling in the treatment of MDR-TB: low costs and high benefits are mainly because of the incomplete medical costs for the community and the high potential for non-curable TB. Studies show that psychological interventions are effective at increasing the adherence to anti-TB treatment and that this can reduce the incidence of treatment failure, relapse and drug resistance[30].

Health information delivered through Mobile Health (mHealth) is very promising to improve quality and efficiency in health care / treatment. In addition, mHealth can discuss important aspects of treatment noncompliance in terms of patients by facilitating new and sophisticated ways of providing financial and non-financial incentives. The types of mHealth needed to increase the compliance of the TB patients come in 5 categories, namely Video Observation of Therapy (VOT), Indirect technology monitoring - Patient facilitated (IP), Indirect monitoring technology - Device

facilitated (ID), Direct monitoring technology - Embedded sensors (DE) and Direct monitoring technology- Metabolite testing (DM)[34].

This review is limited, considering that the studies related to the initial searches with broad search strategies can be implemented. The findings of this systematic review are based on the secondary findings from the studies that have been included. The studies taken were not explored thematically, so there might still be untouched aspects. This study focuses on the context of interventions that can be used to improve the treatment compliance of TB patients who might limit the data taken. However, this systematic review was designed to obtain data specifically in the context of interventions that can be used to improve the treatment compliance of TB patients.

There are many limitations associated with this systematic review. The journals used in this systematic review were journals related to interventions used to improve tuberculosis patient adherence to treatment, while not being directly related to the success of the treatment itself. The sample in this study consisted of patients aged > 18 years or adult TB patients. The interventions discussed were for TB patients in general and not based on strict categories (category 1, category 2 or MDR TB). Therefore, specific interventions for each category and a discussion of the interventions that increase adherence that are directly related to treatment success are important areas for further study.

5. Conclusion

The results showed that there were various categories of interventions that can be used to improve the medication adherence of TB clients, namely the Short Course of Direct Observed Medicine (DOTS). This is a government program, health education program and psychological counseling, and a utilization of information technology, incentives and support (family, peers and professionals). The intervention strategy will be more effective and provide more benefits if they are applied as part of a combination system, and not just as a single intervention.

Table 1. Summary of the findings

No	Title, Authors, & Time	N	Design	Data Collection	Main Result
1	The relationship between social support, treatment interruption and treatment outcome in patients with multidrug-resistant tuberculosis in China: a mixed-methods study[17]	218 & 10	Mixed methods (quantitative and qualitative)	• Structured questionnaire validated • In-depth interviews	DOT and financial support are effective strategies for increasing treatment success in MDR-TB patients, but this is done without considering the patient's perspective. There is an urgent need for consistent and specific psychological support for MDR-TB in their communities
2	Video Directly Observed Therapy to support adherence with treatment for tuberculosis in Vietnam: A prospective cohort study[29]	78	Prospective cohort study	Structured questionnaire Likert scale 1-10	VDOT is feasible and results in a high level of medication adherence in limited resource settings
3	Development of a Patient Centred, Psychosocial Support Intervention for Multi Drug Resistant Tuberculosis (MDR-TB) Care in Nepal [25]	15	Mixed methods (quantitative and qualitative)	Michie et al (2011) Framework Interviews, focus group discussions and field notes	The results of the study state that MDR TB patients need support from various parties, especially family support (economic/ financial, emotional, information and instrumental), social support to

No	Title, Authors, & Time	N	Design	Data Collection	Main Result
					avoid stigma and support from professional calm health (about MDR-TB disease, treatment and side effects medicine and treatment)
4	Treatment outcomes and factors affecting treatment outcomes of new patients with tuberculosis in Busan, South Korea: a retrospective study of a citywide registry, 2014–2015[18]	4732	Retrospective study	Korea National TB surveillance data system	TB control programs must maintain close monitoring and provide greater socio-economic support to patients at high risk of poor treatment outcomes
5	Effectiveness of comprehensive social support interventions among elderly patients with tuberculosis in communities in China: a community-based trial[8]	201	Community-based, repeated measurement trial was conducted	Social Support Rating Scale (SSRS)	Intervention programs in combination with health education, psychotherapy and family and community support interventions can increase the social support for elderly patients. This intervention program is more effective when implemented in combination compared to a single health education.

No	Title, Authors, & Time	N	Design	Data Collection	Main Result
6	Effect of Short Message Service on Management of Pulmonary Tuberculosis Patients in Anhui Province, China: A Prospective, Randomized, Controlled Study[22]	350	Prospective, Randomized, Controlled Study	SMS sent every day to TB patients	Management of pulmonary TB patients via SMS can effectively strengthen the complete treatment level of pulmonary TB patients and reduce missed dose levels and discontinued treatment rates, and increase their re-examination awareness. Therefore, texting about patient management can be a promising new therapy strategy for pulmonary TB
7	The effect of interactive reminders on medication adherence: A randomized trial[23]	46.581	Randomized trial	SMS reminder that contains basic reminder conditions, prediction conditions And condition of commitment	The results of the study show that, as long as the reminder increases compliance by 0.95 percentage points ($p < 0.05$), and this effect is driven by conditions of prediction and commitment. During the three month postal period, reminders increased compliance by 0.98 percentage points ($p < 0.05$), and this effect was driven by

No	Title, Authors, & Time	N	Design	Data Collection	Main Result
					basic reminders and the conditions of commitment.
8	Association between Health-Related Quality of Life and Medication Adherence in Pulmonary Tuberculosis in South Africa [28]	131		1. Generic Short-Form12 (SF-12) 2. Life quality 5 dimensions 5 levels (EQ-5D-5L) 3. St George's Respiratory Disease Questionnaire (SGRQ) 4. Hospital Anxiety and Special Depression Scale (HADS) for HRQOL 5. Compliance is measured by Morisky Scale 8 item Compliance (MMAS-8)	1.A positive relationship exists between adherence and HRQOL, but this relationship is very weak, most likely because HRQOL is influenced by a number of different factors and is not limited to the effect of compliance. Therefore, management of TB Clients in addition to adequate medication treatment must also meet specific mental and psychosocial needs 2.HRQOL improved during 6 months of TB treatment, while adherence meant the score remained constant with participants reaching a

No	Title, Authors, & Time	N	Design	Data Collection	Main Result
					moderate level. About 76% of clients have high compliance and 24% report low compliance
9	Social support a key factor for adherence to multidrug-resistant Tuberculosis treatment [24]	20	Qualitative with grounded theory	In-depth interview	To improve compliance with MDR TB treatment, a Client-centered approach must be considered at the programmatic level. There is a need to formulate strategies that include motivational counseling, nutritional supplementation and mobilization of social support for medication adherence. The participants suggested that the "PSG" Patient Support Group be a model of care for better levels of adherence and treatment in MDRTB treatment
10	Implementation of a psychosocial support package for people receiving	135	Mixed methods (quantitative and qualitative)	Quantitative: Screening tools (HSCL, MSPSS and PHQ-9) Qualitative: Semi-structured format of researcher diaries	The psychosocial support package consisting of eight health education sessions can be received by the

No	Title, Authors, & Time	N	Design	Data Collection	Main Result
	treatment for multidrug-resistant tuberculosis in Nepal: A feasibility and acceptability study [32]				Client. All aspects of the intervention package are given to the Client, including screening, information, group work and counseling. Clients need someone to talk to about their concerns and problems. Information material developed is feasible to be delivered in the form of structured psychological counseling
11	Impact of socio-psychological factors on treatment adherence of TB patients in Russia[7]	1387	Cross-sectional	Cross-sectional questionnaires were modified by the researchers	1.Research shows that certain social, psychological, and behavioral characteristics of Russian TB Clients contribute to non-compliance with TB treatment. Clients who are at high risk for non-compliance must be identified at the start of treatment, and offer services

No	Title, Authors, & Time	N	Design	Data Collection	Main Result
					from a psychologist. 2. Better health education must be given to clients, especially in the field of social-psychological
12	Psychological and Educational Intervention to Improve Tuberculosis Treatment Adherence in Ethiopia Based on Health Belief Model: A Cluster Randomized Control Trial [3]	698	Cluster Randomized Control Trial	1. A structured questionnaire to assess knowledge about TB 2. Perception questionnaire based on six HBM domains 3. VAS questionnaire to measure non-compliance	Psychological counseling and educational interventions, guided by HBM theory, significantly reduced the rate of medication non-compliance among the intervention group. Provision of psychological counseling and health education for TB Clients who undergo routine treatment is recommended. This can be achieved well if this intervention is guided by theoretical behavior and incorporated into TB treatment strategies
13	Treatment interruptions and duration associated with default among new patients	1771	Retrospective Study	Questionnaire for collecting demographic data, social history information, and microbiology laboratory results obtained from medical records.	1. Social support and incentive programs must be universally available to all

No	Title, Authors, & Time	N	Design	Data Collection	Main Result
	with tuberculosis in six regions of Russia [19]			Information about treatment outcomes is obtained from the TB list 13	Clients from the beginning of the advanced treatment phase, during the intensive phase for Clients who are considered at risk of failing to complete treatment programs, and for Clients who have lost at least 2-3 days of treatment during the intensive phase. 2.Therapy that is observed directly at home (home visit) can be a recommendation for some clients.
14	Emotional representation of tuberculosis with stigma, treatment delay, and medication adherence in Russia [1]	105	Cross-sectional descriptive	Revised Illness Perception Questionnaire (IPQ-R) (Moss-Morris et al., 2002) The Social Impact Scale (SIS)	TB is associated with serious emotional and social consequences. When the coherence of the disease increases, negative emotional and social consequences of the disease can be reduced. This is the role of Russian health

No	Title, Authors, & Time	N	Design	Data Collection	Main Result
					care professionals to provide clients with adequate education / understanding and psychological support, and this role requires preparation.
15	Psychosocial trauma of diagnosis: A qualitative study on rural TB patients' experiences in Nalgonda district, Andhra Pradesh[6]	110	Qualitative	semi structured interview	1.TB diagnosis is generally seen as a shocking and demoralizing experience, and raises a number of social and psychological problems among Clients. Six prominent themes emerged from in-depth interviews with respondents: 1) worried, 2) did not believe, 3) shame, 4) fear of death, 5) fate, and 6) relief. 2.Effective treatment for TB requires a much broader approach than focusing on anti-TB drugs and technical diagnostics. Knowledge of the nature of psychosocial

ABSTRACT

Tuberculosis (TB), the leading cause of death due to a single infectious disease worldwide, is difficult to diagnose, difficult to treat and prone to the development of drug resistance. Every day approximately six thousand people die of Tuberculosis (TB). This study aimed to analyze the risk factors of pulmonary tuberculosis in the most dominant risk factor. To identified the most potential risk factor of pulmonary tuberculosis. A systematic search was performed in Scopus, Proquest, and SAGE databases with the last 5 years (2013-2018). According to findings, risk factors can be categorized as agent (mycobacterium tuberculosis) 40%, host 75% (age ≥45 years, gender where men more dominant, social economy, education, cooking fuel, tobacco smoke play a significant role and drink alcohol 40g per day) and environment 20% (condition room, occupancy density). There are various risk factors that cause Pulmonary tuberculosis and the dominant potential risk factor is host such as age, social economy, education, cooking fuel, tobacco smoke and drink alcohol.

Keywords: tuberculosis, potential, risk factor

1. Background

Tuberculosis (TB) is a pulmonary infectious disease caused by *Mycobacterium tuberculosis* (Mtb) infection. It is the ninth leading cause of mortality worldwide. It remains the most deadly infectious disease, ranked above HIV/AIDS [1]. The disease causes illness for 10 million people each year and it is one of top ten causes of mortality worldwide [2]. The 5 countries that have the largest incidence rate in the world are India, Indonesia, China and the Philippines [2]. It is crucial to understand the risk of acquiring tuberculosis infection and its risk of progression from infection to the disease in order to adopt a strategic plan for TB control [3]. In high density settings such as prisons and hospitals where people are socially closer and there is overcrowding, people will be frequently be more exposed to pathogens. Endogenous factors lead to the development of the disease and increase the severity from infection to active disease [4].

The largest spread of TB disease is in the Asian region (59%), followed by Africa (26%) [2]. A small number of cases occur in the Mediterranean area (7.7%), Europe (4.3%) and America (3%). The five countries with the highest number of cases in 2011 were India (2 million-2.5 million), China (0.9 million-1.1 million), South Africa (0.4 million-0.6 million), Indonesia (0.4 million -0.5 million), and Pakistan (0.3 million-0.5 million)[4]. But little is known about the amount of ongoing transmission between the different subgroups in the population, particularly in high incidence areas. Understanding transmission patterns and "who infects whom" is important for improving control, as it can help direct contact tracing to the most likely sources of infection[5].

Many factors influence the occurrence of pulmonary TB disease. However, knowledge of what makes some persons develop TB and others not (risk factors) has the potential of helping to further

refocus the search for novel public health TB control strategies [6]. The reported TB risk factors include HIV infection, male sex, co-morbidities such as diabetes, a family history of TB, the absence of a Bacillus Calmette–Guérin (BCG) scar, smoking, alcohol use, single marital status, overcrowding, and poor socioeconomic status [7].

Thus, conducting a systematic review will provide us with a comprehensive assessment of the TB that might be useful for stakeholders, such as policy makers, health experts and researchers to allow them to implement appropriate strategies for high-risk populations. This study aims to analyze the risk factors of pulmonary tuberculosis in the search for the most dominant risk factor.

2. Method

2.1 . Data sources and search

The journal search strategy began with asking the research question "What are the potential risk factors of pulmonary tuberculosis?" The databases used for the journal searches were Scopus, PubMed, Science Direct, and Proquest. The keywords used were "tuberculosis, potential, risk factor". The journals were limited (2013-2018) according to their publication year, focused on the areas of nursing, medicine and English-language journals.

2.2 . Article selection criteria

The feasibility of the study was assessed using the PICOT approach. The study population consisted of Tb patients. The study inclusion criterion was the dominant risk factor of pulmonary tuberculosis in Tb patients. As a comparison to the occurrence and management of tuberculosis cases that occur in developed countries, we referred to articles from several developed countries. The outcome was to analyze the risk factors of pulmonary tuberculosis in the most dominant risk factor with no time selection criteria.

The inclusion criteria being applied were as follows: 1) demographic, socio-economic, and behavioral risk factors of the TB cases; 2) tuberculosis infection and/or TB disease diagnoses as confirmed by laboratory diagnosis and 3) the epidemiological study of primary or secondary data analysis.

2.3 . Exclusion data

There were no exclusions based on the study setting or on the anatomical site of the disease.

2.4 . Research design

Of the 10 selected articles, they originated from 3 continents, namely: the Americas, the European continent and the Asian continent. Articles from the Americas came from the USA and Argentina. The articles from the Asian continent came from China, Korea, Pakistan and Malaysia. Articles from the Asian continent are expected to reflect the profile and characteristics of the cases of tuberculosis that occur in both the young and old in the communities. As a comparison of the occurrence and management of tuberculosis cases that occur in developed countries, we refer to the articles from several developed countries and the study design was a randomized controlled trial study (RCTs).

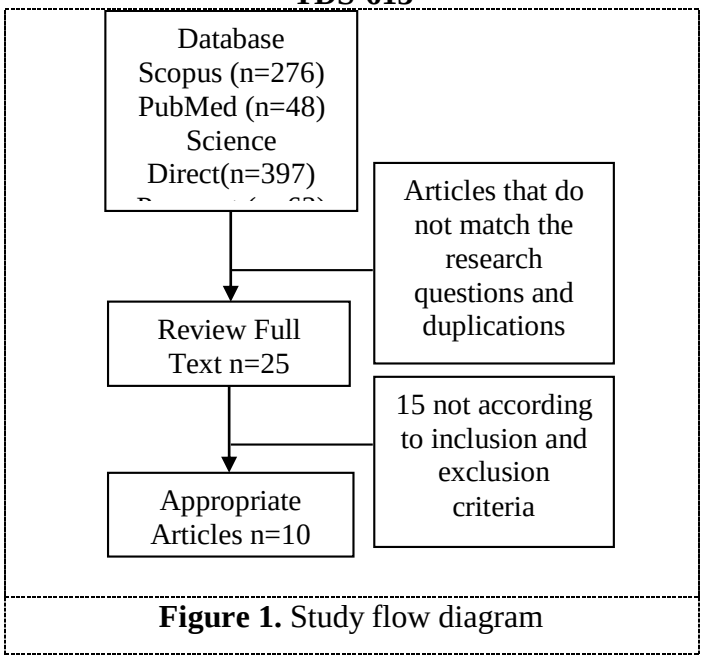

Figure 1. Study flow diagram

3. Results

3.2. Respondent's Characteristics

The number of respondents in the selected articles varied between 109 respondents and 257179 respondents, with variations in age between 0 to>40 years. All of the respondents were individuals who experienced tuberculosis outside of the hospital, both in public areas and in private areas (e.g. the house). The Asian continent is expected to reflect the profile and characteristics of the cases of tuberculosis that occur in both the young and adult members of communities. After reviewing the results, there are 3 types of risk factor that can be categorized as agent (*Mycobacterium tuberculosis*), host (age, gender, social economy, education, cooking fuel, tobacco smoke and drink alcohol) and environment (condition room, occupancy density).

3.3. *Agent (Mycobacterium tuberculosis)*

Research by Shaweno *et al.*, 2018 of *Mycobacterium tuberculosis* as an agent of tuberculosis have identified a relationship and increased risk of *Mycobacterium tuberculosis* causing exacerbations in the approximately 2–3 billion people in the world who are latently infected with *Mycobacterium tuberculosis* (Mtb); 5%–15% of these people will suffer from a reactivation of TB during their lifetime [6][5]

3.4. Host (age, gender, social economy, education, cooking fuel, tobacco smoke and drink alcohol)

Age seems to be associated with TB infection. However, the exact age range is unclear. Different behaviors may be the factor. Young people are more likely to be exposed to TB because they are more likely to work and are more mobile, thus they have less time for treatment [8][6] A higher smoking rate among younger people weakens the immune system, putting them at risk of developing TB diseases and related conditions caused by the Mycobacterium TB [9]. However, several studies considered the differential cases of TB with an association of demographic risk factors and their

potential reasons. Most of the studies found that the TB cases were statistically significantly higher among men compared to women. Tobacco smoking can alter the lung's immune response to Mtb and can therefore contribute to a higher susceptibility to individual TB infection. The relative risk of TB infection in tobacco smokers compared to non-smokers ranges from 2 to 3.4, and the TB reactivation and mortality rates are also higher in the tobacco group. People with a low socio-economic status also tend to have a higher infection rate compared to those of high socio-economic status. A high family income can provide the opportunity to buy medicine and undergo treatment. All of the selected studies showed an increase in TB infection among the patients with a lower education level. Drug consumption is another behavioral risk factor associated with TB infection, Drug abuse is an independent predictor for death among drug-resistant TB patients[6]. Those who have a history of intravenous or subcutaneous drug use were more likely to become infected with MDR-TB disease. Alcohol consumption also influences TB infection. As shown by Ai et al, (2016), the results at the initial diagnosis of a previous occurrence of TB (aHR: 4.09, 95% CI: 1.52–11.02) were more likely show there to be recurrent TB among alcoholics. People who drink more than 40 g alcohol per day, and/or who have alcohol use disorder fall into this category. Alcohol may assert a direct toxic effect on the immune system, thus rendering the host more susceptible to TB disease.

3.5. Environment (condition room, occupancy density).

Our study indicates the association between the patients' housing area and TB infection. Unpleasant environments can make a person more vulnerable to infection [6].

Table 1. Respondent's characteristics

Occupancy density	[9]
Drug consumption	[6][9]

4. Discussion

This systematic review aimed to identify the articles around the dominant risk factors of tuberculosis in the community. Several studies considered differential cases of TB with an association between the dominant risk factors and their potential reasons. In this review, we found that host have 75% statistically significant as categorized are a more at risk to be infected with TB[10][3]. One possible reason for this is that men predominantly drink alcohol, smoke, consume drug and are more like to be incarcerated than women. These behavioral factors put the person more at risk of being infected with TB. Age seems to be associated with TB infection. However, the exact age range is unclear. Different behaviors may be the factor[7]. Young people are more likely to be exposed to TB because they are more likely to work and are more mobile. A higher smoking rate among younger people weakens the immune system, putting them at risk of developing TB and related conditions caused by the Mycobacterium TB. Although younger TB patients spend more time on social activities such as drinking alcohol, taking drugs and smoking, the infection can still occur among older people as well [6][11][12]. The majority of the studies proved that TB affects the younger age group (below 40 years). In contrast, Ai et al (2016) found that the older age group was more vulnerable to TB (40 above) with a mean age of 42.36 ± 17.77 years. Smokers were observed to more susceptible to TB infection. This was proven when it was found that passive smokers have less than a 76% chance of developing active disease upon infection compared to non-passive smokers. On the other hand, a longer duration of drug use and substance misuse also increased the vulnerability to TB infection [6][13]. An imbalanced immune system, both natural and cell mediated, seems to be one of the causes of drug use being a risk factor, especially in latent TB cases [6].

Another study assessed whether TB infection occurred among low income families, regarding the findings for previously treated MDR-TB cases and with newly diagnosed MDR-TB cases. This suggests that people in the lower income group have a higher tendency to develop TB. However, the studies prove that the environment has a 20% statistically significant association between education level and occupation density. Cooking fuel seems to be one of the causes of TB cases[14].

The limitation in this study was the limited time available of 3 weeks. The other limitations of this review included the bias in reporting the results of the thresholds between studies concerning the significant and non-significant findings.

5. Conclusion

Based on the chosen 10 articles, the authors found there to be various risk factors that influence the occurrence of tuberculosis. These were identified and classified after reviewing the results. There are 3 types of risk factor that can be categorized as agent (*Mycobacterium tuberculosis*), host (age, gender, social economy, education, cooking fuel, tobacco smoke and drink alcohol) and environment (condition room, occupancy density). There are various risk factors that cause pulmonary tuberculosis and the dominant potential risk factor is the host, with sub-factors such as age, the social economy, education, cooking fuel, tobacco smoke and drink alcohol.

The results of the review of various studies can be implicated when giving help to find the most dominant risk factor of pulmonary tuberculosis. Nurses can provide structured education to ordinary people about health education on how to reduce the risk factors of tuberculosis with the self management related to adequate coping behavior. The compliance of the changing behavior of the TB patients included quitting smoking that reduced over the time when they were being treated and after the course of treatment, they lessened how much they drank alcohol, used drugs and how to manage the condition room. The patients actively participated in implementing the self management of the disease.

EXPERIENCE OF TREATMENT MULTIDRUG RESISTANT TUBERCULOSIS (MDR-TB) PATIENTS: A SYSTEMATIC REVIEW

N Arifah[1], T Sukartini[2], Harmayetty[2]
[1]Magister of Nursing, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
[2]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
E-mail: nurarifahbachtiar@yahoo.com

ABSTRACT

Multidrug tuberculosis (MDR-TB) is a global threat for the control of tuberculosis. Increased MDR-TB cases are caused by a history of non-adherent treatment or transmission of mycobacterium tuberculosis which is resistant to anti-Tuberculosis drugs. The purpose of this systematic review is to explore the experience of treating multidrug tuberculosis patients. Searching the database for Scopus, Proquest, Science Direct and Sage Journal using the keywords "multidrug resistant tuberculosis AND experience AND patient AND treatment AND qualitative study" with the period research of 2014 until 2018. Implementation of the PRISMA guidelines using qualitative research there were 16 articles included, because considered relevant to the purpose of this review. The results of this study are several problems faced by MDR-TB patients during treatment such as drug side effects, stigma, financial problems, lack of self efficacy towards treatment, lack of health care support, lack of social support from family or those closest to them. Future research that will enhance current knowledge for treatment outcomes and can be the basis of alternative interventions to increase the comfort of MDR-TB patients while undergoing treatment and improving health services.

Keywords: multidrug resistant tuberculosis, treatment, experience, qualitative

1. Introduction

Tuberculosis (TB) is one of the deadliest infectious diseases in the world. The WHO reported that between 2013 and 2016, there was an increase in cases of pulmonary TB from 9 million cases to 10.4 million cases. The number of new TB cases in 2016 was by 10.4 million and this resulted in 1.8 million deaths [1]. The WHO in 2018 reported that there are seven countries with the highest number of TB cases, namely India, Indonesia, China, the Philippines, Pakistan, Nigeria and South Africa.

The progress of TB control in the world has succeeded in identifying Mycobacterium tuberculosis and the discovery of the BCG vaccine and anti-Tuberculosis drugs that are effective for TB control. However, the progress of TB treatment has been challenged by the emergence of a type of Mycobacterium Tuberculosis that is resistant to anti-tuberculosis drug. The HIV AIDS epidemic has worsened the TB epidemic.

Multidrug Resistant Tuberculosis (MDR-TB) is caused by bacteria that do not respond to isoniazid and rifampicin, which are the two most effective anti-tuberculosis drugs in use regarding TB control. The WHO, in 2017, implemented 5 priority actions to overcome the MDR-TB crisis globally including (1) preventing the occurrence of MDR-TB / RR-TB, (2) improving rapid testing and the detection of MDR-TB / RR-TB cases, (3) providing access to effective MDR-TB services including adequate quality and supply of medicines, (4) preventing transmission through infection

control and (5) increasing the political commitment in terms of financing. However, the number of MDR-TB cases is still a problem. The WHO, in 2017, reported 600,000 cases of MDR-TB and 240,000 deaths. The number of new cases of MDR-TB is 4.1% while in older cases or in TB patients who have received treatment, 19% are resistant to anti-tuberculosis drugs.

The increase in MDR-TB cases is a global threat to controlling tuberculosis (TB). MDR-TB can be caused by a history of irregular treatment or the transmission of anti-tuberculosis drug resistant Mycobacterium tuberculosis. Contact transmission of Mycobacterium tuberculosis that has experienced drug resistance will create new cases of MDR-TB patients who experience primary resistance [2].

Multidrug treatment for tuberculosis resistance takes a very long time, with a minimum duration of 18-24 months. MDR-TB treatment provides many experiences including negative ones that can hinder treatment. Positive experiences can come in the form of support for the patients so then they can complete the treatment up until they recover. Several studies have shown that several factors that prevent MDR-TB patients from undergoing treatment such as the physical side effects of the MDR-TB drugs, financial burden, apprehension about the efficacy of the long-term treatment, and stigma [3–7]. The incidence of MDR-TB cannot be separated from a history of previous TB treatment non-compliance. Non-adherence to treatment is a major predictor of MDR-TB because it can cause gene mutations in Mtb so then it is resistant to treatment[1]. There are several factors that influence client disobedience in terms of TB treatment, including a lack of knowledge, low awareness, inadequate health facilities, stigma, the economy [8]and the anti-tuberculosis drug side effects. These are the main causes of noncompliance in the previous treatment regimes. Increasing MDR-TB cases are a global health threat because it can cause the transmission of MDR-TB that is resistant and that requires a very long treatment plan. Increasing MDR-TB can be a barrier to achieving the TB elimination target in 2030.The aim of this systematic review was to explore TB patients who were undergoing treatment. The impact of MDR-TB treatment in the long term requires attention, so this data is expected to inform the policy makers and health workers to allow them to be able to develop appropriate interventions.

2. Methods

A systematic search was conducted of the Scopus, Proquest, Science Direct, and Sage Journal electronic databases using the keywords "multi-drug resistant tuberculosis" AND experience AND patients AND treatment AND qualitatively with all studies. The inclusion criteria consisted of original research articles about MDR-TB, publications from 2014 to 2019 and articles published in English. Articles in other languages, incomplete articles (abstract), research not on humans, and those not in accordance with the research objectives issued were not included.

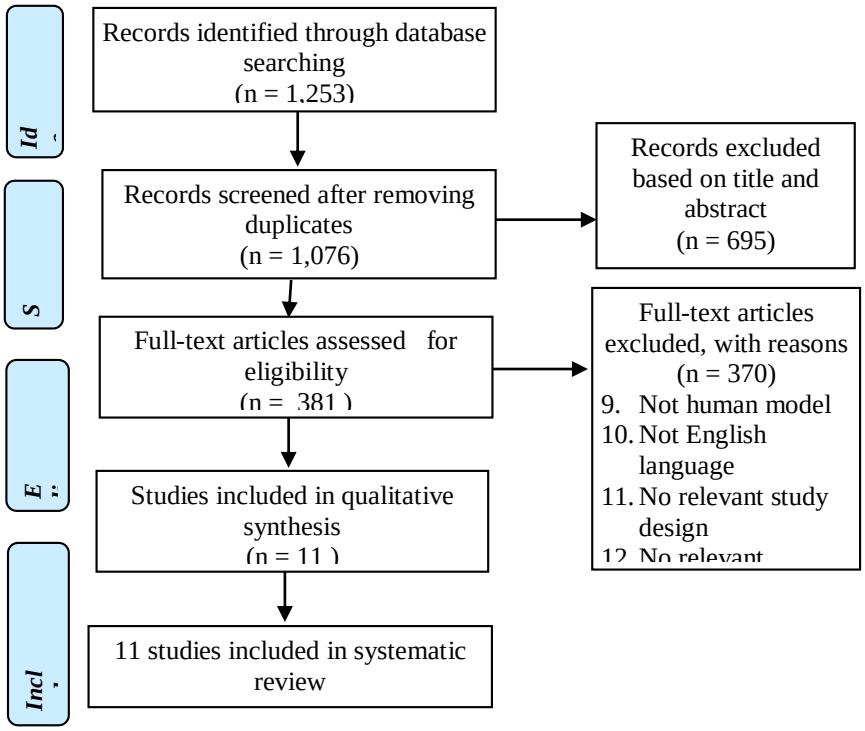

Figure 1. Flow Diagram

3. Results

The four electronic databases used in this review were searched using keywords that were set to identify 1253 abstracts. An extensive review of the article titles and abstracts facilitated the elimination of duplicate articles and any articles without relevance to the current reviews; 11 articles were identified for a full text review. Following the application of PRISMA, the articles were chosen to be included in the review because they were to be considered relevant for the purpose of the study (Figure 1). The total respondents in the literature selected were 618 participants in the range of 6 - 381 participants. The participants were aged between 18 and 60 years old.

1076 articles were found after duplication screening; 695 articles were eliminated due to irrelevant studies based on the titles and abstracts. A total of 381 articles with full text were taken with 370 studies excluded because they did not meet the inclusion criteria such as being an intervention research, not using English, having irrelevant goals, and where the results that were not in accordance with the objectives of the systematic review. As a result, 11 articles were used to carry out systematic review.

Table 1. Characteristics of the included studies

No	Title, Author & Time	Design	Result
1	The battle continues: An interpretative phenomenological analysis of the experiences of Multidrug-Resistant Tuberculosis (MDR-TB) patients. [3]	Qualitative study	1.Fear of being diagnosed with MDR-TB 2.Feeling isolated as an effort to prevent transmission 3.An infection alongside the anti tuberculosis drug side effects, finances, and doubts about long-term treatment success 4.Negative stigma 5.Trying to accept the condition and to continue to fight for family and self.
2	Social support: a key factor for adherence to multi-drug resistant tuberculosis treatment. [9]	Qualitative study	Motivation, awareness of illness and treatment, counseling support, family support, nutritional support and social support are important drivers for successful treatment.
3	Proposed guidelines to minimize multi-drug resistant tuberculosis treatment default in a multi-drug resistant unit of Limpopo province, south Africa. [10]	Qualitative study	The factors that contribute to the failure of the patients regarding the MDR-TB treatment were identified and organized into four themes. A guide was developed to address each factor and to provide recommendations about the solutions that outline collaboration between the Health department, health practitioners, patients, and their family members to help prevent treatment failure.
4	Resilience and extensively drug-resistant tuberculosis: the unlikely ally. [6]	Qualitative study	Slow diagnosis, lack of care capacity, the availability of drugs and a lack of psychosocial support during long-term treatment are the main obstacles experienced when undergoing MDR-TB treatment.
5	Development of a Patient Centered, Psychosocial Support Intervention for Multi Drug-Resistant Tuberculosis (MDR-TB) Care in Nepal. [11]	Qualitative study	Our findings highlight the negative effects of MDR TB treatment on mental health and the greater impact felt by the patients with limited social and financial support, especially married women.
6	Where there is hope: a qualitative study examining patients' adherence to multi-drug resistant tuberculosis	Qualitative study	Expectations, knowledge and perception of the importance of treatment are very supportive of adherence so there is a need for an individual to utilize a holistic approach. Compliance is supported by

No	Title, Author & Time	Design	Result
	treatment in Karakalpakstan, Uzbekistan. [12]		involving the patients as active participants in their care so then they have a sense of responsibility for their care.
7	Reasons for defaulting from drug-resistant tuberculosis treatment in Armenia: a quantitative and qualitative study. [4]	Mixed Method: Quantitative and qualitative study	Poor treatment tolerance, perceptions of inefficient treatment, lack of information, wrong perceptions of healing, work factors, economics, and behavioral problems are the factors associated with treatment failure.
8	Patient and Provider Reported Reasons for Lost to Follow Up in MDRTB Treatment: A qualitative study from a Drug Resistant TB Centre in India. [7]	Qualitative study	Drug side effects, lack of service, financial support, conflict with treatment service times, alcoholism and social stigma can influence compliance with MDR TB treatment. It requires health care efforts to solve medical problems such as the effects of drugs, developing short-term treatment regimens, reducing the pill burden, counseling, flexible times for the DOT services, and social support
9	The importance of providing counseling and financial support to the patients receiving treatment for multi-drug resistant TB: mixed method qualitative and pilot intervention studies. [13]	Mixed Method: Qualitative and quantitative study	The healing rate of the patients receiving counseling was 85%, those receiving combined support (counseling and financial support) had a healing rate of 76% and those without support had a healing rate of 67%.
10	"Home is where the patient is": a qualitative analysis of a patient-centered model of care for multi-drug resistant tuberculosis. [14]	Qualitative study	Home-based care is accepted by the patients, families, communities and cadres because it is safe, conducive to recovery, facilitates psychosocial support and allows for more free time and earning potential for both the patients and nurses.
11	Are We Doing Enough to Stem the Tide of Acquired MDR-TB in Countries with High TB Burden? Results of a Mixed Method	Mixed Method: Qualitative & Quantitative study	Poor implementation of the DOTs program, where for the treatment, 34.3% of patients were never monitored by the health workers. Only 31.8% of patients

	Study in Chongqing, China. [15]		had accessed TB health education before TB diagnosis.

4. Discussion

Treatment history

A history of noncompliance with treatment is the main predictor of multidrug-resistant tuberculosis. [1]. Non-compliance in TB treatment is influenced by several factors, namely a lack of knowledge, or a low awareness of TB treatment, the wrong perceptions of recovery, poor response to treatment, stigma, poverty, a lack of access to transportation, especially in remote areas, the need to continue working, and the facilities where the treatment is ongoing is functioning poorly and the staff attitude is negative[4,8,16].

Obstacles

MDR-TB drugs are given free of charge but many patients cannot comply with their medication because of one or a combination of factors such as economic barriers, drug side effects, mental health etc. The results of the study [11] show that a greater negative impact is felt among those with limited social and financial support, especially married women.

The treatment of MDR-TB over a long period of time - between 18 and 24 months - is an obstacle. The side effects of the MDR-TB drugs include nausea, vomiting, rash, a loss of appetite, ringing in the ears, bodily weakness, a feeling of warmth, sensitivity to light, excessive saliva, and insomnia [3]. There are side effects in terms of weight when there are comorbidities such as diabetes mellitus. The severity of the side effects of the drugs that are felt by the patients every day for a long period of time is a challenge for the MDR-TB patients [7].

Shame and stigma are also obstacles for the patients undergoing treatment. Shyness and stigma causes the patients to hide their condition by resorting to alternative treatment options[2]. A lack of information is also a problem in medicine because knowledge is the basis that must be owned by the patients with the aim of the patients knowing the benefits of the treatment. They are expected to be able to comply with the treatment. The results of the study [15]showed that 34.3% of patients were never monitored by the health workers during their treatment and that only 31.8% of patients had access to health education before their diagnosis. Providing education is one of the tasks of the health workers that is needed to support compliance. There is a need for an individual and holistic approach to compliance support with the involvement of the patients as active participants in the care of those who feel that they are responsible for their care [14]. The obstacles experienced by the patients during long-term treatment with a minimum duration of 18 months included the severe side effects of the drugs, which can make the MDR-TB patients have doubts about the success of the treatment.

Support

There are many obstacles that are felt by the patients that require psychological and socio-economic support etc. Various factors influence a patient's decision to adhere to the MDR-TB treatment. Self-motivation, awareness of the illness and treatment, counseling support, family support, nutritional support and social support are the important drivers of successful treatment. To improve compliance

with the MDR-TB treatment, the patient approach must be considered at the program level. Based on the research[7], it is suggested that peer group support has better levels of adherence and treatment for MDR-TB.

Support can be formed with cooperation between the patients, their families and the health workers who provide information and support. They act to normalize TB, to reduce stigma and to prevent the abuse of the anti-tuberculosis drugs [10]. They are in a situation to improve the social, knowledge and support aspects of their family and friends in order to influence compliance.

Adverse drug side effects require health care efforts to resolve medical problems such as adverse drug effects, developing short-term treatment regimens, reducing the pill burden, motivational counseling and flexible timing for the DOT services [7]. Increasing TB health seeking behavior, reducing patient delays and detection, improving DOT quality, overcoming financial and systemic barriers and increasing the access to TB health promotions is urgently needed to address the growing prevalence of MDR-TB in China[15].

Home-based care is accepted by the patients, families, communities and cadres because it is safe, conducive to recovery, facilitates psychosocial support and allows for more free time and income potential for both the patients and nurses[12].

5. Conclusion

The incidence of multidrug tuberculosis (MDR-TB) is increasing worldwide. A broad database search has identified the limited research that examines the experience of MDR-TB patients. The results of this study showed that the barriers felt by the patients undergoing the MDR-TB treatment should be the main focus of the health workers, and in particular that the patients need an explanation of the treatment and prevention as well as things that need to be done to reduce the drug side effects. For the community, the patients need psychological support and motivation, especially from the closest people to them.Furthermore, future qualitative studies covering the results reported by the patients will play an important role in guiding the strategies aimed at minimizing the burden of treatment, improving the treatment procedures and ultimately increasing the level of comfort and well-being of MDR-TB patients.

ABSTRACT

Tuberculosis is one of the top 10 diseases that cause death in the world. Therefore, until now TB is still a top priority in the world and is one of the goals in the Sustainability Development Goals (SDGs). The systematic review aims to identify and synthesize studies that use empowerment approaches in the field of treatment and care of TB patients. Studies were identified from searches with keywords: "models of empowerment, tuberculosis, family support dan health behavior" on the database (Scopus, ProQuest, ScienceDirect, PubMed, SageJournals, SpringerLink and JSTOR) from 2014 to 2019. Search, selection and reporting in accordance with PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyzes). Five eligible studies were included with outcome was health behavior in TB. These studies conclude the number of studies on empowerment in TB is very low. The empowerment approach is actually implemented but it seems that the term empowerment is still unfamiliar in the management of TB treatment programs.

Keywords: empowerment program, health behaviour, tuberculosis, systematic review

1. Introduction

Empowerment is a process through which people, organizations and communities gain mastery over their situation [1]. It is postulated that individual or psychological empowerment has a positive impact on people's health and that empowered people engage in creating healthier environments ('community empowerment')[2]. In order to implement empowerment in practice, a wide range of approaches are used: participatory strategies, the provision of social support to strengthen people's self-esteem and self-efficacy, the raising of critical consciousness etc. However, 'authentic' empowerment is considered to be more than simply a technique or a strategic approach in health promotion. It is a value-based attitude that underpins professional practice[3].

Initially, the empowerment approach was used predominantly among marginalized communities in programs in developing countries, particularly when dealing with poverty, suppression and powerlessness which necessitates empowering strategies. Today, the main focus of empowerment in health promotion in developing countries remains focused on vital issues such as access to drinking-water, health care and housing conditions. In industrialized countries, health promotion programs are meant to engage people to encourage them to live healthy (healthier) lives or to create healthy (healthier) environments in their communities[4].

Therefore, applying the concept of empowerment to complete a TB program seems to be promising. However, the empowerment related to the TB program has not yet been evaluated. Whereas the challenge of control (or even power) is obvious when working with disadvantaged communities who are struggling with basic needs, little is known about applying empowerment theory as well as empowering the TB program. Thus, the starting point for the current systematic

review was the question: “How can the empowerment approach be applied to the subject of patient TB?”

In the health-care sector, ‘empowerment’ is often used in a different way than in health promotion, i.e. in terms of ‘patient empowerment’ or self-management regarding a certain disease[5]. Considering that the empowerment concept has been used by a growing number of scientific disciplines, a substantial though very heterogeneous body of literature on empowerment and empowerment projects is now available. In recent years, systematic reviews on the different aspects of empowerment have been conducted. The most comprehensive review was compiled by Wallerstein on behalf of the WHO[6].

To date, no narrative or systematic review on the subject of empowerment and health behavior in TB programs has been published. Thus the aim of the current systematic review was to identify studies that used an empowerment approach within the field of health behavior in TB programs.

2. Methods

Studies included in systematic reviews must meet the following selection criteria: (i) the studies must be published as original articles, (ii) the concept of empowerment must be important for the intervention and therefore explicitly mentioned and (iii) the research must be based on empirical data collection (i.e. qualitative or quantitative processes or the outcome parameters reported). Studies were excluded if the paper was a systematic review (comment), commentary, letter or conference, if no abstract is available or if the language of the article was not English.

The articles were identified through a database search (Scopus, ProQuest, ScienceDirect, PubMed, SageJournals, SpringerLink and JSTOR). The latest database update came in January 2014. The titles, abstracts and keywords were searched using the following search terms: (Model of Empowerment) AND (Tuberculosis) AND (Family Support) AND (Health Behavior))

The titles and abstracts of the articles were initially filtered to meet the selection criteria. The authors performed the filtering procedures independently of each other. Cases of nonconformity were discussed afterwards until consensus was reached. Furthermore, the rest of the study potentially fulfilled the requirements and the articles were assessed in detail by reading the full text paper.

The summary table was designed to collect any interesting research characteristics (see Table 1). The appropriate data was then extracted by the author. As for the definition and conceptualization of the empowerment approach, the information was extracted from the articles in accordance with the author's expression.

The systematic review was conducted based on the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) Statement in order to maintain the quality of the search process and an adequate level of reporting within the present paper[7].

3. Result

Section 1.01 *3.1 Study selection*

The database searches produced 1,990 results (Scopus, ProQuest, ScienceDirect, PubMed, SageJournals, SpringerLink and JSTOR). After excluding any duplicates, there were 1,936 articles that qualified for further screening. The screening of the titles and abstracts according to the inclusion and exclusion criteria led to 16 articles which were then examined as full-text papers. Finally, 5 studies were included in the current systematic review. The process of selecting the studies has been illustrated in the flow diagram (see Fig. 1).

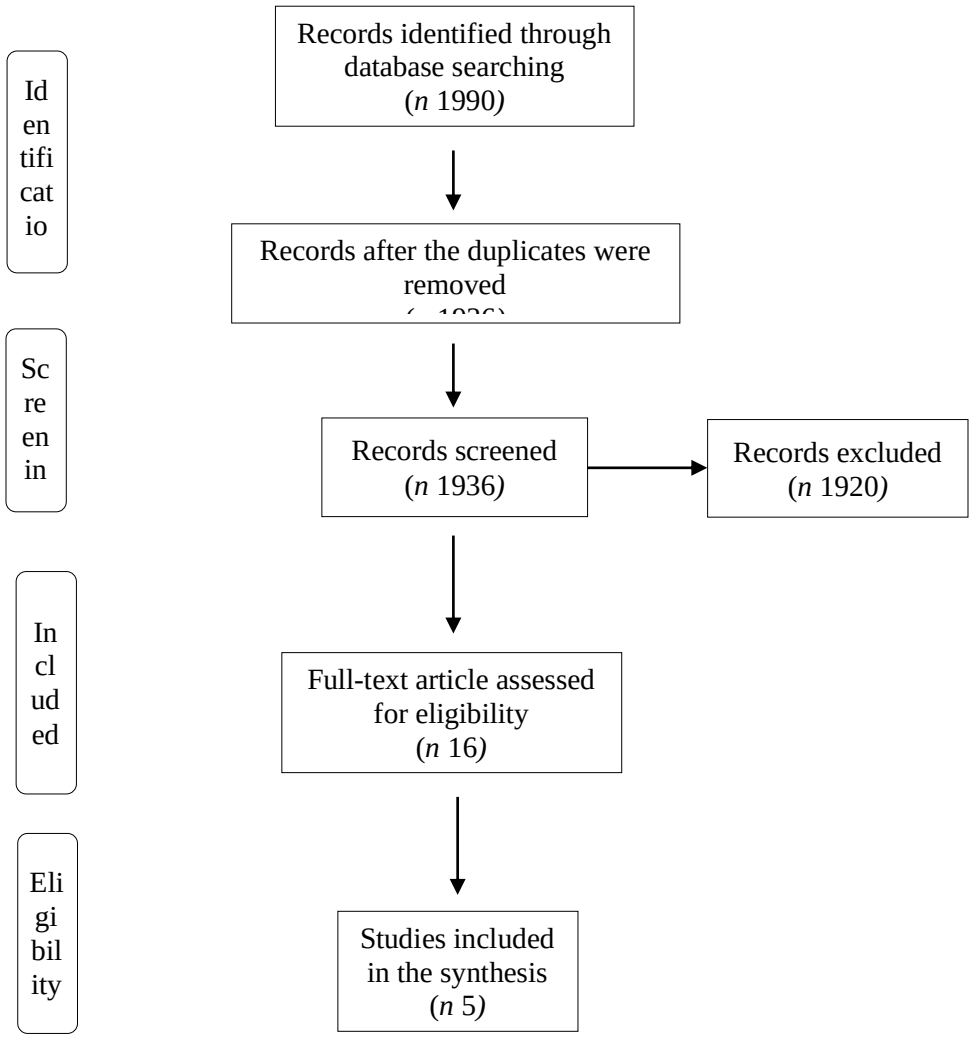

Fig 1. Flow diagram of the study selection process

Section 1.02 3.2 Study Characteristics

Table 1 provides an overview of the main characteristics of the five studies included[8–11]. The studies were conducted in India, Armenia, Ethiopia, Brazil and South Africa. All of the studies target TB patients. This review included three studies using quantitative research designs to evaluate the results, and two used qualitative methods for the data collection and analysis.

Table 1 - Main characteristics of the studies included in the present review

No.	Title, Authors and Year	Country	Target group And setting	Research Design	Quantitative evaluation: Outcome(s):	Qualitative evaluation: Outcome(s):
1.	A case study on tuberculosis treatment defaulters in Delhi: Weak health links of the community with the public sector, unsupported migrants and some misconceptions [8]	India	TB patients at the New Delhi Government Hospital	Case study	-	Proposals from the community: 1. The TM / CAM program is recognized as access to TB treatment programs. 2. Increased medical services at affordable costs. 3. The existence of empowerment initiatives for social support for immigrants. 4. Provision of tools that are suitable to the needs of the community.
2.	People-centered tuberculosis care versus standard care in the form of directly observed therapy: study protocol for a cluster randomized controlled trial [9]	Armenia	TB patients and families at the Armenia Outpatient Center	Cluster Randomized Controlled Trial	With this empowerment model, the patients and families both get the support needed to carry out their role in TB treatment.	-
3.	Psychological and Educational Interventions to Improve Tuberculosis Treatment Adherence in Ethiopia Based on the Health Belief	Ethiopia	TB patients at Addis Ababa City Health Center	Cluster Randomized Controlled Trial	It is recommended to include psychological counseling and health education interventions when carrying out the DOTS strategy to reduce the level	-

	Model: A Cluster Randomized Control Trial [10]				of medication non-compliance.	
4.	Patients' perception regarding the influence of individual and social vulnerabilities on the adherence to tuberculosis treatment: a qualitative study [12]	Brazil	TB patients in the city of Campina Grande Brazil	Qualitative descriptive Cross-sectional study	-	Advice from patients: 1. The need for an explanation to the public about TB in the community so then the negative stigma towards the patients or TB that is still very strong in the community can be reduced or lost. 2. Required social support such as financial assistance and additional nutritional assistance. 3. The support of the closest person / family is needed to accept the illness and overcoming obstacles in the treatment period. 4. The need for health education and the empowerment of families in order to provide support to TB patients.
5.	Tuberculosis knowledge and the attitudes and practices of patients at	South Africa	TB patients at Mangaung Metropolitan South Africa	Cross-sectional study	The results of this study highlight the need for	-

primary health care facilities in a South African metropolitan: research towards improved health education[11]		health education in the Puskesmas area in Mangaung to overcome misunderstandings about TB and to correct the misinformation that prompted the social isolation of TB patients.

4. Discussion

Section 1.03 4.1 Principal finding

The aim of the present review was to explore the empowerment concepts on the topic of health behavior in a TB program. This resulted in the inclusion of five studies. Given the widespread dissemination of empowerment programs for health behavior and initiatives utilizing an empowerment approach, this is a surprisingly low number. It seems that promoting health behavior in TB via an empowerment approach may be unfamiliar to scientists, politicians and stakeholders in the health-care sector. Within many of the included studies and their respective intervention projects, the explicit measures or methods used to operationalize empowerment were not described in detail.

As far as the other included studies are concerned, we would have expected to learn more about how the goal of enabling people to take control over their lives was achieved in the specific intervention measures or what made the particular intervention an empowerment intervention. Unfortunately, due to incomplete or imprecise reporting, it was frequently unclear how the theoretical description of empowerment corresponded to the implemented measures in the practical intervention projects[13].

Section 1.04 4.2 Empowerment and behavior

The relationships between empowerment and behavior (change) are varied. The link might be unidirectional, reciprocal or even non-existent. This applies to the field of health behavior (change) as well. From a theoretical point of view, the tensions between empowerment and behavior (change) arise if the conceptualizations of empowerment, health-promoting behavior and health are derived from different paradigms. This is assuming that a narrow bio-medical model of health will impose difficulties on arguing how empowerment goals could translate into health. From this perspective, an increased level of autonomy, which is an example of an empowerment goal, has nothing in common with making healthier food choices. However, when referring to a more comprehensive understanding of health (e.g. according to the definition by the WHO), the links between being empowered and experiencing autonomy and bio-psycho-social health are obvious, as they are states of empowerment and the feeling of autonomy that represent health per se just as they are assumed to be the fundamental basics of health. Rappaport argues accordingly that when he states that a certain behavior can be seen of as an expression of health and as an expression of empowerment[2]. Tengland provides a detailed discussion of how empowerment goals (e.g. autonomy, control) are related to health (behavior) goals. He suggests that health-related abilities (e.g. self-confidence, self-efficacy) might mediate the relationship between empowerment and health, but that empowerment goals also need to be pursued for their own sake[14].

This discourse is not novel in the field of health promotion, but it seems to be especially crucial for health promotion in terms of healthy nutrition. Still, the predominant paradigm in nutrition

sciences is the bio-medical one, which might explain why empowerment is still used scarcely, as was shown in the current systematic review.

5. Conclusion

Overall, the concept of empowerment is almost non-existent in health promotion programs that focus on health behavior. The public health discipline has used the most empowering interventions available in the field of HIV / AIDS prevention. HIV / AIDS prevention empowerment strategies have been shown to improve health status by increasing condom use and reducing HIV infection rates[6]. This can inspire further empowerment interventions in other disciplines.

Many studies included in the current systematic review lack a detailed and comprehensive implementation-related description of the empowerment concepts. A detailed analysis could not be completed because of the low number of studies included. Further research on empowerment in health promotion that focuses on health behavior in TB is needed. The researcher must focus on a thorough description of the application of empowerment in practice.

AN UPDATE POTENTIAL RISK FACTORS FOR ASTHMA: A SYSTEMATIC REVIEW

T G Sesaria[1], N M Moh Myint[1], H Widodo[1], M R Maulana[1]
[1]Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
Email: tifanny.gita.sesaria-2018@fkp.unair.ac.id

ABSTRACT

Asthma is a heterogeneous entity that is the result of complex interactions between environmental and genetic factors. In fact, WHO through extrapolation from existing data, predicts a further increase in the number of asthmatics by an additional 100 million in 2025.This highlights need for application of standardized and validated methods to enable improved evaluation of temporal trends of asthma prevalence by managed the various risk factors. A systematic review to conduct of various risk factors that caused asthma based on international studies, systematic reviews, and literature reviews. There are 1100 identified articles published between 2014-2018 through database search such as Scopus, Proquest Springer, and Science direct and 12 articles relevance with inclusion criteria choosen for arranged systematic review. According to findings, risk factors can be categorized as internal and external factors such as childhood, adult and very late onset asthma, genetics, indoor allergen exposure, microbiome exposures, respiratory viruses, environmental tobacco smoking, air pollution, smoking, obesity, occupational exposures, sex hormones, stress events and medication related asthma. There are various risk factors that cause asthma and the dominant potential risk factor is external factor such as air pollution, allergens and smoking.

Keywords: asthma, potential, risk factors

1. Introduction

Asthma is a heterogeneous entity that is the result of complex interactions between environmental and genetic factors[1]. Despite therapeutic advances, the continued rise in asthma prevalence suggests that the fundamental causes of asthma are still poorly understood. Akin to the prevalence data, the study of the risk factors and protective relationships in asthma has proven to be difficult due to the myriad of related factors. Of note, there is an extensive degree of overlap between the risk factors for childhood and adult onset asthma [2].

Asthma is a global problem that is estimated to affect 300 million people around the world. The global prevalence of asthma is variable. According to some relatively standardized and comparable studies, the prevalence rate of asthma has varied between 1% and 18% for children and adults[3]. Studies from Turkey conducted relying on the European Community Respiratory Health Survey (ECRHS) methodology reported that the prevalence of asthma was between 0.3% and 7.6%, which are similar to most European countries[4]. Studies have shown that social and environmental factors may affect asthma prevalence, like a lack of exclusive breast feeding, the use of antibiotics, cockroaches at home and the use of feather pillows. A study about the modifiable risk factors of asthma revealed that most of the asthmatic children lived in urban areas, had exposure to tobacco smoke at home, were living in covered houses, had pets and had carpets at home.

Moreover, the increase in knowledge can increase the prevention of asthma associated with family careers. It is important to implement educational and behavioral interventions for the reduction in the prevalence of asthma at the primary level[5]. The purpose of this study was to conduct a systematic review of the various risk factors that cause asthma. The findings originate from various international studies, systematic reviews and literature reviews.

2. Method

2.4.Data sources and collection process

The journal used an English language search strategy that began with asking the following research question: "Which risk factors influence asthma?" The databases used for searching for the journals were Scopus, PubMed, Science Direct and ProQuest. The keywords used were "asthma", potential" and "risk factor". The journal articles were limited to 2014-2018 for the publication years, within the areas of nursing, respiration and English-language journals. The authors chose 12 articles from the 652 suitable titles that were in accordance with the inclusion criteria. The data from the studies was extracted by the means of a data extraction form. This data included the first author and year of publication, the year and country where the survey was carried out, the number of participants, the participants' age and gender, their exposure assessment and the number of participants in each group.

2.5.Article selection criteria

The search resulted in 652 suitable articles, and the authors chose 12 articles that met the inclusion criteria. They then analyzed the results, advantages and limitations and also discussed the study. The study inclusion criteria were that they 1) included various asthma patients, 2) stated all of the risk factors that affect the common causes of asthma in varied age patients and 3) that they referred to various demographics and economic statuses.

2.6.Research design

From the12 selected articles, most of them used a cross-sectional, cohort or case study design.

3. Result

3.1 Respondent's Characteristics

The number of respondents in the selected articles varied between at least 140 respondents to, at most, 65,372 respondents with variations in age from 8 to 25 years old. All of the respondents were individuals who experienced asthma outside of the hospital, both in public areas and in private areas (e.g. their house).

This systematic review chose 12 selected articles originating from 3 continents, namely the Americas, the European continent and the Asian continent. Articles from the Americas came from the USA and Argentina, and those from the Asian continent came from China, Korea, Pakistan and Malaysia.

Articles from the Asian continent are expected to reflect the profile and characteristics of cases of asthma that occur in children in Asian communities. As a comparison of the occurrence and management of asthma cases that occur in developed countries, we refer to articles from several developed countries. The search results originally began with 652 articles, and the authors choose 12 articles that were suitable according to the inclusion criteria and then analyzed the results and engaged in a discussion. A total of 12risk factors for asthma were identified and classified in two potential risk categories: external and internal factors and any potential risk factors from external factor that often caused asthma are air pollution, allergens and cigarette smoking. The risk of bias in individual studies was generally high or intermediate, which may impact the validity of our results. The common weakness was in general in the selection procedure, for example the representativeness

of the sample, there was a justification of the sample size and the percentage of non-respondents. However, the risk of bias was eliminated by following the exclusion criteria.

3.2 Air pollution

The United States Environmental Protection Agency (EPA) defines air pollution as any visible or invisible particle or gas found in the air that is not part of the natural composition of air itself[6].

Research from Orelano *et al.*, 2017on air pollution and asthma identified the relationship where there was an increased risk from air pollution due to it exacerbating pre-existing asthma through acute exposure as well as being involved in the development and impairment of asthma through chronic exposure to ambient air pollutants[3]. Various pollutants include ozone (O_3), nitrogen dioxide (NO_2), particulate matters (PM) such as PM_{10} and sulfur dioxide (SO_2)[3]. Research from Buelo *et al.*, 2017 found that the pollutants of interest, including traffic-related air pollution (TRAP), can cause oxidative stress. The ability of the antioxidant defenses to handle the increased load of reactive oxygen species generated in the lungs after exposure is an important determinant of the risk of subsequent adverse effects[7]. Specific polymorphisms in the antioxidant enzyme genes, such as the glutathione Stransferase genes, GSTM1 and GSTP1, can modify risk of asthmatic responses to pollutants 34,35 and these variants (GSTM1 null and GSTP1 Ile105Val) can also interact with a tumor necrosis factor (TNF) promoter variant (G-308A), which affects the expression of TNF, hence the early inflammatory response asthma[4]

3.3 Environmental tobacco smoke (ETS) or smoking

Environmental tobacco exposure (ETS) is well recognized as increasing the risk of asthma in the early stages of life. Exposure from ETS can caused significant direct and indirect effects such as pulmonary physiology effects on asthma severity[7].

Many studies such as those by Ahmad *et al.*, 2018, Bao *et al.*,2017, Buelo *et al.*, 2018 and Kuruvila *et al.*, 2018 have also explained that the prevalence of asthma was higher in smokers than in non-smokers[2][7][8][9]. Additionally, a previous study showed that smoking might cause an asthma severity increase due to the impairment of lung function, and that it can also decrease the response to drugs and thus make the asthma more difficult to control. Moreover, the incidence of smoking in asthmatic patients is high. Around 20–35% of asthmatic patients from the United States and other Western countries self-reported smoking and 35% of asthmatic adults visiting the emergency department reported smoking. These findings indicate that we should educate the general population, especially the asthmatic population, on the benefits of quitting smoking[2].

3.4 Allergens

Allergens are substances that cause an allergic reaction. Allergens can enter the body by being inhaled, swallowed, touched or injected[6]. More than 26 million people in the US have asthma, and allergic asthma is the most common type, affecting around 60% of people with asthma. Both allergic and non-allergic asthma has the same symptoms, such as shortness of breath and wheezing. Having allergic asthma means that *allergens* trigger your asthma symptoms. Allergens cause an allergic reaction because our immune system thinks that it is harmful. Our immune system responds by releasing a substance called immunoglobulin E (or IgE), and an increase of IgE can trigger the inflammation (swelling) of the airways in your lungs[1].

This can make it harder to breathe and this can trigger an asthma attack. Many allergens can be a trigger for asthma including pet animals (cat, dog, rabbit), and also indoor allergens including house dust mites, mice, cockroaches, animal dander, and fungi. In the context of fungi, both qualitative and quantitative measures of fungal exposure have been linked with an enhanced allergy and asthma risk. Cockroach exposure is an even more potential inducer of sensitization, with a threshold 10- to 100-

fold lower than other indoor allergens. Recent data suggests that exposure and allergic sensitization to mouse antigens is a stronger predictor of severe asthma than cockroach allergens[7]. In a US cohort of inner-city residences, 95% had detectable mouse allergens, with increased levels being associated with cockroach infestation. The allergens of cats have been shown to be strong airway sensitizing agents and the allergens of dogs have been shown to be similar to the allergens of cats, with a mild cross-reaction. These allergens easily become airborne, which increases the risk of asthma or outbreak in susceptible populations. At the same time, the relevant literature reported that early exposure to the presence of animal allergens in the environment can reduce the risk of asthma in children. Therefore, the relationship between pet ownership and asthma has not yet been fully defined[10]

4. Discussion

The Asthma and Allergy Foundation of America (AAFA) analyzes data from across the continental United States and ranks the 100 largest cities where it is challenging to live with asthma. Fourteen years after releasing our first report, they have changed the focus for the 2018 Asthma Capitals report to measure the most critical health outcomes – asthma prevalence, emergency room visits due to asthma attacks and asthma mortality. Ten people die every day from asthma. Most of these deaths are preventable with the proper management, access to adequate medical care, housing improvements and better air quality. However, asthma still remains one of the most prevalent chronic diseases in our nation. It is also one of the most costly diseases with an estimated annual cost to society of $82 billion.

This systematic review was about the risk factors that influence the occurrence of asthma and the articles came from the USA and Argentina and the Asian continent, including China, Korea, Pakistan, and Malaysia. The new focus about causes of asthma in this systematic review than study before is about the 3 big causes of asthma that many people can easily modify to decrease the incidence of asthma in their daily lives. Based on the 12 articles, there are 3 potential risk factors for asthma including air pollution, allergens and smoking. Moreover, the presence of the risk factors due to air pollution in 3 articles referred to the allergens related to the risk factors including pet animals (cat, dog, rabbit), also indoor allergens including house dust mites, mice, cockroaches, animal dander and fungi in 4 articles. The third factors was smoking or environmental tobacco smoking (ETS) as found in 6 articles. The discovery of the most common risk factors in the incidence of asthma included air pollution, allergens and smoking. The limitations of this study were that it included only cross-sectional studies. There are relationships between the risk factors and asthma development to some extent. We further matched case control and prospective cohort studies. More is needed to investigate thoroughly and more time is needed to know the relationships in the future because it need more time concern to analysis cohort data.

The results of the review of many studies can be used to help patients with asthma. Nurses can provide interventions and structured management education to ordinary people. Parents who have children with asthma need to know about prevention and environmental modification assistance should be provided to patients with asthma. The factors that affect the life safety of patients with asthma exacerbation can increased with better prevention and management.

5. Conclusion

Based on the 12 articles, the authors found there to be various risk factors that influence the occurrence of asthma. There are both internal and external factors. The internal factors include gender, age, family history, serum IgE level, ethnicity, obesity, damage and lung function and co-morbid asthma (atopic dermatitis, Gastro Esophageal Reflux Disease (GERD), mental health disorder, chronic sinusitis, chronic bronkhitis, eczema and genetics). The external factors include as pet animals, a lack of breastfeeding, carpets and pillows at home, environmental tobacco smoke, air pollution, allergen, poor access to care, low parental education and occupational exposure. The most common risk factors found in the incidence of asthma are allergens, air pollution, and environmental

tobacco smoke (smoking). The identification of these risk factors can be useful for the development of prevention strategies to decrease asthma exacerbation incidences.

ABSTRACT

The increase of Tuberculosis spreading in various regions in West Sulawesi has become a significant issue. Hence, the attention and handling are increasingly massive by various parties. Communities can overcome the problem by taking an active role in compliance and knowledge of tuberculosis therapy. One of factors in the successful therapy is adherence to treatment. Pulmonary tuberculosis can be overcome and prevented if people have good knowledge. This study purpose was to find out about the family as a Drug Control Supervisor on knowledge and medication adherence for patients with pulmonary tuberculosis. This study was a descriptive study with a cross sectional approach. Sampling was carried out in the working area of the Tobadak health center in West Sulawesi. The instrument used was a questionnaire with a total sample of 76 patients. This study showed that 76 pulmonary Tuberculosis patients, (55.3%) men and (44.7%) women. Most patients are in the age group 50-79 (42.1%) years, based on education (52.6%). Good knowledge sufferers (10.5%), sufficient (30.3%), less (59.2%). Compliance in drug use was deivided into obedient category (61.8%) and non-compliance (38.2%). This research showed that adherence to medication is largely a level of lack of knowledge of patients with Tuberculosis.

Keywords: PMO family, pulmonary TB, knowledge, compliance

1. Introduction

The most common cause of failure is the patient's disobedient behavior towards the treatment, so that the cause of the treatment failure and lack of discipline is strongly influenced by the drug supervisor. The working area of the Tobadak Health Center is in a very remote location and it is difficult to reach by the health workers who are supervising the patients taking the medicine. The amount of health workers is not comparable to the number of TB patients, and this causes drop-out cases. The irregularity in taking the medicine is due to the ineffective role of the supervisors. There is a need for the families as supervisors to provide more optimal supervision. One of the causes of failure is the patient's disobedient behavior towards the treatment. The cause of treatment failure and the lack of discipline in the patients with pulmonary TB is strongly influenced by their drugs supervisor[18].

Tuberculosis is a global health problem that mostly occurs in developing countries like Indonesia[1,4]. Nearly 3 million people die each year from Pulmonary TB[2,3]. It is present in a third of the world's population. This disease is a major public health problem in Indonesia although the government's TB control programs have been carried out over the past few decades[1,4]. The medical treatment failure and a lack of discipline in the sufferers of pulmonary TB are strongly influenced by

their drug supervisor[5,6,7]. Tuberculosis (TB) is an infectious disease that is acquired through the bacteria that cause the disease. About 90 percent of those who become infected show no sign of the disease, but the organism has a risk of developing active TB later on. Left untreated, a third of those who do go on to develop the disease will die from it. Many ways to control tuberculosis have been carried out; the incidence and deaths from tuberculosis have declined but the worldwide mortality rate from tuberculosis is still high at 1.8 million in 2016[8,10,11,18].

According to the WHO in the 2016 Global Tuberculosis Report, there were 10.4 million new cases of tuberculosis worldwide in the 2015 statistics, equivalent to 28,500 people worldwide exposed to tuberculosis every day. Indonesia is included in the list of 6 countries which cover 60% of the new tuberculosis cases in the world. Indonesia is in second rank in the world as the biggest contributor of tuberculosis patients after India[22,23,29].

Based on the WHO Global Tuberculosis Report (2017), the incidence of Indonesian tuberculosis is up to 391 per 100,000 population and the mortality is 42 per 100,000 population. The number of new TB cases in Indonesia is 420,994 cases in 2017 (data as of May 17, 2018)[22,23]. The prevalence in 2017 is 919 per 100,000 population while in 2017, it was 628 per 100,000 population. In 2017, there were 425,089 cases of tuberculosis. This can be compared to all tuberculosis cases found in 2016, which amounted to 360,565 cases[22,23]. According to the 2014 West Sulawesi Health Service report regarding TB cases, it found 1,596 cases. In 2015, there were as many as 1,607 TB cases with the highest number of cases being in Polewali Mandar District with as many as 425 cases. This was followed by Mamuju Regency with a total of 388 cases and the lowest case was in Mamasa District with 74 cases. There was an increase in the number of TB cases in the 2016 amounting to 2,330 with the deaths as many as 2.88 per 100,000 population with the highest number of new cases being found by smear (+) TB in Mamasa Regency, by as many as 740 cases. Polewali Mandar District had as many as 425 cases, in Mamuju there were as many as 410 cases, in Majene there were 250 cases, in North Mamuju there were 116 new cases and in Central Mamuju, there were as many as 230 cases[12,14].

2. Research methods

2.1. Types of research

The type of research was quantitative using the descriptive observational method with a cross-sectional design. This was to obtain an overview of the level of knowledge and medication adherence of the pulmonary TB patients in the working area of the Tobadak Community Health Center, Mamuju Tengah District, West Sulawesi.

2.2. Population and sample

2.2.1. Population. The population used in this study was affordable, met the research criteria and were usually accessible to the researchers from their groups. The population in this study was the family of the tuberculosis patients (intensive and advanced stage) in the working area of the Tobadak Community Health Center, Mamuju Tengah District, West Sulawesi.

2.2.2. Sample. The samples were a part of an affordable population that was used as the research subjects. The sampling technique used in this research was purposive sampling. A total sample of 76 respondents were selected according to the inclusion criteria (TB patient's husband/wife or their parents, age of the TB patients ≥ 17 years, TB sufferers in the period of DOT treatment) and exclusion criteria (having hearing loss, not cooperative, patients who hid their disease).

2.3.Research variables

The variables in this study were distinguished between the independent variables (free) and the dependent (bound) variable. The independent variable in this study was the supervisor related to the patient taking their medicine and the dependent variable was their knowledge and compliance with taking the medication.

2.4.Research instrument

The instrument for knowledge consists of the knowledge of the pulmonary TB patients. The knowledge was assessed using a questionnaire with 2 choices for the answers, namely right and wrong. The instruments related to compliance when taking the medication were questionnaire sheets and observation sheets. For the questionnaire sheets, there were 10 questions with 2 choices of answer, namely yes and no. The TB-01 and TB-02 forms are known widely in the various health centers in Indonesia.

2.5.Data analysis

The data obtained at the time of the study was analyzed using descriptive observational analysis techniques systematically with a cross-sectional approach to illustrate the level of knowledge and adherence to taking medication.

3. Results

From a total of 76 respondents, 42 respondents are men (55.3%), while the rest are women 44.7%. The age distribution shows that of a total of 76 respondents, there are different frequencies for each age group. Most of the respondents were aged 50 - 79 years (42.1%), followed by the age range of 17 - 34 years (26%). In addition, most of the respondents only had an elementary school level for their education background (52.6%). There were 7 respondents in the undergraduate category (9.2%) (see Table 1).

Table 1. Characteristics of the family members as drug supervisors

Category		**Frequency**	**Percentage**
Gender	Men	42	55.3
	Women	34	44.7
	Total	76	100.0
Age	50-79 year	32	42.1
	35-49 year	18	23.7
	17-34 year	26	34.2
	Total	76	100.0
Education	Elementary School		
	Junior High	40	52.6
	School	16	21.1
	Senior High	13	17.1
	School	7	9.2
	Undergraduate	76	100.0
	Total		

Table 2. Distribution of knowledge and the patient's compliance to taking the medication

Variable	**Frequency**	**Percentage**

Knowledge	Good	10	13.2
	Moderate	35	46.1
	Less	31	40.8
	Total	76	100.00
Compliance	Compliant	62	81.6
	Non-compliant	14	18.4
	Total	76	100.0

From the total of 76 respondents, the results showed that the level of knowledge of disease and therapy in pulmonary TB patients was varied. There were only 10 respondents that had knowledge to a good level (13.2%), while most of the respondents (35 respondents) had knowledge at a moderate level (46.1%) and some had the lowest level of knowledge (40.8%). Related to the compliance of the TB patient, the results showed that most of the respondents were included in the compliant category (81.6%), while the rest (14 respondents) were in the non-compliant category (18.4%).

4. Discussion

TB eradication in Indonesia has been carried out nationally since 1969 through the Tuberculosis Eradication Program by the Ministry of Health of Indonesia. Since 1995, the program was intensified using the Directly Observed Treatment Short Course (DOTS) strategy which recommended by WHO[22,23]. However, the successful rate of treatment has not yet reached the target set by the Ministry of Health of Indonesia, which was that 85% of pulmonary TB sufferers must be cured. In addition, the WHO has estimated that since 2013, cases of pulmonary TB with MDR (Multi-Drug Resistant) in Indonesia have increased. This can be proven by the data on the incidence rate of new cases being as many as 6,800[9,13,15]. The failure of TB patients in terms of their treatment can be caused by many factors, such as drugs, disease and the sufferers themselves. This is usually caused by co-morbidities or immunological disorders. The factors related to the patients themselves can include a lack of knowledge about TB, cost, laziness when it comes to treatment and feeling healed[8,10,11]. Knowledge and attitude are also important when it comes to increasing the obedience to taking the medication, as low knowledge and education can influence the patient's understanding of carrying out the drug treatment[21,24].

To improve compliance, there needs to be information transmitted through both education and the media to patients about the benefits and importance of compliance to achieving treatment successfully, giving the patients confidence about the effectiveness of the drugs in healing, while also giving the patients an awareness of the risk of non-compliance[9,13]. TB infection control measures are constrained by the way that the health workers direct the patients through effective communication. The low number of health care providers is not comparable with the number of patients in health institutions, there is an absence of isolation TB units for patients in health institutions and there is a limited availability of masks as protection for the health workers[20,24]. Knowledge and attitude is also important when it comes to increasing the obedience to taking medication. A low level of knowledge and education can affect the patient's understanding of taking the medication [20,24]. Quality of life is one of the main criteria for knowing the health service interventions such as morbidity, mortality, fertility and disability. In developing countries over the past few decades, the incidence of chronic disease has begun to replace the dominance of infectious diseases in society. Carrying the burden of chronic illness means that the patient's quality of life becomes a concern for health service[13,16].

One of the components of DOTS is direct supervision when the patient consumes the anti-tuberculosis drugs. To ensure the regularity of the treatment, the family can be drug supervisors, because they are identified, trusted and approved by both the health workers and the sufferers. Besides that, they are respected and live close to the sufferers, and they are willing to help the

sufferers by volunteering[9,11,12]. It is expected that the families will care more about the TB patients through family control, so the supervision will thus be more controlled[20]. There is a significant relationship between the role of the supervisors with taking medication and drinking compliance[24]. The compliance with taking medication for pulmonary TB patients can be achieved by involving the family as their supervisors when taking medication[17,21]. Therefore, increasing the level of discipline and encouraging the patients to be obedient in the treatment program requires support from the patient's family or from their fellow patients[17,19,21]. The selection of the correct drugs supervisor can be done by the health workers or by the community. The duty of the drug-taking supervisor is to monitor the pulmonary tuberculosis patients to encourage them to take their medication regularly until the completion of the treatment. This includes encouraging the patients with pulmonary tuberculosis to seek treatment regularly and to remind the patients with pulmonary tuberculosis to check their sputum at a predetermined time. Thus it is expected that the TB patients will take the initiative to take the medicine regularly when there is a supervisor accompanying them[21].

Previous studies can be used as a basis for the researchers to empower drugs supervisors according to green health influenced by 2 main factors, namely behavioral and external factors. Realizing health behavior requires several stages as part of a health promotion program, which is known as a model of assessment and follow-up (Precede-Proceed Model)[3]. The theory of the Precede-Proceed Model is oriented towards creating a society that successfully changes behavior due to health promotion interventions. Precede has 5 stages; social diagnosis, epidemiological diagnosis, behavior and environmental diagnosis, organizational education and diagnosis and the administration and diagnosis policy. Procede has 4 stages, namely: implementation, process evaluation, impact evaluation and the outcome evaluation[5,6,14]. The process above can be applied by receiving assistance from outside environmental factors. In this case, this refers to the family as the drug supervisors for the patients who suffer from pulmonary TB.

5. Conclusion

From the results of this study, it can be seen that the research conducted at the health center in the Tobadak central work area showed varied results, namely concerning the level of knowledge, especially that of the family as drug supervisors in relation to the medication adherence of the pulmonary TB patients. The research results indicate that the majority are caused due to a lack of knowledge on medication handling, the methods of therapy and medication obedience of Tuberculosis patients, especially in the Tobadak area, West Sulawesi Province, Indonesia.

The patients should remain obedient in terms of taking the medication and the patient’s family as the drug supervisors must continue to provide support to the patients by always reminding and motivating patients to take their medication regularly and taking the time to assist whenever the patients need help.

6. Acknowledgments

The author would like to thank the Dean of the Faculty of Nursing, Universitas Airlangga, Surabaya. My thanks also go to Dr. I Ketut Sudiarsa, M.Kes as Head of the Mamuju Tengah District Health Office, Nur Yadin, S.Kep as Head of the Disease Control and Prevention Division of Central Mamuju District Health Office and their staff. Unlimited thanks go to the respondents who participated in this study.

FINANCIAL BURDEN OF TUBERCULOSIS PATIENTS IN LOW AND MIDDLE INCOME COUNTRIES: A SYSTEMATIC REVIEW

Y A Zainurridha, T Sukartini1 and Harmayetty

Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

ABSTRACT

In order to inform the development of appropriate strategies to improve financial risk protection, we conducted a systematic literature review of the financial burden of tuberculosis (TB) that is faced by the patients and their affected families. Apart from ensuring that the healthcare services are fairly financed and delivered in a way that minimizes direct and indirect costs, there is a need to ensure that TB patients and their families receive appropriate income replacement and other social protection interventions. Most countries aim to provide TB diagnosis and treatment free of charge through the public health services. The method involved a systematic review of financial risk protection with a study selection criteria using a Scopus, Science Direct, Pubmed and Spinger link database search with 2013-2018 for the year of publication range. The search used the English language with 'financial burden', 'tuberculosis patients', 'low and middle income countries' and 'protection intervention' as the keywords. The PICOS approach was used. In total, 1674 journal were found and 15 journals were found to be appropriate and thus assessed. This review shows that while costs are catastrophic for many patients, they are minimal for others. It is crucial to identify the factors that contribute to the costs incurred and to financial ruin.

.

1. Introduction

In order to inform the development of appropriate strategies to improve financial risk protection, we conducted a systematic literature review of the financial burden of tuberculosis (TB) faced by the patients and their families. The total cost of TB for the patients can be catastrophic. Income loss often constitutes the largest financial risk for patients [1]. Apart from ensuring that the healthcare services are fairly financed and delivered in a way that minimizes direct and indirect costs, there is a need to ensure that the TB patients and their families receive appropriate income replacement and other social protection interventions [2]. Most countries aim to provide TB diagnosis and treatment free of charge within the public health services [1]. However, many TB patients are still facing very high direct and indirect costs due to the TB illness and care-seeking, thus hampering access and putting people at risk of financial ruin and further impoverishment [3].

The World Health Organization (WHO) is developing a post-2015 Global TB Strategy that highlights the need for all countries to progress towards universal health coverage to ensure "universal access to needed health services without financial hardship in paying for them", as well as social protection mechanisms for "income replacement and social support in the event of illness". One of the tentative global targets for the strategy is "no TB-affected family facing catastrophic costs due to TB", which is desired to be reached globally by 2020. This target reflects the anticipated combined financial risk protection effect of the progressive realization of both universal health coverage and social protection [4].

Universal health coverage has long been on the global TB control agenda, which stresses the need for universally accessible, affordable and patient-centered services. Social protection has emerged more recently as a key policy area for TB care and prevention [5]. Social protection involves schemes to cover the costs beyond direct medical costs, including the compensation of lost income.

Examples of social protection schemes include sickness insurance, disability grants, other conditional or unconditional cash transfers, food assistance, travel vouchers and other support packages [6]. Such schemes exist in most countries but they may not be fully implemented due to inadequate financing or the insufficient capacities of the healthcare and social welfare systems [1]. Furthermore, they may not include TB patients among those eligible [4].

2. Research Methods

The method of this review was a systematic review of financial risk protection with the study selection criteria using the Scopus, ScienceDirect, Pubmed and Spinger link databases between 2013 - 2019 for the date of publication. The journals had to be in the English language, the keywords used were financial burden, tuberculosis patients, low and middle income countries and protection interventions. The PICOS approach was used. The journals that were found totaled 1674 journals and 15 journals were found to be appropriate and thus were assessed [3].

3. Results

In total, 1674 journals were found and 15 journals were deemed as appropriate and thus assessed. The database search found 270 in Scopus (n=85), Science Direct (n=115), Pubmed (n=45) and Spinger link (n=35). The duplicated articles that were deleted totaled 45; the reviewed abstracts found to be inappropriate were n=225, and there were also articles that did not qualify in terms of mentioning financial burden or that involved tuberculosis patients in low in middle income countries n= 135. The review of the full text stage n = 90, the articles that did not match the inclusion criteria n= 65 and the articles finally used n= 15. This review shows that while the involved costs are catastrophic for many patients, they are minimal for others. In total, 49 studies fulfilled the inclusion criteria. One study was without any cost data but it was still included since it provided data on coping strategies.

3.1 Study Characteristics

The study characteristics were that 2 articles were cross-sectional, 1 article was a quantitative study and 12 were randomized control trials.

3.2 Results of the Review Study

This review demonstrates that the economic burden of seeking TB care is often very high for the patients and that it affects the associated households. Clearly, accessing TB care and continuing treatment comes with a high risk of financial ruin or further impoverishment for many people. In most settings, income loss is a dominating reason for the high costs. This should be expected as the burden is determined by a range of factors, such as socioeconomic status, clinical needs, the health system structure, the TB service delivery model, the distance to the health services, insurance coverage, the capacity to work, the existence of any social protection scheme and the effectiveness of informal social networks supporting the patients and their families [7].

4. Discussion

This review shows that, while the costs are catastrophic for many patients, they are minimal for others. It is crucial to identify the factors that contribute to the costs incurred and thus to financial ruin [8]. Unfortunately, few studies provided sufficient details about the models and context of care to allow us to quantify the relative importance of the different factors. However, the available data hints at some key explanations and intervention entry points [9].

Affordable health services, as well as social protection schemes, are needed to enable access, to reduce delays and to compensate for direct and indirect costs. Social protection schemes cover the general categories of vulnerable persons, such as those with disabilities or sickness and other causes

of limited or reduced income. TB patients may, in some settings, meet the criteria for such support [7].

Another option is to use generic or locally defined irreversible coping strategies as proxy indicators for catastrophic costs [9].

Further work is needed to assess the correlation between a high total cost in relation to income and seemingly irreversible coping strategies [10].

5. Conclusions

This review shows that while costs are catastrophic for many patients, they are minimal for others. It is crucial to identify the factors that contribute to the costs incurred and thus to financial ruin.

THE CORRELATION BETWEEN FAMILY KNOWLEDGE ABOUT PULMONARY TUBERCULOSIS WITH FAMILY EFFORTS TO PREVENT SPREADING INFECTION OF PULMONARY TUBERCULOSIS AT PUSKESMAS KARANG TALIWANG NTB

Dady Zharfan Hanif, Tintin Sukartini, Laily Hidayati
Faculty Of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia

ABSTRACT

Pulmonary tuberculosis is contaminated infection that cause by *Mycobacterium tuberculosis*. This study was purposed to analyze correlation between family knowledge about pulmonary tuberculosis with family efforts to prevent spreading infection of pulmonary tuberculosis at Puskesmas Karang Taliwang NTB. This was correlational research with cross-sectional approach. Population were family pulmonary tuberculosis in work area of Puskesmas Karang Taliwang. Samples were taken by using purposive sampling and obtained 25 samples. Independent variable was family knowledge about pulmonary tuberculosis. Dependent variable was family efforts to prevent spreading infection of pulmonary tuberculosis. Data were taken using the questionnaire. Data were analyzed by using Spearman's rhotest with $\alpha \leq 0,05$. This study shows that there were moderate correlation between family knowledge about pulmonary tuberculosis with family efforts to prevent spreading infection of pulmonary tuberculosis ($p=0,000$, $r=0,695$). It can be concluded that are more higher knowledge, so more higher family efforts to prevent spreading infection of pulmonary tuberculosis. The results of this study suggest the nurses to arrange a health education related to pulmonary tuberculosis and the further research can develop a better research relate this study.

Keywords: knowledge, family of patients with pulmonary tuberculosis

Introduction

Transmission of pulmonary TB in the family can be done through coughing, sneezing, talking or spitting. Patients excrete TB germs into the air, known as bacilli [1]. Baciilli can be resolved in free air for 1-2 hours, depending on the presence or absence of ultraviolet light, good facilities and humidity. In humid and germicidal situations it can take days to months [2]. Patients with pulmonary TB with a positive smear status can transmit to at least 10-15 other people, including their own family. TB germs can become dormant for years by forming thick waxy cell walls. If a person's immune system decreases, then it is likely to be bigger TB [3].

One of the causes is the low or reduced family of transmission of the pulmonary TB virus. There neeeds to be an understanding the family in overcoming causes, ways of transmission, and preventing infections that increase the number of infections, and that increase the number of sufferers. Knowledge can be obtained through reading books, getting information from health workers, or from other facilities. The principle is the learning process, where there will be changes in knowledge and abilities (behavior) in the subject of learning itself [4].

After a preliminary study at the Karang Taliwang Health Center at 5 out of 10 respondents who had families with pulmonary TB sufferers did not understand how to care for those with pulmonary TB at home. In accordance with the results of the observation, pulmonary TB patients who visited the Puskesmas for treatment also did not close their mouth properly when sneezing and coughing and removing saliva. By the results from a brief interview, answers were obtained from 6 out of 10

families with pulmonary TB patients at home from eating utensils such as plates, cups, and containers. 4 out of 10 family members remained in one room with sufferers. Health education has also been carried out by the health center, but only in the community health center, not concentrated in several special places around the homes of residents. Every family who comes into contact with patients are given a short health education to care for patients with pulmonary TB, this is not done at the visual home by the puskesmas but in the homes of residents, so that loans allow for less optimal health.

Based on data from the Mataram City Health Office, Karang Taliwang Health Center ranks second with the highest number of pulmonary TB sufferers after Ampenan Health Center (65 people) in 2015. Based on data obtained from the Karang Taliwang Health Center, the number of tuberculosis patients from 2014-2015 were: 2014 amounted to 46 people from the total suspected tuberculosis of 202 people. While the number of tuberculosis sufferers in 2015 was 55 people from the total suspected tuberculosis of 247 people. TB data in Puskesmas in Mataram City in 2015 were: Ampenan Health Center at 65 people, Tanjung Karang Health Center at 24 people, Karang Pule Health Center 19 people, Karang Taliwang Health Center at 63 people, Mataram Health Center at 26 people, Selaparang Health Center 29 people , Pagesangan Health Center 31 people, Cakranegara Public Health Center 46 people, Dasan Agung Public Health Center 21 people, Dasan Cermen Public Health Center 23 people. Data from the Karang Taliwang Health Center for the third month were 11 people in January-March, 11 people in April-June, 14 people in July-September, and 27 people in October-December [5].

Home and family is an environment that is often interactive for positive TB sufferers, so the potential for disease transmission to occur means that people who live at home / have close contact with patients have a high risk of contracting it. The amount of bacillus that are exposed and continuous can facilitate transmission of infection. Long contact with patients with a higher percentage for household members. A bedtime history will also increase the likelihood of exposure to the TB bacillus. A lack of family knowledge in understanding causes, modes of transmission, and efforts to prevent infection can increase the number of spreads of infection, thus increasing the number of sufferers [4]. In addition, until now there are still many people who do not yet know of a free TB health care program at the Puskesmas.

Various efforts to overcome and terminate the chain of transmission of TB infection have been carried out through health programs at the Puskesmas level, in the form of developing a TB prevention strategy known as the DOTS strategy (directly observed treatment), which has been shown to reduce the number of infections, and also prevent the development of MDR (Multi Drugs Resistence) -TB, but the results are still felt not as expected. The main focus of the DOTS strategy is the discovery and healing of patients, with priority for infectious TB patients. This strategy will decide on TB transmission and is expected to reduce TB incidence in the community. Finding and healing patients is the best way to prevent transmission of pulmonary TB and break the chain of infection [3]. Therefore family support is very necessary, because it supports the success of one's treatment by always reminding the patient to take medication, a deep understanding of the patient who is sick and encouragment for them to continue to be diligent in their treatment. In addition, health workers such as doctors and nurses as part of professional health care providers are expected to always increase their knowledge and skills to be more perfect for detecting and diagnosing TB disease at an early stage.

This research uses behavioral theory from Lawrence Green who tries to analyze human behavior, departing from the level of health. That a person's health is influenced by two main factors, namely: behavioral factors (behavioral causes) which consist of predisposing factors, supporting factors, and driving factors, and non-behavior causes. Based on the above-mentioned explanation, the researchers felt interested in examining the relationship between the level of family knowledge and family efforts in preventing infection with pulmonary TB in the Karang Taliwang Community Health Center.

Research methods

The design of this study is correlational by using the method of collecting data in a cross sectional manner. Correlational research aims to expose important events that occur today. The population in this study were families of pulmonary TB sufferers in the Karang Taliwang Health Center Working Area during January - December 2015 at 63 people with the sampling technique used purposive sampling. The independent variable in this study is the level of family knowledge of patients with pulmonary TB and the dependent variable is family efforts in preventing transmission of pulmonary TB infection. The ethical clearance was carried out at the Airlangga university medical school. After being declared worthy of ethics, researchers then conducted research. Before collecting data, researchers chose patients who were used as respondents using purposive sampling adjusted for inclusion criteria and exclusion criteria. Then the collection of data is done door-to-door to the family homes of patients who have been determined to be respondents. After having the research procedure explained, the families of patients who were willing to respond were given informed consent to be signed and approved. The instrument used in the study was a questionnaire to determine the level of family knowledge and preventive behavior towards pulmonary tuberculosis that has been tested for validity and reliability. Furthermore, the data were analyzed using Spearman's rho statistical test with a significance level of <0.05, meaning that if Ho is rejected, it means that there is a relationship between the level of family knowledge and family efforts in preventing transmission of pulmonary TB infection.

Results

Data on respondents' characteristics will be presented in the table, consisting of age, gender, education level, and respondent's work. Then it will be presented also at the level of family knowledge about pulmonary TB, family efforts in preventing transmission of pulmonary TB infection, and the relationship of the level of family knowledge about pulmonary TB with family efforts in preventing transmission of pulmonary TB infection.

Table 1. Distribution of Characteristics of Respondents in the Karang Taliwang Community Health Center in Mataram, NTB on 8-15 January 2016

Characteristics	f	Percentage (%)
Age		
17-25 (late teens)	5	20
26-35 (early adult)	13	52
36-45 (final adult)	6	24
46-55 (early elderly)	1	4
Gender		
Man	16	64
Women	9	36
Education		
No School	3	12

Primary education (SD/SMP)	15	60
Secondary education	5	20
(SMA/SMK)	2	8
Higher education (D3/S1)		
Job		
Do not have a job	2	8
Private work	3	12
Government Employees	1	4
Farmer	2	8
Laborer	6	24
Entrepreneur	11	44

Based on table 1, it is known from the total number of respondents was at 25 people, it can be seen that the majority of respondents were in the early adult (26-35) years was at 13 respondents (52%). A total of 16 respondents were male (64%) and 9 respondents were females (36%). For education level, most respondents had a basic education, namely 15 respondents (60%). And for work, it can be seen that the majority of respondents have jobs as entrepreneurs, at 9 respondents (36%).

Based on table 2, it is known that the level of knowledge of respondents related to pulmonary TB, most respondents have a lack of knowledge, which is at 10 people (40%).

Table 2. Knowledge Distribution of Respondents in the Karang Taliwang Community Health Center in Mataram, West Nusa Tenggara on January 8-15, 2016

Variable		***Frequency***	***Percent***
Knowledge	Good	8	32
	Enough	7	28
	Less	10	40
	Total	25	100

Based on table 3, it is known that family efforts in preventing infection with pulmonary TB, at most respondents have efforts to prevent transmission of infections that are lacking, namely at 9 people (36%).

Table 3. Distribution of family efforts in preventing infection transmission in the Karang Taliwang Community Health Center in Mataram, West Nusa Tenggara on January 8-15, 2016

Variable		*Frequency*	*Percent*
Preventive Behavior	Good	8	32
	Enough	8	32
	Less	9	36
	Total	25	100

Table 4 shows Spearman's rho statistical test results obtained p value = 0,000 (p <0.05), thus the hypothesis (H1) is accepted and means that there is a relationship between family knowledge about pulmonary TB with family efforts in preventing transmission of infection in patients with pulmonary TB. Correlation coefficient shows a positive correlation (r = 0.695) which means it has a strong correlation. While the direction of the relationship is positive because the value of r is positive, which shows the higher level of knowledge, the more efforts to prevent transmission of infection.

Table 4. Cross tabulation of the relationship of family knowledge about pulmonary TB with family efforts in preventing transmission of pulmonary TB infection in the working area of Karang Taliwang Community Health Center, Mataram, West Nusa Tenggara on January 8-15, 2016

Knowledge	**Family efforts in preventing transmission of pulmonary TB infection**			**Total**
	Good	Enough	Less	
Good	5	3	0	8
Enough	3	2	2	7
Less	0	3	7	10
Total	8	8	9	25

Spearman's rho p=.000, r = 0.695

Discussion

Based on the results of the study, it was found that most of the respondents' knowledge was included in the less category, at 10 people. Conversely, only 8 respondents had good knowledge, and 7 respondents had sufficient knowledge. Understanding of knowledge according to [6] Notoatmodjo (2012) is the result of knowing, which occurs after people make sense of a particular object. Sensing occurs through the human senses, namely the senses of sight, hearing, smell, taste, and touch. Most knowledge is obtained from the sense of sight and sense of hearing. Knowledge is a very important domain in shaping one's actions. Knowledge is also influenced by the learning process that has distinctive characteristics by acquiring something new, unknown, and not yet understood, causing someone to get, know, and understand the information provided.

From the results of this study, most respondents could not answer question number 15, which is about talking to people with pulmonary TB at close range without using a mask that would not cause transmission of pulmonary TB disease. This is due to the low education level of respondents, resulting in less and limited acceptance of respondents to information. In addition, the low level of knowledge of respondents also occurred because they claimed that they still received less information or health education about pulmonary TB. In fact, the provision of health education can cause one's knowledge to increase. This opinion is in accordance with the opinion of Notoatmodjo [6] which states that health education is an effort or activity to help individuals, groups, and communities in improving the ability of both knowledge, attitudes, and skills to achieve optimal healthy living.

Submission of information through health education can change one's understanding from not knowing to knowing, and not being able to be capable. The lack of knowledge of respondents, apart from education factors, can also be influenced by age, employment, and income. The more mature the age and the higher income from one's work, the more mature the way of thinking of that person, which will later affect one's knowledge level.

Based on the results of the study, it was found that most family efforts to prevent transmission of pulmonary TB infection were included in the less category, at 9 people. While those included in the categories of good, namely at 8 respondents, and those included in the sufficient category also have the same number of respondents in the good category, namely at 8 respondents. According to Lawrence Green's theory cited by Notoatmodjo (2003) states that the enabling factors are factors that support a reason to behave or realize motivation to take action. According to Sunaryo [7], socio-economic is one of the exogenous factors that influences a person's behavior. This statement is supported by the theory of Snehandu B. Kar as quoted by Notoatmodjo (2003) that someone will behave if there is a situation that allows them to act. This opinion is supported by the results of research from Ristyo [8] which states that there is a relationship between the socio-economic level and the incidence of pulmonary TB in Jombang. Theory Green & Kreuter (1991) revealed that factors that influence, change, maintain, or improve behavior in a more positive direction one of which is health education. Although health education and health counseling can increase knowledge, where respondents are directed to understand about prevention of transmission of pulmonary TB infection. Then this knowledge will bring respondents to think and build emotions and shape the respondents' beliefs to be able to act in a more positive direction. This theory is supported by the results of research from Handayani [9] which states that there is an influence of health education in the control and treatment groups in Surakarta as well as the results of research from Noor [10] which states that there is an influence of health education on health knowledge and attitudes of clients with pulmonary TB in Sragen. Associated with poverty, which is closely related to work and income, low-income people usually have a low economic level. Income will have much influence on the behavior of maintaining individual health and in maintaining the family. This is because income affects education and a person's knowledge in looking for food intake and treatment affects the environment of residence such as the condition of the house and its condition. The incidence of pulmonary TB is closely related to one's socio-economic condition, which can be known by one of them from work, then family income. Families with sufficient income or in middle to upper economies have relatively better behavior in maintaining health. According to WHO [1], the relationship between poverty and TB is reciprocal, TB is a cause of poverty and because of poverty people suffer from pulmonary TB. This theory is in line with Rosmaniar's research [11] which also proves that there is a close relationship between family income and the incidence of positive smear pulmonary TB in Bekasi. People with low-income jobs are more at risk of increasing the incidence of pulmonary TB than those who work with high income.

From the results of this study, it was found that most respondents could not answer question number 4, about washing and drying the patient's mattress is not an important thing to prevent transmission of pulmonary TB. The lack of family effort in preventing infection transmission is due to the understanding of the family that the patient's mattress is only dried in the sun and washed once a month, if the mattress is dirty. Poor family efforts can be because most families cannot afford to provide separate rooms for sufferers with other family members for economic reasons. In addition, from the observations of researchers during conducting research, most of the respondents' homes lack direct sunlight, rarely families supervise patients in taking drugs directly, and provide masks for sufferers and other family members at home, thus making family efforts in prevention of transmission of this infection fall into the less category. It is supported by the results of a study from Firdiansyah [12] which states that there is a significant influence between ventilation and lighting on TB pulmonary disease in Surabaya Genteng District and the results of Adnani [13] stating that the risk of home residents is sky TB sufferers the ceiling of his house, windows, floors, ventilation, kitchen

smoke holes, the lighting that does not meet the requirements has the risk of pulmonary TB compared to residents who live in homes that are not dense and fulfill the requirements as a healthy home.

Based on the results of statistical analysis using Spearman's rho, using the degree of significance $\alpha \leq 0.05$, which indicates a significant difference with the value of $p = 0{,}000$ ($p < 0.05$), with the strength of a strong correlation ($r = 0.695$), which means H1 is accepted which is a relationship between the level of family knowledge and prevention of infection transmission in pulmonary TB patients in the working area of Karang Taliwang Health Center, Mataram City, NTB. This result is supported by research conducted by Nurfadillah [14] which states that there is a relationship between knowledge about pulmonary TB and prevention measures for transmission of pulmonary TB.

The results of this study are in accordance with the behavioral theory of Green & Kreuter (2005), because Green & Kreuter state that knowledge is one of the predisposing factors that influence a person's behavior. Knowledge or cognitive domains are very important domains in shaping one's actions (Krathwohl, 2002). The theory shows that knowledge has a relationship with efforts to prevent transmission of pulmonary TB infection. The results of this study are also in accordance with the study from Bowo [15] which states that there is a relationship between knowledge and attitudes of patients with the prevention behavior of transmission of pulmonary TB. The lower the level of knowledge, the lower the effort to prevent infectious pulmonary TB infection. The results of this study are also in accordance with the research conducted by Habibah [16] that there is a relationship between the level of knowledge of patients on the behavior of prevention of transmission in Riau. According to the Depkes RI [3], people who have higher levels of education are oriented towards preventive measures, know more about health problems and have better health status. A high level of education will make it easier for a person or community to obtain and digest information to then make choices in health services and implement a healthy life. This theory is supported by the results of research from Riswan (2008) which states that there is a relationship between knowledge and about pulmonary TB disease with the behavior of families and sufferers of pulmonary TB in Yogyakarta. According to Notoatmodjo [6], the factors that influence behavior are the environment, both the physical, socio-cultural and economic environment. Environmental factors are the dominant factors in a person's behavior. The behavior of someone who is not good can also be due to the lack of clarity of attitude and lack of motivation. Transmission of TB is easy among people who live at home. This theory is in line with the research from Sasilia [17] which states that there is a relationship between age, knowledge, comorbidities, and nutritional status with transmission of pulmonary TB in families living in houses in East Aceh. According to the Depkes RI (2011), poor ventilation can cause uncomfortable air (stiffness, bronchitis, recurrent asthma, colds) and dirty air (transmission of respiratory diseases). Ventilation is useful for circulating / changing air in the house and reducing humidity. Human sweat is also known to affect moisture. The more people in one room the higher the humidity, especially because of water vapor from both breathing and perspiration. Humidity in a closed space where there is a lot of human being is higher than the humidity outside the room. Rooms with ventilation that do not meet the requirements, if occupied by someone, there will be an increase in air humidity caused by evaporation of body fluids from skin or due to breathing. In conditions where there is no good air exchange, there will be an increase in the number and concentration of germs, so that the risk of transmission of respiratory disease becomes higher. Pulmonary TB is an infectious disease that can spread rapidly in conditions of poor air circulation due to ventilation that does not meet health requirements. Pulmonary TB will be easily transmitted to housing conditions with high humidity, as well as ventilation conditions that do not facilitate the occurrence of air exchange in the house. This theory is in line with the results of research from Adnani [13] which states that the risk of suffering from pulmonary TB is 5 times higher in residents who live in homes where ventilation does not meet health requirements.

Based on work, this research shows that respondents work more as traders. According to village potential statistics, the most employment or livelihoods in rural areas in Indonesia are agriculture,

which is 97.75%, second place is services by 0.58% and third place is trade 0.57% [18]. This is supported by the research of Rukmini [19] which states that TB risk factors that have a significant effect on the incidence of adult pulmonary TB in Indonesia are age, sex, lighting energy, actions to open room windows, nutritional status and household contact TB.

Based on age, in this study showed that more respondents were aged 26-35 years. According to Azwar [20], the age of an individual starts from the time of birth until the birthday. The more mature the level of maturity and strength of a person will be more mature in thinking and working. In terms of public trust, someone who is more mature will be more trusted than someone who is not mature enough. This is a result of experience and maturity, the older a person is, the more conducive to using coping with the problem at hand. This theory is also supported by research from Dotulong [21] which states that there is a significant relationship between age and TB pulmonary disease incidence in North Tapanuli.

From the results of Riskesdas, it is known that the prevalence of pulmonary TB tends to increase according to increasing age and the highest prevalence at the age of more than 65 years. The prevalence of pulmonary tuberculosis in men is 20% higher compared to women, besides the prevalence is three times higher in rural areas compared to urban areas and four times higher in low education compared to higher education [22]

The most common pulmonary TB is found in young or productive ages from 15-50 years. With the current demographic transition, the life expectancy of the elderly is higher. At more than 55 years old, a person's immunological system decreases, so it is very vulnerable to various diseases, including pulmonary TB disease. Patients with pulmonary TB themselves tend to be higher in men than women. According to Hiswani, who was quoted by the WHO, in one year there were around 1 million women who died from pulmonary TB. It can be concluded that more deaths occur in women caused by pulmonary TB compared to the consequences of the process of pregnancy and childbirth. In the male kelamim type, this disease is higher because of smoking, and alcoholic beverages which results in a decrease in the body's defense system, making it easier to be exposed to agents causing pulmonary TB. According to Haryanto's research (2004), there were proportions according to sex, men were 54.5% and women were 45.5% who had pulmonary TB. Most of them do not work that is equal to 34.9% and have a low education of 62.9% [22]

Knowledge, age, gender, occupation, and income of respondents are things that play a role in changing the behavior of respondents. Actions or behaviors that are based on knowledge will be long lasting than actions that are not based on knowledge, so that respondents with a good level of knowledge, their actions in preventing infection transmission will be good too, and vice versa. If the respondents' knowledge is included in the less category, then the respondent's actions will be even less. So even with age, work and income. The more mature the age and the higher income from one's work, the more mature the person's thinking is.

Conclusion

There is a relationship between the level of family knowledge about pulmonary TB with family efforts in preventive behavior of pulmonary TB infection in the work area of Karang Taliwang Health Center, Mataram City, NTB.

The results of this study are expected to increase the motivation of nurses to provide health education and counseling to people who still do not understand how to prevent transmission of pulmonary TB infection. Puskesmas are expected to hold activities and policies that involve families in preventing transmission of infection with pulmonary TB so that families can better understand pulmonary TB and how to prevent it. It is expected that respondents can maintain and improve knowledge, and change behavior that is not good in terms of preventing transmission of pulmonary TB infection, so that the spread of pulmonary TB in the family can be prevented. For future researchers, further research is needed on family attitudes about pulmonary TB disease, with a wider coverage area and more sample sizes.

EFFECTIVENESS OF EDUCATIONAL INHALER TECHNIQUE INTERVENTIONS TO IMPROVE THE ADHERENCE OF COPD MANAGEMENT: SYSTEMATIC REVIEW

H A Baridah[1], Y Kurniawati[1], M D Kusumawati[1], I Wabula[1]
[1]Magister of Nursing, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
E-mail: hurinin.aisy.baridah-2018@fkp.unair.ac.id

ABSTRACT

Inhaler therapy is the principal pharmacological management of chronic obstructive pulmonary disease (COPD). Each inhaler has certain usage rules to be most effective, proper education of inhaler technique is an important part to improve treatment adherence. This systematic review is to conduct of various educational inhaler technique for COPD indexed in Science direct, ProQuest, Scopus, Ebsco, Pubmed for original research study, then we reviewed systematically. There were 15 journals with RCTs study designs that discussed about educational inhaler technique. This systematic review found five programs, they are face-to-face trainings, pharmacist counseling, health coaching, a model of self-management education, and virtual teach-to-goal. The results of studies was collected mostly for 6 months. An appropriate education of inhaler technique to improve adherence on COPD management which can be used as a monitor effort of COPD management.

Keywords: COPD, adherence, educational inhaler technique , inhaler technique

1. Introduction

Chronic Obstructive Pulmonary Disease (COPD) has been considered a significant global health problem which is a major cause of morbidity and mortality in countries of high, middle, and low income [1]. COPD is a preventable and treatable disease that is characterized by limited air flow not being completely irreversible. Nevertheless, the burden of each disease among patients is high and patients may be frequently hospitalized due to exacerbation [2]. Effective therapy options and evidence-based guidelines have been developed in recent years, disease control continues to be suboptimal in patients with chronic obstructive lung disease like asthma and COPD. There are numerous reasons for the lack of disease control in asthma and COPD patients. One important reason is the incorrect application of inhaler devices, which is associated with worsened health outcomes, such as increased risk of hospitalization and insufficient disease control [3].

The prevalence and severity of COPD in Vietnam has been reported in recent literature with the prevalence rate was found to be 6.7% in 12 Asian countries, while another study indicated that over half of those infected experienced exacerbation episodes[4]. According to research seventy-seven of 103 patients (74.8%) did at least one wrong step. Patients using Handihaler had the lowest compliance failure (42.5%). Low education level is the single most important factor related to the wrong technique [5].

Inhaler therapy is the principal pharmacological management of chronic obstructive pulmonary disease (COPD). The choice of device must be based on the needs of the patient [6]. Many inhaler devices have been developed, and each has specific instructions for use to ensure proper delivery of

drug doses to the airways. Although a number of different devices have enabled technological improvements in airway drug delivery, they certainly still have disadvantages [7]. Most patients in daily use still make inhalation errors. Incorrect inhaler techniques can cause poor control of disease, such as poor adherence, and an increased risk of hospitalization.[8].

The availability of effective treatments such as various educational inhaler techniques is pivotal to the implementation of successful intervention strategies [9]. Some studies do this by way of a systematic literature review, the search in 2000 to 2018 showed a significant influence on the research conducted and there did not show the level of scientific evidence in conducting research in the form of journals. There are some educations of inhaler technique that are used to study the development of interventions. This paper offers a systematic review of studies that investigate of educational interventions focusing on inhaler technique in COPD patients and assess their overall effectiveness.

2. Methods

We use four steps to identify and select journals that meet the criteria specified in this PRISMA review (Figure 1). First, we conducted a major search on the database (Scopus, SAGE journal, and Proquest) to identify relevant English works published in 2013-2019. The keyword used was Chronic Obstructive Pulmonary Disease (COPD), Educational Inhaler Technique, Inhaler Technique, and Adherence.

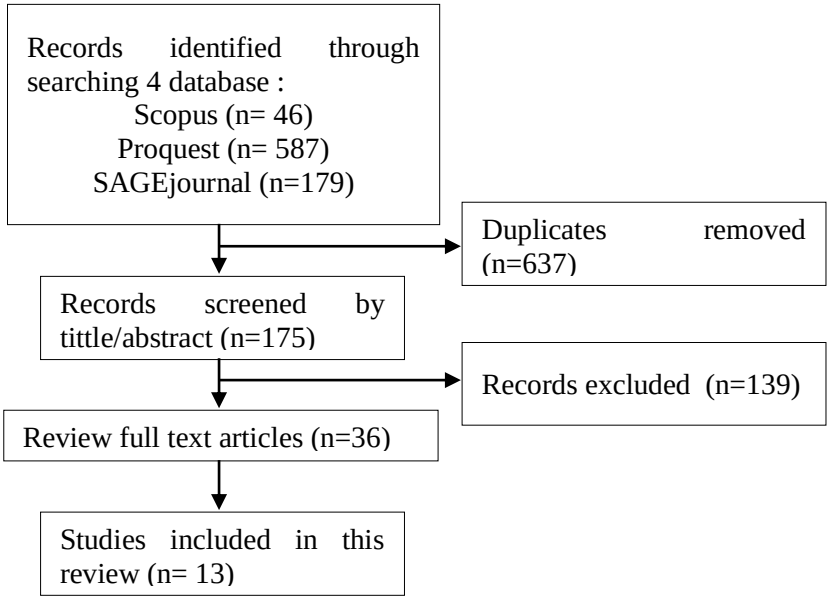

Figure 1. PRISMA flow diagram

The inclusion criteria for the article are articles use English and explain equational inhaler technique for patients with COPD. Articles would be excluded if the review/systematic review study. The feasibility of the study was assessed using the PICOT approach : participants are patients with COPD, interventions are types of educational inhaler technique, no comparison, outcomes are improved inhaler adherence, HRQoL, self-efficacy, self-management, the correct technique for using inhalers, and reduce the incidence of exacerbation. Study design is randomized controlled trial study (RCTs) and cross sectional.

3. Results

There were 13 randomized control trial designs and cross sectional studies of the journals reviewed. All participants were aged ±>45 years with COPD. There was one study with criteria for acute exacerbation participants, and one study with patients experiencing chronic bronchitis with COPD.

Almost all interventions included a physical or video demonstration of inhaler use. Interventions used face-to-face trainings, pharmacist counseling, health coaching, a model of self-management education and Virtual Teach-to-goal™. Six studies used face-to-face trainings. Two studies used pharmacist counseling. Two studies used health coaching. one study used a model of self-management education. Two studies used Virtual Teach-to-goal™.

4.1 Face-to-face Trainings

The research conducted by Aydemir (2015) used face-to-face training by cross sectional study for 3 minutes. The study was a real life desgin and no intervention was done except for the standard face-to-face training sessions conducted by the same trainer[10]. The patients were asked to administer medication using their own inhaler device and the inhalation procedure was observed. The main treatment devices were evaluated (quick-relief inhalers not included). Inhalation ability was assessed based on the Turkish version of the "A Guide to Aerosol Delivery Devices for Respiratory Therapists" published by the American Association of Respiratory Care (AARC) and the inhalation ability chart prepared by the inhalation therapies workgroup of Turkish Respiratory Society. Since the number of inhalation procedure steps was different for each device, three common statuses were defined to facilitate statistical analyses: correct use (CU), incorrect use (IU) and inadequate (false) use (FU). Inhaler device setup and inhalation technique were described using demonstration devices. The inhalation technique was observed immediately after the training [10]. The results of this research show that the physicians should pay attention, in particular, while prescribing pMDIs to elderly patients. Such patients' ability to use the device should be observed after the training, and the physicians should consider DPIs or home-nebulizer devices if inhalation cannot be achieved with the correct technique.

The research conducted by Yoo et al. (2017) used face-to-face trainings by Randomized Controlled Trials for one month. At first visit, we obtained the informed consent from each patient and conducted a knowledge assessment about their chronic airway disease, and tested the inhaler technique before the patients received the educational program. At the second and third visits, this education program was repeated. Questionnaires were completed by patients and physicians at the first visit and third visit to evaluate the following items; the knowledge about COPD, COPD assessment test (CAT), inhaler use technique, and measurement items of each topic were composed of six (knowledge), eight (CAT), seven (inhaler use), three (satisfaction of the patients), and five items (satisfaction of the physicians)[11]. This study showed that in the primary care setting, a comprehensive education program including inhaler training and COPD management resulted in correct inhaler usage and improvement of CAT score, suggesting that such programs should be extended further in the primary care of COPD.

Research Ngo, Phan, Vu, Dao, & Phan (2019) used a cross sectional design with face-to-face interviews which conducted after patients stabilized the acute condition. This study asked patients to demonstrate how they used their inhalers at home and to answer the 12-item Test of Adherence to Inhaler (TAI) [12]. The result of study showed that worse dyspnea, greater health condition impairment, and an increased frequency of exacerbations and hospitalizations were found to be associated negatively with correct inhaler use and treatment adherence. Instructions to COPD

patients about using inhalers should focus on correct inhaler technique and adherence even when feeling healthy.

Research conducted by Takaku et al., (2017) which focused on evaluate the number of instructions that are necessary to minimize errors in using pressurized metered-dose inhaler (pMDI), soft mist inhaler (SMI), and dry powder inhaler (DPI). The intervention program consisted of face-to-face training Inhalation guidance/evaluation was performed successively from 2 times up to 5 times at intervals of 2 weeks to 1 month until no further improvement was observed [13]. This study concluded that it is necessary to repeat at least three times of instructions to achieve effective inhalation skills in both asthma and COPD patients.

Face-to-face training in a study by Goris, Tasci, & Elmali, (2013) was conducted on an intervention group and control group. The intervention group was educated using an inhaler by verbal training, demonstration movie, and leaflet. A follow-up after 3 months was carried out in both groups. Patients in the control group were not educated but have been checked with the same indicators. Quality of life, condition of dyspnea, and attack improved 3 months later in the intervention group compared with the controls. Data were collected by a face-to-face interview for 15 months by the researcher. Three months after the interview, patients were invited for the second one (follow-up). Training took 15–20min on average and was held in a separate room apart from the outpatient clinic in order not to interrupt the conversation[14]. The result of study showed that a planned inhaler training given to the patients with COPD was found to decrease attack frequency and dyspnea, and improve quality of life.

Research conducted by Pothirat et al., (2015) assessed inhalation technique compliance at their routine medical (pre-training) visits by a qualified respiratory nurse without prior notification. The respiratory nurse observed each step of the inhalation technique and recorded each incorrect step. After the assessment, patients were given instructions, face-to-face demonstrations regarding the correct use of the controller devices, and training until they could use the devices correctly. One month later (post-training visit), all patients were requested to demonstrate their inhalation techniques and were reevaluated by the same nurse [8]. The result of study showed that formal training resulted in a statistically significant decrease in percentage of incorrect techniques for all devices and for the pMDI.

4.2 Pharmacist Counseling

There are two articles that used pharmacist counseling. An article from Axtell, Haines, & Fairclough, (2017) used the pharmacist counseling to compare the effectiveness of 4 different instructional interventions in training proper inhaler technique. These inhaler-naive subjects were randomly assigned to 1 of the 4 interventions using a dice randomization process: (1) reading a manufacturer-published MDI package insert pamphlet, (2) watching a CDC video demonstrating MDI technique, (3) watching a general popular YouTube video demonstrating MDI technique, or (4) receiving direct instruction of MDI technique from a pharmacist or fourth-year pharmacy student. Utilizing a timer, all interventions were limited to 2 minutes. Although previous studies suggest that successful health care counseling sessions may require approximately 6 to 20 minutes, the allocation of 2 minutes was considered to be more in line with the amount of time that a community pharmacist may routinely be able to devote to inhaler instruction [15]. The result showed that a 2-minute pharmacist counseling session is more effective than other interventions in successfully educating patients on proper inhaler technique. Pharmacists can play a pivotal role in reducing the implications of improper inhaler use.

Research conducted by Tommelein et al., (2013) used randomized controlled trials to knowing the impact of community pharmacist interventions on pharmacotherapeutic monitoring of patients with chronic obstructive pulmonary disease (COPD). This study was divided into two groups. Control group patients were given usual nonprotocol-based pharmacist care. Patients in the intervention group received a protocol-defined two-session intervention; one session at the start of the study and one session at the 1month follow-up visit. All interventions were given during one-to-one counselling sessions. The duration of interventions was not predetermined; however, we estimated the duration to be between 15 and 25min. To support interventions, pharmacists were provided with information leaflets on COPD, demonstration inhaler units and a list of practical solutions to specific nonadherent behavior [16]. The results this study showed that inhalation score and medication adherence were significantly higher in the intervention group compared with control group.

4.3 Health Coaching Programme

Research conducted by Derya Tuluce (2018) used health coaching on respiratory functions, treatment adherence, self-efficacy, and quality of life in chronic obstructive pulmonary disease patients. The implementation of "the education of COPD patient" initially on topics such as disease physiopathology, diagnosis of signs and symptoms, regular use of medications, exercises, nutrition, and control of exacerbations was performed by power point took about 40 to 50 minutes. After the education implementation, printed educational booklets were given as written materials, which were developed for the patients. The coaching agenda included treatment adherence in 4 coaching interventions for the first 4 weeks, self-efficacy in the next 4 interventions for the next 4 weeks, and the quality of life in the next 4 interventions for the last 2 months. The interventions were held in a room with a quiet and calm atmosphere where there was no interaction with other patients in the outpatient clinic. It took about 30 to 45 minutes [17]. After health coaching intervention, self-efficacy scale general score, and St. George Respiratory Questionnaire, total scores were found statistically significant different between 2 groups in interaction values. There was a significant difference in the 8-item Morisky Adherence Scale scores for degree of treatment adherence between the groups.

Another research conducted by Crane, Jenkins, Goeman, & Douglass (2014) used health coaching to improving inhaler techniques on patients with asthma and COPD. The comprehensive education intervention group received one-on-one technique coaching, which included critical observation of their device technique, verbal instruction regarding ways to improve their technique, physical demonstration of correct technique and encouragement. The device information pamphlets were standard educational pamphlets supplied by Astra-Zeneca (North Ryde, NSW, Australia) and GlaxoSmithKline (Ermington, NSW, Australia) to healthcare practitioners. Device technique was reviewed in both groups, at baseline and at 3 and 12 months. In the active group, this was done prior to education. Device technique was assessed discretely according to current National Asthma Council (NAC) guidelines and critical inhaler technique steps were scored using the NAC checklist for each device. The checklists can be downloaded from the NAC website http://www.nationalasthma.org.au/publication/inhaler-technique-in-adults-with-asthma-or-copd. Lung function, asthma control and medication adherence were also measured as part of the wider intervention[18]. Post education there was a statistically significant improvement in the proportion of participants with correct technique in the active group at 3-month follow-up. The results of this study indicate that provision of passive written information alone, even in pictorial form, is not adequate as a form of inhaler education for older people with COPD.

4.4 A model of self-management education

Research conducted by Bourbeau (2017) used self-management education program with coaching of a case managers who focused on treatment adherence, inhaler techniques, smoking cessation, and the use of an action plan for exacerbations for 1 year in six family medicine clinics (FMCs). Throughout the intervention, respiratory therapists acted as both educators and case managers. The initial visit lasted around 90 minutes and consisted ofan assessment of educational needs, a spirometry, and a 1-hour encounter with the educator (respiratory therapist). During this encounter, the following topics were covered: COPD etiology and pathophysiology, COPD control, smoking cessation, use of a written action plans for acute exacerbations, adequate inhaler technique, and medication adherence[19]. The result this study showed that The COPD self-management educational intervention reduced unscheduled visits to the clinic and improved patients' quality of life, self-management skills, and knowledge.

4.5 Virtual Teach-to-goal™

There are two articles that used Virtual Teach-to-goal™ adaptive learning. Article by Press, Kelly, Kim, White, & Meltzer (2016) used randomized controlled trials to develop and pilot a virtual teach-to-goal™ (V-TTG™) inhaler skill training module, using innovative adaptive learning technology. This study is the first to demonstrate the efficacy of a self-directed adaptive V-TTG™ learning tool to teach the inhaler technique. Among hospitalized patients with asthma or COPD. Then answer adaptive self-assessment through short-answer questions[20]. This study found that the innovative V-TTG™ adaptive learning strategy is an effective tool to teach the MDI technique to hospitalized patients with asthma or COPD. After inhaler teaching with V-TTGÔ, almost all participants demonstrated the improved inhaler technique with reduced rates of inhaler misuse, and nearly half had complete mastery, demonstrating the potential efficacy of this learning tool.

Research conducted by Thomas et al.(2017) used videoconferencing inhaler education program delivered at the patient's home and whether the training improved inhaler. The participant download the videoconferencing software (Cisco Jabber Video for TelePresence 4.5 software) and to complete a test videoconferencing visit. Training was given for prescribed inhalers. After the initial visit, most participants were offered a spacer. Participants were to complete 3 monthly videoconferencing visits with a study pharmacist trained in TTG methodology. The TTG method breaks down the technique for each inhaler into a standardized checklist of 12–17 steps, depending on the inhaler. With pharmacist input, the checklists were adapted. Each TTG training visit began with the pharmacist assessing the participant's baseline inhaler technique and assigning a pre-training score. The pharmacist then demonstrated correct technique and gave verbal instruction. After that educational intervention, the participant re-demonstrated inhaler technique, and each round was assigned a score of post-training 1, post-training 2, etc. The training was repeated until the participant demonstrated mastery (missed $\leq$ 2 steps) or after 3 cycles. TTG scores were used both as an educational tool to assist with inhaler training and as an objective measure of inhaler technique[21]. The results of this study showed that Inhaler training provided by a pharmacist using home videoconference technology in this pilot study improved inhaler technique during each participant visit, and improvements were sustained at the 1- and 2-month video- conference visits. In addition, participants reported improvements in COPD self-efficacy, COPD health-related quality of life, and inhaler adherence following the inhaler training.

4. Discussion

Various effective treatments are available for COPD, but patients still do not achieve treatment goals, partly because of low adherence to therapy. Non-compliance with treatment is associated with ineffective monitoring of symptoms, errors in inhaler techniques, and decreased quality of life related to health. There are many types of education on inhaler techniques that have been applied to COPD patients. This review showed that educational inhaler technique are effective, at least in the short term. Most of the results of the study show the impact of educational programs on inhaler techniques to increase the use of appropriate inhalers, quality of life, self-efficacy, self-management, and treatment adherence. Retrieved from seven articles related to improving of inhaler technique [10,11,13,8,15,18,20], there is one article that has an impact on quality of life [14]. Two articles related to improving treatment adherence [12,22]. There is one article that discusses quality of life and self-management [19]. Retrieved from two articles to improving quality of life, self-efficacy, and treatment adherence[17,21]. This systematic review showed that face-to-face trainings are more widely used with six journals. Face-to-face trainings increase the use of the correct inhaler technique [10,11,13,8], impact on quality of life of COPD patients [14], improve treatment adherence even when feeling healthy [12].

5. Findings

This systematic review has several limitations is some subjects may not be motivated to learn the right inhaler techniques as well as patients who are aware of the fact that inhalers are an important element in treating their COPD so that this can lead to bias. A list of standard assessments is used for all participants to minimize bias, and ratings for each step in the inhaler technique only give 2 choices : competent or incompetent. The educational inhaler technique what extended further in the primary care of COPD are effective to improve the correct inhaler technique, quality of life, and treatment adherence.

ABSTRACT

Resistance band exercise is considered as simple and easy exercise and its implementation does not require an extended time to do which can be used as a sport alternative. To describe resistance band exercise for elderly health improvement by conducting a systematical review. This study was conducted by scrutinizing selected articles published in Pubmed, Sciendirect, Ebsco, Proquest, and Scopus in accordance with the specified criteria. The search was carried out in the period of June 2018 until January 2019 and analyzed by using PICO/PICOS. The articles that fulfilled the criteria were found to be 9 articles published in the period of 2010-2019. Predominantly, resistance band exercises without any additional exercise showed improvement in health status. The majority range of interventions was more than 4 months. Resistance band exercise is proven to be having great health benefits for the elderly. In addition to the health side, it is also beneficial in terms of financial that might be issued if the elderly are sick.

Keywords: Resistance band exercise, Health, Elderly

1. Introduction

In the elderly, there are many common health issues including cardiovascular disease, diabetes mellitus etc. On top of that, in general, the elderly often have more than one health disorder [1]. These conditions can be eliminated by exercising regularly and changing their lifestyle. The aim of exercise is to improve the physical abilities of the elderly and their physiological functions. Exercise is one of the planned, structured, and repetitive sports that has the ultimate and intermediate goal of improving or maintaining physical fitness [2].

Elastic band exercise is one of the regular exercises that can be given to hypertensive patients. The senior elastic band exercise can increase body flexibility to allow them to become fresher and to generate better sleep at night [3]. In addition, it is an effective exercise program used to improve muscle strength, bodily abilities, and to facilitate blood circulation in the body [4]. Moreover, the exercise can improve the activities of daily living, increase lung capacity, increase upper and lower body flexibility, and increase muscle strength and endurance [5]. The most popular and easiest elastic band exercise to be implemented is resistance band exercise which also can improve health, especially for the elderly who experience various health problems. Resistance band exercise is able to improve blood vascularity and the physical strength of the elderly [6]. In addition, it is also believed to increase the range of joint motion and body balance in the elderly [7].

In Indonesia, considering that the number of elderly people is increasing every year, it requires further management so then the elderly do not become a burden. In 2017, the number of elderly

people was reported to be approximately 0.93% of the 23.66 million population [8]. The aim of the management of the elderly is to improve or maintain their health through exercising regularly. Resistance band exercise is considered to be a simple and easy exercise and its implementation does not require an extended time, which is ideal as a sports alternatives. The purpose of this article review is to describe that resistance band exercise can improve the quality of health of the elderly who generally have a decrease in body function.

2. Methods

The writers collected online literature across several journal databases by entering the keywords "physical activity", "exercise", "elastic band exercise" and "elderly health". The online database search was conducted from June 2018 to January 2019 in Ebsco, Proquest, Pubmed, Scopus, and Sciencedirect. The process of identifying the various articles was based on the inclusion and exclusion criteria that had been set. The screening process details can be seen in Figure 1.

The inclusion criteria for the article analysis included English-written articles, the implementation of elastic band exercises as the main topic of the articles, clear measuring instruments used to assess the outcomes of the implementation, the subject of the articles devoted to the elderly, clear implementation objectives in the articles, and they should have been published in the period from 2010 up until 2019. On the other hand, the exclusion criteria were articles discussing cross-cultural implementation, articles only in abstract form, and the subjects having physical limitations in their bodily functions. For instance, using a wheelchair. Furthermore, the articles being analyzed must be categorized as quantitative study articles.

The process of analyzing the articles that have met the criteria was conducted using the PICO or PICOC model approach [Population, Intervention, Comparison, Outcomes, Context] which made it easier to arrange them in a table form [9]. The population within the analysis of this article was intended for elderly people in a stable condition who were able to exercise independently. Interventions that could be reviewed about specific elastic band exercises can be carried out independently. The further comparison was conducted by comparing the previous research studies to the latest research related to exercise that allowed it to be implemented in the context of the patients. The outcomes can be measured and assessed by applying valid and reliable measuring instruments. The context discussed in this article was particularly related to the health of the elderly.

3. Result and discussion

The search of the associated articles was conducted from June 2018 until January 2019, which resulting in 1,104 journals that matched the keywords. The article identification process can be seen in Figure 1. However, only a total of 9 articles elaborated that elastic band exercise can improve the life quality of the elderly.

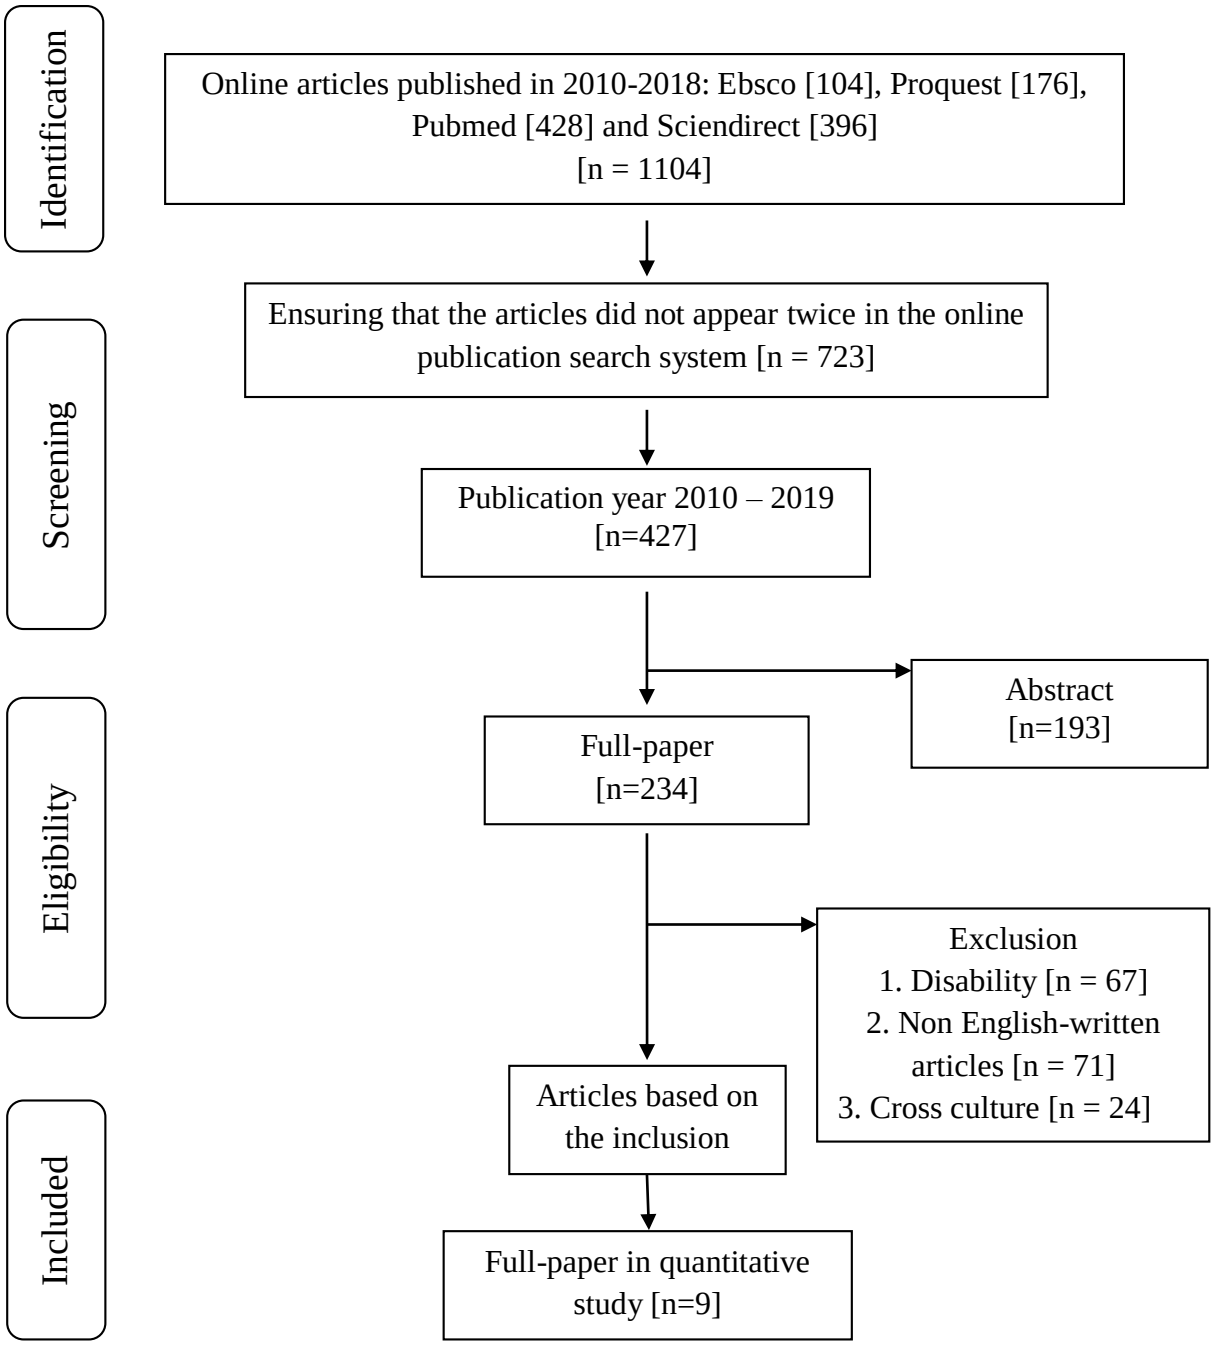

Figure 1. Flow Chart Diagram of resistance band exercise articles

The results of the article review revealed that 77.78% of the articles discussed resistance band exercise as an independent exercise without any additional exercise paired with it. Meanwhile, the rest discussed resistance band exercise either as an additional exercise or as the main exercise with the supplement of other therapies. Resistance band exercise consists of 3 actions namely a warm-up exercise, the resistance exercise [the main action], and a warm-down exercise. Resistance exercise is an exercise that has been proven to improve the health status of the elderly in a comprehensive manner. It is also able to improve quality of life if it is implemented for more than 3 months on average [Table 1].

Table 1. Elastic band exercise analysis related to elderly health

	N	Intervention	Period	Outcome
Smith [6]	Exercise group [7], control [9]	Resistance band exercise	6 months	Vasodilation of the upper and lower limbs, and improvement in quality of life
Kwak [10]	Experimental [23], control [22]	Resistance band exercise	30 minutes/days, 3 x/weeks, 8 weeks	↑ body balance, easy walking, joint movement, ↓ risk of falling
Liao [11]	Experimental [33], control [23]	Elastic resistance exercise	9 months	↑ muscle mass, ↑ physical ability, ↑ life quality of the elderly
Ahn [12]	23 subjects	Elastic Band Resistance Exercise	3 x per weeks [5 months]	Able to stand on one leg, ↑ cardiopulmonary
Ahn [13]	Exercise group [11], control [11]	Elastic Band Resistance Exercise	3 x per weeks Min 1 hour [4 months]	↑ physical ability, ↓ stress, ↑ immune
Fritz [14]	Handle group [22], Elastic group [21], control [20]	Elastic Band Resistance Training	2 x per weeks [8 weeks]	Improvement of body composition, improvement of physical appearance
Oesen [15]	Cognitive [29], Resistance [33], Resistance & nutritional [28]	Elastic Band Resistance Training	6 months	Safely implemented, providing benefits to improve the body function
Brito [16]	10 subjects	Elastic Band Resistance	> 3 months	Maintain conditions and improve cardiovascular strength
Wu [17]	Control [17], Exercise [16], Resistance & Exercise [17]	Elastic Band Resistance and Aerobic Training	± 20 minutes/days 6 months	↑ exercise ability, ↑ Quality of life

Resistance band exercise can improve blood vascularity, which is clinically able to stabilize blood pressure [6]. During exercising, the sympathetic nervous system experiences increased modulation whereas the parasympathetic nervous system encounters decreased modulation. This is characterized by an increase in heart rate. This condition is caused by an increase in oxygen consumption by the body in the formation of adenosine triphosphate [ATP] for energy. The body automatically responds by decreasing the blood pressure [18]. In addition, regular exercise will not only reduce the plasma concentration of endothelin-1 [ET-1] which acts as a strong vasoconstrictor,

but it will also increase the production of Nitrite Oxide [NO] in the blood vessels [19]. NO, based on various studies, can restore blood vessel elasticity and reduce peripheral arterial stiffness [20, 21].

Another benefit is that resistance band exercise increases muscle mass and the ability of the lower extremities. This is because, after exercising, the blood smoothly flows and consequently carries nutrients to the lower part of the body [6]. In these conditions, the ability of the elderly to stand on one leg is very possible. When muscle mass increases, the ability of the elderly to mobilize also increases as well. The burden of treatment related to this issue can thus be suppressed [22]. Furthermore, this is evidenced by their ability to walk as far as 8 meters before doing the resistance band exercise which took around 16.41 ± 6.90 s. In contrast, after carrying out the exercise, this improved to 13.18 ± 5.33 s. The speed of moving also improved from 55.63 ± 18.30 cm s to 68.97 ± 22.57 cm/s [12].

Resistance band exercise can improve the balance of the elderly based on the Functional Reach Test [FRT] value, which showed that before the action, it took about 18.1 ± 3.6 cm whereas after the action, it was 22.0 ± 3.6 cm. The conditions indicate that the elderly have a reduced risk for falls compared to before doing the resistance band exercise. Some researchers discovered that elderly people who have an FRT below 25.4 cm have a higher risk of falling than an FRT above 25.4 cm [7, 10]. However, elderly people with a less than 15.24 cm FRT indicate as having a four times higher risk of falling than those with a less than 25.4 cm FRT from the measured value [10, 23].

Resistance band exercise can be used to burn body fat by as much as 8.5% of the total. Individuals who do resistance band exercise need ATP because the body needs more ATP than during daily activity. The body compensates by breaking down the fat deposits available under the skin to meet these conditions. The resistance band exercise is mostly carried out over a period of 4 months which allows for a continuous process, meaning that it does not occur only once [14, 24].

4. Conclusion

Resistance band exercise is proven to have good health benefits for the elderly. In addition to the health side, it is also beneficial in terms of finances, which might be an issued if the elderly are sick. It consists of three actions, which are a warm-up exercise, resistance exercise [the main action], and a warm-down exercise. That being said, resistance band exercise can improve quality of life, improve body balance, faster walking, more free joint motion, increased lower extremity muscle mass, the ability of the physical and cardiovascular systems, being able to stand on one leg, and more a stable immune system. Furthermore, resistance band exercise can reduce stress and the risk factors for falls.

THE CORRELATION BETWEEN NURSES' EXPERIENCES, WORKLOADS, ABILITIES AND NURSES' INDEPENDENT ACTION IN HOSPITALS

Hani Tuasikal[1], Moomina Siauta[1], Selpina Embuai[1]
[1] Akper Rumkit Tk. III dr. J. A. Latumetten
Email: hanituasikal@gmail.com

ABSTRACT

Unoptimal independent actions performed by nurses in hospitals may increase the risk of decubitus and length of stay (LOS). The population was all nurses in the inpatient wards of RSUD dr. M. Haulussy Ambon amounted to 212 nurses. A total sample of 165 nurses recruited using probability sampling was used in this study. Data were collected by using questionnaires and observation, and analyzed using the Spearman rank correlation test and multiple linear regression tests. The results showed that the nurses' independent actions in the form of activity of daily living, caring and support, and rehabilitation were good. The experiences, abilities, and workloads of nurses were correlated with the nurses' independent actions. This study concluded that some factors associated with the nurses' independent actions were age, sex, education, years of service, experiences, abilities, and workloads. Nurses' knowledge, with the highest beta coefficient, was found to be the most dominant factor related to the nurses' independent actions. Based on the results of the study, it is suggested that the hospital management improve the nurses' independent actions by increasing the nurses' abilities through training and advanced study.

Keywords: independent action, years of service, experience, ability, workload

1. Introduction

Independent nursing actions are the nurses' actions delivered to the patients to improve the healing process based on the nurses' knowledge. Independent nursing actions aim to meet the bio-psycho-socio and spiritual needs of the patients when they are in the hospital[1]. They provide the most significant contribution to nursing services. When optimally implemented, independent nursing actions can increase patient satisfaction, accelerate patient recovery and improve safety. Therefore, all nurses should implement optimal and qualified independent actions to cure their patients.

Nurses in inpatient wards have a great responsibility as they have a longer time to care patients[2]. Nurses are the health workers who spend the longest time with the patients, amounting to 50-60%. They have to work for 24 hours through shift assignments and they are very close to the patients[3][4]. This situation arises as the nurses should perform a lot of nursing actions to patients with various conditions to speed up their recovery. However, many independent actions are not taken by the nurses on the ward.

Independent nursing actions which are not carried out or completed will have a negative impact on the delivery of nursing services; one of which is patient dissatisfaction with the services provided. Previous studies showed that out of the 12 procedures that nurses should carry out during their shift, it was indicated that only a few were carried out and that some were not carried out at all during one shift[5–7]. The results of a study in the USA found that 56% of patients in surgical installation reported dissatisfaction with the actions given by the nurses. A similar case was also reported in child care installation where 57.2% of patients felt dissatisfied with the services provided by the nurses.

Moreover, regarding the administration of the procedures, 53.3% of patients in non-surgical installation reported dissatisfaction with the explanation of the procedure performed by the nurses. In the installation, it was found that 14.7% of patients were less satisfied with the nursing services provided[3,7].

In hospitals in the UK, it was reported that there are many independent nursing actions which are not carried out by the nurses which impacts on the quality of the nursing service provided. The National Health Service hospital reported that independent actions such as oral care, providing health education to the patients and oral feeding were not carried out by the nurses. Actions that are not carried out are considered to be one of the failures in improving patient safety[8].

The results of the interviews with the nurses at a hospital in Ambon found that some of the nurses still found it difficult to distinguish between independent nursing actions and medical actions. High workloads tend to make the nurses do routine actions that are more likely to be medical actions and administrative activities. The results of the observation on the implementation of 10 independent actions also revealed that the nurses in the hospital carried out only four actions routinely. Some actions were not carried out including helping to feed the patients, listening to the patients' complaints, mobilizing the position of the patients and discussing the patient's condition with the patients themselves.

The impact of unperformed independent actions results in an increased decubitus rate that occurs in the hospital setting, which according to Ambon in 2015 amounted to 11.8%. An increasing rate of decubitus will have an impact on the quality of the nursing services given to the patients that indirectly reduces the quality of independent nursing actions. Dabney (2014) reported that unperformed independent actions will have an impact on patient wounds, new infections and patient falls[9]. Such a condition may happen due to the lack of ability of the nurses to monitor patients with total care dependence that requires position changes every 2 hours.

The nurse's inability to perform independent actions has an effect on the patient's dissatisfaction with nursing services. A study by Agusin in 2008 showed that a low quality of services regarding what the patients received resulted in a low level of satisfaction[10]. This situation may affect the perception of the health care users that the nurses are incapable of carrying out independent actions. If this issue is not immediately addressed, then it will affect the professionalism of the nurses in the hospitals. This is in accordance with a study conducted by Novitra in 2004 which argued that the nurses' professionalism has become an important element in an effort to improve the patients' health status[8,11].

Ensuring the quality of the independent actions is important to improve patient recovery. Independent actions that are given optimally can help the patients distinguish between the nursing actions and medical actions that are given to them[7,12]. Therefore, the patients will better understand that nursing actions can help to cure their disease, in addition to medication administration.

A study by Andrianiin in 2016 reported that most of the nurses in the wards did not perform nursing actions such as hair care (66.9%), dental and oral care (78.2%), toileting (66.2%) and perineal care (84.2%)[13]. These results indicate that the implementation of personal hygiene was not good on the ward. If this condition occurs continuously, then it will result in an increased number of LOSs, patient dissatisfaction and decreased self-care for the patients[6,14].

A study by Susantiin in 2013 reported that there was a significant relationship between experience and motivation in fulfilling the patients' personal needs in Dr. H. Koesnadi Bondowoso. The nurses gained a lot of experience in caring for the patients with various types of nursing diagnoses[7]. Such experience will provide the nurses with a clear picture of how to carry out independent actions. Not only experience, however, but workload also has a relationship with the quality of employee performance.

The nurses' workload is closely related to the nurses' performance in the hospital. One of the elements of the nurses' performances in the hospital is taking independent actions. The high workload

of nurses due to medical and administrative procedures has an impact on the quality of the actions given. This high workload is influenced by the ratio between the number of nurses and the number of patients and their level of dependence[15]. Therefore, based on the explanation above, it is important to examine the correlation between the nurses' abilities, experience, workload and the quality of their independent nursing actions.

2. Methods

2.1 Research design

This study used a cross-sectional design involving a data collection technique using observational studies to connect two or more dependent variables with the independent variables.

2.2 Sample size

The samples used in this study totaled nurses in 14 inpatient wards of RSUD Dr. M. Haulussy Ambon, including the pavilion unit, female surgical ward, male surgical ward, ENT, skin, and genital ward, Cendrawasih ward, children's ward, female medical ward, male medical ward, gynecology, neonatology, lung, and neurology. The total number of samples was 165 nurses calculated according to the multivariate regression linear formula, adjusted for the number of independent variables. The samples were recruited using probability sampling. The inclusion criteria for taking the samples were nurses working in inpatient wards and staff nurses. Meanwhile, the exclusion criteria were nurses pursuing higher education and nurses on leave.

2.3 Instrument

The nurses' abilities were measured using a questionnaire developed by Hersey and Blanchard which consisted of 35 item statements using a Likert scale: 1=strongly disagree, 2=disagree, 3=neutral, 4=agree and 5=strongly agree. The results showed a maximum score of 175 and a minimum score of 35. To measure the workload, the NASA-TLX questionnaire developed by Sandra G Hart and Lowell E Staveland was used. This questionnaire consisted of 6 workload indicators using a rating scale with the highest value possible being 21 and the lowest value possible being 1. The results showed a maximum score of 126 and a minimum score of 6. To measure the variable of experience, a question item was used. Observations regarding the implementation of independent actions were carried out related to 14 nursing actions which include the activities of daily living, caring and support, rehabilitation and monitoring.

The questionnaires used for measuring the nurses' abilities and workload were translated into Indonesian by linguists after permission to use and modify the questionnaires was granted. The questionnaires were modified and then tested for validity. The results of the validity test focused on the questionnaire used to measure the nurses' abilities showed that all items were valid with the lowest r-value being 0.383 and the highest being 0.795. The r-value> from r-table = 0.361 and the reliability value was 0.963. For the workload questionnaire, it was found that all items were valid with the lowest r-value being 0.422 and the highest being 0.697. The r-value>of the r-table = 0.361. The reliability test showed a value of 0.792, indicating that the questionnaire is reliable as the Cronbach's alpha value was $0.7>\alpha\geq 0.6$.

2.4 Ethical consideration and data collection

This study has been approved by the research ethics committee of the Faculty of Medicine of Diponegoro University in March 2017. Prior to the data collection, informed consent was obtained from the respondents.

2.5 Data analysis

The Spearman rank analysis was used to identify the relation between the factors that could be modified (experience, workload, ability) and the unmodified factors (genetic and marital status) that influence the quality of the nurses' independent actions in the inpatient ward of RSUD Dr. M. Haulussy Ambon.

3. Results

3.1 Characteristics of the respondents

Table 1 shows that the respondents consisted of both male nurses (18.8%) and female nurses (81.2%). About 92% of respondents were married and 7.3% were not married. These results indicated that most of the nurses working in inpatient wards were females and that most of them were married.

Table 1. Characteristics of the Respondents (n=165)

Characteristics	f	(%)
Sex		
– **Male**	31	18.8
– **Female**	134	81.2
Marital Status		
– **Married**	153	92.7
– **Unmarried**	12	7.3

3.2 Quality of the nurses' independent actions, experience, workload and abilities

The nurses in the wards showed a mean value of 10.67 in performing independent actions, with the highest score being 14 and the lowest score being 5. The mean value of nurses' experiences was 4.42with the highest experience of 30 years and the lowest of 1 year. The nurses' workload showed a mean value of 62.15 with the highest score bein 122 and the lowest score being 6. Meanwhile, the nurses' abilities showed a mean value of 141.30 with the highest ability being 173 and the lowest ability being 106.

Table 2. Quality of the nurses' independent actions, experience, workload and abilities (n=165)

Variables	Mean	SD	Min-Max
Independent actions	10.67	2.625	5-14
Experiences	4.42	3.691	1-30
Workloads	62.15	29.598	6-122
Abilities	141.30	10.744	106-173

3.3 Description of the Quality of the Nurses' Independent Actions, Experience, Workload and Abilities

The results of the analysis in Table 3 shows that 55.8% of nurses carried out independent nursing actions in the good category and that the remaining 44.2% carried out independent nursing actions in the lesser category. Regarding experiences, 61.2% of nurses had high experience and 38.8% had low experience. The ability of the nurses showed a value of 53.3% and 46.7%, indicating that the

nurses had a good ability or a lack of ability respectively. Regarding the workload, 52.7% of nurses had a high workload and 47.3% had a low workload.

Table 3. Description of the Quality of the Nurses' Independent Actions, Experience, Workload and Abilities (n=165)

	Variables	f	%
	Experiences		
-	**High**	101	61.2
-	**Low**	64	38.8
	Workload		
-	**High**	87	52.7
-	**Low**	78	47.3
	Abilities		
-	**Good**	88	53.3
-	**Less**	77	46.7

Table 4. Bivariate Analysis of Experience, Workload, Abilities and the Quality of the Nurses' Independent Actions (n=165)

Variables	Quality of Independent Actions	
	Correlation Coefficient	*p-value*
Experiences	r = 0.266	0.001
Workload	r = 0.232	0.003
Abilities	r = 0.257	0.001

The results of the bivariate analysis in Table 4 showed that there was a significant correlation between experience, workload, ability and the quality of independent nursing actions. The correlation between the variables was weak with an r-value ranging from 0.1 to 0.40.

Table 5. Results of the Multiple Linear Regression Analysis

Variables	β-coefficient	S.E	Coefficient correlation (β)	Sig	R	*p-value*
Experiences	0.069	0.052	0.097	0.185	0.645	0.000
Workload	0.014	0.006	0.006	0.011		
Abilities	0.036	0.015	0.150	0.023		
Constant	-0.965	2.539	-0.380	0.704		

Note: *) significant if α = 0.05

3.4 Most dominant factor influencing the quality of the nurses' independent actions

The results of the multiple linear regression analysis in Table 5 showed that all of the variables affected the quality of the nurses' independent actions, including experience (r=0.097; CI95%: 3.85-4.99; p=0.185), workload (r=0.006; CI95%: 57.60-66.70; p=0.011) and abilities (r=0.150; CI95%: 139.65-142.95; p=0.023). Of all the variables, the nurses' abilities were the most influencing factor of the nurses' quality independent actions with an r-value of 0.150.

4. Discussion

This study found that there was a correlation between the nurses' experiences on the ward and the nurses' independent actions. The majority of nurses gained a high level of experience for as long as three years. Over that period, a nurse has a lot of experience, especially in giving actions to the patients such as mobilizing the patients' position, bed making, and helping to provide food to the patients. A number of actions that the nurses perform can improve the quality of their independent actions. There will be a difference between the nurses who have experience and those who do not. Based on the results of this study, the longer the employers work, the more experience the employers gain[16]. Working experience increases a great deal of expertise and work skills. In contrast, limited work experience results in lower levels of expertise and skills[17]. Working experience is an individual main capital needed to engage in a particular field.

The results of this study are in accordance with a study which reported that each nurse has different experiences when caring or performing actions that affect the patients[18]. These different experiences will also have different effects for the individual nurses in carrying out their independent actions. Experiences also determine the extent to which the nurses are professional when carrying out their duties, especially in providing services to the patients[19]. This is because nurses have different characteristics and knowledge.

According to Ace in 2014, work experience increases expertise and work skills. Conversely, limited work experience results in lower levels of expertise and skills[20,21]. The working experience of an individual is sometimes more valuable than the high level of education. Work experience is the main capital for someone to get involved in a particular field[16,19]. Therefore, the nurses' experience in the ward should be a consideration for the hospital management when conducting recruitment or rotating nurses, as it will affect the delivery of independent actions to the patients.

The quality of independent actions is also influenced by workload. Thus, qualified independent actions will decrease the nurses' workload. This result is in line with a study conducted by Aprianathat, in that there was found to be a significant relationship between workload and nurse performance[22,23]. According to Gurses as cited in Satria in 2013, workloads can affect nurse stress, patient care and safety [24]. Performing independent actions is one form of nurse performance in the hospital. If the nurses' performance decreases, then it will affect the quality of the independent actions given. As a result, the patients are dissatisfied with the services provided, the quality of the patient care declines and the professional image of nurses will also decrease among the health care users.

Heavy workloads may cause stress for individuals which will ultimately affect the nurses in carrying out their independent actions. On the contrary, a light workload will lead to boredom in the work, which in the end will also cause the nurses to lack skills when carrying out their independent actions. Nurse workload is strongly influenced by the number of nurses and patients, and the condition of the patients [25]. A high workload is closely related to patient safety[26]. The higher the workload, the higher the risk for the nurses to make a mistake when giving the actions to their patients[27]. To reduce the nurse workload, it should be ensured that the number of nurses meets with the existing needs, that the provision of duties is in accordance with the proportion, and that there is the ability to create a work system that can reduce the work efforts [28]. Increasing the

capacity of the nurses when carrying out independent actions to improve their efficiency and effectiveness referring to the caring hours is also a way to handle the high workload on the wards.

Nurses are required to be able to provide optimal service to their patients. This ability involves the dimensions of knowledge and skills. According to Hersey and Blanchard, an ability consists of technical skills, social skills and conceptual skills [29].

The technical skills include the nurses' mastery of medical devices, independent action procedures and the obligations and duties of the nurses. The social skills include the ability to work with other nurses, which relates to the ability to empathize and work in teams. Conceptual skills include the understanding of the policies, goals and targets of the hospital. These three abilities have an important role in improving the quality of independent actions. Hence, nurses are required to have these abilities at work.

The nurses' abilities have a correlation with the quality of the nurses' independent actions. The results of this study are consistent with a study by Hartanto as cited in Listiyono (2015), that an individual's ability greatly determines their performance in a company or organization. Working ability is important for a nurse to perform and complete their independent nursing actions well.

This study showed that the nurses' ability was good. This result indicates that good ability will increase the nurses' independent actions. Nurses with low ability will spend more time and make more of an effort to complete the actions compared to the nurses with high ability. The nurses' abilities determines the nurse's performance in the hospital [29]. The success of implementing independent actions in hospitals is very dependent on nurse performance. High levels of abilities are important for the nurses to be able to complete their nursing duties properly as every action requires certain knowledge, skills, and attitudes in order to achieve optimal results.

The working ability of the nurses is determined by their high level of education and experience. These two elements determine the knowledge and skills obtained [30]. A high level of education supported by work experience will create nurses who have a high level of ability. High working ability creates high productivity, which results in the optimal implementation of nursing actions reflected toward the patients.

The ability of the nurses to improve the quality of their independent actions is one of the factors that needs to be taken into consideration by the hospital management to improve the nurse's performance. The hospital can delegate nurses to participate in training related to independent nursing actions. Increasing the quality of their independent actions will reduce the number of LOSs, and increase patient safety and patient self-care [31,32]. If all of the three components are addressed optimally, then complete nursing services will also be achieved.

5. Conclusion

This study concluded that the nurses' experience, workload and capacity were related to the quality of the nurses' independent actions in the inpatient wards. The nurses' capacity was the most influential factor in independent nursing actions. This study recommends that the hospital management should improve the nurses' independent actions by increasing the nurses' capacity through training and advanced study. Further studies may take other factors such as policy and supervision into consideration in the study.

6. Acknowledgement

The authors would like to thank the students of Akper Rumkit Tk III Dr. J. A. Latumetten and the nurses for their participation in this study.

ABSTRACT

The Objective of study was systematically review emotional intelligence for nurse caring behavior. Literature search used using the keywords Emotional Intelligence, and Caring nurses. Search is done on the Ebscohost, Elsevier, Sciendirec and Google Schoolar sites. The result showed there were five journals related to the theme. The results of the literature review found that a person's caring behavior can be influenced by emotional intelligence possessed by someone Some studies show that emotional intelligence can influence nurses' caring behavior. A person's emotional intelligence greatly influences the caring behavior of nurses where emotional intelligence can help a person to understand emotions themselves and others help to shape behavior.

Keywords: emotional intelligence, caring nurses

1. Introduction

Nursing as a profession is required to develop science as a form of concern in order to maintain and improve the health status of patients in hospitals, health centers and other clinical settings. Nurses work to increase their concern for their clients in the central nursing practice. This is a dynamic approach called caring[1].

Aiken's research (2012) showed that the percentage of nurses who have poor caring service quality in Ireland was 11% and in Greece, it was 47%. In Indonesia alone, caring is one of the assessments undertaken related to the users of the health services. Based on the results of the patient satisfaction survey in several hospitals in Jakarta, 14% of patients were dissatisfied with the health services provided due to poor caring behavior.[2] Nursing services are currently not satisfactory due to a lack of caring behavior from the nurses. This can be seen from the studies conducted in several hospitals. Among others, the study by Prabowo et al (2014) showed that 50% of the nurses behaved in a less caring manner. Another study conducted by Gaghiwu et al. (2013) found that 26.7% of nurses behaved poorly. Another study by Martiningtias et al (2013) showed that 29.6% of nurses were less caring concerning their patients. Ardiana's study (2010) also revealed that 46% of the nurses behaved in a manner that was not caring according to the patient perceptions. From the results of the above research, it can be seen that there are still many caring behaviors within the nurses in Indonesia. According to Marmi's study (2015), it was shown that the nurses' caring behavior according to the perceptions of the client or the client's family was in the best category, by as many as 13 people (72.2%).

There is the existence of individual factors, psychological factors and organizational factors that can influence caring behavior, which includes emotional intelligence skills and the demographic

characteristics of age, gender and education. Attitudes, personality and motivation, social level, demographic characteristics, human resources, leadership, rewards, structure and work all also tie into this. The caring behavior that is lacking in nursing services can result in a decrease in the quality of the nursing services. This results in a decrease in patient satisfaction. A lack of contact with patients can result in the psychological care of the patients [3]. Providing caring nursing can have a positive impact that can improve patient recovery. This is because the patients feel fulfilled in terms of their physical, emotional and spiritual needs. The patients feel comfortable with the nurse services[4]. The impact of a lack of caring behavior still needs to be improved.

According to Skinner, behavior is the result of interactions between the stimuli received with the responses given[5]. The caring behaviors of the nurses can be improved through caring training, increasing the intrinsic motivation of the nurses and increasing their emotional intelligence. Lestari's study (2017) found that there was a positive relationship between emotional intelligence and caring behavior, meaning that the higher the emotional intelligence of the nurses, the better their caring behavior, and vice versa. The lower the emotional intelligence of the nurses, the worse that their caring behavior is.

Emotional intelligence helps a person when moving, acting or encouraging the productivity of his work[6]. Emotional intelligence is very important when it comes to building a relationship between the nurses and their patients. This is because with emotional intelligence, a health worker will be more empathetic, have compassion and be wiser. Is there an influence of emotional intelligence on increasing the caring of the nurses?

2. Research Methods

The systematic review used nursing management articles to identify emotional intelligence and if it can improve caring in nursing. The article inclusion criteria used were emotional intelligence that increased the caring of the nurses, while the exclusion criteria were abstract articles, articles that did not use English and the articles where the full text was not available. The article search was limited to articles in English accessed through internet searches from select databases, namely EBSCOhost, Elsevier, ScienceDirect and Google Scholar, with the keywords 'emotional intelligence', 'nursing' and 'nursing caring'. Articles that met the inclusion criteria were collected and examined systematically. The search was for literature published between 2012 and 2017. The search process obtained 5 articles that met the requirements for the inclusion and exclusion criteria.

3. Results

The search obtained as many as 12 articles that were deemed to be in accordance with the objectives of the study which were then put together and screened according to whether the titles of the articles were the same or not. After screening, there were 9 articles with the same title. From the 9 articles, the screening was then based on eligibility according to the inclusion and exclusion criteria which found 5 articles for further review. The research consists of several studies conducted in various countries.

Table 1. Search strategies

Search engine	***EBSCO Host***	***Sciencedirect***	***Google schoolar***
Search results	20	14	28
Full text, pdf, 2012-2017	7	10	12
Appropriate title	3	2	7
The same title		9	

Eligible according to inclusion criteria and exclusion	5
4. **Results**	5

The analysis of the 5 articles showed that 2 journals used a correlation study design, 1 journal used a non-experimental quantitative design, 1 journal used a descriptive design and 1 used structural equation modeling. After a study of the quality of the 5 articles, they can be categorized as high before the data is extracted. The data extraction was done by analyzing the data based on the name of the author, the title, year and the results, namely grouping together the important data in the article.

5. Discussion

The nurses understand caring in nursing as a relationship with the patients that is characterized by the nurse's part through an individual approach using empathy, attention, experience and sensitivity. Through care, active communication takes place by providing information that reduces anxiety and that lessens the obstacles in the work. This relationship helps to protect the effectiveness, dignity and comfort of the patients. This requires experience on part of the nurses and this is influenced by their environment. The personal qualities of the nurses (what professional knowledge, attitudes and skills they have) and the availability, reliability and emotional and physical support that they offer is important to the patients [7].

The results of the study were r = 0.698 collectively while the results of the calculation of the coefficient of determination was 48.72%. The remaining 51.28% was influenced by the other factors that were not examined. With the level of hypothesis testing at an error rate of 1%, the value of the t count was 13.28% greater than Table 2.660, thus it can be concluded that Ho is rejected, meaning that emotional intelligence has a positive influence on employee performance in the district office of the Ministry of Religion Karawang [8].

The results indicate that spiritual intelligence affect emotional and psychological intelligence. Emotional intelligence affects psychology, fatigue and nurse caring behavior. A person's psychology influences fatigue and nurse caring behavior. Fatigue influences the caring behavior of the nurses. Psychology mediates the relationship between spiritual intelligence and caring behavior and between emotional intelligence and nurse caring behavior. Fatigue mediates the relationship between spiritual intelligence and caring behavior and between the psychological factors and nurse caring behavior[9].

Based on the research, it was found that the nurses 'caring behavior was greatly influenced by the nurses' emotional intelligence. Based on the results of the research conducted on the general nurses in both international and surgical hospitals, nurses who already have emotional intelligence tend to be good. However, the caring behavior shown is still lacking. This certainly requires a follow-up in the form of an effort to explore more about the factors that influence the nurses' caring behavior, especially in internal wards and in Surgery Badung Hospital[10].

In her research, it was explained that there is a positive relationship between emotional intelligence and caring behavior, meaning that the higher the emotional intelligence in the nurses, the better the caring behavior and vice versa; the lower the emotional intelligence in the nurses, the worse that their caring behavior is[11].

6. Conclusion

Several studies show that emotional intelligence can affect the nature of the caring exhibited by the nurses. Emotional intelligence can help someone to understand their emotions and those of others in

order to influence their behavior. With the existence of better behavioral changes, they are able to improve their nursing performance, especially caring in order to meet patient satisfaction.

CULTURE PHENOMENON OF FOOD SELECTION AMONG CHILDREN WITH LEUKEMIA IN SURABAYA

Indriatie[1], Aida Novitasari[1], Enung Mardiyana[1]
[1]Nursing Program of Soetomo, Health Polytechnic of Health Ministry, Surabaya, Indonesia
E-mail: ndrie.65bambang@gmail.com

ABSTRACT

The disease can occur as a result of the food consumed does not have nutritional value for the body or low quality or an unbalanced diet, mistakes in choosing a diet or a food menu. Food was one of the risk factors for cancer, such as leukemia. The aim of the study was to analyze the relation of culture based menu selection with the occurrence of leukemia in children at the Surabaya. The population in this study were all mothers or families and pediatric patients with leukemia who lived in Surabaya, with a capacity of ± 30 people. The independent variable in this study was the culture of food menu selection, consist of familly culture in the selection of food menus, knowledge about nutrition, the social function of food selection, preference food of familys. The dependent variabel was incident of leukemia. Linear regression used to see relation between dietary menu patterns with the incidence of leukemia in children. The result of this research was culture of food menu selection namely family belief, knowledge of nutrition, social functions, preferences food of family's were not contribute to the occurrence of Leukemia in children at Surabaya. This was likely because when carried out this study the mother or family of children suffering from leukemia who became respondents were already in the treatment period so that many of they were exposed to information from health workers, so many inappropriate cultures have been changed to follow a healthier food selection culture. There were other factors that cause leukemia besides food such as viruses, drugs, radiation, and genetics. Although there was no relationship between the culture of food selection and the incidence of leukemia, the family is expected to continue to implement a culture that supports the selection of healthy food for the family both on the component family belief, knowledge of nutrition, social functions, preferences food of family's.

Keywords: menu, culture, food consumption, leukemia

1. Introduction

The disease can occur as a result of the food consumed which does not have value for the body or which is low quality or forms an unbalanced diet, or mistakes in choosing a diet. Food is also one of the important risk factors for cancer, such as leukemia. Leukemia is a disease that can affect all types of ages, including children. Leukemia is a type of cancer that is often found in children under the age of 15 years. Leukemia is a chronic disease that ranks second and third as a cause of death in children [1].

The causes of leukemia have not been known for sure. Some studies have found several risk factors that can cause leukemia including pesticide use, electric fields, a history of miscarriages in the mother, radiation, chemicals (benzene), viruses, genetic disorders, mothers who are relatively old at birth, mothers who smoke while pregnant, alcohol consumption during pregnancy, marijuana use during pregnancy, magnetic field, parental work, birth weight, prenatal and postnatal radiation, vitamin K, and diet [2]. Children who suffer from leukemia tend to experience malnutrition threefold compared to children who are healthy / do not have a history of cancer. A balanced diet is

very helpful in the prevention of leukemia (Shils, 2008). Factors that influence the fulfillment of nutrition in children who suffer from leukemia include internal factors consisting of physiological factors, Psychological factors, External Factors: Culture, Religion, Ethical Decisions, Economic Factors, Social Norms, Health Education /Awareness, Media and Advertising. Culture is the main determinant of food selection. (Barasi. ME, 2007: 22). The basic human needs that must be fulfilled to carry out life are eating and drinking. Food is a manifestation of culture from the process of processing raw materials to ready-to-eat food, including culture in the way it is presented and consumed.

Food safety is the condition and effort needed to prevent food from the possibility of biological, chemical and other objects that can interfere with, harm and endanger human health. Food safety is a necessity of the community because safe food will protect and prevent disease or other health problems (Krisnamurni, 2007).

According to Anwar (2004), unsafe food can cause diseases called foodborne diseases, namely diseases arising from consuming foods containing toxic substances or compounds or pathogenic organisms, including chemical contamination such as fertilizers, pesticides, insecticides, mercury, arsenic, cyanide and so on. Based on qualitative research using a phenomenological approach to the mother or family and leukemic pediatric patients treated in Bona I Room, Dr. Hospital Soetomo Surabaya in November 2014 in 5 patients and their families, it was found that children suffering from leukemia mostly had a history of consuming fast food in the form of instant noodles in the daily food menu for a long period of time [3].

2. Methods

This type of research uses analytics using a simple linear regression/correlation approach, by looking at the dominant factors that influence the culture of food menu selection with the incidence of leukemia in children. The population in this study were all mothers or families and pediatric patients with leukemia who lived in the Surabaya shelter, composed of 30 respondents, with a total sampling technique.

Variable research on food menu selection culture in children with leukemia, with sub-variables as follows: trust in food menu selection, nutrition knowledge in food menu selection, social function in food menu selection, and preference for daily food menu selection variable independent to the incidence of leukemia in children. Analysis of the data used is the Regression Logistics Test to see the dominant factors that influence the culture of food menu selection with the incidence of leukemia in children. Accepted if P> 0.05.

3. Results AND DISCUSSION General data

3.1 Characteristics of Leukemic Patients in Shelter Houses

Table 3.1 Characteristics of Leukemic Patients in Shelter Houses from July 14 to August 21, 2017

Characteristic aspects	Category	Frequency	Percentage
	Women	18	60%
Age of the patient	5 year	14	47%
	> 5 year	16	53%
Patient Education	Low (no school - junior high school)	14	47%
	SMU	15	50%
	High (Bachelor)	1	3%
Family Income	> Rp. 1.000.000,-	16	53%
	< Rp 1000.000,-	14	47%
Number of siblings biological	< 2	13	43%
	> 2	17	57%
Previous medical history	there is	7	23%
	There is no	23	77%
Diet' pattern of mothers during pregnancy	Rice, fish, vegetables	17	57%
	Rice, fish, vegetables, Instant noodles	13	4 3%

3.2 Selection of food menu

Table 3.2 Culture Selection of food menus in children with Leukemia at the Shelter House for July 14-August 21, 2017

1. Trust

Category	Frequency	Percentage
Well	25	83%
Enough	5	17%
Less	0	
total	30	100%

2. Mother's Knowledge (Selection of food menu)

Category	Frequency	Percentage
Well	28	93%
Enough	2	7%
Less	0	
total	30	100%

3. The social function of parents in the food menu selection

Category	Frequency	Percentage
Well	16	53%
Enough	13	43%
Less	1	4 %
total	30	100%

4. Preferences

Category	Frequency	Percentage
Well	26	87%
Enough	4	13%
Less	0	
total	30	100%

5. Food selection pattern

Category	Frequency	Percentage
Well	20	67%
Enough	8	27%
Less	2	7%
total	**30**	**100%**

Based on table 3.2 above, it is explained that the culture of food menu selection for children with leukemia in a shelter about community trust shows that almost all of them are good (83%) and small enough (7% 0), a small portion is enough (7%), social function shows mostly good (53%), almost half is good (43%), a small portion is less (4%). preference or preference on the food menu shows almost all good (87%), a small portion is enough (13%), and the pattern of food menu selection shows that most are good (67%), almost half is enough (27%), a small portion is less (7%).

3.3 Leukemia in children

Table 3.3 Occurrence of Leukemia in children at Shelter Houses on July 14-August 21 2017

Type	Frequency	Percentage
ALL	27	90%
CML	3	10%
total	30	100%

Based on table 3.3 above, it is explained that the incidence of leukemia in children at halfway houses shows almost ALL (90%) and a small portion of CML (10%).

3.4 Cultural Relationship Selection of food menus with the incidence of leukemia

Table 3.4 Relationship Culture Menu selection with the occurrence of Leukemia at Home Stop on July 14 to August 21, 2017

The culture of food menu selection		B	S.E.	Wald	df	Sig.	Exp(B)
Step 1[a]	Trust Knowledge Social function	-.015	.038	.159	1	.690	.985
	Preferences or preferences	-.141	.114	1.525	1	.217	.868
	Menu selection pattern	-.098	.102	.929	1	.335	.907
	Constant	352	.290	1.471	1	.225	1.422
		-.046	.098	.219	1	.640	.955
		-6.519	20.463	.101	1	.750	.001

Based on table 3.4 above the Cultural Relationship Selection of the food menu starts a trust,

knowledge of the food menu, social functions, preferences or preferences, menu selection patterns show no influence according to the results of significance (P> 0.05).

4. Discussion

Culture selection of food menu about trust, knowledge of food menu, social function, preferences or preferences, the pattern of food menu selection for children at Rumah Singgah shows that almost all of them are good. This is according to the maternal characteristics that education has almost half (50%) of high school education and a small portion of PT (3%) so that it is sufficiently understanding while understanding is quite influential on behavior. Understanding someone's behavior according to Shiffman and Kanuk [4] is a behavior that is considered by someone in finding, buying, using, evaluating and ignoring products, services, or ideas that are expected to satisfy someone to be able to satisfy their needs by consuming the products offered. In addition, a person's behavior according to Loudon and Della Bitta (1993) is a process of decision making and physical activity. All of these behaviors involve individuals in assessing, obtaining, using or ignoring products. Knowledge and education in this study of parents of children have enough information about Leukemia, especially about the factors that contribute to or influence the incidence of this disease. The culture of menu selection related to social functions and the pattern of food selection in this study is a little less. This is according to social functions (religious functions and communication) which are still less applied so that important media in the efforts of humans to relate to each other is performed less, especially in the provision of food served [5]. The culture of menu selection related to the pattern of menu selection from the results of this study still has a small portion lacking, this is in line with family income, which is still almost half less than 1million rupiahs, so it is very influential in considering choosing a family food menu and menu type. According to Sanjur [6], it was explained that plaque selection of food was based on group ethnicity and excellence so that consideration in choosing menu types was not considered by parents.

Prevalence: The prevalence of leukemia in children at Shelter Houses is almost entirely diagnosed with ALL and there is a small percentage diagnosed with CML. It is appropriate that almost all children age acute lymphocyte leukemia or called LLA is the most common form of leukemia in children, this disease is the most common childhood malignancy. LLA incident is 1 / 60,000 people per year, with 75% of patients aged less than 15 years. The peak incidence is 3-5 years [7]. Whereas chronic myelogenous leukemia (CML) is also included in myeloid stem cell malignancy. However, more normal cells are compared in the acute form, so the disease is lighter. Genetic abnormalities called the Philadelphia chromosome are found in 90% to 95% of patients with CML. CML rarely attacks individuals under the age of 20 years, but the incidence increases according to the age of the child (Hockbenberry, 2007). The results of this study only identify the types of cancer in children (Leukemia) ALL but at the condition of other cancer stop houses such as; retinoblastoma, brain tumor, Wilms tumor, and there is a tendency or trend to increase the incidence of other types of tumors that have not been identified as a trend in numbers from 2014 to 2016 as follows: 7%, 15% and 22%.

Linear logistic analysis test results show that the relationship between the culture of food menu selection begins with trust, knowledge of food menus, social functions, preferences or preferences, menu selection patterns show no influence according to the significance results (P> 0.05). This is because parents of children are already in the stage of chemotherapy treatment so that they have been exposed to information about cancer, especially the trigger factors for cancer.

From several regressed factors, there are several factors that can contribute, namely knowledge factors, menu preferences or preferences and the socio-cultural function of food menu selection. Knowledge factor, one's knowledge is usually obtained from experience that comes from various sources, such as mass media, electronic media, manuals, health workers, poster media, close relatives and so on. Knowledge can also be obtained through learning processes such as counseling, training or knowledge courses can help explain important aspects of the world and predict events [8].

Preference or preference factors, the results of the Drewnowski (1999) study state that there is a significant relationship between food preferences and the frequency of eating in women. There are three main factors that influence food consumption, namely: individual characteristics, food characteristics, and environmental characteristics. A model or framework of thinking is needed to examine food consumption in relation to these characteristics, and the relationship between the characteristics themselves [6]. Social function factors, Food is an important medium in human efforts to relate to one another. In the household, the warmth of relationships between members occurs at the time of the meal together. Likewise, among large households, a meeting is held regularly with meals to maintain and strengthen the relationship of friendship. Between neighbors, they often exchange food [5].

5. Conclusions

Food menu selection culture with the occurrence of leukemia in children is as follows: Culture of food menu selection from the trust, knowledge of food menus, social functions, preferences or preferences of menu patterns do not contribute to the occurrence of Leukemia in children in Surabaya shelter trust, knowledge of food menus, social functions, preferences or preferences, menu selection patterns. So, the Cultural Recommendation Food menu selection is about trust, mother's knowledge, social functions, prevention and menu selection patterns are maintained. For other researchers, future researchers can conduct research with children newly diagnosed with ALL.

KNOWLEDGE OF STUDENT PRACTICES ABOUT SAFETY PATIENTS IMPROVE THE ABILITY OF FALLING RISK ASSESSMENT

Abdurrouf, Issroviatiningrum, Fraditha
Faculty of Nursing, Sultan Agung Islamic University, Semarang
Email: muh.abdurrouf@gmail.com

ABSTRACT

Falling patients are incidents in hospitals that can cause injury to patients. Falling risk prevention is very important and is one of the goals of patient safety. The incidence of falling patients can be caused by several factors, one of which is students undergoing clinical practice because of a lack of student knowledge about patient safety. This study aims to determine the relationship between students' knowledge about patient safety with falling risk assessment. This study is a type of quantitative research with an analytical survey approach. The design used is cross-sectional, the data collection technique uses total sampling. The number of samples was 65 respondents. Data analysis using spearman correlation test. The statistical test results show a p value of 0,000 ($p<0.05$) with a correlation coefficient of 0.492 and a positive relationship direction, this indicates a relationship between the knowledge of students about patient safety and risk assessment of falls. Increasing the knowledge of students about patient safety will improve ability of falling risk assessment.

Keywords: knowledge, patient safety, falling risk assessment

1. Introduction

Falling patients are frequent incidents in hospitals that can result in serious injury or even death. Falling risk prevention is the sixth patient safety goal and is important to do because patient falls are very alarming incidents in all hospitalized patients and have become the second most adverse event in health care after medication errors (Joint Commission International, 2011).

The incidence of falling patients has a detrimental impact on patients, one of the adverse effects of which is the impact of physical injury which includes abrasions, torn wounds, bruises, some severe cases of falls can result in fractures, bleeding, and head injuries. AHRQ (2008) said the incidence of patients falling in US hospitals was reported to be 700,000 to 1,000,000 patient falling each year. Reports from hospitals and mental health units in the UK in 2011 amounted to 282,000 patients each year, of which 840 patients had hip fractures, 550 patients had fractures, and 30 patients had intra-cranial injuries (National patient safety agency, 2007).

Data of falling patients in Indonesia based on a report from the XII PERSI congress (2012) showed that the incidence of patients fell into three major hospital medical incidents and was ranked second after medicine error. Data from the report shows that at 34 cases or equivalent to 14% of incidents fell in hospitals in Indonesia.

This proves that the incidence of patients falling is still high and still cannot reach the accreditation standard stating that the incidence of falling patients is expected not to occur in the hospital or 0% of events. (Joint Commission International, 2011). Efforts to anticipate and prevent the occurrence of falling patients really needs to be assessed from the beginning as well as a periodic fall risk assessment, this study needs to be carried out since the patient starts registering (Budiono, 2014). Nurse students have many roles in preventing patients from falling one by doing assessment risk falls such as the Morse Fall Score, (MFS) assessment or Humpy Dumty Fall Scale.

The results of research conducted by Iswati (2015). Student knowledge is still lacking in patient safety, including the process of correctly identifying 32%, effective communication at 61%, increasing the drug correctly by 74%, reducing the risk of infection 86%, and reducing the risk of falling 43%. The research conducted by Sari (2015) shows that students' knowledge of patient safety is far from being 100%. Students have limited clinical experience so that the risk of making mistakes in giving action to patients, so that when a procedure is done imperfectly or wrong it can endanger the patient's condition (Khasanah, 2012).

The results of a preliminary study conducted on September 5, 2018 at Sultan Agung Islamic Hospital Semarang with a questionnaire method and observations of 16 nurse students obtained results of 6 students (37.5%) had good knowledge about patient safety and were skilled in carrying out the fall risk assessment on patients, 8 students (50%) had sufficient knowledge about patient safety and were skilled enough in implementing a fall risk assessment, 2 students (12.5) had less and less skilled knowledge in carrying out fall risk assessment to patients. This illustrates that many nurse students who already have sufficient knowledge of patient safety to prevent the risk of falling but there are some students who are still lacking in patient safety knowledge and the implementation of falling risk assessments.

2. Research Methods

This type of research is quantitative by using an analytical survey method through a cross sectional approach. In this study the population is nurse students who practice at Sultan Agung Islamic Hospital Semarang in November 2018. The sample used in this study is all students who practice professions who practice at the Sultan Agung Islamic Hospital Semarang in November a number of 65 nurse students. Inclusion criteria are the general characteristics of the research subjects in the target population and in the affordable population. The inclusion criteria in this study were nurse students who practiced at Sultan Agung Islamic Hospital Semarang who were willing to be respondents and students who had received material about patient safety.

The instrument of students' knowledge about patient safety with 24 statements with 2 choices of right and wrong answers. Statements made to obtain data on students' knowledge in the form of a Guttman scale by weighting each answer consisting of 5 items to determine the accuracy of patient identification, 3 items for effective communication, 4 items for drug safety improvement, 2 items for the right location, right procedure, right patient operation, 7 items for increased risk of infection related to hospital health services and 4 items for reducing the risk of patients falling in hospitals Observation is used to assess students in carrying out the risk assessment of patients who fall 18 statement. Statements with answers always score 3, sometimes score 2, and never score 1.

Data analysis was performed by univariate and bivariate analysis. Univariate analysis is used to explain the frequency distribution and the percentage of the research subject and is presented in the form of a frequency distribution table. Bivariate analysis is used to determine whether or not there is a relationship between the independent variables and the dependent variable, the data of this study indicates an abnormal distribution of p value 0,000 (<0.05) so that bivariate analysis in this study uses a non-parametric statistical test (rank spearmen test).

3. Results

Table 1.1. Distribution of student characteristics based on age in Sultan Agung Islamic University (n=65)

Age	Frequency	(%)
20-21 years	30	46,2
22-23 years	35	53,8
Total	**65**	**100**

Table 1.1 shows that students at the age of 22-23 years were 35 students (53.8%) and those aged 20-21 at 30 students (45.5%).

Table 1.2. Distribution of characteristics of students based on gender in Sultan Agung Islamic University (n=65)

Gender	Frequency	(%)
Male	10	15,4
Female	55	84,6
Total	**65**	**100**

Table 1.2 shows that female students are 55 students (84.6%) and male students are 10 students (15.4%).

Table 1.3. Frequency distribution according to student knowledge in Sultan Agung Islamic University (n=65)

Knowledge	Frequency	(%)
Good	18	27,7
Enough	34	52,3
Less	13	20,0
Total	**65**	**100**

Table 1.3 shows that the majority of students who have sufficient level of knowledge are 34 (52.3%) students, and a small proportion have less knowledge level, at 13 (20.0%) students.

Table 1.4. Frequency distribution according to the implementation of the risk assessment falls by students in Sultan Agung Islamic University (n=65)

Falling Risk Assessment	Frequency	(%)
Good	16	24,6
Enough	40	61,5
Less	9	13,8
Total	65	100

Table 1.4 shows that the majority of professional student nurses in the implementation of risk assessment fell quite well at 40 students (61.5%) and a minority of less well at 9 students (13.8).

Table 1.5 Test for Normality of Student Practices with Implementation of Falling Risk Assessments in Sultan Agung Islamic University (n=65)

Variable	Kolmogorov smirnov[a]	
	n	*P value*
Risk assessment falls	65	0,000
Knowledge of patient safety	65	0,000

Table 4.5 shows the results of the normality test on the knowledge variable of the students about patient safety and the implementation of falling risk assessments that are abnormally distributed i.e. 0,000 (p value <0.05) because the abnormal data of the researcher uses rank spearmen data test

Table 1.6. The spearmen test is the relationship between the knowledge of students about patient safety and the implementation of falling risk assessments in Sultan Agung Islamic University (n=65)

Variable	R	*P value*
Knowledge of patient safety and the implementation of falling risk assessments	0,462	0,000

Table 1.6 shows the results that in this study obtained data there is a meaningful relationship between the knowledge of students about patient safety with the implementation of risk assessment falls in Sultan Agung Islamic Hospital Semarang with p-value of 0,000 or p-value <0,05 and correlation coefficient which is 0.462. with the direction of a positive relationship indicates the existence of a close relationship between the two variables. The results showed a significant relationship, if the safety knowledge of students is good then the better the implementation of risk assessment falls, this applies to the opposite.

Table 1.7. The results of cross tabulation of the relationship between the knowledge of students about patient safety and the implementation of risk assessment in Sultan Agung Islamic University (n=65)

		the implementation of risk assessment			Total
		Good	Enough	Less	
Knowledge of students about patient safety	Good	11 16.9%	4 6.2%	3 4.6%	18 27.7%
	Enough	4 6.2%	30 46.2%	0 .0%	34 52.3%
	Less	1 1.5%	6 9.2%	6 9.2%	13 20.0%
Total		16 24.6%	40 61.5%	9 13.8%	65 100.0%

Table 1.7 cross tabulation shows that students who have good patient safety knowledge with the implementation of risk assessment fall well there are 11 (16.9%) students. Students who have enough patient safety knowledge with the implementation of the risk of falling are quite good, there are 30 (46.2%) students and students who have insufficient patient safety knowledge with the implementation of a risk assessment of falling poorly there are 6 (9.2%).

4. Discussion

The results of the study showed that the majority of students were 22-23 years old. In general, the younger the age of students or less than 25 years, the more risky the less good in implementing patient safety. Whereas in the age of more than 25 years the better the implementation of patient safety.

This is in line with Suryani's research, et.al (2015) that there is a relationship between age and knowledge in implementing patient safety by students. Robbin's research (2003) says that age increase is closely related to the ability to analyze problems faced, commitment to an action or work, and be able to control emotions better.

The results of the research at the Sultan Agung Islamic Hospital found that the age of students greatly influenced nursing knowledge and practice, where the older a person's knowledge and ability to think they will be more mature and will create better work skills.

The study found that most of the students were female. The results of this study have similarities with the research conducted by Putra (2013) where most female student nurses do patient safety better than men.

This is consistent with the opinion of Kozier & Erb (2010) on the philosophy of the mother instinct that the majority of medical teams, especially nursing, come from women, where a woman has the instinct to care for herself as reflected in a mother and has a simple instinct to maintain family health, especially children.

The study at the Sultan Agung Islamic Hospital found that gender has a relationship in maintaining patient safety. This is because in the field of nursing there more women compared to

men. This is because women have more caring characteristics than men. Women also have an instinct to care for themselves and have simple instincts in maintaining health so that they will be better at carrying out patient safety measures.

The study found that the majority of students had enough knowledge. Research conducted by Jamshed et al (2014) found that students who have good knowledge have the ability to measure the accuracy of drug dosages and make appropriate decisions for patient safety. Manorek, et al. (2018) found good knowledge in nursing will affect the application of good patient safety goals. Knowledge is an important factor in someone making a decision, but someone's knowledge cannot always help them to avoid undesirable events, for example students who have a good level of knowledge do not always carry out patient safety properly because all actions taken are at risk for errors.

The study found that students' knowledge had a relationship with patient safety. Good student knowledge will produce good performance too. For this reason, it is necessary to add information sources through training, seminars or workshops on patient safety. In training students are provided with knowledge, skills and experience related to patient safety.

The study found that students in the implementation of risk assessments fell quite well. Harianto, et al. (2015) research results in which student knowledge of patient safety is in the sufficient and lacking category so knowledge management is needed to improve the competence of nursing students.

The study at Sultan Agung Islamic Hospital found that the implementation of risk assessment fell on students who were not good due to lack of knowledge and experience so that they had not reached a good level of skills in the virginity world, therefore the need to always involve students in training - skills training students are getting better.

The results of statistical tests using Spearmen Rank correlation obtained the correlation coefficient value of patient safety knowledge of 0.462 with a p value of 0.000 ($P < 0.05$), so that there was a significant relationship between the knowledge of students about patient safety and the implementation of falling risk assessment. The correlation value is 0.462 with a positive sign indicating a moderate relationship between the two variables. This can be interpreted if the knowledge of the students is good about patient safety, there will be increased skills in implementing the risk assessment to fall at Sultan Agung Islamic Hospital, Semarang.

The importance of patient safety knowledge in hospitals is needed by students because without good knowledge, students will not be able to perform and implement patient safety in patients in hospitals correctly and well. Notoadmojo (2015) states that cognitive knowledge is a very important domain in shaping one's actions.

A person's knowledge is closely related to one's actions in fulfilling their obligations, so further education is very important in trying to improve and obtain knowledge.

Patient safety for nurses is not only a guideline about what should be done, but patient safety is a commitment contained in the nurse's code of ethics in providing safe, competent, and based on a code of ethics for patients (Canadian Nurse Association, 2009). Providing safe services must be preceded by understanding hospital patient safety material that refers to international standards at the Joint Commission International (JCI). JCI is one of the hospital's international accreditation institutions that has been recognized by the world. JCI's main focus is to improve patient care through the provision of accreditation and certification services and through consultancy and education services with the aim of helping organizations implement practical and sustainable solutions (The Joint Commission, 2014).

The results of this study are also supported by Darliana (2016) that the factors of nurse knowledge about patient safety are proven to be able to contribute positively and significantly in influencing the implementation of the patient safety program. Other research by Bawelle, Sinolungan, & Hamel (2013) also obtained the same conclusion that there is a relationship between joint knowledge of experience, continuous information, values and abilities possessed by individuals in translating information that provides a framework for evaluating and adapting to experience and

information new. This is also in accordance with the theory of Health Belief Model (HBM) by Becker (1974, in Akubugwo, Ijeoma, & Burke, 2013) which states that behaviors formed in individuals are influenced by individual perceptions of knowledge and belief in an object.

5. Conclusion

Knowledge of good students about patient safety will improve the implementation of falling risk assessments.

Suggestion

1. For Students

Student knowledge about patient safety and the skills of implementing a fall risk assessment at the Hospital can be improved by attending training and seminars on patient safety

2. For hospitals

The field of education and training of hospitals should assess students about patient safety before students practice at the hospital. The hospital should carry out training, seminars, or guidance for students to improve student knowledge about patient safety.

3. Future research

It is hoped that this research can be a source for further research by further developing the results of this study with different dependent variables and increasing the number of respondents or conducting research at different hospitals so that the results obtained will be broader.

SPIRITUAL INTERVENTION AND THERMAL STIMULATION IN PREGNANT WOMEN WHO HAVE BACK PAIN IN SEMARANG CITY

Sri Wahyuni, Tutik Rahayu, Hernandia Distinarista, Apriliyani Yulianti Wuriningsih,
Siti Diah Nofitasari
Maternity Department, Nursing Faculty, Sultan AgungIslamic University, Kaligawe Street Km.4 Semarang, Central Java
Email: wahyuni@unissula.ac.id

ABSTRACT

Back pain is one complaint that is often experienced by pregnant women. This complaint increases with increasing maternal age. The purpose of this study is to determine the effectiveness of spiritual intervention and thermal stimulation of back pain in pregnant women. The method use quantitative with quasi experiment pre post test design with control on 40 people, subjects were taken by purposive sampling. Interventions in group 1 were listened to murottal Alqur'an surah Ar-Rahman and giving warm compresses, while in group 2, murottal Alqur'an was the subject's favorite surah and given warm compresses for 20 minutes. Data were analyzed using the Wilcoxon and Man Whitney tests. The Wilcoxon test in group 1 showed that there was an effect of listening to murottal Alqur'an surah Ar-Rahman and warm compresses to decrease back pain, p value 0.000. In group 2, there was an influence of listening to murottal Alqur'an favorite surah and warm compresses to decrease back pain, p value 0.000. The Mann Whitney test from both groups showed no significant difference in decreasing back pain in groups 1 and 2 with p value 1.000. Spiritual intervention and thermal stimulation effective to reduce back pain in pregnant women.

Keywords: spiritual intervention, thermal stimulation, pregnant women, back pain

1. Introduction

Pregnancy is a physiological process that couples always expect in a family. During the pregnancy process the mother will experience changes in her body which often cause complaints. Complaints are common and are felt by almost every pregnant woman, including the back [1].

Complaints of back pain in pregnant women occur because it is influenced by several factors including physical changes that occur during pregnancy. During pregnancy, women generally experience changes in body size, weight gain and the growth of the fetus in the uterus. This condition causes the abdominal wall to become stretched according to the development of the uterus. Stretching of the abdominal muscles can cause the posture of pregnant women to experience lordosis [2].

Lordosis posture in pregnant women causes the shoulder to be attracted to the back due to prominent abdominal enlargement and to maintain body balance and curvature of the vertebrae inward becoming excessive. Sacroiliac joint relaxation that accompanies changes in body shape stimulates an increase in back pain. Complaints of back pain like this usually begin to be felt when gestation enters the second trimester and increases when the gestational age increases. Pregnant women with complaints of back pain have a lower quality of life and more often complain of pain [3].

Complaints felt by pregnant women who experience back pain have an impact on daily activities so that the mother experiences a disruption in carrying out activities such as moving or

changing positions, difficulty walking, sleep disturbances and emotional disturbances during pregnancy that affect the quality of life of pregnant women [4]. Pregnant women with back pain must be careful in carrying out activities and it is very important to be given an understanding of ergonomic positions, avoid maladaptive movements, improper pelvic movements and avoid unbalanced weight[5]. Treatment that is routinely carried out in the antenatal period can reduce pain in malposition due to back pain experienced by pregnant women[6].

Complaints felt by pregnant women should not be ignored and must get good treatment so that the mother feels comfortable during her pregnancy. Back pain in pregnant women can be given pharmacologically or non-pharmacologically. Efforts to treat pharmacology can be done by administering analgesic drugs, while non-pharmacological management can be done by providing acupuncture, relaxation, massage, distraction and exercise therapy[7]. Efforts to treat pain with pharmacology must be careful and it is necessary to monitor drug side effects that may occur, while handling pain with non-pharmacological safer and does not cause side effects [8].

Many studies suggest that pregnant women often get complaints of back pain which cause the mother to experience disruption in carrying out daily activities. As research conducted by[9]which states that multipara pregnant women with back pain have a significant sleep disorder compared to primiparous mothers. From all pregnant women who experience back pain data obtained 57.7% experience disruption of activity and 77.5% of mothers feel bored undergoing an increasingly old pregnancy[1]also mentions mothers with back pain will experience complaints of pain in the legs, neurological disorders and disorders of elimination both urination and defecation.

Management of warm compresses is part of non-pharmacological therapy that can be given in obstetric cases, women in the antenatal, intranatal and postnatal areas. In giving warm compresses the study subjects showed a significant reduction in pain between before and after the intervention[10]. Giving warm compresses in addition to reducing the level of pain can also increase blood flow to the local tissue[11]. In addition to warm compresses, music therapy can also be done to reduce the level of pain and anxiety. As research conducted by[12]which states that giving stimulation of auditory music therapy can reduce pain.

Research on efforts to overcome complaints of pain with the provision of warm compresses and music therapy is most often performed on mothers who face labor, while for mothers who experience back pain has not been done much. The average researcher gives treatment with warm compresses or just music therapy which then measures the pain level to be able to assess the level of reduction in pain that occurs. In this study a combination of warm compressing and murottal Alquran was part of auditory stimulation for distraction therapy.

2. Methods

This research is a quantitative study that uses quasi-experimental design studies with Two Groups Pretest - Posttest Design with control in 40 research subjects taken through purposive sampling technique in Semarang City, Central Java Province, Indonesia. The treatment given to the research subjects was spiritual intervention and thermal stimulation. Subjects in group I were given interventions to listen to Qur'anic murottal Ar Rahman surah and warm compresses, while the research subjects in group II were given to Qur'anic murottal interventions favorite subject's surah and warm compresses with a duration of 20 minutes.

3. Results

Table 1. Results of frequency distribution of low back pain before intervention in group I and group II pregnant women in Semarang City in 2018 (n = 40).

Pain Level	Group I		Group II	
	f	%	f	%
Mild	0	0	0	0
Moderate	11	55.0	10	50.0
Severe Controlled	9	45.0	10	50.0
Severe not Controlled	0	0	0	0
Total	20	100.0	20	100.0

Table 1. shows that before the intervention most of the research subjects in group I had moderate pain of (55%), while in group II the subjects experienced pain at the moderate and severe levels controlled with the same amount of (50%).

Table 2. Results of frequency distribution of low back pain after intervention in group I and group II pregnant women in Semarang City in 2018 (n = 40).

Pain Level	Group I		Group II	
	f	%	f	%
Mild	19	95.0	19	95.0
Moderate	1	5.0	1	5.0
Severe Controlled	0	0	0	0
Severe not Controlled	0	0	0	0
Total	20	100.0	20	100.0

Table 2. shows that after the intervention, the research subjects in group I and group II showed a decrease in the degree of pain. In both groups the majority of the study subjects were in mild pain as much as 95%

Table 3. Results of the normality test for low back pain in group I pregnant women in Semarang City in 2018(n = 20).

Pain Level	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
Pre	.361	20	.000	.637	20	.000
Post	.538	20	.000	.236	20	.000

Table 3. Shows that data on low back pain in group I pregnant women using the Shapiro-Wilk test obtained a significance value of 0,000 which means the data is not normally distributed.

Table 4. The results of the normality test for low back pain in group II pregnant women in Semarang City in 2018 (n = 20).

Pain Level	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
Pre	.335	20	.000	.641	20	.000

			POS-944			
Post	.538	20	.000	.236	20	.000

Table 4. Shows that the data on the level of low back pain in pregnant women in group II using the Shapiro-Wilk test obtained a significance value of 0,000, which means the data are not normally distributed.

Table 5. Differences in the level of low back pain before and after intervention in group I pregnant women in Semarang City in 2018 (n = 20)

	N	Mean Rank	Sum of Ranks
Negative Ranks	20[a]	10.50	210.00
Positive Ranks	0[b]	.00	.00
Ties	0[c]		
Z			-4.053[b]
Asymp.Sig.(2-tailed)			.000
Total	20		

Table 5. Shows that there was a decrease in back pain in the study subjects from before and after intervention the Qur'anic murottal of Ar-Rahman surah with a mean rank of 10.50. In the results of the study, there were no research subjects who experienced an increase in back pain and none had the same or constant pain level before and after the intervention. The study also shows the results of p value 0,000 which means there are significant differences in the level of back pain in group I before and after intervention. So it can be concluded that there is the effect of giving Qur'anic murottal of Ar-Rahman surah and warm compresses to decrease back pain of pregnant women.

Table 6. Differences in the level of low back pain before and after intervention in group II pregnant women in Semarang City in 2018 (n = 20)

	N	Mean Rank	Sum of Ranks
Negative Ranks	19[a]	10.00	190.00
Positive Ranks	0[b]	.00	.00
Ties	1[c]		
Z			-3.938[b]
Asymp.Sig.(2-tailed)			.000
Total	20		

Table 6. Shows that there was a decrease in pain in 19 research subjects before and after Qur'anic murotal listening intervention with the favorite surah research subject with mean rank 10. Data showed no study subjects had increased back pain and there was 1 study subject who experienced decreased pain but who was still in the same or constant degree of pain. The processing results obtained p value 0,000 so that Ha was accepted, there were differences in back pain before and after intervention in group II research subjects and it can be concluded that there was an influence of listening to murotal surrah and giving warm compresses to decrease back pain.

Table 7. Effectiveness of spiritual interventions and thermal stimulation on decreasing back pain in pregnant women in Semarang City in 2018 (n = 40)

Group	N	Mean Rank	Sum of Ranks
Group I	20	20.50	410.00
Group 2	20	20.50	410.00
p			1.000
Total	40		

Table 7. Shows that the results of processing data are p value 1,000, which means Ha is rejected, meaning that there is no significant difference in decreasing back pain in giving Qur'anic murottal Ar-Rahman surah as spiritual intervention and thermal stimulation by giving Qur'anic murottal favorite subject's surah as spiritual interventions and thermal stimulation. These results mean that Qur'anic murotal spiritual intervention of listening to Ar- Rahman surah and thermal stimulation by giving spiritual intervention, and listening to the subject's favorite surah and thermal stimulation with warm compresses, has the same impact on decreasing back pain in pregnant women.

4. Discussion

Research shows that murotal spiritual intervention of listening to Ar- Rahman surah and thermal stimulation by giving spiritual intervention, and listening to the subject's favorite surah and thermal stimulation with warm compresses, has the same impact on decreasing back pain in pregnant women.

The intervention given to both groups equally significantly affected the reduction of pain in pregnant women.

Spiritual intervention in the form of listening to Qur'anic murrotal is part of distraction therapy. Distraction therapy is a form of therapy that is done to divert attention to other things that can make patients forget about the pain that is felt [13]. Auditory stimulation can affect emotions, activities of the brain and also the nervous system and cardiac output [14].

The auditory interventions provided one of them can be Qur'anic murotal listening. Qur'anic murottal interventions are received by the auditory system, transmitted to the brain which in turn affects the limbic system. Hearing stimulation is accepted by the brain in the midbrain region which stimulates the midbrain to secrete Gama Amino Butyric Acid (GABA), enkepalin and beta endorphin, which act as electric conductive inhibitors, have an analgesic effect and function as a softener. Increased hormone endorphin is able to reduce stress levels and control the pain felt by individuals[15].The use of the Qur'anic murottal stimulation is a simple action to be carried out and optimizes the religious side of the research subject. Qur'anic murottal administration when compared with other auditory therapies such as music has more influence on pain reduction[16]. Patients who experience long-term pain conditions need a spiritual touch to increase their enthusiasm and strength in dealing with their pain.

Providing warm compresses of thermal stimulation has the benefit of increasing the temperature of local skin, promoting blood circulation, stimulating blood vessels, reducing muscle spasm, relieving pain sensations, and providing calm and comfort [17]. Warm water is a means of slowly pumping the heat to the body which has a positive effect. Warm water can also affect the outer body, inner body and blood circulation. Warm temperatures can make a positive value for the body's energy because it has a good influence on cell components which consist of various

electrons, ions and others[18]. Warm water with a temperature of 35-40 ° C has a physiological impact on the body which can prevent muscle spasm and smooth blood flow so as to reduce pain. The water temperature at the time of giving compresses for thermal stimulation must be maintained. Giving compresses can be carried out in between 15 and 20 minutes [19].

The physiological effects of heat therapy can relieve pain, increase blood flow and metabolism and increase the elasticity of connective tissue. Thermal therapy in the form of a warm compress is passed on by the TRPV1 1 TRP nerve transduction receptor (TRPV1), which is a heat receptor. This TRPV1 receptor is in the primary afferent neurons, spinal cord, and throughout the brain. Activation of TRPV1 receptors in the brain can reduce antinociceptive. Heat stimulation in tissues stimulates vasodilation and blood flow to the tissues so that the supply of nutrients and oxygen to the location of pain becomes smooth. This condition increases peripheral metabolism, provides warmth, makes the muscles of the body become more relaxed and reduce pain.

Warm compress therapy is one of the non-pharmacological methods for relieving pain that can be done easily, various variations of giving, using available equipment at any time without the need for complicated skills. But if done correctly, it will have a significant impact on reducing pain [20].

5. Conclusion

The study concluded that spiritual intervention and thermal stimulation were effective for reducing back pain in pregnant women in Semarang City. The provision of spiritual interventions by listening murotal and thermal stimulation by providing warm compresses can make pregnant women experience relaxation back pain. The two interventions support and enhance Mother's comfort so that back pain is significantly reduced.

SPIRITUALITY RELATIONSHIP WITH COGNITIVE FUNCTIONS IN ELDERLY IN THE AGE OF PUCANG GADING SEMARANG

Iwan Ardian, Dian Indah Lestari
Bachelor Nursing Program, Nursing Faculty, Universitas Islam Sultan Agung Semarang

ABSTRACT

Cognitive function is conscious activity includes thinking, remembering, learning and using language. In the elderly cognitive function has decreased. Spirituality means the experience of thinking to bring into contact with God (in other words, not only experiences that feel meaningful). The spiritual qualities of the elderly are very important in order to maintain cognitive function. The purpose of this study was to determine the relationship between spirituality and cognitive function in the elderly at the Pucang Gading Retirement Home Semarang. This research was quantitative research with correlational design. Data collection was done by used the Daily Spiritual Experience Scale (DSES) measure on spirituality and Mini Mental State Examination (MMSE) on cognitive functions. Sampling with total sampling of 75 respondents. The method of data analysis used Spearman test rho.The results of the analysis obtained p value 0,000 (p value <0.05) showed that the relationship of spirituality with cognitive function was significant, whereas for the value of spearman correlation rho 0,861 which showed the direction of positive correlation strength. There is any relationship between spirituality and cognitive function in the elderly at the Pucang Gading Semarang Retirement Home and the direction of a positive correlation strength.

Keywords: cognitive function, elderly, spirituality

1. Introduction

Those aged above 60 years are considered elderly. An elderly person would want to spend time in his old age by living quietly, peacefully and spending time with his beloved grandchildren. But in reality an elderly person is perceived as a burden on his family and society. This fact encourages the assumptions that exist in developing communities that a person who becomes an elderly person will suffer many of the health problems experienced by elderly people. This perception arises because an elderly person can only depend on people who are around and who are often sick (Restiana, 2016).

It should be noted that diseases that exist in an elderly person are cognitive functions. Symptoms often arise in the form of inability to carry out activities independently and these symptoms cause a burden on the family and society. Other symptoms that can arise from impaired cognitive function are social function disorders and a decreased role in work (Mace dan Rabins, 2006)

The number of elderly people on Earth in 2010 amounted to 13.4%, the number of all the elderly population was 924,000,000 (United Nation, 2010). In 2012 the number of elderly people in Indonesia was 6.78% of the total population or around 18.55 million (BPS, 2012). The increase in the number of elderly in the province of Central Java in 2010 was 3,275,069 people and in Semarang reached 67,114 (Hamid, 2007). It is estimated that the number of elderly people in Indonesia continues to surge until 2020, namely 11.09% or more than 29.12 million people with a life expectancy of 70-75 years (Maryam, 2008).

The increase in impaired cognitive function in the elderly will have an impact on his family. Research by Mace and Rabins (2006), states that families who care for elderly people with cognitive

impairment can have physical, psychological or emotional, social and financial impacts. The physical impact is fatigue because family members who care for the elderly will have less rest. The psychological or emotional impact will be caused by anger, anger is caused by fatigue in caring for the elderly with a decline in cognitive function. Whereas the social and financial impacts caused are social isolation due to lack of families interacting with friends and the environment, for the financial impact of the family will surely experience financial difficulties, because the family must treat elderly people with a decline in cognitive function so they cannot work (Mace dan Rabins, 2006).

Spirituality is a relationship that is psychological or spiritual in nature that is distinguished by physical or mental aspects (Hasan, 2006). Spirituality also greatly affects holistic health. The aspect of spirituality is very tight between himself and God as a thanksgiving for the situation that is being traversed. People with maximum religion are also referred to as a way to get closer to God. Maximum spiritual development will make it easier for the elderly to face reality, play an active role in life, and formulate the meaning and purpose of their existence in life (Setyoadi, Noerhamdani and Ermawati, 2011). Based on the description above, the researcher was interested in examining "The Relationship of Spirituality with Cognitive Functions in the Elderly".

Spirituality also plays an important role in the elderly with a decline in cognitive function, Mukarramah's study (2016), states that there is a relationship between the intensity of reading the Koran and cognitive functions in the elderly in Sangiasseri Village that 60 elderly (82.2%) intensity of reading the Qur'an both have good cognitive function with a p value of 0,000. While another study by Handayani, et al. (2012) showed that the elderly boarding school program had an effect on cognitive function, with the results of increasing cognitive function in women as much as 31.25% and in men reaching 60% (Handayani, et, al 2012).

From the results of a study conducted on Wednesday, September 12, 2018 at the Pucang Gading Semarang Elderly Service House, data was obtained that 45 elderly had cognitive impairment from 110 elderly people. The researcher conducted a survey using the interview method, with respondents numbering 5 people. Of the 5 people there were 3 men and 2 women, the results obtained by 2 people had normal cognitive function because respondents answered often to worship, pray, and believe in the existence of God, 2 respondents were also able to mention how long they stayed, able mentioning what year and stay where, the respondent is able to communicate well by answering all questions raised by the researcher. While the other 3 respondents were unable to communicate and did not answer when asked about God.

2. Research Methods

This type of research uses quantitative research with a correlational research design. In this study, researchers wanted to find out the closeness between spirituality and cognitive function in the elderly at the Pucang Gading Elderly Service Home Semarang.

Respondents who were used in this study were all the elderly who were at the Ivory Semarang Old-Age Services Home. This research conducted on 29 October 2018 - 6 November 2018 at 75 respondents.

The research instrument used a demographic questionnaire, the Daily Spiritual Experience Scale (DSES) questionnaire for spirituality and the Mini Mental Examination State (MMSE) questionnaire for cognitive function variables. Demographic questionnaires cover age, gender, and religion.

The DSES questionnaire uses a Likert scale and this statement only consists of Favorable statements. DSES consists of sixteen items. Fifteen items have six answer choices, namely often = 6, every day = 5, almost every day = 4, sometimes = 3, rarely = 2, never = 1. A number sixteen consists of four answer choices namely very not close = 1, close enough = 2, close = 3 and always close = 4. A number sixteen is an additional item to support the research subject's response. Interpretation for 15 statements: 15-40 = low spiritual level, 41-65 = moderate spiritual level, 66-90

= high spirituality level. The statement of 16 interpretations, namely the value 1 = not at all, 2-rather close, 3 = very close, 4 = as close as possible.

The MMSE questionnaire consisted of 11 statements in a favorable form using a Likert scale with the choice of answers: orientation = 10, registration = 3, attention and calculation = 5, considering = 3, language = 9. The interpretation was scores 0-17 = weight, 18-23 = medium, 24-30 = normal.

3. Results

A. Univariate Analysis

1. Age

Table 4.4 Frequency distribution of elderly at the Pucang Gading Elderly Home Semarang (n = 75)

Age	total	Percentage (%)
60-74	50	66,7
75-94	25	33,3
Total	75	100,0

Based on table 4.1, it can be seen that the elderly in homes with advanced age for pucang gading semarang are more in the 60-74 year old group, amounting to 50 respondents (66.7%) while the elderly with 75-90 years old are 25 respondents (33.3%)

The results of the study showed that the age of the respondents was the most in the age group 60-74 years i.e. 50 respondents from 75 respondents or 66.7%. The survey results of the Badan Pusat Statistik Kota Semarang (2017), showed that the age group in the range of 60-74 years was 83,949 elderly, that number was greater than the 75-90 year age group, which only amounted to 21,816 elderly.

It can be interpreted that the majority of the elderly with the age group 60-74 years is greater. This result is also in line with the research from Coresa & Ngestiningsih (2017), showing that the respondents at most are aged 60-74 years and were 30 respondents out of 41.

2. Gender

Table 4.2 Frequency distribution of elderly sex at the Pucang Gading Elderly Hospital Semarang (n = 75)

Gender	Frequency	Percentage (%)
Man	28	37,3
Women	47	62,7
Total	75	100,0

Based on table 4.2 shows the data on male sex is fewer, namely 28 respondents (37.3%) while the number of female elderly is 47 respondents (62.7%).

The gender of 75 respondents was dominated by women, at 47 respondents or 62.7%. And according to the Semarang City Central Bureau of Statistics (2017), the number of elderly people is also dominated by women at 58,614 people while in men there are 47,151 people. This is supported by research from Coresa & Ngestiningsih (2017), that the number of female sex is 31 elderly from 41 respondents.

It can be concluded that female respondents are found more often than men, so that the opportunities men have are fewer than women.

3. Religion

Table 4.3. Elderly religious frequency distribution at Pucang Gading Elderly Service Center Semarang (n = 75)

Religion	frequency	Percentage (%)
Islam	66	88,0
Kristen	6	8,0
Katolik	2	2,7
Budha	1	1,3
Total	75	100,0

Based on table 4.3 respondents who have more Islamic religion are 66 respondents (88%), Christians 6 respondents (8%), Catholics 2 respondents (2.7%) while Buddhists only 1 respondent (1.3).

The results of the study showed that almost all respondents were Muslim, at 66 respondents (88%) from 75 respondents.

The survey results of the Semarang City Central Bureau of Statistics (2018), the followers of the largest religion in Central Java are Islam with a total of 32,235,239 people. This is in line with the results of research that shows that the majority of elderly people are Muslim.

4. Spirituality in the Elderly

Table 4.4. Frequency distribution of elderly spirituality at the Pucang Gading Semarang Elderly Service Home (n = 75)

Spirituality	frequency	Percentage (%)
Low	32	42,7
The Middle	17	22,7
High	26	34,6
Total	75	100,0

The results of the study prove that from 75 respondents who had low spirituality, there were 32 respondents, or 42.7%. According to Azizah (2011), spiritual change is seen from the religious level of the elderly who are increasingly integrated, and regularly in their lives.

But in reality spirituality experienced by the elderly experiences low spirituality, this is because

the elderly experience physical changes and health status. According to Smeltzer & Barre (2002), someone with increasing age has various weaknesses in physical function and the appearance of disease.

In UU RI No 6 2015 concerning the Implementation of Social Welfare of the Governor of Central Java, Article 13 paragraph 2 point D concerning social rehabilitation is given in the form of spiritual mental guidance spirit in the service provided (Puspita, 2009). A holistic approach requires a nurse to look at the individual as a whole including physiological, psychological, sociocultural and spiritual aspects. But in reality nurses who are at the Pucang Gading Semarang Elderly Service House rarely touch on the spiritual aspects, for example not facilitating the elderly who cannot stand up to sit or lie down and not pay attention to the place in a sacred condition. It is hoped that the Pucang Gading Semarang Elderly Service House will provide services in the form of spiritual guidance that has been mentioned in the law so that the elderly can get their rights and with spiritual experiences can reduce impaired cognitive function.

5. Cognitive Functions in the Elderly

Table 4.5. The frequency distribution of cognitive function in elderly people at the elderly pucang gading semarang (n = 75)

Cognitive Functions	Frequency	Percentage (%)
Normal	23	30,7
Middle	14	18,7
Weight	28	50,6
Total	75	100,0

Based on table 4.5 shows that the majority of respondents experienced severe cognitive impairment which amounted to 38 respondents (50.7%), while respondents who were still in the normal category amounted to 23 respondents (30.7%) and moderate 14 respondents (18.7%).

The results showed that respondents who had severe cognitive function amounted to 38 respondents (50.7%) from 75 respondents. This is supported by other studies taken at the same place by Coresa & Ngestiningsih (2017), finding results that elderly with severe cognitive impairment were 60.9%.

Factors that influence the cognitive function of the elderly at the Advanced Pucang Gading Hospital in Semarang have severe cognitive function, one of which is age, low level of education, and lack of exercise or lack of activity. This is evidenced by the research of Maryati et al. (2013) that influences changes in cognitive function including age and level of education. Decreasing cognitive function can also be minimized by physical fitness exercises, because the elderly who are active in performing physical fitness exercises and having hobbies presents a great opportunity to experience normal cognitive function (Lanawati et al. 2015).

B. Bivariate Analysis

Table 4.6. The results of spirituality correlation with cognitive function of the elderly at the Pucang Gading Semarang Elderly Service House using the *Spearman Rho* test (n=75)

		Cognitive Functions					
		Weight	Middle	Normal	Total	P value	r
Spirituality	Low	32	0	0	32		
	Middle	3	13	1	17	0,000	
	High	3	1	22		0,861**	

					26
Total		38	14	23	75

**. Correlation is significant at the 0.01 level (2-tailed).

Table 4.6 shows that the value of ρ value 0,000 <0,05 which shows the correlation between spirituality and cognitive function is meaningful. The hypothesis results show that the significant level <α then H0 is rejected and Ha is accepted. The spearman correlation value of 0.861 shows that the direction of positive correlation with the strength of the correlation is very strong, which means the higher the spirituality of normal cognitive function.

This is supported by previous research conducted by Sunardi, et al. (2017) regarding the Relationship between Spiritual Level and Elderly Cognitive Function in Pangesti Lawang Nursing Home Area with a value of 0.471 and a sig value of 0.008. Vifonissi, et al (2018) also stated that there was a positive relationship between spiritual intelligence and students' cognitive learning outcomes.

According to Handayani, et al. (2012) the way to reduce the risk of decreasing cognitive function in the elderly is by the elderly boarding program, because after attending the three-month old boarding school program the elderly experience an increase in cognitive function. This means someone who has a high spirituality can influence cognitive function to be normal, because by making efforts to improve spirituality such as reading the Qur'an and prayer there is an activity of reading and remembering.

Recent studies on spirituality use sophisticated tools called SPECT (Single Photon Emission Computed Tomograhy) by Andrew Newberg and Eugene D'Aquili in Habibi and Asbi (2015), to observe people who are meditating. The results of their research were recorded in four books and a number of articles. In summary, they introduced the term cognitive operators to refer to a number of areas responsible for spirituality.

The evaluation conducted by Ghozali (2007) that the Pucang Gading Semarang Elderly Service House still lacks in providing services such as a barracks-shaped building because ideally a cottage-shaped building, a polyclinic is still less representative, and a lack of specialized Gerontik nurses based on needs holistically which overcomes the elderly problem, especially in this case, namely the spiritual aspect.

According to Darmawan (2014), there is a need for legal protection for the elderly as stipulated in the regional regulations regarding the implementation of elderly welfare in Central Java as an effort to improve social welfare which is realized for all citizens in fulfilling material, spiritual and social needs so that they have a decent life and are able to develop themselves, so that they can carry out their social functions well. Because in this case the regional regulations that already exist in the Central Java Provincial Government are still partial.

Newberg (2009), studies brain function in people who meditate or pray. He argues that mystical and spiritual experiences can be measured and explained through complex anatomical pathways. The frontal lobe is one of the parts most affected by religious activity. Newberg focuses on the prefrontal cortex and its relationship to the thalamus, posterior superior lobe and limbic system (especially the amygdala and hippocampus), by measuring blood flow in Newberg's conclusion that the more an individual enters a spiritual or religious activity the more active the frontal lobe and limbic system .

The frontal lobe is a part that plays an important role in concentration and attention and the limbic system is a part where emotions and feelings and behavior are regulated. Interestingly, when the frontal lobe and limbic system are active, the parietal lobe becomes less active. Studies conducted by assessing brain activity using a topographical electroencephalogram, cerebral blood flow or cerebral metabolism showed that there was an increase in temporal lobe activity during religious activities. The autonomic nervous system (sympathetic and parasympathetic) also experiences

significant activity during meditation and other spiritual activities. Activation that occurs in the autonomic nervous system causes a decrease in heart rate and breathing rate is the effect of relaxed feeling and can calm anxious limbic and transient structures strengthen the neural connection and synaptic relationships located in the pre-frontal cortex (Bingaman, 2015).

From the theory that has been explained, it can be concluded that those who regulate cognitive and spiritual systems work together so that the two systems influence each other, if one of the systems is interrupted then the other system is interrupted.

5. Conclusion

Spirituality with cognitive function in the elderly at the Pucang Gading Semarang Elderly Service House has a very close relationship. The higher the level of spirituality, the better cognitive function. Good spirituality also affects the physical aspects such as orientation, registration, attention and calculation, language and visual construction, memory so that it can reduce the problem of cognitive function disorders in the elderly.
