PREFACE

Praise the presence of Allah SWT, for his mercy so that Faculty of Nursing Universitas Airlangga can produced the proceedings of the 10th International Nursing Conference with the theme "Tropical Health Coastal Region Development". This conference was held on 6-7 April 2019 in Surabaya

This proceeding book contains a number of research articles and literature reviews in the fields of nursing and health. The article is the work of health workers and practitioners outside of health who have an interest in health. The article in this proceeding was presented at the 10th International Nursing Conference event at the Grand Mercure Hotel Surabaya

Hopefully this proceeding book can provide benefits for the development of science, policy, methods of intervention and technology, especially in the field of nursing. In addition, this proceeding is expected to also be a reference for the development of Indonesia's health sector. Finally, we thank all those who have played a role and participated in this international conference. We apologize for the things that are not pleasing. We will wait for constructive suggestions and criticism for the sake of the perfection of this proceeding books.

Surabaya, Desember 2019

Chairman of 10th INC

GREETING FROM THE CHAIR PERSON OF THE 10th INC 2019

Assalamu'alaikum Warahmatullahi Wabarakatuh

The honorable Rector of Universitas Airlangga
The honorable Dean of Faculty of Nursing, Universitas Airlangga
The honorable Head of Co-Host Institutions
Distinguished Speakers and all Participants

Praise the presence of Allah SWT, for his mercy so that Faculty of Nursing Universitas Airlangga can organized The The 10th International Nursing Conference 2019 "Tropical Health Coastal Region Development". Welcome to Surabaya, The City of Heroes Indonesia. On behalf of the Organizing Committee. I would like to extend our warmest welcome to you at The 10th INC 2019. This annual conference is the tenth event after the ninth has been successfully conducted in 2018.

This conference is organized by Faculty of Nursing Universitas Airlangga with cooperation of three nursing institutions throughout the nation. These institutions including, Universitas Islam Sultan Agung Semarang, STIKES Pemkab Jombang, and Universitas Muhammadiyah Surabaya. Once more aims to elaborate with the aforementioned institutions and international universities through holding an international nursing conference. The international universities include: La Trobe University (Australia), University of Malaya (Malaysia), National Cheng Kung University (Taiwan) and Edinburgh University (Scotland).

The conference aims to provide a forum for researchers, lecturers, nurses, students both from clinical and educational setting, regional and overseas area. We have accepted 333 abstracts for oral and poster presentation coming from different universities from many countries. Moreover, I would like to announce that Proceeding of this International Nursing Conference will be submitted to SCOPUS. The selected papers will be submit at Journal Ners and online ISSN proceeding.

The committee extent very kind thank to all participants for the success of the conference. Finally the success of this conference lies not only in the quality of papers but also on the dedicated team work of the organizing and scientific committee. Finally, I would like to thanks to all speakers, participants, and sponsors from Jaya Kelana Abadi CV so that this conference can be held successfully. Please enjoy the international conference, I hope we all have a wonderful time at the conference. Thank you.

Wassalamu 'alaikum Warahmatullohi Wabarokatuh

Dr. Abu Bakar, M.Kep., Ns., Sp.Kep.MB
The 10th INC 2019 Chair Person

OPENING REMARK FROM THE DEAN OF FACULTY OF NURSING

Assalamu'alaikum Warahmatullahi Wabarakatuh

The Honorable Rector of Universitas Airlangga, The Honorable Head of Co-Host Institutions, The Honorable Chief of Indonesian National Nurses Association (INNA), The Honorable Chief of Association of Indonesian Nurse Education Center (AINEC), Distinguished Speakers, and All Participants.

First of all, I would like to praises and thanks to Allah SWT for the blessing and giving us the grace to be here in a good health and can hold this conference together.

Secondly, it is a great privilege and honor for us to welcome every one and thank you for your participation and support for The 10th International Nursing Conference 2019 "Tropical Health Coastal Region Development". The INC topics presented in this conference cover Public Health and Policy, Epidemiology, Food Nutrition and Health, Medical Microbiology, Molecular Biology, Pharmacological Aspect and Treatment, Tropical Diseases, Helath Law and Policy.

The Industrial Revolution 4.0 is a new challenge not only in technology but also in the field of tropical health coastal region development. Industrial Revolution in Indonesia starting with improving the competence of human resources through the link and program match between industrial education. Faculty of Nursing Universitas Airlangga got accreditation A (Excellent) for Bachelor and Master Degree. We already got accreditation of AUN (ASEAN University Network). Today, we are preparing for next Accreditation Agency for Degree Programs in Engineering, Informatics/Computer Science, the Natural Sciences and Mathematics (ASIIN)'s international accreditation. Most of our lecturer already have Scopus ID and we have many of doctoral degree lecturers. We will launch Double Degree Joint Program with University of Malaya for Master Degree and with La Trobe University for Doctoral Degree soon. We have own jurnal that is Jurnal Ners which has been accredited as a 2nd Grade Scientific Journal by the Ministry of Science, Research, Technology and Higher Education of Indonesia since 2010. Jurnal Ners indexed in major databases, such as Directory of Open Access Journal (DOAJ), Index Copernicus International (ICI), ASEAN Citation Index (ACI), PKP Index, Science and Technology Index (SINTA), WorldCat, Indonesian Publication Index (IPI), Google Scholar, Bielefeld Academic Search Engine (BASE), and will be indexed by SCOPUS soon.

Along with Universitas Airlangga vision to become a world class university and enter top World University Ranking, Faculty of Nursing, participates actively in reaching the vision. To achieve World Class University ranking, faculty needs to meet the standards of World's top Universities such as Academic reputation, employer reputation, publication, faculty standard ratio, international students and exchange. International Nursing Conference is one of the few strategies that have been implemented by the faculty to increase publication standard.

Finally, I would like to thanks to all speakers, participants, and sponsors that helped the success of this event. I hope that this conference having good contribution in increasing the quality of research. Many thanks to the organizing and scientific committee of INC 2019 who have worked very hard to run the conference. We thank our participants to present their research papers, to share extensively and exchange of ideas thoughts and discussions so that this conference facilitates the formation of networks among participants. Please enjoy the international conference. I hope, we all have a wonderful time at the conference and your presence in Surabaya would be a memorable one. Thank you.

Wassalamualaikum Warahmatullahi Wabarakatuh
Prof. Dr. Nursalam, M.Nurs (Hons)
Dean, Faculty of Nursing Universitas Airlangga

WELCOME SPEECH FOR PROCEEDING BOOK OF THE 10 INTERNATIONAL NURSING CONFERENCE 2019 BY RECTOR OF UNIVERSITAS AIRLANGGA

Universitas Airlangga is strongly committed to significantly contribute to the development of health science globally by providing quality academic engagements. This includes improving our teaching-learning processes, academic mobility, research activities as well as community development. Aligned with this aim, it is a great honour for Universitas Airlangga to host The 10th International Nursing Conference 2019 "Tropical Health Coastal Region Development"

We are now in the Industrial Revolution 4.0 at which we must be prepared for a disruption era of technology. Referring to the medical and health problems and the disruptions, we all have to be ready to combine physical domains, digital, and biology. This combination leads to Artificial intelligence, new materials, big data, robotics, nanotech and biotech, augmented reality and genetic editing. We will face constant changes, uncertain and unpredictable future where there will be a deep shift from physical to virtual, human to automation and robotic, and intermediacy to disintermediacy. I believe at this moment we are facing these shifts in the medicine and health sciences. Thus, the conference focuses on Tropical Health Coastal Region Development.

The conference is addressed to answer global challenges on how universities, institutions, organizations in higher education can give their contributions to the global medical, health, and policy issues that have been emerging for years. This conference invites more than one hundred scholars including academics, researchers, and professionals from all over the world, to share their ideas, thoughts and current research. Thank you for the warm support given by our partners and our faculty of nursing for the purpose of strengthening academic and research collaboration through this conference. Universitas Airlangga is hoping that this collaboration will continue to be fruitful for many years ahead, and bring success to you and Universitas Airlangga.

This conference brings all scholars to work together, coming up with excellent ideas presented in plenary and parallel sessions. In addition, they can expand their networking for future collaborations that support the development of medical and health sciences. All in all, I hope that this conference will not only give insights to all of the parties, but it will also provide us more enlightenment to answer the challenges on the medical and health issues.

Thank you very much for your kind attention.

ABSTRACT

Family caregiver as informal caregiver are the most important person who cares for elderly with schizophrenia. About one in seven schizophrenia patients is older than 65 years, and the number of elderly with schizophrenia will increased. Changes associated with aging (e.g.,physical illness, cognitive impairment, social losses) may generate new care needs or modify existing ones. This cause a high burden who care of elderly with schizophrenia. The purpose was to review concept and factors related to burden on family caregivers caring for elderly with schizophrenia. A literatures were searched from databases: SCOPUS, Pubmed, CINAHL, and Science Direct. Articles were found 1016 articles and 15 articles that match the inclusion criteria. Keywords used to retrieve literature include caregiver, burden, schizophrenia, elderly. Searching was limited in English language, full text published, and the year of publication from 2013 to 2018. The result showed that the caregivers caring for elderly with schizophrenia experience burden. Burden was defined as a negative impact of caring. Generally two kinds of burden; objective and subjective burden that involves emotional, physical health, social life, and financial status. Factors related caregiver burden on family caring elderly with schizophrenia were : caregiver's factors, patient's factors and environmental factors.

Keywords: caregiver, burden, schizophrenia, elderly

1. Background

Aging is a global trend [1]. Roughly one in seven schizophrenia patients are older than 65 years. The number of elderly patients with schizophrenia will double within two decades[2]. The changes associated with aging (e.g., physical illness, cognitive impairment, social losses) may generate new care needs or modify existing ones[2]. This will cause a high burden for those who care for the elderly with schizophrenia.

Schizophrenia dramatically affects not only the patients suffering from it but also their family members [3]. The life morbidity risk for schizophrenia is approximately 1% (mean/median 11/7 per 1000), the median point prevalence per 1000 is 4.6 (10, 90 percent quantiles 1.9, 10.0), and the median yearly incidence per 100.000 is 15.2 (10, 90 percent

quantiles 7.7, 43.0)[1]. Family caregivers as informal caregivers are the most important person who cares for the elderly with schizophrenia [4].

People with schizophrenia often cannot fulfill the expected roles in their families and communities. They experience difficulties and need constant care and support from their families. This is because most schizophrenic patients live with their families who have the responsibility to provide care[5].

Asian families are the main caregivers who provide care for people with mental disorders [6]. Families experience physical, emotional and financial problems (living expenses, medication and transportation) due to the patient's abnormal behavior, the patient's inability to support himself and the patient's social dysfunction[7].The need for care to be provided and the need to overcome the client's behavioral difficulties results in changes in the family dynamics. These changes cause stress to the family members, especially the family caregivers who live with their patients. This is because it will reduce their ability to provide care and support for other families [8].

2. Method

The journal search strategy began by asking the research question, "How is problems, burden, stress and anxiety felt by the family providing care for the elderly with schizophrenia?" This review was based on articles obtained from the published literature in international journals. Online references were searched in the following databases and aggregators: ProQuest, SCOPUS, Ebsco Cinahl and ScienceDirect. The journal search strategy was conducted using the following keywords: caregiver, burden, schizophrenia and elderly. The journals were restricted to those obtained including the articles published between 2013-2018, the articles published in the English language, focused on the nursing area and where the full text was published.

This article aims to review the contained articles by systematically exploring the articles and conducting a critical assessment of the articles that discussed the caregiver burden on families providing care for the elderly with schizophrenia. This review included the articles that matched the inclusion criteria: (1) quantitative or qualitative studies, (2) the sample consisted of families as the caregivers who care for a schizophrenic client and where the patient has mental disorders according to DSM-IV, (3) articles published in English and (4) the full text is published.

The data was extracted from the full text of the studies that met the inclusion criteria. The excluded studies included there being a formal caregiver, it being a hospital-based study and no schizophrenic diagnosis.

The risk of bias was assessed using Cochrane Collaboration's tool for assessing risk of bias [9]. This assesses selection bias, which covers the method of random sequence generation and allocation concealment prior to assignment, performance bias which covers the blinding of the participants and study personnel, detection bias which covers the blinding of the outcome assessors, attrition bias which covers the level, nature and handling of the incomplete outcome data and reporting bias, which covers selective outcome reporting.

The data related to the objectives of the review in the articles has been recorded and presented. The data consisted of the demographic data, intervention data and other data relating or related to the study conducted. Although in this review we did not show the meta-analysis of the review, the data was very encouraging in terms of evaluating the results of the studies carried out by making it easier to improve the review process.

3. Results

The results of this review will explain and contain the results and study selection process, the study characteristics, the characteristics of the participants and the results of the study review. The search obtained as many as 1016 articles from the four databases. There were 256 articles from Science Direct, 362 articles from Ebsco, 246 articles from ProQuest and 152 articles from Scopus. The details of the identification and journal selection process can be seen in Figure 1. The results of the appropriate article selection were then given serial numbers to facilitate the review.

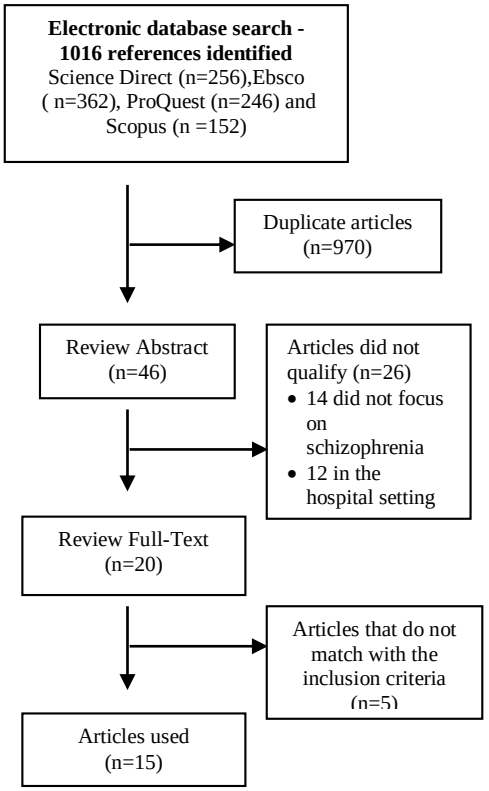

Fig 1. Flow diagram of the study selection.

This study reviewed 15 articles that matched the inclusion criteria. This articles included cross-sectional and qualitative studies: 14 articles used a cross-sectional study ([6][3][4][7][10][11][12][13][14][15][16][17][18]) and 1 article was qualitative [19]. The articles came from several countries: India had 4 articles[6][7][10][11], Spain had 1 article [3],

NewYork had 1 article[19], Turkey had 1 article[16], Brazil had 1 article[4], South Africa had 1 article[13], Arica Chile had 2 articles[15][8] and 4 articles came from China[12][14][18][17].

Most studies in this review were conducted with the parents, spouses[3] and family caregivers of schizophrenia patients in the community[14], as they were the main caregiver of the family [4]. The primary caregiver was identified as the person who provided the most support, thus devoting the largest number of hours each day to taking care of the patient[18].

Most articles defined burden as a negative result experienced when providing care for someone whose condition is disturbed[8][15][20]. These negative experiences in turn have a negative impact [13].

Caregiver burden is the extent to which the caregiver feels a negative emotional condition, impaired physical health, social life and financial status when providing care for their client [8][11].

Several studies have shown that families who care for family members with schizophrenia experience a high burden. Caregiver burden is defined as a psychological condition plus a combination of physical, emotional and social stresses, such as the economic limitations that arise as a result of caring for patients [8][11].

The term 'burden of care' is used to describe the consequences or adverse effects of caring for patients with mental disorders felt by the family caregivers [20].

The burden of care in recent years has been expanded, and it now involves the physical, psychological, social and financial problems experienced by the families caring their for relatives with chronic or mental illness [11][13].

Following the review of the articles, generally there are two kinds of burden: objective burden and subjective burden[3]. Objective burden refers to the consequences of the caregiving tasks on the caregivers' household activities, such as their economic resources, health and free time activities[3][4][11]. Subjective burden refers to the emotional burden of care, such as feelings of guilt, worries about the future[4][11], the caregivers' negative appraisal of their circumstances and feelings of loss, guilt, shame and anger[3].

Some studies have showed that there are several factors that influence the level burden of the family providing care, which includes the patient's condition, gender, the client's level of disability, family coping, a sense of coherence, level of education, level of income and marital status [3][4][7][10][13].

Based on a review of the articles, the global factors that influence the burden are the caregiver factors[3][13], client factors[10][4][13] and environmental factors, primarily social support (family and friends), satisfaction with the support provided by professionals and the accessibility of care resources[3][13].

4. Discussion

The need for care provided to older adults with schizophrenia results in changes in the family dynamics. These changes cause stress to the family members, especially the family caregivers who live with their patients. This is because it will reduce their ability to provide care and support to other families. The caregiving situation can be defined as the caregivers'

perception of the burden based on how they are impacted by evaluating and assimilating the patient care needs[3].

The results showed that most of the families of patients with schizophrenia experience a high level of burden[10][13][15][21].

Overall, the definition of burden is the same as negative effects while caring for people who are sick (schizophrenic client). The impact can be on the household (objective burden) or on the feelings involved (subjective burden). Burden is known as the physical, psychological, emotional, social and financial problems felt by the family when caring for schizophrenic clients [8][20][19][11][7][13][4][22][10][18].

Most of the articles classified there as being two kinds of burden; objective burden and subjective burden[3][8]. Objective burden explained in detail includes ignoring other family members, the disruption of the family in social relations, marriage problems, disruption and obstacles in terms of daily social activities, relaxing, social isolation and a lack of social support, the withdrawal of support or a loss of contact with their friends, family and neighbors, a loss of employment, income or decreased productivity/increased absenteeism, increased medical costs and financial problems, increased workload and taking over tasks such as shopping, repairing, washing clothes and small tasks, changing household routines, ignoring hobbies, difficulties in going on vacation, difficulties in inviting people into the home, obligations to supervise and having to accompany the patients outside the home, having a chaotic lifestyle and poor quality of life, needing ongoing care services and experiencing disease-related stigma [13].

Subjective burden describes guilt and self-blame because they do not recognize the symptoms early and / or because of the causes of the disease. There is also apathy and the rejection of disease, feelings of loss (from potential family members due to illness), worry especially about the patient's future, fear (especially violence), tension, anxiety, grieving, sadness, crying and stress, which causes depression. The problems of emotional well-being include mental health and psychological morbidity, while the physical problems include withdrawal, revenge, confusion, a loss of hopeless control and frustration, in addition to helplessness and despair, loneliness and emptiness, shame in social situations, humiliation and the feeling of not having the power to influence the disease even if they have to sacrifice themselves. They also feel unable to care for thir patients adequately, in addition to motional fatigue and the confusion of the increased energy released to overcome the behavior of the patients with psychotic symptoms, poor self-care, poor medication adherence, a lack of sleep, low self-esteem, a feeling of inferiority, feeling marginalized and lacking support[13][19].

Based on this review, there are several factors associated with the burden. These factors include the caregiver’s demographic factors, such as gender, economic status, occupation and the time spent per day caring for the client [3][13][10]. Clients with schizophrenia may experience disturbances in their thought process that affect their behavior. Their behavior is strange and sometimes dangerous for themselves, such as suicide ideation[13][23] or violence to her/himself and/or to others [13]. In addition, the disease can recur during treatment and recovery[24].

Patients with schizophrenia are often hospitalized and usually require long-term care and treatment. Although there are several factors associated with the burden of caring for people with schizophrenia, the most important is how the caregivers are able to use coping techniques and utilize social support [7]. Both of these factors acts as a buffer for stressors[6][10]. In addition, strategies to overcome and receive more practical support from their social networks have been shown to reduce the family burden over time [13].

Regarding age, several articles reported that, when looking into the families caring for family members with schizophrenia in China, the results showed that caregiver age was positively correlated with caregiver burden. When the caregivers were the oldest, they were worried about who would continue on the caring in the future[12]. Older carers are unable to provide good care for their sick family members. The age of the caregivers when they are younger have better human senses while caring for their sick family members [11][12].

Concerning gender, women have higher scores in terms of burden and depression. Women are dominant in terms of spending more time caring[10][12].

Several articles have investigated the relationship between the caregiver's demographic characteristics and the family when providing care for their family members with schizophrenia in China[16][25]. The results showed that level of education had a negative correlation with the burden of care. It is assumed that the higher the level of education, the higher the salary that will be obtained. A high salary will reduce the financial problems related to care for sick family members[12][13][25]. The education level of the caregivers also tends to indicate that have more knowledge to deal with tense events. Therefore the level of caregiver education affects the burden of care[26].

Several studies showed that a low income was associated with a higher level of burden on the caregivers[13][7]. Having a lower income is a stressor that affects the feelings of stress while providing care for sick family members. In addition to the caregivers who care for sick family members, they also have to solve their financial problems and find sources of money[27].

The best predictor of caregiver burden is health status [25][28]. Caregivers with a good health status find that the perceived level of subjective burden will be lower.

The time spent caring per day is related to the overall burden. There is a significant positive correlation between the hours of care per day and the caregiver burden. The higher the number of hours spent giving care per day, the greater the burden of care [12][13][29]. The more time that is spent caring, the more that the objective burden felt by the caregivers is higher. This is have they have less time for themselves. Finally, it has an impact on the burden of the caregivers in carrying out their daily activities [25].

The client factor that influences burden is the age of the client. There is a correlation between the age of the client and the subjective burden felt by the caregivers. Young patients with schizophrenia have not be able to care for themselves, and they may only be in the early stages of the disease[13][22][25]. One of the articles described schizophrenia in the elderly as a more complex problem concerning the aging process and about the signs and symptoms of psychosis[2]. Both younger and more elderly patients with schizophrenia are significantly associated with a higher level of burden.

Clinical symptoms and disability has an influence on caregiver burden. Some of the previous studies have found that clinical symptoms and disabilities are the predictors of caregiver burden[11][12]. Positive symptoms cause a higher burden than negative symptoms[4]. Other factors that influence burden include the severity of the patient[28].

For the availability of health services and the utilization of health services[3], a previous research study focused on 333 caregivers in Germany and 170 British caregivers with schizophrenia to compare the burden experienced by the caregivers in the different countries. The results showed that the British caregivers were more burdened with care than the German caregivers. The main cause of the differences in burden was the difference in the provision of mental health services. Germany has an average of 7.5 psychiatric beds per 10,000 inhabitants while the UK only has 5.8. Therefore, the care needs are not being met[30].

For social and family support, the results showed that perceived social support and perceived family function had a negative correlation with the burden of care. Good family functions have an impact on the better ability to adapt associated with effective preventions. The use of formal support received has a positive correlation with burden. The care burden will increase when the informal support cannot meet the needs of the caregivers[11][12][29]. Reduction burden was found in the families who received social support[6][13].

All of the articles reviewed had the same result, in that the family caregiver caring for people with schizophrenia experienced a high burden, and that there are many factors that can influence the level of burden. The findings of this review indicate that the articles have implications for nursing and research practices.

In the area of nursing practice, this will provide basic information for the nurses, specially nurses in the community who are providing appropriate care to the family as caregivers to reduce the burden while the caregiver is caring for their family member with schizophrenia. For further research, it is expected for the researcher to investigate how the caregivers can reduce the burden, such as the use of different kinds of family support, social support and the determination of the best intervention to reduce the burden on the family caring for the elderly with schizophrenia.

5. Conclusion

The results of the review of the articles showed that the family caregivers who cared for older adults with schizophrenia experienced a high burden. For most of the articles, the definition of burden was the same. Burden was the negative impact incurred while caring for a family member who is sick involving physical, psychological, social and financial factors. There are two kinds of burden, namely objective and subjective. There are many factors that influence caregiver burden, including socio-demographics, the characteristics of the caregivers, the patient factors and the environmental factors.

Some studies cannot be generalized because of the different cultures involved. The previous research was conducted in Western countries and on small research samples.

E-mail: agustinha-soares-2018@fkp.unair.ac.id

ABSTRACT

Out-of-Hospital Cardiac Arrest (OHCA) is a major problem causing death outside the hospital and also is a challenge for health workers. Various factors that influence the rate of safety of OHCA patients need to be considered so that the provision of assistance can run optimally. Thepurpose of writing this article is to find ou survival rates in OHCA patients and what factors influence them.The method used is a systematic review of factors that affect the survival rate in OHCA patients. Article searches were conducted on several databases, Scopus, Science direct, Pubmed, and Proques. From the results of a review of 17 selected articles it was found that the survival rate varied between 4.1% and 50.5% with the most influencing factors found in the selected articles, namely:- trained helper, speed of time response, prehospital defibrilation,duration of CPR, female sex, and non-trauma cases. Factors involved in determining the survival rate in OHCA patient are trained helper factors, the speed of give help,and the technique of giving heart pulmonary resuscitation.

Keywords: out of hospital cardiac arrest, survival rate, predicting factor, cardiopulmonary resuscitation

1. Introduction

Out-of-Hospital Cardiac Arrest (OHCA) is a major problem causing death outside of the hospital and it is a challenge for the health personnel system [1]. OHCA is also a major health problem that occurs in the community. The delivery of patients using ambulances quickly followed by cardiopulmonary resuscitation (CPR) and defibrillation by emergency medical service providers is the most important thing [2].

Overall, the survival of the patients admitted to hospital with ongoing CPR was very poor, because 39.2% of patients did not survive and CPR was stopped [3]. Out of hospital cardiac arrest (OHCA) is the leading cause of death within the context of hospital mortality, which is 70% [4]. OCHA which is unknown and immediately taken to hospital by lay people has a poor universal outcome [5].

The high mortality rate of OHCA patients is influenced by many factors: the first is their personal characteristics, such as age, sex, and comorbidity. Other factors like response time, transport distance, population density, and rural-urban differences are present. [6]'s study found out some of the positive linkages that affected OHCA survival including sex, events that occurred in the public area, exposure to an automated external defibrillator (AED), the use of the laryngeal mask airway (LMA), non-traumatic patients and ambulances passing by the house [6].

Actual CPR can actually increase the chances of the patients staying alive, but it is also necessary to know the factors that influence the outcome of help when performing CPR in OHCA

patients. Efforts need to be made to increase the awareness and empowerment of lay people in providing early CPR assistance before the arrival of ambulances or medical teams [7]. This study aims to determine the survival rate in OHCA patients and the factors that affect all OHCA patients, incluided events due to tobacco use, overweight, elevated blood pressure, blood cholesterol and diabetes.

2. Research Methods

2.1. Data sources and search

The journal search strategy began with asking the research question, namely "What factors influence the survival rate in OHCA patients?" The databases used for the journal searches were Scopus, PubMed, Science Direct and Proquest databases. The keywords used were "out of cardiac arrest hospital" AND "survival rate" AND "predicting factor" AND "cardiopulmonary resuscitation". The journals were limited to 2014 – 2018 for the publication years with areas of nursing, medicine, and English-language journals.

2.2. Article selection criteria

The feasibility of the study was assessed using the PICOT approach. The study population consisted of OHCA patients. The intervention used was the provision of CPR. Comparison - Output: OHCA patient survival rate and the factors that influence it.

The study inclusion criteria consisted of 1) survival rate in adult OHCA patients, 2) the factors that affect survival in adult patients and 3) pulmonary cardiac resuscitation techniques that affect the survival rate of OHCA patients.

2.3. Exclusion data

Research exclusion criteria refers to articles that discuss patients with cardiac arrest that occur inside the hospital and to OHCA patients that do not get help.

The authors searched for articles published in the Scopus, Pubmed, and ScienceDirect databases and found 29 articles approprite to the topics. Then the authors chose 17 articles by excluding articles that did not meet the inclusion criteria.

2.4. Research design

Of the 17 selected articles, most of them used a cross-sectional, cohort, retrospective and experimental design.

3. Results

This systematic review reviewed 17 selected articles originating from 3 continents, namely the Americas, the European continent and the Asian continent. The PRISMA flow of article selection has been shown in Figure 1. The articles from the Americas came from the USA and Canada, the European continent articles came from Denmark, France and the UK, and the Asian continent articles came from Japan, Taiwan, South Korea and Malaysia.

Articles from the Asian continent are expected to reflect the profile and characteristics of events and the management of cases of cardiac arrest that occur outside of hospitals in Asian communities. As a comparison of the occurrence and management of cardiac arrest cases that occur in developed

countries, we refer to articles from several developed countries, namely the USA, Canada, the UK, Denmark and France.

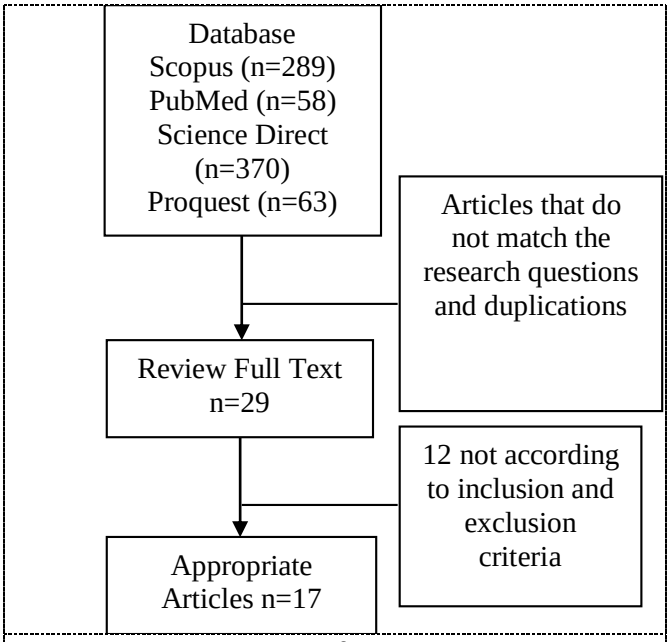

Figure 1. Study flow diagram

3.1. Respondent's Charateristics

The number of respondents in the selected articles varied between at least 21 respondents up to 85553 respondents, with variations in age between 40 to 75 years. All of the respondents were individuals who had experienced cardiac arrest outside the hospital, both in public areas and in private areas (eg houses). The number of samples and respondent characteristics have been illustrated in Table 1.

Table 1. Respondent's characteristic

[2]	41054	1693 (4,1%)	-	26366	14688

As can be seen in Table 2, the 24-hour survival rate is highly dependent on age; as the age increases, so too does this significantly affect survival and poor neurological results. Gender showed that there are relatively lower survival rates for female patients, as did the location of the incidence of cardiac arrest, intensive cardiac care, response time and when the event was witnessed [1]. The duration of heart massage is related to survival and favourable neurological results and it is more effective with a 45 minute CPR duration [8]. This indicates that the potential for survival depends on transportation, trained personnel and response time. They can start CPR before the ambulance arrives to maintain the ROSC with spontaneous circulation. From the results of the review, the results showed a higher rate of Return of Spontaneous Circulation (ROSC) in OHCA patients contained in

the table below, as in the OHCA patients found in the 17 selected articles.

Table 2. List of factors that indicate higher ROSC numbers

Factors that Show Higher ROSC Numbers	Author
Female Gender	Chien chou chen, Masahiro Kashiura, Jenna E Tuttle
Occurance in the Prehospital public	Chien chou chen
Prehospital defibrillation	Chien chou chen, Masahiro Kashiura, Seo Young Ko , Ki Hong Kim
Advanced airway management	Chien chou chen , Masahiro Kashiura
Non-traumatic case	Chien chou chen , Josephine Escutnaire, Ismail AK
Referred to the nearest hospital	Chien chou chen ,
High density public area	Chien Chou Chen,
Mechanical CPR	Ching-Kuo Lin
First responder	Seo Young Ko, Shang Li Tsai, Masahiro Kashiura, Shang Li Tsai, Jenna E Tuttle, Thomas C Sauter
Respon time	Shang Li Tsai, Seo Young Ko, Jenna E Tuttle
CPR >45 minutes	Masahiro Kashiura, Thomas C Sauter, Frederic Adnet
Younger age	Shang Li Tsai, Jenna E Tuttle

4. Discussion

Some studies on the success of help in OHCA patients have shown variable numbers the results. The success of CPR is influenced by various factors, namely the help factors, victim factors, and technical assistance. Ko et al [9] stated that assistants who have been trained to do CPR will increase the life expectancy and neurological improvement in OHCA patients as trained helpers do CPR more effectively, increase the frequency of CPR and defibrillators, and respond quickly and precisely to OHCA patients compared to a helper who is a layman.

Tuttle & Hubble [10] explained that paramedics who are trained and who had handled ≥15

OHCA patients increased spontaneous circulation by 21% compared to paramedics who had little experience of providing help. Sex also has an influence on the return of spontaneous circulation in OHCA patients. The study of Ak et al [7] found that female patients had a higher percentage of return of spontaneous circulation after experiencing cardiac arrest. This can be caused by the condition of past disease history, hypertension, diabetes mellitus and ischemic disease.

The technique of giving a heart massage can also have an affect where the depth of the chest compresses is less than optimal, which it can cause an increase in the safety rate of OHCA patients, . The duration of CPR implementation must also be considered by the helper. [8] states that a duration of 45 minutes for CPR administration can provide benefits towards neurological improvement and the survival of all OHCA patients.

The research by [11] also provides an overview of the No Flow intervals (NF; starting when cardiac arrest occurs at the beginning of CPR administration) and Low Flow intervals (LF; when giving CPR).

Low Flow is when giving CPR until the cessation of resuscitation. The NF interval greatly affects the LF interval. An NF duration of more than 18 minutes and an LF of more than 33 minutes results in a 1% chance of life in OHCA patients. The duration of CPR giving for more than 40 minutes can increase life chances by more than 1%.

In addition to the duration of CPR administration, the determination to stop CPR also affects the level of safety of the OHCA patients. The decision to stop help causes irreversible complications and various neurological responses [5] [3].

5. Conclusion

The success of CPR for out of hospital cardiac arrest patients is influenced by various factors, namely the helping factor, victim factor and helper factor. The provision of CPR for out of hospital cardiac arrest patients performed by trained helpers will increase life expectancy and neurological improvement in OCHA patients compared to laypeople. Sample limitations, CPR administration techniques and time constraints played a part, as did the duration that the patients were on location before the ambulance arrived.

ABSTRACT

Peripheral Intravenous Cannula (PIVC) is a standard procedure carried out in the hospital to allow rapid and accurate administration at medication. However, the placement of an intravenous cannula can have undesirable effects; the most common is phlebitis. It is an irritation of tunica intima layers of the superficial vein which is caused by mechanical, chemical or bacterial sources. In Malaysia, the incidence of phlebitis had become a national nursing indicator with a standard of less than 0.9%. The standard care of the patient with intravenous includes a routine PIVC assessment. However, what the assessment should be based on remain unclear. Do nurses perform this assessment using the same method? This study uses an audit-based approach to determine nurses' existing assessment technique during PIVC routine checking. Data analysis was carried out using the Statistical Package of Social Sciences latest version. Results of the study revealed that palpation techniques often not been carried out as compared to observation technique. Palpation technique is crucial in order to detect 'warmth to touch' because it differentiates between the early stage of phlebitis or medium stage.

Keywords: peripheral intravenous cannula (PIVC), phlebitis assessment, thrombophlebitis

1. Introduction

A peripheral intravenous cannula (PIVC) is a standard procedure carried out in the hospital to allow rapid and accurate administration at medication[1]. It is a minor invasive procedure which usually performed in a hospital. Nowadays, the usage of PIVC among hospital inpatients increased significantly, where 30-80% of patients were reported to have had at least one PVC inserted during their hospital stay [2]. The epidemiology of complication is less well described among pediatric than adults[3].Because cannulation is done for different purposes and for different lengths of time, it represents a potential risk for some safety incidents, including microbial growth[4]which can cause an infection into the local tissue at the site of cannulation or direct into the bloodstream. Without proper management, it can lead to severe complications, which is phlebitis. Thus, this study aims to determine the nurses' assessment of PIVC checking to identify any occurrence of phlebitis. This research is similar to a study conducted by Coomarasamy in 2014 in one of the established teaching hospitals. However, in this study, the researcher will be more focus on how the nurses' in the pediatric setting performing PIVC assessments.

PIVC - related phlebitis is an inflammation of the tunica intima of a superficial vein caused by the presence and use of a PIVC[5]. It can be diagnosed clinically based on the appearance of at least

two of the following signs: pain, erythema, swelling, induration or a palpable venous cord near the site of the venous catheter. PIVC allows for the rapid and accurate administration at medication. However, the placement of an intravenous cannula can have undesirable effects; the most common is phlebitis.

The predisposing factor of PIVC-related phlebitis divided into two: patient-related and PIVC-related characteristics. A patient-related characteristic, such as age and gender, influence the occurrence of phlebitis[9]. A patient whose age is > 65 years and men were more likely to develop PIVC-related phlebitis [9]. Patient's condition, such as immunosuppression, circulatory impairments, and malnutrition, have been shown to increase the risk of phlebitis[6]. One study found that the increase of PIVC-related phlebitis caused by lack of agreement on a definition of PVC-related phlebitis and the use of different measurement tools to identify phlebitis [10]. Apart from the undesirable effects; such as discomfort and pain, few studies reported that material and cannula size, insertion site and placement technique, duration of site use[7] and type solution infused [8]influence the occurrence of phlebitis.

In one observational study conducted by a tertiary government hospital, it had been found that 35.2% of the 428 medical and surgical patients with peripheral cannula developed thrombophlebitis[9]. To add on, the rate of thrombophlebitis in a private specialist hospital in Malaysia had reported that 6.8% in 2011, and it decreased to 3.1% in 2012 and even further to 2.5% from January – June 2013. The reduction of thrombophlebitis is due to the implementation of the protocol from the above findings[10]. The acceptable phlebitis rate, according to the Intravenous Nurses Society, is 5% or less in any given population[11]. In Malaysia, the incidence of thrombophlebitis among adult clients with PIVC is a national nursing indicator with a standard of less than 0.9%[12].

Recently, the relationship between nursing care and the incidence of PVC-related phlebitis has been in much concern among the researchers. The risk of PVC-related phlebitis has been reported to be lower when patients are cared for by an experienced nurse, and when nurses follow evidence-based guidelines[13].Nevertheless, ensuring compliance with the available protocol[14]are often impossible due to high workloads in the wards such as an increase in the number of patients that a nurse is required to care for communication failures within the healthcare team, and shortages of resources at the bedside[15]. The amount of nursing care given to patients daily, the proportion of care offered by graduate nurses educated to university level, and the skills mix of the nursing staff have mainly been associated with unfavorable clinical outcomes[16].

All patients with PIVC should have the access site checked at least at every shift. There some phlebitis assessment scale has been developed to be widely used in most Malaysian hospitals. However, the most commonly used are the Visual Infusion Phlebitis (VIP) scale. The VIP scale is a valid and reliable measure for determining when an intravenous catheter should be removed [17]. The technique used to perform VIP assessment not only visual but through palpation and communication with patients. Figure 1 shows the VIP scale used by nurses to assess the cannula.

The aim of this study was to identify the incidence of phlebitis in pediatrics setting and to observe nurses' PIVC assessment skills in recognizing phlebitis.

2. Methods

This research design was descriptive and analytical using a cross-sectional approach analysis

that was conducted over six months in a pediatric ward setting. The study was conducted in one of the biggest maternal and pediatric hospitals and involved six multidisciplinary medical-surgical wards and four intensive care unit ward. The respondents were identified from the hospital staff starting from Jan 2017 to the end of Jun 2018. The sample size calculation was determined using the Raosoft Software. Considering the 5% margin of error and 95% confidence level, with a 110 population size and 10% dropouts, the total sample was 86. The potential respondents were selected from the pediatric ward. The response rate was low at only 65.1% due to a dengue outbreak causing human resource constraints. All appointed registered nurse (RN) researchers were unable to perform PIVC-AS on the selected respondents within the time frame allocated. The inclusion criteria were all registered nurses working in the medical and surgical pediatric ward involved directly in providing PIVC care. The exclusion criteria were all paramedics or those with a working experience of less than three months, where the staff worked in the clinic.

Two RN researchers were identified in each ward/unit (total of 18 researchers) to perform PIVC assessment skills among respondents. The selection of the RN researchers was appointed by the nurse manager of the hospital based on their experience and if they had attended PIVC care training. The RN researchers evaluated the respondents within the time frame of this research. The selection of the ward was based on the total incidence rate from the ward obtained from the infection control unit. One RN researcher specializing in infection control was appointed to evaluate the presence of phlebitis daily through the direct observation of the PIVC sites using the VIP scale (Figure 1). The incidence rate of phlebitis was calculated based on the following formula; the number of new cases divided by the number of assessed PIVC x 100. The grades of phlebitis will be identified based on phlebitis scale reported using Visual Infusion Phlebitis (VIP) scale. Upon the highest incidence of phlebitis being found among the wards, the researcher identified the PIVC-assessment skills, and the data collection was carried out after. Next, the participants were selected by the team leader in each ward to perform the PIVC assessment among the nurses. PIVC-AS was performed twice, based on the incidence of phlebitis being every two months. Figure 2 shows the recruitment and data collection process. The data analysis was performed using the Statistical Package of Social Sciences version 23.0 software. The incidence of phlebitis was assessed based on the number of cannulas inserted in the past six months. The audit criteria's performance and monthly incidence rate pattern have been displayed in the form of a chart and percentage.

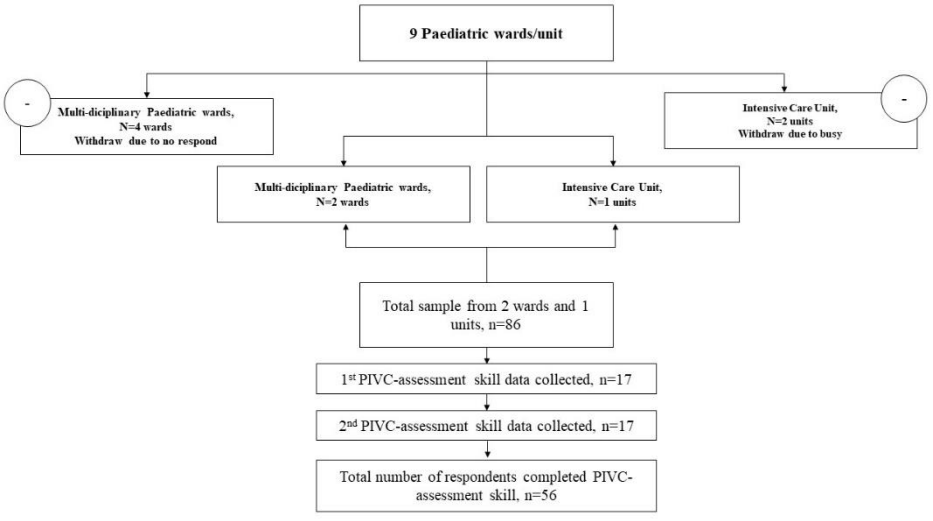

Figure 2 – Recruitment of the participants and the data collection process

The research instruments were two appointed RN researchers. Each ward is responsible for assessing the nurses' PIVC assessment skills (PIVC-AS). The PIVC-AS checklist was adapted from Coomaraswamy [1] to measure the nurses' assessment skills. Nine steps need evaluation and they were rated as "entirely met," "partially met," and "not met." Marks will be awarded for each step. The full marks possible for the new rubric are 27. The following points below indicate the nine audit criteria.

1. Criteria 1: Introduce self and explain the purpose of PIVC to the client.
2. Criteria 2: Check the location and total number of PIVCs of the patient.
3. Criteria 3: Check the cannula size and the reason for the application.
4. Criteria 4: Is the PIVC checked every shift?
5. Criteria 5: Observe the PIVC area for evidence of erythema and swelling.
6. Criteria 6: Ask the client for any evidence of pain at the IVC site and along the cannula path.
7. Criteria 7: Palpate the PIVC area for any evidence of venous cord and warmth related to PIVC.
8. Criteria 8: Document the phlebitis score accurately.
9. Criteria 9: Perform the appropriate PIVC care based on the phlebitis score.

The study was approved by the National Institutional Health and Medical Research Ethics Committee (NMRR-17-2400-34037-IIR).

3. Results

3.1 Demographic data of the respondents

A total of 28 respondents were recruited from four different pediatric wards/unit. The majority, 60.3% (17), of the respondents were from intensive care units and 39.7% (11) were from pediatric multi-disciplinary wards. The mean age of the respondents 38.7; SD= 8.5, and 65.4% of respondents were women.

3.2 The incidence rate of phlebitis in maternal and child hospital in Sabah

A total number of 42,733 PIVCs were assessing from January through to June in this setting. The incidence rate of phlebitis in this study ranged between 0.03 – 0.07% for Jan – Jun 2018. This rate is congruent with the standard set by the Infusion Nurse Society in 2006. The most common grades of phlebitis were between grades 1 and 2 (88.2% and 11.8% respectively). The lowest incidence rate from Jan to Jun 2018 was in June, which was 0.03% (only 2 cases reported out of 7132). The highest number of incidences was in Jan and March, which were 0.07% (6 cases out of 8483 PIVCs for January and 4 cases out of 6807 PIVCs).

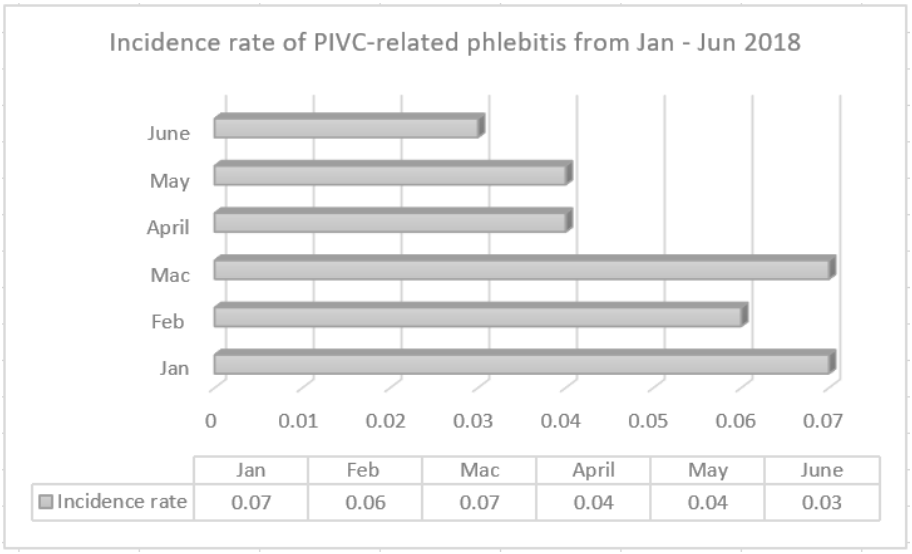

Figure 3 – The incidence rate of PIVC-related phlebitis from Jan - Jun 2018

3.3 PIVC assessment skill: Criteria Score

The audit criteria were based on the standard set by the nursing board. There are nine steps that need to be evaluated and these were divided into three categories; "entirely met," "partially met," and "not met." Marks will be awarded for each step and there needs to be time taken regarding the coefficient. The full marks available for this rubric are 27.

The compliance with the audit criteria was determined as follows (refer Figure 4). The first and second assessment was combined and summarized in the following bar chart. Based on the PIVC-AS checklist, step number 8 is "Document the phlebitis scored accurately" and step number 9 is "Perform the appropriate PIVC care based on the phlebitis score". These have the lowest compliance rate of 71.4% and 73.2% respectively. Step number 1 had the third lowest compliance rate (76.8% compliance). This low compliance rate can be explained by this study having been done in the pediatric setting. Most of the respondents lack communication skils due to handling a pediatric patient. The second lowest was step number 7: Palpate PIVC area for any evidence of venous cord and warmth PIVC (67% compliance).

Most of the respondents only depending on their visual judgment when performing PIVC assessment. Without palpation, the respondent will not be able to distinguish between phlebitis grade 2 and grade 3.

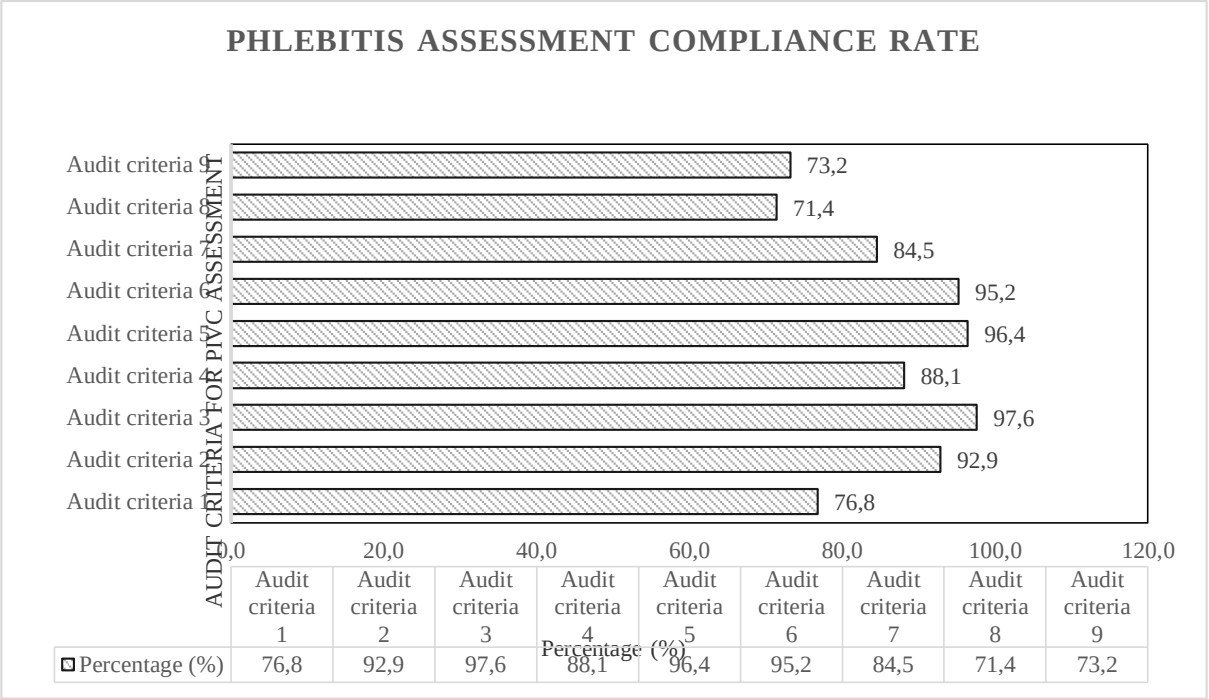

Figure 4 – PIVC assessment compliance rate

4. Discussion

This study investigated 42,733 PIVCs and the results showed that the total incidence for the past six months (January to Jun) 2018 ranged between 0.02 – 0.07%. This rate is still within the Intravenous Nurse Society's <5%. This study showed there to be similarities in terms of the incidence rate in two studies conducted by Urbanetto *et al.*[4] and Salgueiro *et al.*[18]. However, these two studies took place in an adult setting. In a study done by Cho *et al.* (2015), the incidence rate of phlebitis was 5.07% [19]. Compared to Nagpal *et al.* (2015), they reported that the incidence rate of phlebitis was 71.25% and that this was found to be higher for grade 2 phlebitis. This considerable difference needs to be explored further and it is suggested for future researchers to do a comparative study.

There is also the compliance rate of PIVC assessment among the nurses in a pediatric setting. Audit criteria 2, 3, 5 and 6 indicate that nurses able to perform PIVC assessment as per the nursing standard. Audit criteria 8 shows that the documentation of the phlebitis score accurately recommends that the nurses must use a valid document. Accurate documentation depends on the nurse's competency in performing the PIVC assessment. The knowledge of PIVC care must be given to the nurses to improve the accurate documentation. The compliance rate (below 80%) is still weak. From the researcher's opinion, the lack of this criterion is probably due to the nurses not seeing the importance of accurate documentation. It is recommended that continuous education, monitoring, reinforcement, tracking and the trending of compliance with this criterion has to be done frequently by the clinical nurse educator in each ward[1].

Audit criteria 9 indicates that performing the appropriate PIVC care based on the phlebitis score shows that the prolonged placement of PIVC has been associated with the incidence of phlebitis and catheter-related bloodstream infections. Thus, to reduce the risk of phlebitis and infection, the Centre for Disease Control and Prevention has recommended that small peripheral cannulas be re-sited

within 72 to 96 hours. This study showed that the majority of the incidence rate was in grade 1 and 2 phlebitis. These findings are consistent with the findings by Nagpal *et al.*(2015)[3]. Salgueiro (2012) also reported similar findings, in which the phlebitis grade 1 and 2 contributes 37.0% and 53.6% respectively[18].

Audit criteria 7 indicates that palpating the PIVC area for any evidence of venous cords and warmth related to PIVC shows that these criteria are crucial. The compliance rate was 84.5%. In this study, the researchers found that when performing the PIVC assessment, the majority of nurses did not perform the palpation technique. If referring to the VIP score (Figure 1), then grades 2 and 3 can be distinguished by the palpation technique. The inaccurate grading of the phlebitis score can lead to wrong nursing actions. In the pediatric setting, the patient's PIVC commonly is secured using a crepe bandage and a modifiable splint to prevent the PIVC accidentally being pulled out by the pediatric patients. Thus the palpation technique during the PIVC assessment was very seldom performed by the nurses. However, further research needs to be done to identify the reason for not performing the palpation technique.

This study has some limitations. First, the study did not involve random assignments. The researcher is aware that there was a potential for bias about the outcome because it was difficult to mask the nursing group. The outcome measures were obtained by the nurse who was not a part of the study team but one of the resident nurses in the ward. Second, the small sample size and multiple dependent variables such as ward condition and also patient condition which may increase the type I error rate, thus it limits the transferability of the results. Thus, the outcome of this research must be interpreted with caution when it comes to potential clinical application. It is suggested that further research may increase the total number of respondents and establish a detailed protocol on the selection of the participants. Lastly, despite these limitations, the knowledge offered in the present study is the first to report on the audit compliance rate among nurses in Borneo.

5. Conclusion

In conclusion, this study shows that the technique of palpation is often neglected by the nurses when performing the PIVC assessment. More research needs to be done and this should be conducted in a larger population. The outcome of this study supports the formation of a PIVC assessment checklist, especially for Infection Control Units.

GENERAL DESCRIPTION OF HEALTHCARE ASSOCIATED INFECTION (HAI) HOSPITALS DR. SOETOMO SURABAYA

Moecharam
Faculty of Nursing, Universitas Airlangga, Surabaya, Eas Java, Indonesia
Email: moecharam-2017@fkp.unair.ac.id

ABSTRACT

Healthcare Associated Infection (HAI) is an infection that occurs in patients who are hospitalized for more than 48 hours. HAI is the cause of increasing patient morbidity and mortality, so special care is needed. Prevention of HAI can be done optimally by performing hand hygiene and applying HAI bundles. The purpose of this paper is to describe the incidence of infection in health services at the Regional Hospital Dr. Soetomo Surabaya (RSDS). this paper uses a design description analysis. Data taken from preliminary studies, tables and analyzed, with a span of time from 2013 to 2017. Variables used included attitudes, knowledge, adherence to adherence to HAI, hand hygiene. Research shows the results of attitudes, knowledge, and age related to adherence to prevention of HAI. Prevention of HAI has not been done optimally because nurses have not done handhygiene and the application of bundles. Preventive compliance behavior HAI considers the background factor.

Keywords: healthcare associated infection, handhygiene

1. Introduction

The Regional General Hospital Dr. Soetomo is a hospital located in the city of Surabaya. It is often called the Karang Menjangan Hospital by the people of Surabaya because it stands in a village called Karangmenjangan. The Regional General Hospital Dr. Soetomo Surabaya is a state A class hospital by the government designated as having the highest references. The Regional General Hospital Dr. Soetomo Surabaya is required to provide quality health services that can meet the health needs of all patients. When the patients are being treated, they can get an infection [1]. Health care-related infections (HAI) occur in patients during their treatment in hospitals or other health care facilities that were not present at the time of admission. In addition, health workers can also be infected by working in the service area [2]. Invasive actions such as catheters, ventilators and the surgical procedures received in health care can be associated with infection [3].

Based on extensive studies in the US and Europe, the frequency of HAI events ranged from 13.0 to 20.3 episodes per thousand patient-days [4]. Based on preliminary studies conducted at the Regional General Hospital Dr. Soetomo Surabaya, it showed a number around 0.09 to 6.0 per thousand patient-days [5]. With the increase in infections, there has been an increase in the length of stay, long-term disability, increased antimicrobial resistance, increased socio-economic disorders, and increased mortality. The risk of an increase in infection is due to the less developed supervision system and non-existent control methods. In the description of this article, a brief description of the distribution of the infection in General Hospital Dr. Soetomo, the causes and the control method are considered to be short but more focused.

2. Material and methods

2.1 Design

This paper is a description of the analysis undertaken. The data used was taken from retrospective preliminary studies, where tables were then created and analyzed.

2.2 Types of HAI infections

The most common types of infections include the infection of the primary bloodstream, urinary tract infection, surgical site infection and lung infection due to the installation of a ventilator. In brief, details have been given in the following sections [6].

2.2.1 Central Line Associated BSI (CLABSI). IADP is a deadly nosocomial infection with a mortality rate of 12% -25%. Catheters are placed in the central line to provide fluids and drugs but long-term use can cause serious blood flow infections which result in increasing health care costs. The IADP data of Dr. Hospital Soetomo as in Table 1 shows that fluctuations occur and there was an increase in 2016 of 1.51%. The highest incidence was in the critical wards such as in Intensive Care Unit (ICU) [3,7].

2.2.2 Urinary tract infections (UTI). UTIs are the most common type of HAI in general. According to the Dr. Soetomo hospital referring to the care between 2013 to 2017, the incidence rate happened to go up and down. The highest point was in 2016 which was 2.99%. UTIs are caused by the endogenous original microflora of the patients. The catheter that is installed serves as a channel for the entry of bacteria while the imperfect drainage of the catheter makes the volume of urine in the bladder become a medium for bacterial growth. UTIs can develop into complications such as orchitis, epididymitis and prostatitis in men and pyelonephritis, cystitis and meningitis among all patients [8].

2.2.3 Surgical Side Infection (SSI). SSIs in Hospital Dr. Soetomo affect 1.5% of patients undergoing surgery. The highest number occurred in 2016 at 0.41%. This is the most common type of infection mainly caused by Staphylococcus aureus resulting in prolonged hospitalization and a risk of death. The pathogens causing SSI arise from the endogenous microflora of the patients [9].

2.2.4. Ventilator related pneumonia (VAP). 86% of nosocomial pneumonia is related to ventilation. This usually occurs within 48 hours after tracheal intubation. 2016 had the highest number at 6.0%. Fever, leukopenia and bronchial sounds are the common symptoms of VAP [10].

2.3. HAI Pathogens

The pathogens responsible for this infection are bacterial viruses and fungal parasites. These microorganisms vary depending on the different patient populations, the medical facilities and even differences in the environment in which the care is given [11].

2.4. Bacteria

Bacteria are the most common pathogens responsible for nosocomial infections. Some are a natural part of the flora of patients and they are causes of infection if the autoimmune patients are susceptible to infection. Acinetobacter Baumanii is a genre of pathogenic bacteria responsible for infections that occur in the ICU. These bacteria are in the soil and water and they cause 80% of reported infections. Clostridium difficile causes the inflammation of the large intestine causing antibiotic-related diarrhea

and colitis, mainly due to the elimination of the anal flora. Enterobacteriaceae (carbapenem resistance) causes infection if it travels to other parts of the body from the intestine where it is usually found. Enterobacteriaceae originates from the Klebsiella species and Escherichia coli. Their high resistance to carbapenem causes the defenses against them to be more difficult. Methicillin-resistant S. aureus (MRSA) transmits through contact, open wounds and contaminated hands. This causes sepsis. Pneumonia is very resistant to antibiotics and it is called beta-Lactam [12].

2.5. Virus

Viruses are also an important cause of nosocomial infections. Monitoring revealed that 5% of all ordinary nosocomial infections were due to viruses. They can be transmitted by hand-mouth, breathing and fecal-oral. Hepatitis is a chronic disease caused by a virus. Health workers can transmit the hepatitis virus to both patients and workers. Hepatitis B and 100 are usually transmitted through unsafe injection practices. Other viruses include influenza, HIV, rotavirus, and the herpes simplex virus [13].

2.6. Fungi parasite

The opportunistic fungal pathogen that causes HAI acts as a parasite, meaning that the individual's immunity decreases. Aspergillus Niger spp. can cause infection through environmental pollution. Candida albicans and Cryptococcus neoformans are also responsible for infection during hospital stay. Candida infections arise from the endogenous microflora of the patients while Aspergillus infection is caused by the inhalation of fungal spores from contaminated air during the construction or renovation of the health care facilities [14].

3. Result

HAI affects a large number of patients in general, where morbidity increases and the financial losses are significant. According to the PPI report, around 5 – 6% of the patients treated in the critical ward in the hospital had pneumonia infections. HAI of 1 – 2% from urinary tract infections occurred in the surgical and critical wards, the highest incidence of IADP in the critical treatment area was 33%.

Table 1. The results of the incident rate of HAI in General Regional Hospital Dr. Soetomo Surabaya from 2013 to 2017.

	Year				
	2013	2014	2015	2016	2017
Surgical Side Infection	0.01 %	0.09 %	0.23 %	0.41 %	0.08%
Central Line Associated BSI (CLABSI)	0.09 ‰	0.09 ‰	0.74 ‰	1.51 ‰	0.6 ‰
Urinary tract infection	0,25 ‰	0.05 ‰	1.23 ‰	2.99 ‰	1.0 ‰
Ventilator Associated Pneumonia	0.6 ‰	0.41 ‰	2.40 ‰	5.31 ‰	6.0 ‰

4. Risk factors

The risk factors that determine nosocomial infections depend on the environment in which the care is given, the vulnerability and condition of the patient and the lack of awareness of the infections that occur between staff and the health care providers [13].

4.1. Living environment

Poor hygiene conditions and inadequate waste disposal from the health care arrangements [15].

4.2. Vulnerability

Immunosuppression in patients, long stays in intensive care units and the prolonged use of antibiotics [16].

4.3. Unconsciousness

The use of improper injection techniques, the knowledge of basic infection control measures and the use of invasive devices (catheters) that are inappropriate and a lack of control policies [17].

4.4 Reservoir and transmission

4.4.1. Patient microflora. The bacteria that are included in the patient's endogenous flora can cause infection if they are transferred to tissue wounds or surgery sites. Gram negative bacteria in the digestive tract can cause SSIs after stomach surgery [18].

4.4.2. Patient and staff. The transmission of pathogens during treatment through direct contact with the patients (hands, medical equipment, etc.) by staff through direct contact or other environmental sources [19].

4.4.3. Living environment. Pathogens that live in the health care environments, namely in the water, food, and equipment, can be a source of transmission. Transmission to other patients creates one more reservoir for non-infected patients [13].

4.4.4 Prevention of nosocomial infections. Being the main cause of illness and death, nosocomial infections need to be prevented from the start so then the spread can be controlled [14].

4.4.5. Transmission from the environment. An unhygienic environment serves as the best source for pathogenic organisms to breed. Air, water and food can be contaminated and transmitted to patients through health care delivery. Policies must be in place to ensure cleaning and the use of cleaning materials on the walls, floors, windows, beds, bathrooms, toilets and other medical devices. Good ventilation and filtered fresh air can eliminate bacterial contamination in the air. The regular screening of filters and general ward ventilation systems, operating rooms and ICUs must be maintained and documented. Water-borne infections are caused by the failure of the health institutions to meet standard criteria. Microbiological monitoring must be used for the water and air analysis. Infected patients must be kept separate. Handling inappropriate food can cause foodborne infections. Areas must be clean and the food quality must meet the standard criteria [16].

4.4.6 Transmission from staff. Infection can be transferred from the health staff. The task of the PPI is to take a role in infection control. Personal hygiene is needed for everyone. Hand hygiene with disinfectant is a method of prevention. Safe injection practices and sterilized equipment must be used. The use of masks, gloves, headgear and the right uniform is very important for the provision of health services [4].

4.4.7 Management of hospital waste. Waste from hospitals can act as a potential reservoir for pathogens that need proper handling; 15% -25% of the waste produced by health facilities is referred to as dangerous. Infectious health service waste must be managed properly through an incinerator. Waste contains a lot of heavy metals and waste from operations from people who are infected, and thus it is contaminated with blood and phlegm. Diagnostic laboratory waste must be disposed of separately. Staff and health workers must be informed of the dangers of waste and their proper management [7].

4.4.8 Infection control program. Although significant efforts have been made to prevent HAIs, there is more work needed to control this form of infection. Within a day, one in 25 hospital patients can get at least one type of HAI. Health Institutions must design a control program for this infection. Administrations, workers and individuals treated in or visiting the hospital must consider these programs to play their part in preventing infection. An efficient infection control program is shown in;

4.4.9 Use and microbial resistance. Microbes are organisms are too small for the eye to see but they are found everywhere on earth. Antimicrobial drugs are used against microbes that are pathogenic to living organisms. Antimicrobial resistance occurs when microbes develop the ability to fight the effects of the drugs; they are not killed and their growth does not stop [15].

4.4.10. Appropriate use of antimicrobials. Antibiotics are widely used to cure diseases. The use of antimicrobials must justify the correct clinical diagnosis or infection that causes microorganisms. The Center for Disease Control and Prevention estimates that every year, around 100 million antibiotic programs are prescribed by doctors in the office while around 50% of them are not needed. The selection of antimicrobials must be based on patient tolerance in addition to the nature of the disease and the pathogen. The aim of antimicrobial therapy is to use drugs that are selectively active against the most likely pathogens and that will be the least potential cause of resistance and side

effects. Antimicrobial prophylaxis should be used if necessary before surgery to reduce the incidence of postoperative infections at the operating site. In the case of immunocompromised patients, prolonged prophylaxis is used until the marker of immunity is restored [15].

4.4.11 Antibiotic resistance. Antibiotic resistance is responsible for the death of a child every five minutes in the Southeast Asia region. Drugs used to treat deadly diseases have now lost their impact [17]

Figure 2 Transmission based precautions posters

because drug-resistant microorganisms have appeared. Self-medication with antibiotics, inappropriate dosages, long-term use, a lack of standards for health workers and abuse in livestock are the main factors responsible for increasing resistance. This resistance threatens the effective control against the bacteria that cause urinary tract infections, pneumonia and reduced blood flow. Highly resistant bacteria such as MRSA or resistant multidrug negative bacteria are the cause of the high number of nosocomial infections throughout the world. The Southeast Asian report revealed that there was a high level of resistance to E. coli and K. pneumoniae against third generation cephalosporins and more than a quarter of S. aureus infections were resistant to methicillin. "Immediate action is needed to stop the world from heading into a pre-antibiotic era where all achievements made in the prevention and control of infectious diseases will be reversed," said Dr. Poonam Khetrapal Singh, WHO Regional Director for the Southeast Asia Region [20].

4.4.12 Antibiotic control policy. The pandemic of antibiotic resistance around the world shows that it is driven by the overuse and abuse of antibiotics which is a threat to preventing and curing diseases. The WHO's global report on antibiotic resistance indicates that one can prevent infections from occurring with better hygiene, clean water and vaccinations to reduce the need for antibiotics. New diagnostic developments and other tools are needed in health care institutions to stay ahead of the evolution of resistance. Pharmacists must play their role in prescribing antibiotics that are appropriate when needed and policy makers must foster cooperation and information among all stakeholders [21].

4.4.13 Nosocomial infection control. Although the aim of the infection prevention and control program is to eradicate nosocomial infections, the epidemiological supervision for demonstrations of performance improvement is still required to achieve its objectives. Efficient supervision methods include collecting data from various information sources by trained data collectors. The information must include administrative data, demographic risk factors, patient history, diagnostic tests and data

validation. Following the extraction of the data, an analysis of the collected information must be carried out that includes a description of the determinants, the distribution of infection and a comparison of the incidence rates. The feedback and reports after analysis must be disseminated by infection control committees, the management and laboratories while maintaining individual confidentiality. The evaluation of the credibility of the supervisory system is needed for the implementation of effective interventions and continuity. Finally, the periodic implementation of data to maintain the efficiency of the monitoring system, carried out compulsorily. An efficient methodology for the appropriate supervision approach is given in [6].

5. Conclusion

With the increasing burden of nosocomial infections and antimicrobial resistance, the administration of health services and infection control committees has found it difficult to achieve the goal of eliminating intervals. However, by practicing healthy ways of administering care as designed by the infection control committee, controlling the transmission of infection using appropriate methods for antimicrobial use, the resistance to pathogens that appear against antimicrobials can be reduced easily. Efficient monitoring methods guided by the WHO can help health institutions to design infection control programs. Appropriate staff hospital training for biosafety, appropriate waste management and health service reforms and making ordinary people endemic to this in Indonesia all help.

Pandemic antibiotic resistance around the world shows that it is driven by the overuse and abuse of antibiotics, which is a threat to preventing and curing diseases. The WHO global report on antibiotic resistance prevents infections from occurring with better hygiene, clean water and vaccination to reduce the need for antibiotics. New diagnostic developments and other tools are needed in health care institutions to stay ahead of the evolution of resistance. Pharmacists must play their role in prescribing antibiotics that are appropriate when needed and policy makers must foster cooperation and information among all stakeholders.

Although the aim of the infection prevention and control program is to eradicate nosocomial infections, the epidemiological supervision for demonstrations of performance improvement is still required to achieve its objectives. Efficient supervision methods include collecting data from various information sources by trained data collectors. The information must include administrative data, demographic risk factors, patient history, diagnostic tests and data validation. Following the extraction of the data, an analysis of the collected information must be carried out that includes a description of the determinants, the distribution of infection and the comparison of incidence rates. Feedback and reports after the analysis must be disseminated by infection control committees, the management and laboratories while maintaining individual confidentiality. The evaluation of the credibility of the supervisory system is needed for the implementation of effective interventions and continuity. Finally, the periodic implementation of data to maintain the efficiency of the monitoring system must be carried out compulsorily.

With the increasing burden of nosocomial infections and antimicrobial resistance, the administration of health services and infection control committees has become difficult to achieve the goal of eliminating intervals. However, by practicing healthy ways of administering care designed by the infection control committee, controlling the transmission of infection using appropriate methods for antimicrobial use means that the resistance to pathogens can be reduced easily. Efficient

monitoring methods guided by the WHO can help health institutions to design infection control programs. Appropriate staff hospital training for biosafety, appropriate waste management and health service reforms is also a fitting suggestion.

PREVALENCE AND ASSOCIATED RISK FACTORS OF LIPOHYPERTROPHY IN INSULIN-TREATED DIABETES MELLITUS AT HOSPITAL KOTA KINABALU, SABAH

A. N, Rose[1], C.T. Deena[1], N.T.T. Hmwe[2]
[1]University Malaysia Sabah, Faculty of Medicine and Health Sciences, Malaysia [2]School of Nursing and Midwifery, The University of Newcastle, NSW, Australia E-mail: rosenain@ums.edu.my

ABSTRACT

Lipohypertrophy is one of the most common complications of insulin injection. Early detection of lipohypertrophy is very important to prevent the risk of hyperglycemia or hypoglycemia, arisen due to inconsistently in absorption of insulin. Therefore, there is a need to identify factors that may have an association with lipohypertrophy. The purpose of this study is to determine the prevalence and associated risk factors of lipohypertrophy, and to determine the relationship between the presence of lipohypertrophy and associated risk factors. The methods used in this study is a quantitative descriptive study that includes two parts. The first part of the study was a questionnaire survey and second part of the study was the examination of lipohypertrophy based on inspection and palpation techniques. Study participants were patients with diabetes who attended outpatient diabetic clinic in a tertiary hospital, and was on insulin therapy. Results of the study revealed that, the high prevalence of lipohypertrophy shown in this study highlights the need for prevention strategies, which include regular assessment for the presence of lipohypertrophy and health education on insulin injection. Health education should emphasize on self-assessment of lipohypertrophy, and the importance of changing needle and rotation of injection site.

Keywords: lipohyperthrophy, insulin, risk factor, diabetes mellitus

1. Introduction

Diabetes mellitus is a type of metabolic disorder related to the carbohydrate metabolism in which glucose is both underutilized and overproduced, causing hyperglycemia [1]. The number of Malaysians suffering from diabetes is increasing from the 11.6% reported in 2006 to the 22.6% recorded in 2013 [2]. It is critical for the patients to get a rigid sense of blood glucose control in the early stage of diabetes to delay complications. Insulin therapy is one of the prominent treatment methods used to regulate blood glucose level. However, the present challenge with insulin therapy is insufficient knowledge and the attitude of insulin self-administration[3].

Lipohypertrophy is one of the most common complications of insulin injection among diabetic patients. The early detection of lipohypertrophy by using the inspection method at the injection site each time before injection is crucial because it will otherwise contribute to poor glucose control. Pain sensations diminish in the areas where lipohypertrophy is formed and for that reason, diabetic patients prefer to administer their injections to the same site, leading to increasing lipohypertrophic tissue. If insulin is injected into the area of lipohypertrophy, then the absorption of insulin will not be consistent because the insulin absorption is restricted in the

area where lipohypertrophy is developed. As a consequence, the risk of hyperglycemia or hypoglycemia arises due to the inconsistent absorption of insulin. Therefore, there is a need to identify the factors that may have an association with the occurrence of lipohypertrophy. To determine the prevalence of lipohypertrophy, the associated risk factors need to be observed to determine the relationship between the presence of lipohypertrophy and the associated risk factors.

2. Research Methods

2.1. Study design and setting

This was a descriptive correlation study design that included two parts. The first part of the study was a questionnaire survey on the socio-demographic and clinical characteristics of the study participants. The second part of the study was an examination of lipohypertrophy based on the inspection and palpation techniques. The three main sites of insulin injection, the abdomen, thigh and arm, were inspected and palpated by the researcher herself who is a certified diabetic educator to identify the "presence" or "not presence" of lipohypertrophy surrounding of the insulin injecting sites. The presence of a noticeable or palpable lump at the injection site indicated that lipohypertrophy was present. The study participants were diabetic patients treated with insulin therapy recruited from a diabetic clinic in the tertiary public hospital in Sabah, Malaysia.

2.2. Sample size and recruitment

The recruitment period ran from early June 2017 through to August 2017. The sample size calculation was based on the formula used in Jan's study[4], where the sample size calculator for the prevalence study (SSCPS) was version 1.0.01. The level of confidence was set at 95% with a suggested precision (d) of 0.05. The expected prevalence was 50% based on Cunningham[5] with an estimated population size of 200. Thus, the estimation of the respondents for this study was 130. The participants were recruited using purposive convenience sampling.

2.3. Inclusion criteria

The inclusion criteria for the study participants were the patients with diabetes who attended the outpatient diabetic clinic from 8:00 am to 5:00 pm and who were on insulin therapy. The patients who agreed to participate were screened for the inclusion criteria using their appointment cards and case notes. Those who were eligible were recruited into the study.

2.4. Exclusion criteria

The exclusion criteria for this research were the patients who were about to start insulin therapy, who were on continuous infusion insulin therapy or who were on other regular medication that needed to be administered via the subcutaneous route.

2.5. Research instrument

The questionnaires divided into two parts; (part A) which was a structured questionnaire and (part B) consisted of the assessment checklist to identify the presence of lipohypertrophy. The checklist was prepared according to the literature reviews from Hajheydari[6], Blanco[7],

Cunningham[5], Al[8] and Gentile[9]. Cronbach's Alpha test was carried out to check the reliability of the checklist. Cronbach's Alpha for the four items was r =0.82, which means that the internal reliability of the checklist was good. The validity of the questionnaire was also checked to ensure that the tools that were used in this research were measuring what was intended to be measured.

2.6. Ethical consideration

The study was approved by the National Institutional Health and Medical Research Ethics Committee

- NMRR-16-2534-3323(IIR). Informed consent was obtained from all of the participants after they received written information about the study purpose and procedures. The information was given in either English or in the national language of Malaysia depending on the participants' preference. In order to ensure confidentiality, the research questionnaires remained anonymous for each respondent. No name or identification number was taken.

2.7. Data collection procedure

The data collection was conducted by the distribution of a survey form using a purposive convenience technique. A total of 130 respondents completed the survey form and their insulin injection sites were examined. The insulin injection site examination was performed by an experienced nurse specializing in diabetic management and clinical teaching as well. The survey form was distributed and collected manually on the same day.

2.8. Statistical analysis

The data analysis was performed using the Statistical Package for the Social Science (SPSS) version 23.0 software. Descriptive statistics, frequency and percentage were used to analyze the participants' demographic and clinical characteristics. The association between lipohypertrophy and the selected factors was assessed using the Chi-square test. Statistical significance was set for p-value < 0.05.

3. Results

3.1. Sociodemographic data and characteristic of study participants

The table below represents the descriptive findings of the sociodemographic data. The majority of the participants were aged between 50 – 59 years old, were male, married, Chinese, had a secondary school level of education and a BMI of 25-29 (overweight).

Variables	Frequency (%)	
Age group		
18-28 years	5	(3.8)
29-39 years	12	(9.2)
40-49 years	20	(15.4)
50-59 years	67	(51.5)
60 years and above	26	(20.0)
Gender		
Male	70	(53.8)
Female	60	(46.2)
Race		
Malay	35	(26.9)
Chinese	54	(41.5)
Kadazan/Dusun	18	(13.8)
Others	23	(17.7)
Marital status		
Single	23	(17.7)
Married	100	(76.9)
Divorcee	7	(5.4)
Level of education		
No formal education	5	(3.8)
Primary school	3	(2.3)
Secondary school	118	(90.8)
Tertiary school	4	(3.1)
BMI		
19-24 (Normal)	26	(20.0)
25-29 (Overweight)	68	(52.3)
30-39 (Obese)	32	(24.6)
40-54 (Extreme obesity)	4	(3.1)

Table 1. Sociodemographic data

The descriptive findings of the clinical characteristics, namely the risk factor data, have been shown in Table 2. More than one-third of respondents (38.5%, n=50) were on insulin injections for between 0-5 years. Almost half of the respondents were injecting three times a day (48.5%, n=63) and more than half of the respondents (53.1%, n=69) had an insulin dosage of between 30-60 units per day.

The majority of respondents (62.3%, n=81) change needles for each injection. While 91.5% (n=119) of respondents preferred their insulin injection site to be the abdomen, only 8.5% (n=11) rotated he insulin injection site between the abdomen, arm and thigh. The majority of the respondents (95.4%, n=124) rotated the injection site to a different area at each time of injection and 4.6% (n=6) occasionally rotated the injection site.

EPD-710		
Clinical Characteristic	**Frequency (%)**	
Duration of injection		
0-5 years	50	(38.5)
6-10 years	44	(33.5)
10-19 years	21	(16.2)
20 years and above	15	(11.5)
Total injection in a day		
Once daily	7	(5.4)
Twice daily	33	(25.4)
Three times daily	63	(48.5)
Four times a day or more	27	(20.8)
Total insulin unit per day		
Less than 30 unit	26	(20.0)

Rotate to a different area for each injection		
Yes, I move	124	(95.4)
Occasionally, when I remember	6	(4.6)

Table 2. Clinical Characteristics (potential risk factors)

3.2. Prevalence of lipohypertrophy

The prevalence of lipohypertrophy was 51.5%, calculated using the formula below:

Prevalence = (Numerator / Denominator) X 100

Numerator = Person having a particular attribute (which in this case is the presence of lipohypertrophy)

Denominator = Population attending the diabetes clinic from June to August 2017.

Prevalence = (67/130) x 100 = 0.515 x 100 = 51.5%

The injection site examination is performed using the inspection and palpation technique, and the finding of the examination is recorded as "presence" and "not presence" based on the features of lipohypertrophy. The features of lipohypertrophy include a palpable lump, the swelling of the fatty tissue around the subcutaneous insulin injection site, a thickened 'rubbery' swelling of the tissue that is soft and firm and a lessened pain sensation. The respondents who had one or more of these features were considered to have the presence of lipohypertrophy.

3.3. The relationship between potential risk factors and lipohypertrophy

The relationship between the potential risk factors and lipohypertrophy has been shown in Table 3. Out of a total of 67 (51.5%) respondents with lipohypertrophy, 70.5% (n=31) of the respondents were on insulin injections for between 6 to 10 years. The Pearson Chi-Square test indicated that there is a statistical relationship between the years of insulin injection and the presence of lipohypertrophy ($\chi 2$=14.99, df =3, p = .002). The frequency of changing needles was related to the presence of lipohypertrophy ($\chi 2$=9.30, df =3, p = .026), indicating that the patients who did not change the needle frequently were likely to have lipohypertrophy. The rotation of the injection site was also related to the presence of lipohypertrophy, as indicated by the Fisher Exact Test (p = .017). The frequency of daily injection, the daily insulin dosage and the injection site were not related to the presence of lipohypertrophy (p = .068, p = 0.76 and p = 085).

Variables	Presence of lipohypertrophy			
	Yes (n=67)	Yes (n=67)	No (n=63)	
			χ^2 (df)	*p*
Duration of insulin injection				
0-5 years	16 (32%)	34 (68.0%)		
6-10 years	31 (70.5%)	13 (29.5%)	14.99 (3)	.002 [a]
10-19 years	13 (61.9%)	8 (38.1%)		
20 years and above	7 (46.7%	8 (53.3%)		
Frequency of injection per day				
Once daily	2 (28.6%)	5 (71.4%)		
Twice daily	18 (54.5%)	15 (45.5%)	7.13 (3)	.068 [a]
Three times daily	38 (60.3%)	25 (39.7%)		
Four times daily	9 (33.3%)	18 (66.7%)		
Insulin dosage (units per day)				
Less than 30 units	18 (69.2%)	8 (30.8%)		
			5.14 (2)	.076 [a]
31-60 units	35 (50.7%)	34 (49.3%)		
More than 60 units	14 (36.4%)	21 (63.6%)		
The frequency of changing the needle				
At every injection	4 (100%)	0		
Every 2-3 injection	18 (45.0%)	22 (55.0%)		
			9.30 (3)	.026 [a]
Every 4-5 injection	40 (49.4%)	41 (50.6%)		
When cartridge/pen in finished	5 (100%)	0		
Insulin injection site				
Abdomen	64 (53.8%)	55 (46.2%)

4. Discussion

4.1. Prevalence of lipohypertrophy

The prevalence rate of lipohypertrophy in insulin-treated patients with diabetes mellitus is 51.5 %. These findings are similar to a previous study conducted in Saudi indicating that almost 50% of patients with type I diabetes had lipohypertrophy [8]. In this study, the researcher determined the prevalence of lipohypertrophy based on the injection site examination by both inspection and palpation. The gold standard for confirming lipohypertrophy is using ultrasound. However, the reason why the researcher used the inspection and palpation technique is that it

is inexpensive and not time-consuming. Performing biopsies for histopathological examination to detect lipohypertrophy is the most reliable method. However, it is neither practical nor economical. The findings from this study show that half of the insulin-treated diabetes patients (51.5%) had developed lipohypertrophy. This is an alarming figure because lipohypertrophy in patients with insulin injection increases the possibility of hyperglycemia and hypoglycemic attack due to the interruption of insulin absorption, which leads to an uncontrolled glycemic level.

The high prevalence of lipohyperthrophy may be related to the lack of routine examination of the injection site by insulin-treated diabetic patients. The prevalence rate of lipohypertrophy should not be ignored and well-trained diabetic nurses should take the initiative to examine every person who uses insulin [5]. Providing specialized training in diabetes management for nurses will enhance their assessment skills when it comes to identifying lipohyperthropy. Kadiyala[10] suggested that the injection sites should be examined at least annually by a health care professional for the early detection of lipohypertrophy and that the patients should also be taught to examine their injection sites and how to detect lipohypertrophy.

4.2. Potential risk factors of lipohypertrophy

This study has revealed that the potential risk factors for the occurrence lipohypertrophy are the duration of insulin use. The occurrence of lipohypertrophy is shown to be higher in patients who had a longer duration for needing insulin injections. This finding is consistent with a previous study indicating that a longer duration of insulin injection increases the chances of developing lipodystrophy [6]. The reason behind this may be explained by the fact that the growth-inducing character of insulin has a multiplying effect on fat tissue [11].

In this study, the total number of insulin units per day is also one of the potential risk factors for the occurrence of lipohypertrophy. A higher insulin dose given in a day contributes to a higher risk of developing lipohypertrophy. The prevalence of lipohypertrophy was higher in those who changed the needle after every 4 - 5 injections, followed by those who changed needles after every 2 - 3 injections. Similarly, in the previous studies, multiple reuses of a single needle were found to be associated with the occurrence of lipohypertrophy[8-7]. Failure to change the needle frequently and the reuse of needles causes the sustainability of the needle to be insecure. This may cause tissue damage. As mentioned by Vardar & Kizilci[11], the use of the same needle causes damage to the tip of the needle and this leads to the loss of the silicone coating, thus preparing a foundation for tissue damage and the subsequent development of lipohypertrophy. Reusing an insulin needle can dull its tip [12] and this may cause more tissue damage at the injection site. This study finding suggests that a lower frequency of changing needles is considered to be a risk factor that should be emphasized when giving health education on insulin injections.

The current study showed that the majority, 61% (n=67), of the respondents claimed that they rotated their injection site each time they had an injection. However, the researcher observed the examination of the injection site and found that the patients tended to inject the insulin in the same place based on their preferred site as results in less of a pain sensation. This becomes a potential risk factor for the occurrence of lipohypertrophy. According to Wallymahmed[13], many patients with lipohypertrophy are aware of the importance of rotating insulin injections sites but they continued to inject into the same area regardless. As indicated in the previous studies, there was a relationship between lipohypertrophy and the rotation of

injection sites. Namely either not rotating the sites or rotating them incorrectly[8-6]. Therefore, this study suggests that the failure of the rotation of the injection site each time is considered to be a risk factor for the development of lipohypertrophy. This should be emphasized during the health education given on insulin injections.

5. Conclusion

The high prevalence of lipohypertrophy shown in this study highlights the need for prevention strategies, which includes the regular assessment to assess for the presence of lipohypertrophy and to provide health education related to insulin injections. Health education should emphasize the self-assessment of lipohypertrophy, the importance of changing needles and the rotation of the injection site. Further research within a large-scale multi-centered study is required to represent the whole population of diabetes patients treated with insulin injections in the Malaysian context.

The limitation of the study was found during participant recruitment and follow up. The patients were likely to be more knowledgeable. Thus, these results may not be an accurate reflection of the patient's practice of insulin injection. The study results may not be generalizable to the whole population of patients with diabetes mellitus in Sabah state. This is since this study was only conducted in one general hospital in Kota Kinabalu city.

The findings can only be generalizable to diabetes mellitus in an urban area. Since this was the first study conducted in Kota Kinabalu, Sabah, the information and literature available to indicate the prevalence of lipohyperthrophy among Sabahan was none. Therefore, most of the information and literature was from other countries. Another limitation was that the questionnaire included only categorical variables and there were limited options for analysis. Recommendations for future research include to increase the sample size by including more patients from other hospitals and diabetic clinics in the district and also to conduct further studies on the trends of the injection techniques among the patients undergoing insulin therapy.

This study found that half of the patients treated with insulin therapy developed lipohyperthrophy. Thus, patients and the health care providers, especially diabetes educators, need to recognize the importance of the early identification of lipohyperthropy. Therefore, the researchers suggest that an injection site examination should be performed regularly in order to detect the early signs and symptoms of lipohyperthrophy.

Patients should be aware of the risk factors of lipohypertrophy and how to prevent it. Patients should be taught of the proper insulin injection technique and the prevention of lipohyperthrophy. There is a need to develop policies and examination checklists to reassure nurses and doctors to perform injection site examinations as part of their routine examination procedures in hospitals and clinics. The findings from this study provide baseline data, thus contributing to identifying a solution for a clinically relevant problem regarding the development of lipohypertrophy and the associated risk factors.

ABSTRACT

Technological advancements and the promotion of online games led to an increase in the use of online games in adolescents. Internet Gaming Disorder is mental health disorder caused by online games uncontrolled. The purpose of this systematic review was reviewed the differences of emotional regulation among regular and irregular young gamers who used of online games and the impact on Internet Gaming Disorder. The method of this reviewed ware: 1) Using Scopus, Sage Journals, PubMed, Springer Link, and Science Direct database 2) search from 3 January-23 February 2019, and 2013-2019 publications 3) English language 4) Used Internet Gaming Disorder, Game Online, Young Gamers, Regular and Irregular Game Online keywords 5) PICOS approach. Total the journal ware found 1.544 journals and 18 appropriates and assessed. Low emotion regulation was the main factor cause of Internet Gaming Disorder. Alexithymia, reactive, comfortable with the virtual environment, impaired dorsolateral prefrontal activity, low knowledge, depression, anxiety, and low reassessment abilities ware a symptoms found in adolescents with regular using game online. The conclusion this reviewed was that regular online game have a lower emotional regulation than irregular gamer so that it can deeper addiction.
Keywords: internet gaming disorder, game online, young gamers, regular and irregular game online

1. Introduction

Adolescents are a group that is prone to mental health problems caused by uncontrolled internet use. Technology developments have a negative and positive impact. Prevention has been carried out, but increasing sophisticated technological developments and attractive promotions, have caused the young generation easy to get a mental health disorder.

Internet users have increased by 0.2% in 2017 and they reached 3.8 billion in 2018, making up 51% of the total global population. The increase in internet usage also has an impact on increasing the number of online game users, especially in the young generations. The results of the study indicate that the majority of the population of the United States aged 12-17 years is an active online game user [1].

The use of online games that is not controlled can lead to pathological conditions such as impulsive behavior and aggression, Internet Gaming Disorder (IGD), mood instability, decreased achievements and health problems [2]; [3]; [4]. As much as 1.2% of IGD occurred in children aged 13-18 years in 2013, then this went up to 2.5% in 2016 and up to 5.9% in 2017

[5]. The adolescent's real life, daily activities and social life are conditions that must be watched due to IGD [6].

IGD is a type of internet addiction where the condition is caused by excessive and prolonged internet use. This condition leads to cognitive impairment, progressive behavior, a loss of self-control in the game, a lack of tolerance and withdrawal symptoms. The study said that impaired self-control in adolescents with IGD was defined as the inability to control their impulses, emotions and the temptation to play online games [2].

The psychopathological symptoms caused by IGD are mood disorders including depression and irritability [7]. IGD can affect a person's emotions, where emotional regulation contributes to the symptoms of IGD [8]; [7]. Emotion dysregulation is a predictor of the IGD factor [9]; [10].

Adolescents experience the "over-arousal" of their body and emotions, so it is very possible for adolescents to be unable to understand and control themselves [11]. Adolescents tend not to be able to control their emotions, especially when it comes to impulsive behavior. Adolescents tend to act to get satisfaction as an effort to divert themselves from their problems. This is due to the adolescents not having yet been able to manage themselves in the face of a difficult situation [12]. Emotional regulation is therefore needed by the adolescent. Emotion regulation is able to prevent IGD [7]. The study believes that emotion regulation is able to prevent negative behavior and that it is able to influence psychology due to the strong intensity of their emotions, to increase the focus of their attention and to organize the adolescents to allow them to better regulate their behavior in order to achieve a goal [13].

The study said that about 90% of adolescent gamers are more intensive and regular when it comes to playing online game than older gamers [11]. Regular gamers make use of online games continuously. This can be impact on the adolescents such as the inability for emotional regulation, being unable to express their emotions, having difficulty identifying their emotions and describing their emotions poorly [11]. The emotions of regular gamers are important to know in order to provide an accurate description of the regulation of emotions so then if they really need therapy, then the therapy is accordance with the condition of the adolescents.

The output of this review analyzed the emotional regulation of regular and irregular young gamers who use online games and the impact on IGD. This review can be used as an increase in the knowledge of emotional regulation in adolescents who use online games to prevent the occurrence of IGD. This research was also expected to provide further information for nurses, school teachers, parents and the adolescents themselves to allow them to improve their emotional regulation independently. Finally, this research is expected to prevent IGD in adolescents.

2. Method

2.1. Search Strategy

The journal search strategy started with asking the following research question: "What is the difference between emotional regulation in regular and irregular adolescents who use online games and what is the impact on IGD?" The journal reviewed all indexed journals related to emotional regulation that had an impact on IGD.

The databases used for journal searches were Scopus, Sage Journals, PubMed, Springer Link and the Science Direct database. The keywords used are TITLE-ABS-KEY (emotion AND regulation AND adolescents AND internet AND gaming AND disorder) AND DOCTYPE (ar) AND PUBYEAR > 2012; TITLE-ABS-KEY (emotion AND regulation AND irregular AND irregular AND gaming AND adolescent) AND DOCTYPE (ar) AND PUBYEAR > 2012. The journal search begins on 3rd January and ran until 23rd February 2019. The studies were selected from 2013 to 2019. The language that was chosen was English.

The data extraction was done by first searching for journals related to the variables to be studied. The researcher then chose the area and titles that corresponded to the variable of mental health, of adolescents using online games, of emotional regulations and then the IGD. In the first step, the researcher identified and searched through the following databases: Scopus, Sage Journals, PubMed, Springer Link and Science Direct. The total number of journals found and matched were 1.544. The researcher than reviewed the journal titles and found 370 journals to be appropriate. Then the researcher assessed the abstract and found 187 journals. Then the journals were assessed the full text and found 102 journals to be appropriate. Finally the researcher found 18 journals.

2.2. Selection Procedures and Data Extraction

2.2.1. Population. The selected population in this review was adolescents who used online games both regularly and irregularly.

2.2.2. Intervention. This study did not use an intervention but instead it assessed the emotional regulation and IGD based on the DSM V criteria,

2.2.3. Comparison. The review compared the emotional regulation of regular and irregular adolescents who used online games and also the impact on IGD.

2.2.4. Output. The review reported that there are differences between the emotion regulations in regular and irregular adolescents who use online games. Regular gamers have a lower emotional regulation ability than irregular gamers, so they have a deeper addiction.

2.2.5. Study Design

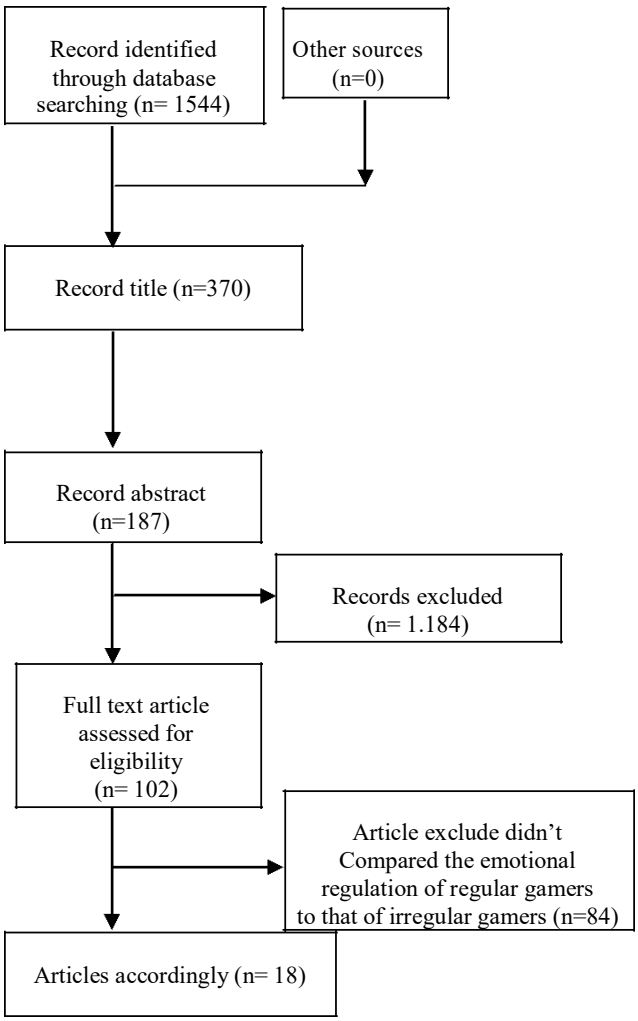

Fig. 1. PRISMA Flow Diagram of the Emotional Regulations Based on Using Online Games and the Impact on Young Gamers: A Systematic Review

3. Results

3.1. Study Result and Selection

The results of the review found that the majority of respondents who used online games regularly were 10 - 21 year olds with an average age of 13 years. Based on the gender of the online game users, they were 81% male and 19% female. The use of online games averaged > 4 hours/day on weekdays and >8 hours on weekends or around >40 hours/week. The respondents had used online games >2 years. The respondents who used online games irregularly were adolescents with an average age of 14 years. As many as 33% of the boys and 67% of the girls were irregular gamers. The used of online games averaged <4 hours/day. The respondents used online games < 2 years. The average respondent in this review was a student. The adolescents were spread throughout Asia and Europe, namely China, Taiwan, Korea, Turkey, Iran, Italy, Spain and France.

Table 1. Characteristics of the Population Studies

Descriptions	Regular gamers	Irregular Gamers
Age	10-21 years (M= 13 years)	10-21 years (M= 14 years)
Gender	81% boys 19% girls	33% boys 67% girls
Time gaming	>4 h/d in weekday >4 h/d in weekend >40 h/weak	< 4 h/d
Period time of gaming	>2 yeas	< 2 years

Emotion regulation is self-regulation as a cognitive process that effects the emotions. Initiation, inhibition or the modulation of aspects of the emotional functioning is a complex process that occurs in the context of emotion regulation. There are two strategies of emotion regulation; reappraisal and suppression. Reappraisal is a positive emotion that includes greater positive emotions, better interpersonal functions and improved well-being [7]. Suppression is closely related to negative emotions and poor interpersonal functioning [7]. Adolescents with emotion levels that are difficult to control will lead to negative emotions that tend to control themselves. Emotional regulation has been shown to mediate emotions, which can reduce negative symptoms such as mood disorders including stress and depression. Emotional dysregulation can also cause self-injury behavior, risky sexual behavior, suicidal movements, eating disorders, drug use, aggressive behavior and low self-esteem [14]; [15].

Emotion regulation is a treatment that is quite popular in adolescents with addiction. Emotion regulation is used as a treatment and this refers to the ability of the individuals related to emotions that are quite extensive, including (a) their awareness, acceptance and understanding of emotions; (b) the ability to control impulsive behavior when experiencing strong emotions and (c) the use of situational appropriate emotion regulation strategies to flexibly manage their emotions [14]. The results of the study show that regular gamers tend to enjoy virtual environments more compared to the real environment. They also find it easier to regulate their emotions in a virtual environment compared to the real environment.

In adolescents with regular online gaming use, it was found that based on sex, boys experienced more emotional regulation and suppression compared to girls. Boys tend to have higher reactive emotions than girls. Girls express their emotions more easily than boys. Thus it can be seen that boy adolescents have alexithymia higher than girls. Regular gamers feel their emotions more intensely and more often than irregular gamers. Whereas in adolescents with an irregular use of online games, it was found that their cognitive reappraisal was higher than that of regular gamers. Irregular gamers tend to be better at conveying their emotions, so the gamer's alexithymia levels are lower. Irregular gamers also have lower emotion intensity compared to regular gamers. Irregular gamers tend to be better at conveying their emotions, so the level of alexithymia is lower. Irregular gamers also have less intense emotion than ordinary gamers. Irregular gamers are able to manage the real environment well compared to regular gamers. Based on gender, some tend to use a reappraisal strategy that is higher than their suppression, and thus they have lower emotional reactivity than regular gamers.

Table 2. Emotional Regulation in Regular and Irregular Gamers

Descriptions	Regular gamers	Irregular Gamers
Virtual environment	More comfortable in virtual environments than real environments	Able to manage the real environment
Gender	Boys: Suppression strategy Girls: Reappraisal strategy	Boys and girls both tend to use reappraisal strategy
Reactive emotions	Boys > girls	Boys = girls
Alexithymia	Boys < girls	Boys = girls
Intense emotions	Boys > girls	Boys = girls

Internet Gaming Disorder (IGD) is an addiction due to the uncontrolled use of online games. IGD is an excessive pattern of online gameplay that results in cognitive and behavioral symptoms, included a progressive loss of control of the game, lowered tolerance and withdrawal of symptoms (Lee, Chun, Cho, & Al, 2015). This is due to the existence of impulsive behavior and aggression in children, especially in this case, adolescents. The results of the study said that in adolescents with IGD, it was found that impulsive behavior (cognitive and motoric), aggression (physical and verbal), feelings of hostility and anger were greater than those who did not experience IGD [2]. In adolescents with IGD, there was also a disturbance in the dorsal anterior cingulate cortex (dACC). This is the main area of person's cognitive and emotion control when performing tasks. The results of the study by Lee et all (2015) found that dACC in adolescents with IGD was low, so it can be concluded that the presence of low dACC activity correlates with high cognitive impulsivity in adolescents with IGD.

The problem that often occurs in adolescent gamers is the difficulty of controlling their emotions. Emotional regulation is an ability needed by adolescents to regulate the emotions within themselves. The study showed that adolescents tended to have low emotional awareness and understanding, so adolescents need the emotion regulation skill to tolerate and modify their emotions, and to have good emotional awareness and understanding [14]. Emotional regulation has an impact on emotional behavior, so this needs to be instilled in the students to prevent IGD [15]; [16]; [17].

Adolescent gamers who regularly use online games tend to have low emotional regulation. This can increase the risk of IGD. Poor emotional regulation is an important factor in the occurrence of addictive behavior [9]; [18]. Adolescents with an irregular use of online games have the ability to convey their emotions well, so they will be better able to control their emotions. Boys tend to be more at risk of IGD. The study said that as many as 81% of men experience IGD compared to 19% of women [7].

For as many as 19%, low emotion regulation in adolescents with IGD can cause depression [7]. Low reappraisal can predict depressive symptoms in adolescents [19]. For as many as 18%, low emotion regulations in adolescents with IGD can also cause anxiety. This is supported by the existence of poor cognitive reappraisal. For as many as 12%, adolescents with IGD predict hostility. Cognitive reappraisal predicts hostility. Thus, it can be concluded that low cognitive reappraisal and the high suppression of emotion regulation can cause depression and anxiety in adolescents.

4. Discussion

Adolescents are an age group that is vulnerable to mental health problems due to the use of online games. Emotional regulation is needed by adolescents to control their emotions. Emotion regulation strategies are divided into reappraisal and suppression. Reappraisal is a condition where people are able to interpret the emotions that are felt so then they can reduce the negative impact of their emotions. People can have greater positive emotions, better interpersonal functions and increased well-being overall when reappraisal is successfully carried out [7]. The results of the study found that adolescents with online game addiction have lower emotion ratings and higher suppression strategies, so it can be concluded that emotion regulation in adolescents using online games was lacking [7]. Some of the factors that cause this are gender, age, time of gaming, virtual environment, alexithymia, emotion reactivity, emotion intensity and the weakness of dACC.

The review results found that on average, regular gamers tend to be young boys. Online games are considered to be suitable games for men, more so than girls. In addition, boys also have a higher level of competitiveness than girls and thus online game content is better understood by boys. Gender influences the adolescent's emotional regulation strategy [7]. Adolescent boys tend to be less able to regulate their emotions and they use more emphasis regulation strategies compared to adolescent girls [11]. Thus it is natural that regular gamers are dominated by boys compared to girls. The difference is that irregular gamers are more likely to be dominated by adolescent girls. In addition, irregular girl gamers are more able to regulate their emotions and to reassess better compared to boys who are irregular gamers.

The age of the online gamers influences the regulation of adolescent emotions [7]. Adolescents tend to have difficulties in terms of identifying, describing and expressing emotions that are appropriate when experiencing an event [11]. There is no difference between regular and irregular gamers based on age. The average online game user is 13 - 14 years old. At that age, adolescents tend to act only to get personal satisfaction as an effort to divert themselves from the problem at hand.

The duration of time spent gaming by regular gamers is more when compared to irregular gamers. The results of the study said that there was not much difference between the number of regular users and those who were irregular at online gaming [11]. The review results revealed that regular gamers spend around > 40 hours a week playing online games. The study said that activities

that take up more than 30 hours of free time per week can affect the development of their education, health and social aspects in adolescents [20]. Thus the long time spent playing online games can risk influencing the adolescents in their development, especially for regular gamers. The duration of the time spent gaming also results in the adolescent being more exposed to and comfortable with the virtual environment. The convenience of living in a virtual environment causes the adolescents who play online games regularly to be able to regulate their emotions virtually compared to regulating their emotions in real life. This must be done immediately, because these conditions will try to take over the individual's environment in a real way and it can control the regular life of gamers through a virtual environment. Thus, regular gamers tend to risk having a condition of unreality.

The results of the review found that regular gamers tend to be less able to express their emotions compared to irregular gamers. This is due to the lack of reactive emotions in regular gamers. In addition to being unable to express their emotions, a flat emotional response to the environment also triggers regular gamers, who tend to have alexithymia at a higher level than irregular gamers. The results of another review stated that regular gamers have a higher emotional intensity compared to irregular gamers. Alexithymia is a factor that causes the adolescents who are regular gamers to have a higher emotional intensity. Intense emotions in adolescents who are unable to convey their emotions appropriately will result in emotional build up. This will eventually become an iceberg phenomenon which will eventually cause the adolescents to become very emotional in response to something. The impulsive and aggressive nature of adolescents who are regular gamers is also caused by intense emotions.

Dorsal Anterior Cingulate Cortex (dACC) is the main area where a person's cognitive and emotion control is centered when they are faced with a problem. The results of the study by Lee et al (2015) found that there was a weak dACC condition in adolescents who were regular gamers. The weakness of dACC was related to the regulation of bad emotions. Internet Gaming Disorder (IGD) is one of the addictive conditions caused by the use of online games that are not controlled. The study said that poor emotional regulation was a predictor of IGD [9]; [10]. Adolescents with poor emotional regulation when using online games are at risk of developing IGD. Aggression and impulsivity were the main factors that caused the adolescents with poor emotional regulation to experience of IGD. This tends to be more experienced by regular compared to irregular gamers. IGD can cause depression, anxiety, cognitive impairment, hostility, anger and the symptoms of social isolation in adolescents related to the use of online games.

Depression in adolescents can be caused by a lower reappraisal strategy compared to suppression strategies in terms of emotional regulation. The study said that as much as 19% of low reappraisal can cause depression in adolescents with IGD [7]. Depression in adolescents with ED can also be caused by their prohibitions when playing online games by those closest to them. Thus, reappraisal was the most important ability in adolescents with IGD to prevent depression.

Anxiety in adolescents with IGD tends to be caused by suppression. The study said that 18% of IGD in adolescents can cause anxiety [7]. Excessive focus on threats will increase the cognitive and emotion responses of adolescents which contributes to the improvement of anxiety symptoms. Unlike depression, the strategy for regulating emotions that are a cause of anxiety is high suppression. Another effect of suppression is that it can increase cardiovascular activity in adolescents [7]. Adolescents with IGD were also at risk of developing cognitive impairments. Cognitive disorders in adolescents with IGD are similar to addictive disorders in people, such as gambling and cocaine.

Thus, suppression as a negative emotional strategy has a very bad impact on adolescents, especially on regular gamers. Anger can also be caused by IGD in adolescents. As much as 12% of IGD can cause hostility. This is caused by bad reappraisals. Thus it can be concluded that a low reassessment can cause anger or hostility related to IGD.

5. Conclusion

The conclusion of this review is that emotion regulation is an important strategy for adolescents who use online games to prevent the occurrence of IGD. The emotional regulation of regular gamers was lower than that of irregular gamers. This is due to differences in sex, age, the duration of use of online games, the virtual environment, alexithymia, emotional reactions, emotional intensity, and weak dACC. Reappraisal strategies are needed to promote good emotion regulation in adolescents. IGD is one of the effects of online gaming addiction in adolescents. IGD can be caused by a lack of emotional regulation. IGD can cause depression, anxiety, cognitive impairment, hostility, anger and the symptoms of social isolation in adolescents with the use of online games. Thus, an increase in the emotion regulation strategy used is needed especially for regular gamers to prevent IGD and other effects.

ABSTRACT

Several self-management programs have been developed to empower patients with severe mental illness in achieving recovery. Peer support is one of the interventions used to help patients improve self-management through the support of other schizophrenic patients. While there was strong evidence of the influence of peer based support, this systematic review aims to identify and appraised peer based support research with a sample of adults with schizophrenia. The literature review was employed the PRISMA guidelines, we systematically reviewed articles from the Scopus, Proquest, CINAHL Ebsco, and Science Direct databases for RCT research with 2013-2019 limitations and using English. Twenty articles were identified, and fifteen articles were analyzed based on interventions that peer based in schizophrenia patients with reported results of self-management, psychological result and quality of life. Thus, systematic reviews showed participants valued support to connect with community-based resources, emotional supports offered and practical supports provided. This increases the patient's level of activation (knowledge, skills and confidence) to manage their health and health care. More highly activated are more likely to engage in positive health behaviours to manage their health conditions more effectively and improve quality of life.

Keyword: schizophrenia, self-management, peer-led, support, QoL

1. Introduction

Schizophrenia causes serious damage to the social, cognitive, affective and daily functioning aspects of an individual's life. Pharmacotherapy is effective at controlling the active symptoms of this disorder and reducing the vulnerability to relapse but it does not overcome the problem of a lack of various abilities that occurs due to schizophrenia. In general, they lack social functioning after hospital treatment. The management of clients with schizophrenia needs to be managed in an integrated and comprehensive manner for optimal repair and to prevent recurrence. This handling requires the integration of medical, psychological and psychosocial inputs.

Some of the previous studies suggested that self management is an effective technique used to help manage disease and it can also facilitate the carrying out of regular medical checks on people with a variety of serious mental disorders, increase the regularity of their drug consumption as a prevention of relapse in the patient's schizophrenia, the control of the symptoms of various disorders, self-care, social skills and it can also improve the social functioning of individuals with schizophrenia

who live in the community. Self management is a part of the technique known as behavior modification that focuses on producing behavioral changes based on the principles and procedures that include self-monitoring, self-reward, contracts or agreements. Self-contracting and stimulus control is used to improve the skills of the patients in the expected learning process. Self management is the ability of the individuals to manage the symptoms of diseases such as the physical and psychological changes that are a consequence of the self-changing patterns of life during treatment that are inherent in chronic conditions. In the last few years, self-management has been realized as important in terms of empowering patients with chronic diseases to facilitate treatment, including in chronic recurrent schizophrenia which is listed as a severe mental disorder [1]. Schizophrenia is one of the most common medical diagnoses and it is a severe or chronic mental disorder. The most common cause is low economic status. Schizophrenia is ranked the fourth most common disease in the world, where an average of 1-2% of the global population is experiencing mental health problems.

In Indonesia, the prevalence of schizophrenia is 1.7%, with the prevalence in the East Java province at 2.2% within the population. Included in the category of chronic diseases, schizophrenia causes serious damage to the social, cognitive, affective and daily functioning aspects of one's life [2]. The pharmacotherapy given cannot overcome the persistent psychotic symptoms, impaired social functioning, dissatisfaction with poor quality of life and their work status. This fact makes schizophrenia the eighth most common cause of disability in individuals aged 15 - 44 years [3]. To prevent disability in these patients, good self-management from the patients is needed. The cognitive, skills and psychosocial abilities due to the poor self-management of the schizophrenic patients triggers a relapse [2].

Some studies have found that the symptoms of schizophrenia relapse in about 50% of individuals in the span of one year after the remission of the previous episode; 85% of individuals experience a relapse within 5 years after the previous episode[4]. Based on the medical record data at Menur Mental Hospital Surabaya in 2018 in the third quarter, it was found that the number of patients with old cases totaled 335 patients, which is more compared to completely new cases. For this reason, self-management must be possessed by schizophrenic patients. Various approaches have been developed to improve and promote the self-management of schizophrenic patients [5]. One of the interventions developed was the provision of peer-based support. Peer specialists are experienced individuals who have recovered from mental illness who are trained to provide services that promote recovery, resilience and well-being. Peer specialists are a growing segment of the mental health workforce in the U.S. and in other countries. For example, in the United States, more than 30 states have some level of Medicaid reimbursement for peer specialists. This number is expected to grow with the implementation of the Affordable Care Act.

Specialist colleagues are a plus for health interventions because they bring credibility, trust, resilience and hope to people with schizophrenia. They also function as positive role models who use their experience to provide role, information and emotional support. Peer-based programs for people with schizophrenia produce as good or better results than non-peer-based programs for certain outcomes (e.g. hospitalizations, engagement in care, empowerment), particularly when peer specialists deliver evidence-based interventions. For instance, a manual peer-led self-management program was found to be superior to the usual care services at lowering the severity of mental health symptoms and producing greater hopefulness and the quality of life [6]. Despite these promising results, the impact of peer-based interventions for self management relate to the quality of life of

people with schizophrenia remains unclear. To address this important gap, we conducted a systematic literature review of the peer-based support for people with schizophrenia. The aims of this review were to rate the methodological quality of peer-based health intervention studies, to summarize the intervention strategies and study outcomes and to evaluate the inclusion of racial and ethnic minorities in the studies.

2. Research Methods

2.1. ***Search Method and Study Selection***

We used the PRISMA guidelines to inform our literature review. We searched through several databases such as Scopus, Proquest, CINAHL Ebsco and ScienceDirect. The limitations used were that the research articles had to use English and that they had to have been published in the range of 2014 - 2019. Our search strategy included the term schizophrenia and other mental disorders such as hallucinations, illiteracy, suicide risk and bipolar disorder. The interventions provided were peer-based interventions and support. The studies were quasi-experimental or randomized control trials within the community and hospital settings.

The articles were included if they met the following criteria: (1) published in English in the range of 2014 – 2019; (2) described the health interventions or support delivered by their peers or their peers facilitated by health workers; (3) included adult patients who experience schizophrenia and (4) evaluated the impact of interventions focused on physical and psychological health, patient activation, self-management ability and quality of life. To evaluate the feasibility of an article, the author reviewed the articles' title, abstract and full text. Any disagreements in eligibility were resolved by consensus. The initial search found 174 studies. After deleting the duplicates, we selected 20 articles and narrowed them down to 14 articles that were in accordance with the specified inclusion criteria.

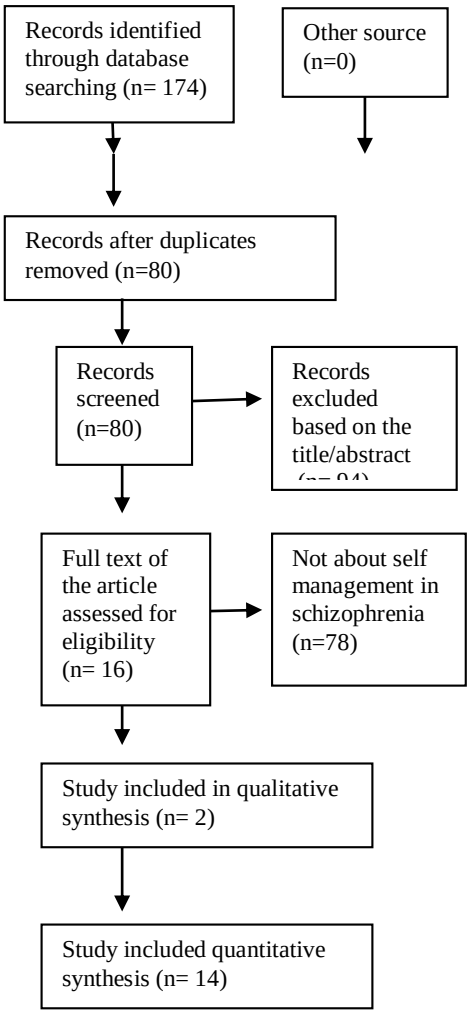

Figure 1. PRISMA flow diagram on the literature search and inclusion methods.

*2.2. **Analytical Strategy***

Standardized forms of abstraction for the data were used to systematically code the study characteristics, including the research objectives, location, design, intervention characteristics (e.g. format, duration of intervention), the type of peer involvement, peer training and supervision, the feasibility of the study criteria, the total sample size, the sample characteristics (e.g., age, gender, race and ethnic group), the outcome measures, the summary of the research findings and the limitations of the study. The extraction of the data was done using the PICOS approach. The selected population in this review was adults with schizophrenia based on the DSM V criteria. The intervention of this study was peer-based self-management support in either a group or individual format. There was no comparison between one intervention with other interventions. The output reported that there is an effective impact of peer-based support on the psychological results, self management and quality of life.

3. Results

*2.1. **Study Characteristic***

The study characteristics are as described in Table 3.1, with 14 articles consisting of randomized control trial studies and 1 article using mixed methods. The number of samples included in the study was 10 - 428 samples with a mean of 187. The majority were male (88%). The age of the respondents in the sample was adult individuals ranging from 17 - 65 years old with chronic mental illness, such as schizophrenia, schizoaffective disorder, bipolar disorder, depression and Post Traumatic Syndrome Disorder (PTSD). For the research setting, as many as 5 studies took place in the USA, 2 studies took place in the UK and Australia and the rest were in Germany and Norway. The study setting was both hospitals and communities. The duration of the intervention given was in the range of 6 - 8 weeks with 12 months of follow-up.

2.2. ***Intervention Characteristics***

The summary of the interventions from the research has been summarized in Table 3.2. The entirety of the studies used interventions that were delivered or carried out by their peers, namely schizophrenic ex-patients who had been trained to do so. All of the studies defined peer specialists as people with the experience of recovering from mental illness but their qualifications varied from having a high school diploma to completing formal instructions and some form of internship. Peer specialist training on the health intervention also differed in intensity, duration and method. One article used a smartphone as a medium [7]. The basis of the intervention program was the same, namely a chronic disease self management program (CDSMP) that was developed into various programs, namely the Health and Recovery Program (HARP), Living Well, BRIDGES and SHARE which involved a team consisting of both doctors and psychiatrists [8]. Fourteen articles used a group intervention and ended with 12 months of follow-up.

2.3. ***Study Outcomes***

In this section, we summarized the findings of each of the health outcomes examined across the 14 articles. We also categorized the effects that the interventions had on the outcomes in terms of them being beneficial, mixed or limited based on the study findings.

3.3.1. Self Management. Twelve articles reported on the results of independent management. In accordance with the core elements of self-management, this included breaking and setting goals, defining a trigger and the indicator of decline. Several studies have reported on the results of several indicators issued in the implementation of self-management that include empowering[9,10], medication adherence attitude [7,9], perceived social support [9] and community involvement [11]. Other studies have shown a change in attitude and demeanor that indicates readiness to undertake self-management and confidence [12], psychiatric self-management skills [5,7,13], self-efficacy [7,8,10,14,15] and self-management knowledge [16]. This readiness is also enhanced by an increase in Patient Activation Measures.

3.3.2. Psychiatric Symptoms. Eight articles reported changes in the psychiatric symptoms. These symptoms include the recurrent symptoms experienced by the patients including improvements in their cognitive and social functioning and psychological well-being[9,17]. The changes occurred after the 12 months follow-up. One article reported that there was no difference between the treatment

group and the control group after the intervention, but the treatment remained influential on the psychiatric symptoms [8].

3.3.3. Quality of Life. Four articles reported quality of life-related outcomes, including health and mental health-related quality of life. The effects of these interventions on the quality of life indicators were mixed. Changes in quality of life were obtained on average after 6 months of follow-up [18]

4. Discussion

Self-management is a strategy used to overcome chronic problems by using education to teach individuals to overcome active challenges and to solve problems related to their illness. Self-management also shows potential as an effective paradigm with patterns of preparation for health early on in life and it also provides strategies to reduce disease and to manage it early [19]. In schizophrenia, self-management is defined as an approach designed to involve individuals with schizophrenia as active agents in patient care by teaching the patients to monitor their clinical patient status themselves, to avoid high-risk stressors, to carry out treatment according to their regimen and to use various coping strategies and compensation when other symptoms and problems related to the patient's mental condition arise [20]. Living with chronic disease, including schizophrenia, requires self-management to facilitate well-being, to reduce the effects of the disease and to limit the development of the disease. Self-management in schizophrenic patients not only helps the patients to manage their condition but it can also improve their ability to make treatment decisions and the ability to manage their psychotic symptoms. In the concept of chronic disease, self-management is defined as an important step that allows individuals to play an active role in the disease experienced [21].

Cognitive limitations and skills due to schizophrenia are a complicating factor for patients implementing self-management, which ultimately makes the patient's health condition worse, especially in terms of their psychosocial abilities. Peer-based support is one of the interventions used to help patients to improve their self management. This form of intervention for patients with schizophrenia has the common goal of being a long-term disease management program in general while providing information, teaching skill recovery, providing emotional support and increasing empowerment and self advocacy. Most programs led by coworkers have the core component of sharing it with friends, which emphasizes that the participants play a central role in, and are responsible for, their own recovery. [10]. The participants are encouraged to make their own decisions and to set realistic recovery goals that they like. These approaches allow the participants to learn to help themselves and each other through peer support, sharing their strength and sense of personal responsibility. This empowerment process increases expectations, self-esteem and self-confidence.

The results of the literature review conducted showed that peer-based support gave positive results when referring to the self-management of schizophrenic patients. The interventions carried out increase patient activation, in which patient activation shows the patient's self confidence and self-efficacy in the context of self-management. Self-efficacy is one component in self-management where this component is affected, one of which is support. Good self-efficacy in the patients provides them with the ability to carry out the tasks and roles given to them, one of which is self-management [22]. Increased self-efficacy shows a high acceptance of challenging tasks, lasting longer on assignments and overcoming setbacks quickly. Increased self-efficacy can also predict appropriate

coping strategies, imperfect life acceptance and personal growth[15]. It is also possible for it to influence self-management behavior.

The selection of one's peers as a facilitator and as a source of support also influences changes in self-management. Peer support is a facilitator coming from ex-schizophrenia patients who have been trained to provide support to other patients. The role and peer tasks as a facilitator relate to the ability to reflect on their own experiences and coping skills, the competence and willingness to actively use their own experiences as a resource in order to make it visible for users and to argue them critically, the conscious use of their own experiences to reduce inhibitions or to challenge appreciations and prejudices and a constructive approach when dealing with public stigmatization [15]. The existence of peer support can increase the bonding between patients both emotionally and practically. Using peer facilitators with a group format provides a credible source of social support for health behaviors which is the main key to maintaining disease management [14]. In addition to providing support, peers as a facilitator also helps the patients to share their life experiences. Life experiences shared with others helps t ignite their hope for the future and it also provides valuable social contact where limited social contact is a common issue identified in schizophrenic patients [17]. The expectations obtained can also affect the patient's self confidence and self-efficacy in terms of self-management.

Peer-based support provides meaningful activity for the patients, which influences the increase in their daily activities which can improve the wellbeing domains that are intellectual, social and psychological. This can reduce the persistent symptoms that arise. Furthermore, effective peer-based support interventions given in the first month after discharge from the hospital were identified as being delivered at the right time because at that time, the services were not optimally coordinated and a number of risks were at a higher level [11]. The further effects that the patients get from peer-based support include reduced readmission and improved functioning. The quality of life of the patients is possible but the study undertaken in the literature review shows no significant changes in the short term.

Establishing peer relationships is another approach used when providing social support other than through the family. This has become effective because of the benefits obtained based on several studies. Self management with peer support connects two or more individuals who experience the same chronic condition with the same feelings and anxiety related to dealing with the disease. This can help to change the required behavior and this leads to a more positive lifestyle. The results can be maximized with the involvement of health professionals as the facilitators.

The limitations obtained from peer-based support interventions are, in all studies, showing that the effects such as self management skills and reduced symptoms only last no more than 6 months to 18 months of follow-up [13]. We need a sustainable intervention that affects the quality of life of the patients. The maximal effect is possible due to the presence of fewer patients at each session; a strong commitment from the patient and a renewal of the intervention is needed. This systematic review has limitations, namely that there is limited research related to peer-based support. Some researchers only report on the feasibility and protocols of peer-based support so further research is needed.

5. Conclusion

Our systematic review found that peer-based support had a significant effect on the self-management of schizophrenic patients. Some of the articles showed the result that the support

provided by the patients' peers provides positive results related to the self confidence and self-efficacy of patients in terms of self-management. Peers as an intervention facilitator also plays a role as a credible source of support for health behavior which is the main key to health management. The use of the group format is also recommended to increase the desired results and the timing of the intervention, which is 1 month after hospital treatment. However, the effectiveness of peer-based support showed a decline after 6 - 18 months follow-up. A follow-up plan is needed following the intervention to provide long-term effects, especially related to the quality of life of the patients. Collaboration with other health workers such as psychiatrists, psychologists and nurses is also needed to look at the effects of wider interventions. The limitations of the systematic review of the research articles was that it was only limited to protocols and the feasibility of the specific form of peer-based support used; this needs to be followed up.

ABSTRACT

End of life care contradict with the expectation of the elderly sometime. Culture and ethnicity maybe play the main role in the end of life care decision making. The aim of this study was to explore about end of life care preference among the elderly. Literature search performed in 2015-2019. Data base used in this study were Scopus, Sage, Elsevier, and Oxford. Inclusion criteria were full-texts of the selected article. Exclusion criteria were literature review, editorial, and critical synthesis. Ten articles were included in the systematic review: 2 cross sectional, 4 qualitative study, 1 cohort, and 3 mixed method. Culture played a role how individuals had an end of life care decision making. Many elderly did not chose end of life care, except for supportive or non-curative services so they would likely pursue them. Some of their preference were liked to die at home and avoided a high cost. End of life care sometimes is not suitable with the expectation of the elderly. To avoid inappropriate end of life care to the elderly, we recommend to respect to the elderly's autonomy by looking the culture.

Keywords: end of life care, decision making, elderly

1. Introduction

A global phenomenon is an aging population. That phenomenon brings in new challenges because of the increasing number of older people with chronic illness and disabilities [1]. The chronic illness and disabilities of older people involves end of life care. Cultural values and the ethnicity of a person may play an integral role in end of life care decision making. End of life care is a medical treatment that can be provided against an individual's wishes sometimes, so this increases their burden and discomfort both financial and emotionally [2]. If the wishes of the older people's approach to end of life care are better understood, then family conflict can be reduced [3].

Frailty is the most condition among the elderly in end of life situations [4]. Support could include helping the patients and family support. Health care professionals can help the patients to express their wishes [3]. In America, those who die in every year spend the last phase of their lives experiencing repeated hospitalization that is ineffective and the burden of high-intensity treatment [5]. Thus the aim of this study is to explain the preferences related to end of life care among the elderly in order to fulfill the elder's wishes, to reduce family burden and to prevent inappropriate care being given to the elderly.

2. Methods

2.1 Inclusion and Exclusion Criteria

The inclusion criteria were that the full text available of the selected article. The exclusion criteria were a literature review, editorial and critical synthesis.

2.2 *Search Strategy and Selection of the Studies*

The preparation of this systematic review began with the selection of the topics. The keywords were then determined and the literature search was performed between the years 2015 and 2019. The databases used in this study were Scopus, Sage, Elsevier and Oxford. The keywords used were "end of life care", "end of life", "elderly", "decision making" and "preference end of life".

3. Results

3.1 Summary of the Articles

No	*Author*	*Title*	*Methods*	*Results*
1	**(Ohr *et al.*, 2016)**	Cultural and religious beliefs and values, and their impact on the preferences for end-of-life care among the four ethnic groups of community-dwelling older persons	**D:** cross-sectional **S:** 453 elderly (≥65 year old) from 4 ethnic groups (Anglo Celtic, Mediterranean, Eastern European and the Asia/Pacific) in Australia **V:** - Truth telling and advanced care planning - Preferences for EOL care **I:** EOL care survey (Straw & Cummins, 2003) **A:** Cronbach's alpha	***Death and dying*** - More than 92% of the respondents believe that death is a normal part of life. More than 70% feel comfortable talking about death and dying. ***Truth telling*** - More than 74% of respondents want the doctor to tell them when they are dying and 80% of the respondents said that they would tell their family if they were dying. ***Advanced care planning*** - Almost 60% of respondents reported that they have thought about medical care when they were dying. ***Preferences for end of life care*** - More than 60% of the elderly claimed that they did not want to prolong their life, such as being supported by a breathing machine, if their brain has stopped, tube feeding and feeling severe pain. - More than 80% of the respondents strongly

				agreed that comfort and being free of pain were important to long life if they had an untreated disease. - Almost 60% of the respondents claimed that it is better to be treated at home than in the hospital if they had an unhealed disease. There are differences between *truth telling* and preferences for EOL care.
2	**(Nakanishi, Niimura and Nishida, 2016)**	Factors associated with end-of-life care by home-visit nursing-care providers in Japan	**D:** Cross-sectional **S:** 138.008 samples from 3513 data providers **V:** End of live care (dependent) and the patient, demographic details and the institutions (independent) **I:** Survey of Institutions and Establishments for Long-Term Care (SIEL), **A:** Multivariate binomial logistic regression analysis	- 138.008 samples; 2280 (1.7%) got a nursing home in the last month of their life. - 2280 patients had nursing at home: age (average 78 years old), sex (woman), high dependency, severe cognitive impairment, type of extended family and primary disease - 1651 patients received nursing at home because of cancer
3	**(Boucher, 2017)**	Faith, Family, Filiality and Fate: Dominican and the Puerto Rican Elders' Perspectives on End-of Life Decisions	**D:** Exploratory study used grounded theory **S:** 51 elderly in Dominican NYCHA, Dominician non-NYCHA, Puerto Rican NYCHA and Puerto Rican non-NYCHA **V:** The characterization of the family involvement in health decisions, filial piety, religiosity/spirituality and fatalism as they relate to attitudes/ intentions toward end-of-life (EOL) planning/decision making among elderly **I:** Using an interview guide **A:** Nvivo 10 (QSR	- There are no significant differences between attitude and the intention towards advanced care planning between Dominican and Puerto Rican or NYCHA and non-NYCHA residents. ***Fatalism and spirituality/religion*** - Everything will be as it will be, including this life. Thus there is no specific planning related to end of life decision making. - God's will ***Family involvement in health decisions and filial piety***

			International)	- Most of the respondents express their wishes to involve their family in decision making near to the end of their life. However, they are often obstructed by distance, emotions and truth. - 12 respondents have discussed their *end-of-life decisions* with their family. - Some of the respondents are uncomfortable discussing the *end of their life*. - The barriers to discussing end of life decisions are that they are too young, that they have no illness and that they don't understand about advanced care planning. - Most of them did not like to be supported by machine.
4	**(Dennis and Washington, 2016)**	"Just Let Me Go": End-of-Life Planning Among Ojibwe Elders	**D:** Qualitative descriptive **S:** 20 elderly (average age was more than 70 year old) **V:** The elderly's view about the end of life and their attitude and behavior towards advanced care planning. **I:** Semi-structured questions **A:** analisis tematik induktif	**Hasil** - **Need a little formal planning** The respondents did not show any anxiety about facing the end of their life, although some of them had a chronic illness or multiple diseases. They claimed that life will progress naturally. There is no formal planning for end of life care. - **Open mind about advanced care planning** No one had a formal note about their preference for end of life care. However, they considering starting thinking about that. - **Want a peaceful death** The respondents expressed that they

				always prayed in order to get a peaceful death. A peaceful death means that when they are dying, they are surrounded by their family and children.

3.2 Demographic Characteristics

The age of the elderly in this research was 60 year olds and over in the Hunter Region of Australia divided into ethnicities such as Anglo-Celtic, Mediterranean, Eastern European and Asia/Pacific; Dominicians living in New York, Japan, America, California including Caucasian, Asian Americans, African Americans, African Americans and Hispanic Americans, and China.

3.3 Preference End of Life

3.3.1 Institutionalized Care at the End of Life Was Preferred. The reason for institutionalized care at the end of life stage was because they did not want to be a burden on their family or because their family could not provide good care. The second opinion was because the children were living at a distance away from them, so they had no choice but to go into an institutions, most commonly a health institution [3]. For example, the chronically ill with end stage renal disease (ESRD) will likely use the ICU or life support equipment and they are more likely to die in the hospital [4]. Most of the respondents with heart failure, stroke, lung cancer, and colorectal cancer went t a hospice or a nursing home [5].

3.3.2 Life-Prolonging Measures Were Not Preferred. When the elderly had a terminal disease, they desired not to have medical treatment to prolong their life [3]. The respondent's beliefs are that death should be avoided at all costs. The respondents also indicated that they did not want to live as long as possible if they were on life support or a breathing machine, if their brain had stopped working, if they had to be fed through a tube and if they were in severe pain. Almost all of the respondents strongly agreed that being comfortable and out of pain was more important than prolonging the duration of life [2]. Several interviewees clearly stated that that they did not want to be on life support if it meant being on a machine for weeks or being in pain [6].

3.3.3 Autonomy, Family, or a Doctor in End of Life Decision Making. The respect given to the

doctor's medical opinion at the end of their life by the elderly is because they believe that the doctors are professional and knowledgeable [3]. They would tell their family if they were dying more than they would say so to a doctor [2]. The elderly expressed a desire to involve their family in the end of life decision making but several of the elderly noted that this was not possible due to geographic distance. There is the parent's expectation of their children as well as their own experience of caring for their parents during illness to consider [6]. Many of the interviewees strongly agreed that the combined power of personal choice and strength from God allowed them to make the correct decision [6].

3.3.4 Nursing Home End of Life Care. Greater physical dependence, being older, severe cognitive impairment and being diagnosed with a malignant neoplasm meant a significantly greater likelihood of receiving end of life care. Only 1.7% the elderly receiving nursing care at home within the last month of life in Japan [1].

3.3.5 Little Formal Decision Making. The elderly were generally accepting of what comes next. Most of them utilized control including diet, exercise and following the medical providers' advisement, but how one will die was universally put into the hands of God and down to random chance. They ultimately know God to be the final arbiter [6].

4. Discussion

The older people, regardless of their cultural background, preferred to be told if they were dying with a strong belief that dying is a normal part of life. They have thought about the care that they want at the end of life and they talked to their family when they were really unwell. More than half told the doctor or their general practitioner [2]. Clinical complexity is closely linked to uncertainty in end of life care and concerning the patients, so it causes difficulties in both diagnosis and decision making [7]. On the other hand, wisdom and subjective well-being effect a greater number of the elderly for nursing home residents and hospice patients in the end of life care sample [9].

Culture has been prominent in health care. Death should be avoided at all costs [2]. However, it is contrary to the findings of the study; most of the respondents with heart failure, stroke, lung cancer and colorectal cancer had been to a hospice or nursing home in the last two month [5]. Contrary cases should be considered as there are some factors influencing end of life care, including finances, family beliefs and behaviors, culture and religion, and health care system communication between the doctor and patient [7].

In terms of culture, their ethnical background indicated that they do not want to live for as long as possible if they are on life support, if their brain had stopped working, if they had to be fed through a tube and if they were in severe pain. Contrary to this, African Americans wanted aggressive care at the end of their life. The Asia/Pacific group had strong preference for being in the hospital or emergency room for an incurable disease [2].

Other research showed that the percentage of the elderly that were pro-ANH (artificial nutrition and hydration) in Japan was very low. Many of the elderly did not have clear wishes about their end of life care [10]. The limitations of this study are that it needs more literature to support the review and that it doesn't focus on a specific ethnicity, culture or religion to make a specific conclusion related to the preference for end of life care.

5. Conclusions

The research shows that the preferences for end of life are varied, and that cultural and religious beliefs may have an impact. The different ethnicities from the different cultures involved had different viewpoints. In this review, all of the involved ethnicities – Anglo-Celtic, Mediterranean, Eastern European and Asia/Pacific, Dominicians living in New York, Japan, America, California including Caucasian, Asian Americans, African Americans, African Americans, Hispanic Americans and the Chinese - had their own opinion on end of life care.

ABSTRACT

Indonesia is a disaster laboratory. Many disasters have occurred in Indonesia. There is no systematic review that explains the prevalence and incidence of PTSD after natural disasters in Indonesia. Objectives of this review were to explain the prevalence of PTSD in children, the elderly and all age groups between, after natural disaster in Indonesia. A systematic review, following PRISMA guidelines, was undertaken to identify the incidence and prevalence of PTSD after natural disaster in Indonesia. The following databases were searched: Scopus, EBSCO, SienceDirect, Springerlink, and PubMed were used to search scientific contribution which is published between 2007-2017. Articles pre-identified by using relevant keywords. A total of fourteen papers were identified about 178 articles both meet inclution and exclution criteria and were reviewed. The papers were identified are natural disaster such as tsunami, earthquake, and volcanic eruption. The mean prevalence of PTSD in Aceh was 77.1%, in North Sumatra was 33%, in Central Java was 52.4%, and Bantul was 37%. Some study identified PTSD incidence in Aceh as 20.6%, 63.1%, 10.39%, 70%, 24.6%, 35.6 % and 48% between 2008-2015. The mean prevalence rates of PTSD were highest in Aceh and lowest in Bantul.

Keywords: PTSD, natural disaster, Indonesia, incidence, prevalence

1. Introduction

PTSD develops in response to a traumatic event. About 60% of men and 50% of women experience a traumatic event at least once in their lifetime. Most people who are exposed to a traumatic event will have some of the symptoms of PTSD in the days and weeks after the event. For some people, these symptoms are more severe and long lasting. The reasons why some people develop PTSD are still being studied. There are biological, psychological and social factors that affect the development of PTSD[1]. Disaster is a defined as a potentially traumatic event which may be collectively experienced and that can be attributed to natural, technological or human causes. [2]

Natural disasters such as earthquakes can threaten and disrupt the lives and livelihoods of people caused by natural and / or non-natural factors and human factors resulting in human casualties, environmental damage, property losses, and psychological impacts (Undang-Undang No.24 Tahun 2007). These psychological impacts can cause many mental health problems[3].

Trauma to individuals associated with an event can include a dangerous physical or emotional threat that can be life threatening and it can cause a loss of effects in relation to individual functions and mental, physical, social, emotional or spiritual well-being [4]. The most common reactions such

as the sadness, anxiety, anger and stress experienced by victims after a disaster are normal responses to very abnormal situations[4].

Even though everyone will be affected in some traumatic events, the reactions and feelings of each person can vary. Many people may feel very scared or anxious or they can feel numb and feel separated. Some people can have a mild reaction but a few will experience a severe reaction. Many factors determine a person's reaction such as the nature and severity of the trauma experienced, previous traumatic experiences, the support that they have from others, physical health, their personal and family history of mental health problems, cultural and traditional backgrounds and age (children from different age groups will react differently).[5]

Everyone has the strength and ability to overcome life's challenges but some people who are very vulnerable in crisis situations will need additional assistance such as special groups of children and adolescents. Children and adolescents are vulnerable to mental health problems after a disaster. Most teenage victims only display transient psychological symptoms as a normal reaction to traumatic events [6]. Children who survive earthquakes may have many psychological problems, such as stress, depression and anxiety[7]. Other psychological impacts include prolonged sadness, substance abuse disorders, distorted perceptions, pessimism and suicide attempts[6].

The re-exposure to disasters has a worse effect on the mental health of children and adolescents. Children and adolescents who have been exposed to disasters will be more sensitive to the negative impacts of subsequent disasters [3]. The psychological impact of mass catastrophes in developing countries is rarely evaluated systematically. Post-traumatic stress disorder is indiscriminate: the condition can manifest in people from different cultures, demographics and parts of the world and after a variety of disaster-types. Researchers have examined the prevalence of PTSD in children, the elderly and all of the age groups between [8]. Indonesia is often hit by disasters caused by both natural and human factors. The Asia Disaster Reduction (2019) reported that Indonesia experienced 47 earthquakes, 41 floods, 47 landsides, 14 volcanic eruptions, 7 episodes of heavy rain, 6 tsunamis, 4 incidences of volcanic activity and 14 flash floods in the 19-year period between 2000 and 2019. One of the most recent disasters in Indonesia was the tsunami in 2004. During the tsunami, more than one million people died.[9] This study is intended to determine the prevalence and incidence rate of PTSD related to natural disasters in Indonesia.

2. Research Methods

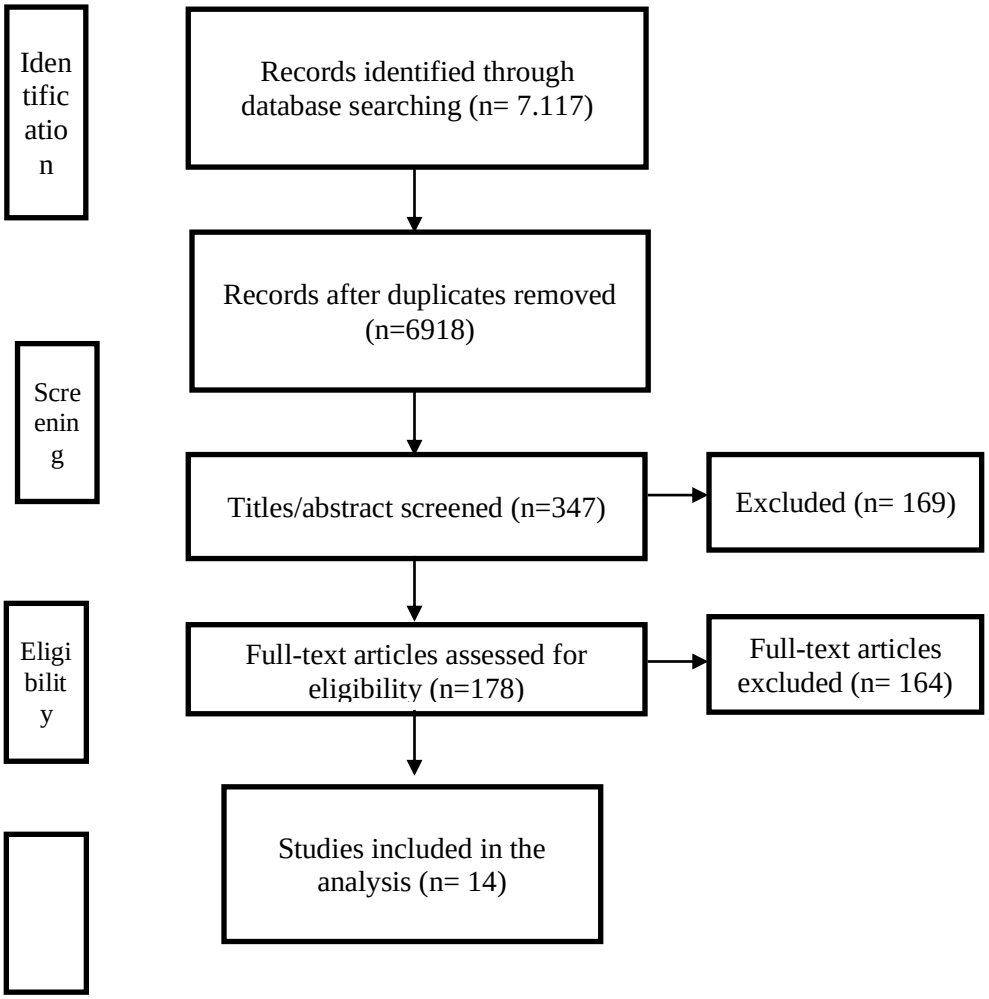
The study employed a systematic review methodology using the guidance of PRISMA, which aimed to establish, through the available literature, the incidence and prevalence of PTSD in Indonesia.

2.1. Search strategy

Systematic searches were conducted through the following electronic databases: Scopus, EBSCO, ScienceDirect, Springerlink and PubMed. This was in order to identify published studies on the prevalence of PTSD. The following search terms and strategy was used (“traumatic stress” or PTSD or posttraumatic or posttraumatic stress disorder or trauma or post traumatic or post-traumatic) AND (disaster or natural disaster) AND (prevalence) AND (incidence) AND (Indonesia). The databases were searched from January 2007 to December 2017 (date last searched).

Figure 1 shows the results of the systematic search. As can be seen, this returned a preliminary database of 7.117 papers. The titles and abstracts of these articles were reviewed in order to exclude

irrelevant studies and the remaining studies were evaluated against the inclusion criteria. Where the abstract failed to provide sufficient information, the full article was reviewed. The full-texts were examined for eligibility out of the 14 articles that met the inclusion criteria. Full copies meeting the inclusion criteria identified during the search were used for the synthesis of the data. Articles found in the reference lists were considered if their titles were relevant.



1.1.1.1.1.1 Figure 1. Study inclusion based on the preferred reporting items for systematic-reviews

2.2. Inclusion and exclusion criteria

This review considered all studies that involved human subjects of any age that currently had PTSD following a natural disaster in Indonesia. The review considered all of the published studies related to the epidemiology (incidence/prevalence) of PTSD in Indonesia. Grey literature, unpublished articles, retrospective studies and reviews were excluded but there were no limits for language.

2.3. Data extraction

Articles that seemed to meet the aims and inclusion criteria according to their titles and abstracts were read in full text to determine whether the paper should be included. Using a data extraction table, the 3 authors extracted the data from the included articles. The following data were collected: author, date of study, title, source, study geographical location, study setting, study design and the

prevalence/incidence of PTSD.

2.4. Studies included/excluded

A total of 7.117 studies were found during the initial search of the databases and 6.918 duplicates were removed. Following the removal of duplicates, the titles and abstracts where relevant were reviewed and 169 articles were excluded based on the inclusion and exclusion criteria, particularly geographical location. The full texts of the remaining 347 articles were reviewed. Another search of the included articles within the bibliographies identified 178 additional papers. Following this, 164 papers were excluded because they did not meet the inclusion criteria. Finally, 14 papers were included for data extraction and quality appraisal. The flow of papers through the search has been shown in the form of a PRISMA flow chart (Fig 1). Due to the differences in the data collection methods, study populations and study settings, the results have been presented as a narrative summary for ease of understanding and to better appreciate the data. For the prevalence and incidence measures, the denominator was the total number of people reported in the articles who participated in a particular study.

3. Result

3.1. Geographical location

The articles included in the review were from Province Nanggroe Aceh Darussalam (50%; n=7), combined Province North Sumatera and Nanggroe Aceh Darussalam (14.29%; n=2), Province Daerah Istimewa Yogyakarta (14.29%; n=2), combined Province Daerah Istimewa Yogyakarta and Central Java (7.14%; n=1), Central Java (7.14%; n=1) and one of the articles included in the review was from a general province in Indonesia.

3.2. Study setting

Most of the studies were conducted in the affected districts and sub-district impacts following a natural disaster. Furthermore, 4 studies were conducted in schools such as elementary school, junior high school and senior high school. Finally, 1 study was conducted in a rural community in Indonesia.

3.3. Study population

The population of these studies consisted of all of the people affected by natural disasters and 1 study had a population that was not directly exposed to the disaster in order to compare the prevalence of PTSD after trauma (Irwanto, Faisal, & Zulfa, 2015). The participants were of either gender and of different age ranges. The population characteristics were different in each study and these have been recorded in the data extraction table as shown in Table 1.

3.4. Sample size

The total sample size of all 14 included studies was 25.839. The smallest sample was 64 and the largest sample was 20.500. The largest sample was obtained for the study by employing a cross-sectional design focused on tsunamis in the two combined provinces of Nanggroe Aceh Darussalam and North Sumatera.

3.5. Outcomes: prevalence and incidence of PTSD

Only one of the included studies measured the incidence of PTSD - 10.39% in Nanggroe Aceh Darussalam, which was a randomized controlled trial study. The remaining 13 studies reported on

the PTSD prevalence rates. Seven studies reported on the prevalence of PTSD in Nanggroe Aceh Darussalam with tsunamis, 1 study reported on the prevalence of PTSD in twos province in Nanggroe Aceh Darussalam and North Sumatera with earthquake and tsunamis, 3 studies reported on PTSD in Daerah Istimewa Yogyakarta with earthquakes, 1 study in Daerah Istimewa Yogyakarta and Central Java was focused on earthquakes and volcanic eruptions and one study in Central Java was focused on earthquake. The mean prevalence was 47.62%, with the lowest prevalence of 5% in Daerah Istimewa Yogyakarta with earthquakes and the highest prevalence being 47.58% for earthquakes and volcanic eruptions in Daerah Istimewa Yogyakarta. The prevalence and incidence findings that have been presented by province are shown in Table 2.

4. Discussion

This systematic review provides an overview of the published literature reporting on the prevalence and incidence of PTSD following natural disasters in Indonesia. The quality of the included studies was assessed. We identified 13 studies reporting the prevalence of PTSD and 1 studies reporting the incidence of PTSD. The reported prevalence or incidence rates were diverse across different follow-up points resulting in a wide range. The prevalence and incidence of PTSD in the included studies varied widely, similar to what was found by Greene and their colleagues, who noted that the heterogenity apparent in their findings was a result of the samples involving different levels of trauma exposure [10]. All of the studies in this systematic review were carried out at least 2 months after exposure to the disaster. The disasters identified in this systematic review included earthquakes, tsunamis and volcanic eruptions. Nine studies reported a high prevalence of PTSD in tsunami events in the provinces of Nanggroe Aceh Darussalam and North Sumatra. The prevalence shown is the highest prevalence compared to other disasters because a tsunami is a severe disaster. The severity of exposure to a disaster can increase the risk of mental health disruption [2]. In our findings, several studies showed that the area overall was not affected by trauma and this allowed them to be compared to the respondents who immediately received exposure to trauma. The result is that the respondents who are directly exposed to trauma have a greater prevalence of PTSD than those who are not directly affected by the trauma. Depression in this case can cause PTSD to occur after a disaster and this affects almost 25% of victims directly who have been exposed to the disaster [6]. Several studies report that the prevalence of depression ranges from 14.5% -40.8% among the children who survived the Wenchuan earthquake in China. Previously, disaster psychology studies showed that youths had a higher risk than adults in terms of dealing with disasters related to psychiatric problems [11].

One limitation that can be attributed to the lack of studies that discuss natural disasters in Indonesia is that Indonesia is one of the countries with varying natural disasters. In research, more natural disasters were studied that cause many casualties. Other natural disasters that occur regularly such as floods, strong winds, flash flood, landslides and wild fires that cause few fatalities are rarely found. The incidence and prevalence of PTSD can occur in anyone who has been exposed to a disaster. The limitation of these studies is that there is no research that discusses PTSD that occurs in the natural disasters that more routinely occur in Indonesia.

5. Conclusion

This article provides the results of a systematic review aimed at determining the prevalence and incidence of PTSD in the provinces of Indonesia. The highest mean prevalence rate of PTSD was seen in Daerah Istimewa Yogyakarta and the lowest mean prevalence was seen in Daerah

Istimewa Yogyakarta and Central Java. Only one study reported on the incidence of PTSD and this was conducted in an elementary school of Nanggroe Aceh Darussalam with a randomized controlled trial. Areas that are directly exposed to trauma have a higher prevalence of PTSD compared to areas that are not exposed even though they are in the same province. It is clear that reported studies about the incidence and prevalence of PTSD are still limited in Indonesia. Therefore, it reveals a large gap in terms of determining and comparing the prevalence and incidence between the provinces in Indonesia. The current data from this review demonstrates that there is an urgent need for encouraging research in the Indonesia country to contribute on a wider scale to the literature on PTSD and to develop studies that are of a higher quality and quantity.

ABSTRACT

Building the strengths of caregivers can be a valuable approach to care for people with schizophrenia. Studies on caregiver health education have been conducted but little has been done on the caregiver education with mobile intervention. This systematic review investigated the empowering caregivers through knowledge given by mobile intervention. We searched for Randomized Controlled Trials (RCTs), published in English in Scopus, Springer Link and Science Direct databases. Fifteen RCTs use mobile technology in some health problem were included. The mobile intervention was evaluated positively augmenting knowledge for caregiver to care patient, gives psychological support to caregiver, reduced number and length of medical hospitalizations in patients with schizophrenia also decreased anxiety levels of the family. Mobile intervention can be one of the ways in improving caregiver knowledge and confidence in performing care, relapse prevention and monitoring medication adherence for people with schizophrenia.

Keywords: caregivers, schizophrenia, mobile intervention

1. Introduction

Informal caregivers are essential to providing home-based care for people with mental illness even though caregivers often have limited knowledge about caring for people with mental illness. It is important to provide caregivers with the tools to help them receive caregiving support and knowledge to care for people with mental illness at home. One of the methods that can be used and that may be of low cost is e-Health. This refers to the use of information and communication technology to provide information via the professionals can take the form of a smartphone or tablet application.

As the internet become increasingly important, information and communication technology are used in almost every sphere of daily life, including in health care facilities and private homes [4]. Technology is a tool that supports knowledge building, as it acts as an information vehicle and social medium for exploring the knowledge that enhances learning and communication [2]. The use of technology, in this case mobile phones, is believed to be able to establish the caregivers' knowledge, to engage the caregivers in a dialogue with nurses and to help the caregiver to use what they have known and learnt through the technology [2]. Advances in mobile technology are increasingly viewed as enhancing solutions to expand on the range of health care delivery options [3]. Mobile technology offers a particularly promising platform for the delivery of interventions [1]. One of the

interventions that can be effective for empowering caregivers to care for people with schizophrenia is by giving mental health information to the caregivers.

People with schizophrenia generally return home and are cared for by their family members. These people rely on caregivers for support in their daily activities and in terms of rehabilitation. Their caregivers expect both educational and home-based care for people with schizophrenia. It is important to provide caregivers with the tools to help them to receive caregiving support and to learn of better ways to care schizophrenia. Changes in the psychiatric services involving the early discharge from institutions have transferred much of the responsibility of care from the psychiatric services to the family of the people with schizophrenia, whether or not they are ready to care them at home[5].

The objective of this review was to explore the evidence on the topic of implementing e-Health interventions for caregivers. The results of this study will help caregivers to care for people with mental illness, reducing risk of mental health problems in the caregivers and improving the well-being of people with mental illness.

2. Methods

2.1. Data Source and Search Strategy

The search was aimed at finding articles that contained e-Health interventions for the caregivers of people with mental illness. We were searched for articles that contained terms related to all 3 of the following main concepts: ‘caregivers’, ‘mental illnesses and ‘caregivers’. The databases used for journal searching were Scopus, Springer Link and ScienceDirect. The journal search began on February 26th and went through until March 13th, 2019.

2.2. Study Characteristics

The selection of the studies and criteria was done using the PICO approach characteristics of the study which were related to information delivery for the caregivers of people with mental illness using e-Health. The study characteristics were from 2014 to 2019 in studies that had been Scopus indexed. The language chosen was the English language.

3. Result

3.1. Study Result and Selection

The results were obtained from the databases of Scopus, Springer Link and ScienceDirect. The search obtained the results of the journal. All of the journals that were obtained were then screened according to the area of nursing.

3.2. Study Review Results

3.2.1. Characteristics of Mobile Technology. The results of the study found that mobile technology has gained interest as a device used in treatment. In this research, mobile technology has been shown to be used based on the internet. Mobile technology being used as part of e-health approaches towards providing low cost, sustainable health care to patients with chronic illness, including psychiatric disorders through their caregivers.

3.2.2. Usability of Mobile Technology. Caregivers often have limited knowledge when it comes to caring for people with schizophrenia. As the prevalence of new methods of engagement with caregivers increases, the use of mobile health comes into play to improve their knowledge and to help the caregivers to manage the mental health condition of people with schizophrenia. Mobile technology is an innovative approach used to increase the access to clinical care and also to educate the caregivers. The therapeutic effects of mobile technology empowers the caregivers to care for people with schizophrenia such as improving medication adherence, decreasing the number and length of medical hospitalizations [6], providing psychological support for their family members [2], providing guided self-management interventions for non-professional caregivers [7], opening up access to feasible and innovative resources to address caregiver burden, such as the text message component that was found to be acceptable [8] and also detecting signs of relapse and increasing medication during a warning state [9].

4. Discussion

In modern society, mobile media platforms are rapidly replacing textbooks and print media. The rapid advancement in mobile technology, coupled with the popularization of the smartphone, has opened up new avenues for the delivery of healthcare education. Consequently, health education has been forced to adapt to this change including among the caregivers who care for people with mental illness. Several studies show that the internet and mobile phones are frequently used as a resource for health-related information among caregivers, including the caregivers of depressed patients, young informal carers of persons with mental illness, the caregivers of people with mental or somatic illness and the caregivers of people with Parkinson's disease. Healthcare professionals need to educate the primary caregiver on how to provide care at home. Smartphones have made this information accessible and feasible.

This technology has great potential for education as it allows the caregivers to access information efficiently. Mobile-based interventions facilitate health promotion and mental illness management. Mental illness often relapses. Repeated relapses lead to a worsening of the patient's prognosis. To conduct relapse prevention or to minimize its severity, caregivers need to have a better understanding of the predictors[10]. Through the knowledge from mobile technology, caregivers can investigate when the early warning signs are present in people with mental illness. Therefore the caregivers will be able to conduct the early detection of the prodromal symptoms of relapse. Therefore, preventing relapses and rehospitalization is extremely important for people with mental illness[9]. Furthermore, building up the strengths of the caregivers indicates that the incorporation of the strength approach in the practitioners through an intervention can improve the abilities of the caregivers.

The development of mobile technology is an invaluable resource for caregivers that can impact on the health care related to mental illness both in terms of being cost effective and more accessible. Caregivers can communicate with other caregivers through this resource and thus they can support each other[11]. The use of mobile technology such as in a telephone support group has also been effective at providing educational interventions and emotional support for the caregivers of people with mental illness.

Mobile phone-based interventions have also been used to improve the medication adherence for psychiatric disorders through SMS reminders and daily messages for optimizing maintenance

effects[12]. It appears plausible that mobile phone inclusion may exert sustained benefits on drug-related attitudes and adherence in people with mental illness who are on medication.

Research on the use of text messaging for clinical care was also used in the evaluation of the treatment of depression. Automated SMS systems are quick to set-up, inexpensive and well-received[13]. Besides SMS reminders, providing the caregivers with telephone support also offers some advantages in the day-care setting. Caregivers are also at risk for anxiety, depression and feeling the burden of care for someone with mental illness[14]. Telephone support as a part of mobile technology is provided by qualified counselors without any time pressure and with a high level of flexibility with respect to the time of day. Through telephone support, a brief telephone intervention was given to empower the caregivers by improving their skills and this resulted in a reduction in the burden and depressiveness noted in the caregivers[15].

4.1. Overview of the existing implementation research

The objective of this study was to explore what research has been done concerning the implementation of mobile technology. Interventions for the caregivers of people with schizophrenia were common given the abundance of effectiveness trials for these types of intervention. The fact only a few research studies could be found referring to implementation in its title suggests that implementation research on mobile technology interventions for the caregivers of people with schizophrenia is uncommon.

Healthcare providers are responsible for providing instructions as a part of nursing care. Based on the results of the research that has been done, e-Health can help psychiatric nurses to recognize the potential role of a smartphone as an additional effective medium of providing education. Mobile technology-based education could be a cost-effective and friendly way for caregivers to learn. Psychiatric health care services can benefit from this study when planning to start an intervention for caregivers. However, more knowledge is needed about how to empower the caregivers and when mobile technology can be used.

5. Conclusion

This study concludes that e-Health was positively valued and that it seems to be a feasible and acceptable method to use to increase the healthcare services available to mental health patients. This indicates a great benefit to the overall healthcare system.

ABSTRACT

Families are an important component for hypertension clients and as supporters in providing care and related to nurses when carried out home visits. In fact, not all families have a good responses when nurses carried out family nursing care. The purpose of this study was to analyze relationship between family coping and nurse interpersonal interaction in implemented family nursing care with hypertension. This study used an observational analytic method. The sample was that some nurses in the Puskesmas in the Surabaya District Health Office work area were taken by multistage sampling, totaling 110 people. Variables included family coping and interpersonal interactions. The instrument used is a valid and reliable questionnaire. The result showed family coping can improved interpersonal nursing interaction (p value 0.027). Families as responsible for clients at home provided various facilities for client care. Families as care givers need relationships with nurses and other health teams. Effective coping supported the success of family nursing care carried out. The family is expected to maintain effective coping while maintained good communication and accepted hypertension clients in the family.

Keywords: coping, family, interpersonal, nurse

1. Introduction

Family coping is an important component in caring for sick family members. The family acceptance of family members with hypertension is focused on providing them with continuing care. Families will be able to manage a burdensome situation because their family members are sick, thus expanding their efforts to find solutions to the problems that arise from their sick family members [1]. Family coping varies when treating their chronic family members. Families who have effective coping will care for their family members well. Conversely, families that have ineffective coping are less responsive. This difference will affect the family response when providing care for their family members who suffer from hypertension, including in reference to collaborations with the health services. Interpersonal interactions between the nurses and their clients contributes to the success of the nursing services. The communication aspects built by the nurses are relevant for effective nurse-patient interactions in clinical practice [2].

The prevalence of hypertension is increasing. The Basic Health Research of Indonesia (Riskesdas) 2018 demonstrated that the prevalence of hypertension among its >18 years old population increased up to 34.1% from 25.8% [3]. The doctor's diagnosis and medication are the tools of assessment. In addition, the National Health Survey (SIKESNAS) in 2016 indicated that the prevalence of hypertension among those aged <20 was 10.7% using blood pressure as the indicator.

The total prevalence of hypertension in the city of Surabaya is 18.42%. Surabaya is ranked second for having the most non-communicable diseases in 2015 [3]. The high rate of hypertension is a concern of the government of the Republic of Indonesia and it has included it in the Indonesian Program with a Family Approach. This program has 12 indicators of healthy families, including families with compliance related to hypertension and taking medication. Therefore, the family has an important role in the care of hypertensive clients at home. The purpose of this study was to analyze the family coping relationships in relation to increasing nurse interactions when implementing family nursing care.

2. Methods

This study used an observational analytical method with a cross-sectional approach. The population was the nurses at the Puskesmas in the working area of the Surabaya City Health Office consisting of 175 D III Nursing education and civil servants. The study recruited 110 nurses using the multistage sampling technique. The first stage was to use simple random sampling to determine the sample by randomly selecting 6 (six) Puskesmas in each region of North, West, East, South and Central Surabaya. This meant that 30 (thirty) Puskesmas were decided on. The second stage used simple random sampling to determine the number of respondents from each Puskesmas = 110: 30 = 3.67 or between 3-4 respondents.. The research variables include family coping and nurse interpersonal interactions when carrying out family nursing with hypertension. Family coping is the family effort in accepting hypertensive clients and providing care support. Interpersonal Interactions are the collaboration of the nurses with other nurses, the clients and their families when implementing family nursing care for clients with hypertension. The instrument used was compiled by the researchers using a Likert scale. The questions used in the family coping questionnaire were related to the family acceptance of hypertensive clients, the family problem solving process, family role setting and a spiritual approach to solving problems. The questionnaire on the interpersonal interactions of the nurses consisted of providing information, discussing problems that have not been resolved and monitoring compliance in care. The assessment was based on closed statements using a Likert scale (Never; Rarely; Sometimes; Often; Always). They were found to both be valid and reliable research instruments. The reliability of the instruments was assessed using Cronbach's alpha, where the results were $r > 0.6$. Collecting the data was also done using interviews. For the strategy of collecting the data, the researchers went to the nurses at each Puskesmas. Before the data collection began, the researchers obtained ethical permission from the Ethics Committee of the Faculty of Public Health, Airlangga University, Surabaya. The data analysis used descriptive and inferential statistics via the Spearman rho test. The significance limit of the test was 0.05 so if $p < 0.05$, then the statistical calculation was meaningful which meant that there was a relationship between the variables.

3. Results

The results of this study include the respondent's characteristics, the distribution of interpersonal interactions and nurse performance. The results of the study are as follows:

Table 1. Distribution of the Characteristics of Nurses in the Puskesmas in Surabaya City

Characteristics		n	%
Age			
a.	**20-30 years old**	17	15,5
b.	**31-40 years old**	70	63,6
c.	**41-50 years old**	14	12,7
d.	**> 50 years old**	9	8,2
Gender			
a.	**Men**	38	34,5
b.	**Women**	72	65,5
Education			
a.	**Nursing Diploma**	90	81.8
b.	**Ners**	19	17.3
c.	**Master of Health**	1	0.9

Table 1 explains that the largest group of nurses included those of productive age ranging from 31 - 40 years old. They were mostly women. The most common nurse education was that of a Nursing Diploma.

.

Table 2. Family Coping Frequency Distribution

Family Coping Categories	N	%
Effective	107	97,3
Ineffective	3	2,7
Number	110	100

Table 2 explains that the categories of family coping were mostly (97.3%) in the category of effective coping.

Table 3. Frequency Distribution of Nurse Interpersonal Interactions

Interpersonal Interaction Categories	N	%
Good	55	50
Enough	48	43,6
Lack	7	6,4
Number	110	100

Table 3 describes the frequency of the categories of the interpersonal interactions of nurses with their families as being half-categorized as good.

Table 4. Cross Tabulation of Family Coping and the Interpersonal Interactions with the Nurse

Family Coping Categories	Interpersonal Interactions			Number
	Good	Enough	Lack	
Effective	54 (53,27%)	48 (44,86%)	5 (4,67%)	107
Ineffective	1 (33,33%)	0 (0%)	2 (66,67%)	3
p=0.027				

Table 4 explains that family coping is effective, so most of the interpersonal interactions are good. Ineffective coping is largely referring to the interpersonal interaction of the nurses with the family, which is lacking. The Spearman rho test results obtained an r score = 0.382, meaning that there is a significant relationship between family coping and nurse interpersonal interactions when carrying out family nursing actions for hypertension.

4. Discussion

The family is the main supporter when treating a family member with hypertension at home. Family social support affects the health of the family members who suffer from hypertension. The family is an influential factor because it can provide reinforcement to the sick family members so then the care of the clients becomes better [4,5]. Families need effective coping methods while providing care for hypertensive clients. Family coping is a reference to the family business of managing situations due to the burden of the family members who are suffering from hypertension. Family coping is also interpreted as an internal or external demand that is considered to be a threat. Coping strategies allow the families to tolerate stressful experiences. Such efforts depend on the family actions or attitudes in the face of stressors [6]. The family mood affects the coping mechanism. Family coping affects the support given to the sick family members. Family support is seen of as a coping resource by determining the facilities provided as the predictors of coping for hypertensive clients. It was found that the direct effects of support were given to coping [7].

The results showed that most of the family coping was effective. The family response when one family member suffers from a chronic illness consisted of a psychological response being displayed. This response depends on the type of disease, the duration and severity [8]. Hypertensive clients with various complaints and long-term care require effective family coping. Evangelos C. Karademas C.E., Karamvalis N., Zarogiannos, A. (2009) explained that someone who suffers from chronic illness experiences stress. The stress experienced by them is life stress, so family coping is an important component [9].

Families are responsible for the care of their family member with hypertensive by establishing collaboration with nurses and other health teams. The family interactions with the nurses and other health teams strongly supports the successful implementation of family nursing care which will have an impact on improving the condition of hypertensive clients at home. Families who have positive coping will establish good interactions with the nurses who care for their sick family members. The coping that is commonly used by the families to treat chronic disease clients uses moderate coping approaches (e.g. planning, seeking social support, positive reinterpretation, acceptance and conversion) and rarely using 'avoidant' coping strategies (rejection / release and the use of alcohol and drugs) [10]. The nurses' interpersonal interactions with families are influenced by the communication between them. Communication that is difficult will affect their emotional state [11].

Nurses who do not visit hypertension clients at home every day need the family to help carry out the nursing actions. Therefore the family acceptance of hypertensive clients at home will affect the success of the treatment. Families who succeed in establishing interpersonal interactions with the nurses will work together to treat hypertensive clients.. The success of family nursing care can be evaluated by achieving the fulfillment of their needs and the independence of the client [12].

Interactions between the family and the nurses are effectively a type of manager-worker relationship [13]. A relationship of this type has the nurse as the manager and the family as the workers. The nurse gradually shifts this role to the family. The nurses will set limits on their respective roles. The families are trained in some of the skills needed to care for their sick family members. The nurse monitors the actions taken by the family and coordinates the actions that will and have been carried out by the nurse and the client's family. Hypertensive clients at home will therefore carry out a well-maintained program with family support.

Effective coping from the family can enhance the interpersonal interactions with the nurses who strongly support the success of the hypertension client's care program at home. Good care of the clients of hypertension such as taking regular medication, a low salt diet, exercise and good stress management can improve the health of the clients [14,15]. There are no results in the previous studies that explained the relationship between family coping and nurse interpersonal interactions. The results of this study are novel to explain the importance of family coping in increasing the interpersonal interactions with the nurses. The purpose of the relationship is to improve the health status of the hypertensive clients at home. The limitation in this study was that the measurement of the family coping variables was based on the assessment of the nurses. There is the possibility for an element of nurse subjectivity in the assessment of coping within the family. This limitation has been controlled by the researchers through the creation of closed question instruments,

5. Conclusion

Effective family coping can improve the interpersonal interactions with nurses when implementing family nursing care for the clients with hypertension. The families are encouraged to maintain effective coping while maintaining good communication and accepting hypertensive clients in the family.

ABSTRACT

Sexual abuse of children increases in many countries in the world every year, Children were vulnerable to being victims because they can not take care of them self. Child sexual abuse (CSA) was a social problem that often effect of psychological trauma and leads to psychopathology and behavioral problems. Children who were at risk of sexual abuse require interventions CBT to prevent sexual abuse. The purpose of this systematic review was reviewed the effectiveness of Cognitive Behavioral Therapy (CBT) to prevent children sexual abuse. The methods of this reviewed were systematic review of children risk sexual abuse with study selection criteria using Scopus, Science Direct, Spinger-link and Pub-med database search from 2 January-22 February 2019, and 2014-2018 publication by keywords of CBT, children sexual abuse, prevent children sexual abuse in the school keywords, with PICOS approach. Total the 1450 journals and 15 of them were appropriates and assessed. Children sexual abuse can cause physical, psychological, social, sexual disorders. Physical and psychological disorders will cause mental disorders and can risk suicide in children. The conclusion are CBT can prevent sexual abuse because CBT can be increase knowledge and can prevent deviant behavior for children.

Keywords:CBT, children, sexual abused

1. Introduction

Child sexual abuse increases in many countries in the world each year [1]. Children are vulnerable to becoming victims of sexual abuse because they are innocent and trustworthy in adults, and children cannot protect themselves [2]. Child sexual abuse is the child's involvement in sexual activity, but the child does not understand what is happening [3]. Sexual activity is like touching the sensual parts, showing pornographic videos, sexual intercourse (rape), and showing genitals [4].

Epidemiological data shows that the average global prevalence of sexual abuse in children is 11.8-13.8% with higher rates among girls (18-19.7%). Africa shows the highest rate of sexual abuse in children (around 34%), while the lowest appears in Asia (around 10%) and Europe. The CSA (Child Sexual Abuse) data in Southeast Asia is highly variable, with 40 cases of child abuse in 14 countries in the region, concluding that around 10% of boys and 15% of girls have experienced at least one form of sexual abuse [5]. The Indonesian National Commission for Child Protection (KPAI) in 2010-2014 states that there were 21,869,797 cases of child abuse and half of them were sexual harassment [6], there were 1,032 cases of child abuse consisting of: physical violence 290 cases

(28%), psychological violence 207 (20%), sexual violence 535 cases (52%). The results of the study were 18-20% of women and 7-8% of men under the age of 18 becoming victims each year [7].

Child sexual abuse effects can be physical, psychological, social, sexual and interpersonal disorders in both the short and long term, physical and psychological disorders will cause mental disorders, risk of suicide, sexually transmitted infections and risky sexual behavior [1]. In addition, over time, children who experience CSA will probably have an effect of cycles that will cause the victim, in time, to become a perpetrator so that they create other victims later [8]. Children who are sexually abused cannot react or oppose the authority carried out by the perpetrator, and although he does not agree, he feels he cannot prevent this incident, in the face of threats, children often keep the fact that they have been abused [9]. Children need critical attention in terms of developing effective and necessary approaches to protect them from pedophiles [8]. Children are sexually abused at the age of 10-18 years [10]. This is a serious problem [11], this condition is very worrying because it occurs in all children and this sexual abuse can occur anywhere that is related to us.

Primary schools are the most appropriate environment for implementing sexual health education programs, including prevention of sexual abuse [12]. Primary school is the most important place to provide knowledge, self-protection skills, and attitudes related to health and sexual education [13]. Children need to be taught the ability to recognize, fight, and report sexual violence [14]. Because of that, to prevent sexual abuse in children, education and therapy are needed, one of the therapies to prevent sexual abuse in children is CBT, this therapy is an effective therapy to prevent sexual abuse in children, including post-traumatic stress, anxiety, avoidance, depressive symptoms, cognitive distortions related to abuse, and sexually inappropriate behavior [2]. CBT is therapy used to prevent/treat victims of sexual abuse [15]. CBT is a psychoeducation-based therapy for the prevention and treatment of sexual abuse in children, and this therapy meets the criteria for empirically supported care. CBT contains the following components: psycho-education and relaxation strategies, affective expression and emotional regulation, overcoming cognitive problems, and processing emotions associated with abuse of experience, and enhancing personal safety [15].

2. Method

2.1. Search Strategy.

The journal search strategy begins with asking research questions, namely "does CBT increase knowledge, self-efficacy, self-protection and prevent sexual abuse?". Searching research in all published journals was conducted with the terms of research of Quasi-experiment, Cross-sectional, and Quantitative related to the mental health of children. The databases used for journal searches are the Scopus, PubMed, and Science Direct Databases. The keywords used were CBT, self-efficacy, self-protection, prevent child sexual abuse. The journal is limited to the 2013-2018 publication year, within the area of nursing and medicine, and psychology and English-language journals.

Research inclusion criteria were 1) respondents chosen were aged 10-17 years; 2) willing to participate as respondents; 3) children who are at risk of sexual harassment; 4) who understood the language in accordance with the therapist, research exclusion criteria were 1) children who were not cooperative when doing CBT; 2) children who consumed psychotic drugs; 3) children who chose not to be respondents. The journals were selected using the Prisma method.

The results obtained were obtained from the Scopus, PubMed, and Science Direct databases. The search results obtained as many as 270 journals. The Scopus database obtained 95 journals.

PubMed database returned 22 journals and the database Science Direct gained as much as 153 journals. All journals that have been obtained are then screened according to the area of Medicine, Nursing, and Psychology until there are 225 journals. They were then filtered in accordance with the mental health, youth and orphanages research, which found 125 journals accordingly. They were then filtered, regaining as much as 15 journals according to inclusion and exclusion criteria. All journals are Quasi-experimental, Cross-sectional, Quantitative focusing on knowledge, self-efficacy, self-protection, prevention of sexual abuse and CBT.

2.2 Selection Procedure and Data Extraction

- *Population.* The selected population in this review was children at risk of sexual abuse
- *Intervention.* This study use intervention cognitive behavior therapy
- Comparison. The review compared self-efficacy and self-protection in children before being given CBT therapy and after being given CBT therapy.
- *Output.* The review reported the effectiveness of cognitive behavior therapy for preventing sexual abuse in children, and the effectiveness of CBT for self-efficacy, knowledge, and self-protection for children
- *Study Design*

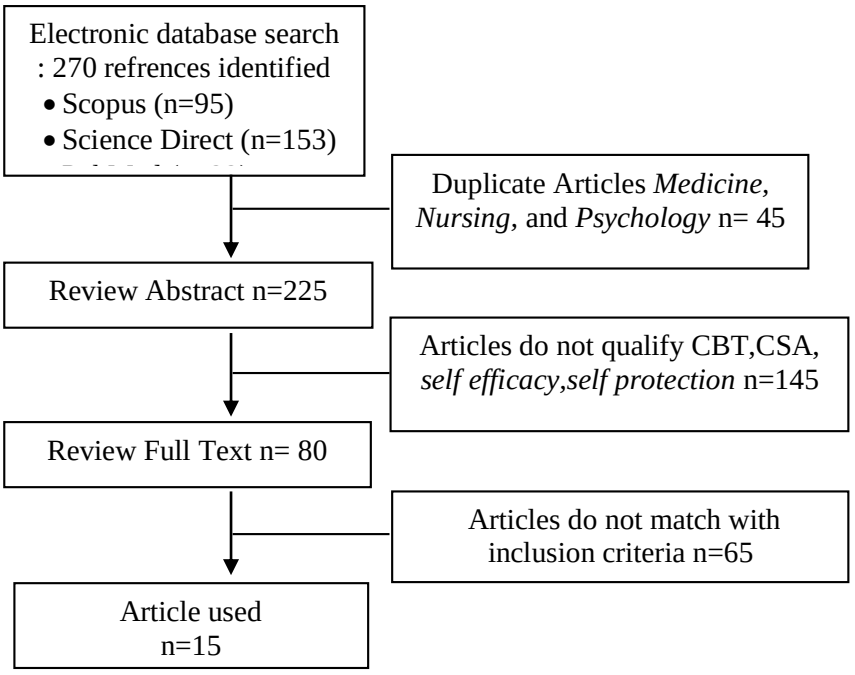

Figure 1. PRISMA Flow Diagram Effectiveness Of Cognitive Behavioral Therapy (CBT) For Child Sexual Abuse Prevention At Elementary School: A Systematic Review

3. Results

3.1 Characteristic of Population Studies

From the results of studies of children at risk of sexual harassment there are children under the age of 18 years, from the results of studies of girls who were sexually abused about 18-20% were women and 7-8% were boys in each city. Children at risk of sexual abuse are have lower family socio-

economic status, a low level of parental education, friends with naughty children, watching pornographic videos, and an absence of family or other adults as a source of psychosocial support for children. The average respondent in this review is a student. Children are spread throughout Asia and Europe, namely China, Taiwan, Korea, Turkey, Iran, Africa, and France.

3.2 Study Characteristics

The characteristics of the study are explained in table 1. All journals obtained from the results of the study have CBT therapy performed on children who are at risk of sexual abuse. All journals are obtained from the results of the study of mental health children, the problems are sexual abuse, preventing sexual abuse in schools, self-efficacy, and self-protection. All studies have a minimum age rating of 10 years to 17 years. All 15 studies were children at risk of sexual abuse and where there was a history of sexual abuse. The study characteristics are 2 articles which are cross sectional, 1 article of qualitative study, and 12 randomized control trials.

3.3. Results of the Review Study

CBT is a therapy that is related to inherently being questioned at this time in everyday life and an increase in cognitive distortion and misunderstandings that may be given to children who are at risk of correcting sexual abuse [15]. Through correction of children with their world perceptions and self in change, trauma can be eliminated and the future changed, a process known as cognitive restructuring [15]. CBT is a therapy to change and process feelings and cognitions related to abuse to change the behavior associated with abuse and integrate it (Fouché and Liana, 2018). Cognitive Behavior Therapy is a short-term therapy (8 to 16 sessions) aimed at helping children improve self-confidence so that children feel more comfortable with their current conditions [16].

CBT therapy is given via providing training modules to children. This module is based on the principles of CBT for depressive disorders such as behavioral activation, cognitive restructuring and preventive strategies and skills [16]. Module CBT has components that can influence stimulation related to trauma by helping children develop better skills and emotion regulation strategies (recognizing and expressing emotions, understanding the influence of thoughts on emotions). In addition, CBT aims to reduce the risk of victimization in the future by developing the ability to protect oneself, giving knowledge through sex education [16].

4. Discussion

Children are vulnerable to becoming victims of sexual abuse because they are innocent and trustworthy in adults, and children cannot protect themselves [2]. Children cannot react or oppose the authority committed by the offender, and although he disagrees, he feels he cannot prevent this occurrence, in the face of threats, children often keep the fact that they have been abused to themselves [9]. Children need critical attention in terms of developing effective and necessary approaches to protect children from pedophiles [8]. To prevent sexual abuse in children, education and therapy are needed, one of the therapies to prevent sexual abuse in children is CBT, this therapy is an effective therapy to prevent sexual abuse in children, including post-traumatic stress, anxiety, avoidance, depressive symptoms, cognitive distortions related to abuse, and sexually inappropriate behavior [2].

Review of some studies shows that the application of CBT can increase knowledge and change the behavior of children. In addition CBT can reduce the risk of PTSD in children. CBT is a therapy that emphasizes psychoeducation as a tool that can change cognitive distortion in children [2]. Giving CBT therapy to children who are at risk of sexual harassment can help children to understand sexual harassment, besides the benefits of CBT can improve children's self-safety skills [2]. CBT can be applied to groups, individuals, or groups [17] In this therapy children are taught to recognize the genital function of the child, the child recognizes his personal parts, and in CBT therapy the child is taught the ability to protect themselves [2].

Cognitive-behavioral therapy (CBT) is therapy designed to prevent/treat victims of sexual abuse, CBT is a psychoeducation-based therapy for the prevention and treatment of sexual abuse in children, and this therapy meets the criteria for empirically supported care. CBT contains the following components: psycho-education and relaxation strategies, affective expressions and emotional regulation, overcome cognitive problems, and processes of emotions associated with abuse of experience, and improvement of personal safety (Olafson, 2011). CBT effectively prevents sexual abuse in children, including post-traumatic stress, anxiety, avoidance, depressive symptoms, cognitive distortions related to abuse, and inappropriate sexual behavior [2].

The results of the review found that CBT can prevent sexual abuse because CBT therapy can help inform education about private parts and sexuality allows children to get knowledge so that they can avoid sexual abuse.

The results of another CBT review shows that it can prevent sexual deviations such as LGBT in children and adolescents, cognitive behavior therapy can increase adolescent knowledge about the negative impact of LGBT, directing adolescents to have the right attitude in dealing with LGBT behavior and increasing assertiveness in rejecting LGBT behaviors.

Giving CBT therapy to children can show increased knowledge, change internal and external behavior and dissociation symptoms in children and increase children's self-confidence. Besides this, therapy can show an improvement in PTSD symptoms in children who are sexually abused [18]. Some studies show that CBT support for children and adolescents can reduce PTSD. TF-CBT in this study was associated with a significant increase before post-treatment care with respect to PTSD and depressive symptoms for adolescents. The results of this study show that CBT not only reduces symptom pressure (i.e., PTSD and depression), but also reduces the psychological impact of others [18]. It can be concluded that CBT therapy can prevent sexual abuse in children and can reduce the risk of PTSD for children.

CBT therapy is a therapy with an inherently cognitive behavioral approach that focuses on the current conditions in one's life and identifies cognitive distortions and misunderstandings that might contribute to problem behavior in children who are at risk of sexual abuse[15]. Through restructuring children with their world and self-perceptions in relation to trauma, symptoms can be reduced or eliminated and future behavior changed - a process known as cognitive restructuring [15]. CBT is a therapy to change and process feelings and cognitions related to abuse to change the behavior associated with harassment and integrate it (Fouché and Liana, 2018).

CBT is a form of therapy designed to prevent/treat victims of sexual abuse [15]. CBT is a psychoeducation-based therapy for the prevention and treatment of sexual abuse in children, and this therapy meets the criteria for empirically supported care. CBT contains the following components: psycho-education and relaxation strategies, an affective expression and emotional regulation,

overcoming cognitive problems, and processing emotions associated with abuse of experience, and enhancing personal safety [15].

Based on the research that has been done in this study, it can be concluded that the results of these journals can be applied in Indonesia. Interventions can be done in terms of mental nursing departments. Such therapy is one of the skills that must be possessed by a specialist nurse. CBT therapy can be given to children who are at risk of sexual abuse and can help children to understand about sexual abuse, besides the benefits of CBT can improve children's self-protection. In its implementation in Indonesia, this intervention can be done in terms of the mental care department. This facilitates nurses in providing comprehensive nursing care.

5. Conclusion

The conclusion of this review shows how CBT therapy for children with the risk of sexual abuse can help children to change negative thoughts into positive thoughts, and that children are able to protect themselves, increase knowledge which is beneficial for them.

ABSTRACT

Anxiety is one of the psychological responses experienced by clients with diabetic ulcers that can affect glycemic control, serious complications, foot self-care behavior and slow the wound healing process. This research used to find out the factors that influence anxiety in clients with diabetic ulcers. This study was a retrospective analysis using medical records and diagnostic results of diabetic ulcers at Haji General Hospital, Surabaya, Indonesia. The sample was 951 people suffering from diabetic ulcers between January 2014 - December 2018. Samples were diagnosed with anxiety based on nursing diagnoses and fulfilling inclusion and exclusion criteria. The multivariable model of diabetic ulcer client anxiety was generated using stepwise logistic regression. There were independent variables affecting the anxiety of diabetic ulcer clients namely wound type ($p < 0.012$; OR = 2.4), duration of illness ($p < 0.038$; OR = 1.03), health insurance ($p < 0.002$; OR = 0.82) and gender ($p < 0.048$; OR
= 0.99) with the contribution of the four independent variables at 31% and the prediction accuracy of 86.6%. Types of wounds that are infection have a risk of 1.65 times experiencing anxiety compared to non-infection, so nursing interventions can be focused on wound care.

Keyword: predictive, risk factor, diabetic foot ulcer

1. Introduction

Anxiety is one of the psychological responses experienced by diabetic foot ulcer (DFU) sufferers because of changes in health, loss of function, and non-intact conditions in the body such as injuries and amputations. Untreated anxiety will affect blood sugar control, worsen disease progression, increase serious complications and affect foot self-care behavior [1]. In addition, anxiety on DFU clients can reduce diabetes self-management (e.g. diet modification, physical activity, insulin injection). This can result in a slow healing process in DFU patients and a decrease in quality of life [2]. The World Health Organization states that the prevalence of DM worldwide is estimated at 9%. In 2030, it is estimated that DM ranks 7th in the causes of death in the world [3]. The International Diabetes Federation (IDF) predicts an increase in the number of people with DM in Indonesia from 9.1 million in 2014 to 14.1 million in 2035. DM patients in Indonesia at the age of ≥15 years of 6.9% are estimated to have an absolute number of 12 million people. Nearly 50% of diabetics experience diabetic foot ulcers with a mortality rate of 8% -35% and 15% -30% of them experience amputation [4]. DM patients in East Java amounted to 2.1% or as many as 605,974 people and 35% of them experienced diabetic ulcers [5].

In Indonesia patients with chronic diseases such as DFU tend to experience anxiety because

the stigma associated with DFU in society is bad. The stigma of DFU in Indonesia is associated with incurable diseases, possible amputation and death. One of the effects of anxiety is the length of the wound healing process. Research conducted by Razjouyan, et al., found an association between anxiety and wound healing. DFU people with anxiety experience delays in wound healing. Pedras, et al., found a significant relationship between anxiety and quality of life of people with DFU. Anxiety that occurs shows that they experience ineffective psychosocial adaptations [6]. People with chronic diseases, such as DFU, who can adapt well will be able to accept the reality of their illness, and rearrange and restructure the environment so that there is meaning and purpose in quality of life that exceeds the limitations posed by the disease [7]. Dealing with anxiety is the responsibility of the health care provider which, of course, includes nurses. Efforts that have been made in the treatment room to deal with anxiety are health education, pharmacological therapy, non-pharmacology and stress management, but have not been optimal in reducing anxiety in clients [8].

Fear, anxiety, and dread may affect a person's relationship to his or her sense of safety, whether in terms of diabetes or in relation to other chronic conditions. These emotions are causal factors that influence whether or not people with symptoms seek treatment in a timely manner. Some of the most informative responses in the research presented here involve avoidance of health care visits because of the fear of being told they have developed DFU. It is important to study related causes of anxiety in patients with diabetic ulcers. Factors that can influence this are individual patient factors or hospital service systems. Individual patient factors include demographics, age, gender, education and others. Service system factors are from insurance to the referral system. Most of the patients in Indonesia are insurance users provided by the government, namely BPJS (Badan Penyelenggara Jaminan Sosial or Social Security Administrator). All hospitals in Indonesia are required to accept patients with BPJS insurance. Failure in management anxiety is due to a mismatch between the anxiety experienced with the therapy provided, so it is very important to study issues related anxiety itself. Nurses are one of the health professions are required to be able to facilitate the basic needs of clients, one of which is psychological needs with a nursing process that views humans as a whole and uniquely puts forward a holistic approach that includes bio-psycho-socio-spiritual and cultural [9]. Previous studies have been carried out and only analyzed anxiety in DM patients not DFU. This study aims to find factors that influence anxiety that occur in clients with diabetic ulcers.

2. Methods

This research was conducted to find out the factors that influence anxiety in clients with diabetic ulcers. The study design was a cohort retrospective analysis.

2.1 *Ethical Clearance*

Ethical clearance was obtained from The Ethics Committee of the Haji General Hospital, Surabaya (ethics approval number 073/13/KOM.ETIK/2019).

2.2 *Participants*

Data was collected by medical records and diagnostic results of diabetic ulcers at Haji General Hospital, Surabaya. The sample was 951 people suffering from diabetic ulcers between January 2014 - December 2018. The inclusion criteria determined in this study were patients over 40 years old, had foot ulcers, HbA1c values above 6.5%, underwent treatment at the Surabaya Hajj general hospital and who were diagnosed with anxiety based on nursing diagnoses. The specified exclusion criteria

are having a mental disorder.

2.3 Variables

Data collected as variables in this study were gender, duration of diabetic ulcers, use of health insurance, type of injury, length of stay and complications. Data is collected using a checklist sheet consisting of these items. The collected data is then categorized based on the provisions set by the researcher. Gender consists of men and women. The duration of suffering consists of more than 7 months and less than 7 months. The wound type consists of infectious and non-infectious. Length of treatment consists of more than 3 days and less than 3 days. Health insurance is divided into BPJS and non BPJS. Complications exist and there are no complications.

2.4 Statistical Analysis

The statistical analysis was conducted using SPSS 25. The multivariable model of diabetic ulcer client anxiety was generated using stepwise logistic regression. The first step is to classify the entire data obtained by categories 1 and 2. The next step is to crosstab the data and choose the chi-square that serves to make variable selection. Variables that have a value of $p < 0.25$ will be included in the multivariate logistic regression analysis with the provisions $p < 0.05$.. The results of logistic regression are then interpreted and presented.

3. Result

Table 1. Characteristics of Participant

Only 1	299	53	1.15	0.91 - 1.44	
More than 1	525	74	0.91	0.78 - 1.06	
CI : Confidence Interval ; OR: Odds Ratio; BPJS : Social Security Administrator					

Table 3. Multivariant analysis of Risk Factor For Anxiety On Clients With Diabetic Foot Ulcer.

Variables	OR	CI 95%	p value	Nagelkelke R Square
Gender			0.040	0.31
Women	1			
Men	0.64	0.42 – 0.98		
Wound type			0.015	
Non Infectious	1			
Infectious	0.61	0.41 – 0.91		
Health insurance			0.001	
Non BPJS	1			
BPJS	0.52	0.35 – 0.77		
CI : Confidence Interval ; OR: Odds Ratio; BPJS : Social Security Administrator				

Participant characteristics can be seen in table 1. Based on the table, there are 742 men and 209 women. BPJS users are more dominant than non BPJS. This is because every hospital in Indonesia is required to accept patients with BPJS. The type of infection wound is the most type and the duration of treatment of more than 3 days is also dominant. Duration of diabetic ulcers is more than 7 months

and complication of more than 1 is also dominant. Of the 951 participants there are differences regarding anxiety status. Participants who experience anxiety are around 824 and are not anxious at 127.

Based on table 2 there are 4 independent variables that fit significant criteria. The chi-square test found a wound type ($p < 0.012$; OR = 2.4), duration of illness ($p < 0.038$; OR = 1.03), health insurance ($p < 0.002$; OR = 0.82) and gender ($p < 0.048$; OR = 0.99). The type of wound is the most dominant factor in this test. Variables that have p value <0.25 will then be made covariate variables in the next multivariate test.

Based on table 3, the multivariate test results were obtained using logistic regression and found three significant variables, namely wound type ($p < 0.015$; OR = 0.91), health insurance ($p < 0.001$; OR = 0.77) and gender ($p < 0.040$; OR = 0.98) with the contribution of the four independent variables at 31% and a prediction accuracy of 86.6%. One variable, duration of diabetic ulcers, is not significant in the second model of the logistic regression test, so it needs to be eliminated.

4. Discussion

To control confounding factors researchers used the restriction method by including all respondents who had the same confounding factors. This means that each respondent has the same characteristics as others so that other confounding factors can be minimized beyond the factors studied. In this study 3 variables were found which affected the anxiety of patients with diabetic foot ulcers. These variables are gender, type of injury, and health insurance. Wound type is the second dominant factor triggering anxiety in patients with foot ulcers. This can be seen from a high OR value that is 0.91 with a p value <0.015. Wound conditions that occur in clients with diabetes can increase the incidence of depression and anxiety [10]. Larger wounds will cause psychological stress, causing negative thoughts on the client. the client will feel that the wound cannot heal. The study found a correlation between wounds with depression and anxiety with measurements obtained by using HARDS and CES-D scale [11]. In this study it was found that infections contribute 0.61 times greater than non-infectious conditions. Wounds experienced by diabetics often result in gangrene, which is an infectious complication. This condition results in patients having difficulty doing activities and work. The study by Charalambous, Vassilopoulos, & Koulouri, found a correlation between the condition of diabetic wounds with the psychological patient. Anxiety that occurs in patients with chronic wounds is caused by bad stigma, previous injury experience, lack of support from both the family and the health care system, the presence of pain and long-term treatment that he experiences [12]. Research conducted by Razjouyan et al. found an association between anxiety and wound healing. DFU people with anxiety experience delays in wound healing [13].

Gender is the dominant factor with OR = 0.98, male and female is one of the factors that influences the occurrence of anxiety in patients with diabetic ulcers with p value < 0.040. In the results of the study differences were found in anxiety between the sexes. Men tend to experience anxiety 0.64 times greater than women. Sex difference is one of the determinants of anxiety conditions. Reisner et al., found a difference in anxiety response in men and women. Men tend to experience anxiety because of their role as the main support in the family [14]. The condition of the illness results in the inability to fulfill the duties and responsibilities in the family [15]. The research findings indicate that gender selectively modulates the influence of anxiety on ambiguous decision-making, but not risk decision-making [16]. Niles et al. found that there is a relationship between

gender and psychological responses to inflammation. In cases of inflammation, a person's tendency to experience symptoms of depression and anxiety increases. Men are more prone to symptoms of depression but respond less with anxiety [17]. The whole participant is over 40 years old and has worked so that the tendency to be unable to meet the needs in the family results in anxiety. While the high proportion of male respondents in the current study is in line with other studies of diabetic foot disease affecting the population, reasons for this asymmetrical gender distribution remain unclear as the prevalence of diabetes in the age group surveyed is almost the same for men and women.

Multivariate models found the effect of health insurance on the anxiety of patients with diabetic ulcers ($p < 0.001$; OR = 0.77). Health insurance is one of the guarantees needed to cover all patient medical expenses. In Indonesia there is health insurance provided by the government, namely BPJS. Most hospitals in Indonesia receive services with BPJS but patients using BPJS must fulfill the entire set of administrations. The complicated process makes patients easily experience stress due to feeling that they have not been taken action upon by health personnel. BPJS users have a tendency to experience anxiety 0.52 times greater than patients without health insurance. Chronic ulcers present a substantial economic burden to the health care system. Health care decision makers are encouraged to consider additional resources to preventative interventions for chronic ulcers to reduce downstream costs [18]. Low-cost DFU primary prevention efforts producing even small decreases in DFU incidence may provide the best opportunity for cost-savings, especially if focused on patients with neuropathy and/or PAD. Mobile phone-based reminders, self-identification of risk factors, and written brochures may be among such low-cost interventions that should be investigated for cost-savings potential [19].

All of these aspects make the patient feel frustrated, dissatisfied, insecure, fearful, helpless and uncontrolled. Individuals with injuries feel unable to carry out daily activities, and often consider themselves unable to play their role in society [20]. The weakness in this study is that there are still 79% of factors that contribute to increasing anxiety in patients with unknown diabetic ulcers, so further research is needed to examine all aspects of patients and other research methods in revealing the results.

5. Conclusion

The most dominant factor found in this study was the type of wound. Infection has a risk of 1.65 times of experiencing anxiety compared to non-infection, so nursing interventions can be focused on wound care.

FACTORS AFFECTING HYPERTENSION IN YOUTH: A SYSTEMATIC REVIEW

Ester Radandima
Fakultas keperawatan Universitas Airlangga, Surabaya
E-mail: ester.radandima-2017@fkp.unair.ac.id

ABSTRACT

Teenagers are the next generation of the nation that will determine the future of a nation. Good health conditions are very important to achieve these goals. Hypertension is a health disorder in adolescents whose prevalence continues to increase. Adolescents who have hypertension will be very at risk of developing cardiovascular disease, diabetes mellitus, stroke, heart disease as adults. The purpose of this study was to study the risk factors for hypertension in adolescents.The literature review is done by searching for sources from the SCOPUS, Sciendirect, proquest, spimgerlink database by entering the keyword Risk Factor AND youth AND hypertension. Literature selection was carried out with the inclusion criteria of adolescents aged 13-17 years who had hypertension. Of the 15 journals reviewed, it was found factors that influence adolescence hypnosis, namely gender, obesity, family history, lifestyle, age, weight, life behavior, food consumption. Body mass index is not mentioned as a factor that affects hypertension but is more likely to be obese. Gender and family history are the most dominant factors affecting the incidence of hypertension in adolescents.

Keywords: hypertension, factors, adolescents

1. Introduction

Over the past two decades, blood pressure in children and adolescents has changed significantly. In pediatrics, normal blood pressure as systolic blood pressure (SBP) and diastolic blood pressure (DBP) <90th percentile (P90) is adjusted for gender, age and height; hypertension as P95 percentile SBP and / or DBP (P95); and pre-hypertension as SBP and / or DBP ≥P90 but <P95, or BP> 120 / 80 mmHg but <P95, can be adjusted for gender, age and height. Although hypertension is considered a problem of maturity, it is now known as a very important beginning of life in its etiology. However, there is some data on TD levels in adolescents. There is also better understanding of the underlying physiological relationships, it is very important to predict its development and increase the risk of cardiovascular related complications, and to implement corrective measures [1].

Various factors have overall implications for high BP in children and adolescents, including obesity (in children themselves and their parents), higher height, lower socioeconomic status, people's lives, lack of regular exercise, and a family history of hypertension or obesity, in more recent research. Adolescents are the next generation that will determine the future of a nation. Health conditions are very important to achieve these goals. One of the health improvements in adolescents whose prevalence continues to increase is hypertension. Hypertension does not only occur in adults or the elderly, but can also occur in adolescents. About 70% of the incidence of hypertension in adolescents is primary hypertension. The national prevalence of hypertensive patients at the age of 13-17 years is 5.3% (men 6.0% and women 4.7%) [2].

Adolescents who have higher blood pressure than normal have a greater risk caused by coronary heart disease or heart failure as adults [3]. Approximately 7% of pre-hypertension occurs in adolescents who turn into hypertension [4]. Pre-hypertension, someone who has diastolic 90 to <95 or if the systolic blood pressure is more than 120/80 mmHg even though it is between the 90th percentile to <95th percentile.

Until now hypertension is a degenerative disease which is a serious problem. Hypertension is categorized as the silent disease or the silent killer because the patient does not know he has hypertension or does not know before checking his blood pressure. The incidence of hypertension increases with age. Death from hypertension is based on data from the Ministry of Health (2006) the prevalence of hypertension continues to increase every year, it is estimated that in 2025 around 29% of adults worldwide will suffer from hypertension [1]. Data from the AHA (American Heart Association) in 2011, in America 59% of patients with hypertension have only 34% where it is controlled, including 1 in 4 adults who suffer from hypertension. Meanwhile, based on NHANES (National Health and Nutrition Examination Survey) in 2010, of 66.9 million hypertensive patients in the US, 46.5% of hypertension was controlled and 53.5% of hypertension was out of control.

Some risk factors that can cause higher blood pressure are family with hypertension and weight gained by increased expenditure. This phenomenon causes changes in the lifestyles of the global community, such as the easier it is to get ready-to-eat food, the lower consumption of fiber, and then the consumption of salt, fat, sugar and calories continues to increase. Efforts to overcome the incidence of hypertension or complications that occur due to hypertension need to be modified in the lifestyle, such as: diet with salt intake, fat, alcohol, quitting smoking, and controlling body weight; physical activity; rest and sleep. Factors that cause hypertension include other factors, weight, diet, alcohol, cigarettes, drugs and other disease factors. Lifestyle also opposes emergence. Unhealthy habits such as an unbalanced diet with high cholesterol levels, salt, minimum exercise, and portion of the restoration can be relied upon for the appearance of blood pressure [5].

Until now there have been many national or international publications that examine the diagnosis and treatment of hypertension. The latest release is the 2013 Hypertension European Society hypertension management guide in the Canada Education Program. The purpose of this study is to provide a systematic overview of factors that influence hypertension in adolescents.

2. Research Methods

This Systematic review uses a guide based on the Preferred Reporting Item for Systematic Review and Meta-Analysis (PRISMA) with a cross-sectional method.

2.1 Data Sources and Searches

The literature used in this Systematic Review uses tracing through 6 (six) electronic databases, namely: Scopus, Science Direct, PubMed, and Springer link which have been published in publications from January 2013 to November 2018. The keywords used are hypertension, factors, adolescents keywords.

2.2 Study Selection

The study design into the inclusion criteria in the Systematic Review is a cross sectional design published in English.

2.3 Data extraction and quality assessment

Data is extracted from each study that meets the requirements. The components taken were objectives, research design, population (number of samples, characteristics and recruitment methods), intervention and treatment for hypertension, outcome measures, data collection methods, and results analysis. The extracted data includes the characteristics of the study, characteristics of hypertension, characteristics of results and summary of results. Studies are grouped according to the factors that influence hypertension. If possible, the research is then grouped based on the time of follow-up and the type of intervention.

3. Results

3.1 Literature Search

Figure 1 below shows the literature search process on the SCOPUS, Science direct, Proquest, and springer link page.

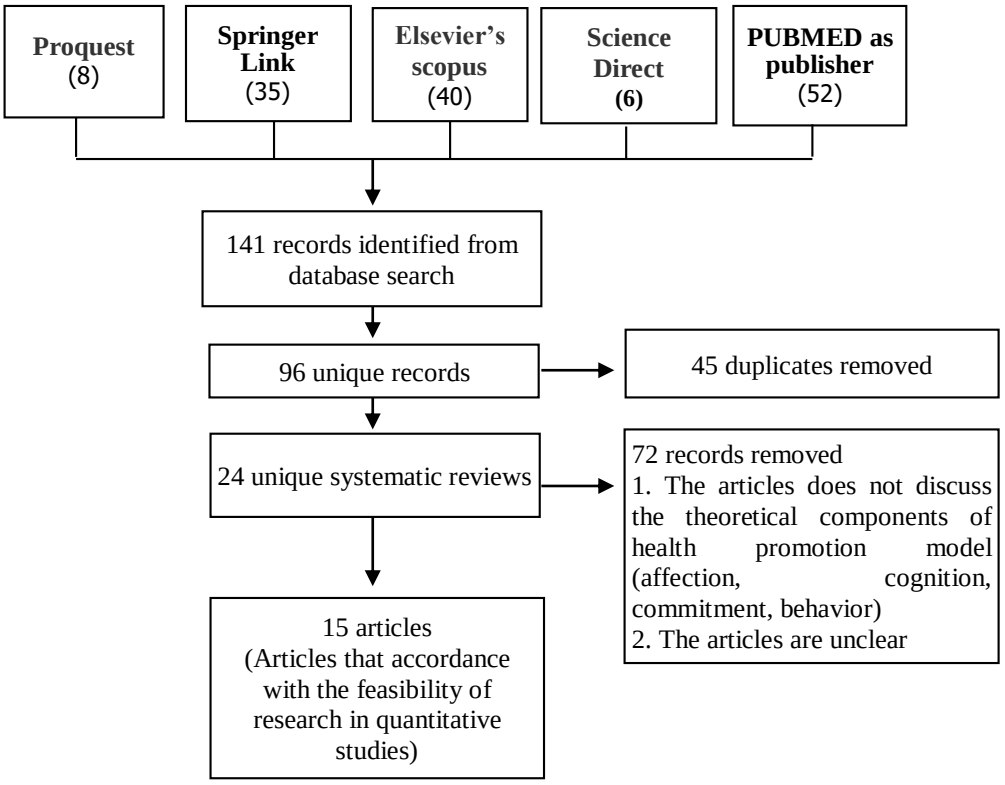

Figure 1. Flow chart of the literature search process

Table 1. Setting, study characteristics and key findings of included studies

Title	Population / Sample	Method / Design	Intervention	Comparison	Outcome
Prevalence of pre-hypertension and hypertension and associated risk factors between undergraduate students at tertiary institutions, Ghana **[6]**	Ghana students 540 people from 6 colleges Samples: 100 students from each college	*Cross sectional*	Observation: Measurement of blood pressure	Blood pressure (BP) is recorded after subjects have relaxed for at least 5 minutes. Measurements were made with the subject in a sitting position using a mercury sphygmomanometer and by an automatic BP monitor (Omron HEM-5001, Kyoto, Japan) placed on the right arm of the subject. Measurements were made twice and read the recorded average. Repeated measurements were obtained at two consecutive, six hours in students with continuous blood pressure	Prevalence and hypertension were quite prevalent among students, with risk factors such as male sex, obesity detected by BMI and WHtR, while family history of hypertension and kidney failure showed possible influences in the development of prehypertension and hypertension.
Decreased adiposity reduces risk of hypertension: Results from a prospective adolescent cohort.	Teenagers in Portugal number 1377 Samples: teens aged 13 and 17 years	adolescents from the Epidemiological Adolescent Health Investigation cohort in Porto	Measuring BMI and Waist Circumference	use a questionnaire for physical examination interventions	The average blood pressure level and the incidence of hypertension were higher among men and adolescents with a family history of the disease, in

	from rural and urban areas			low. Periodic measurements should be done in schools to identify the high risk group of children and adolescents who can develop hypertension.	hypertension in children with a family history of hypertension, diabetes is high and statistically significant.
The prevalence of hypertension and associated risk factors in young adults attending a tertiary care institution from Nagpur: a cross sectional study **[8]**	370 young adult participants attending the department of the urban health training center in Nagpur Samples: ages 18 to 40 years	*cross sectional study*	Data were collected using a trial and pre-designed questionnaire and anthropometric measurements were carried out by standard guidelines. Blood pressure is measured using a sphygmomanometer in a sitting position.	The population with high body mass index, high waist to hip ratio and age group of 30 to 40 years were found to be associated with hypertension. Early surveillance and prompt treatment forms will help in decreasing the cardiovascular risk of young adults in the near future.	Populations with a high body mass index, high waist to hip ratio and 30 to 40 years age groups were found to be associated with hypertension. Early surveillance and appropriate forms of treatment will help in reducing the cardiovascular risk of young adults in the near future
Prevalence of hypertension among young adults in rural North Indian populations **[9]**	Young adults in the rural population of central India. 1061 subjects aged 18-40 years	*cross-sectional*	Observation (recording blood pressure and anthropometric measurements).	Most of the young adults with raised blood pressure were previously undiagnosed. A large number of subjects had prehypertension. Their early identification facilitates early, active management of blood	The prevalence between men is higher (18.8% compared to 15.2% in women). As many as 40.2% of the subjects were found to have pre-hypertension. A higher prevalence of hypertension is seen

Title	Population / Sample	Method / Design	Intervention	Comparison	Outcome
				pressure and formulation of preventive strategies thereby decreasing morbidity and mortality due to cardiovascular diseases and hypertension.	among those who have a history of smoking.
Clinical characteristics and risk of hypertension require Young patients treated with systolic hypertension identified with ambulatory monitoring **[10]**	1,206 patients in the North East of Italy 18-45 years old,	*cross-sectional*	observation (anthropometric measurement)	These data were obtained with ambulatory BP monitoring, showing that in ISH people younger than 45 years only mean BP is a predictor of future hypertension needing treatment, whereas the ISH status per se does not necessarily imply an increase in risk.	BP outpatient monitoring shows that young people with ISH is better than people with diastolic cardiovascular risk profile or SDH. However, this condition is heterogeneous, and the main prognostic factor in the young-to-middle age range is the MBP level of outpatient care.
What are cardiovascular lifestyle risk factors for diseases associated with pre-hypertension in 15-18 years of rural Nigerian youth? A cross sectional study	Nigerian rural youth 1079 people age: 15-18 years	*cross-sectional*	survey	There were no gender differences in prevalence of pre- hypertension, and significant predictors of systolic pre-hypertension (high BMI and older age) were identified. Considering high BMI, older age was a risk for both genders, whilst fried	There were no gender differences in the prevalence of pre-hypertension, and significant predictors of systolic pre-hypertension (high BMI and older age) were identified. Given the high BMI, older age is a risk for both sexes,

Title	Population / Sample	Method / Design	Intervention	Comparison	Outcome
[11]				food preference was a female-only risk, and low breakfast cereal intake was a male-only risk.	while fried food preferences are the only risk for women, and low breakfast intake of cereal is the only risk for men
Effects of a dietary approach to Stop Hypertension (DASH) diets on blood pressure, being overweight and obesity in adolescents: A systematic review **[12]**	Teenagers in Canada Age 10 to 15 years	*cross-sectional*	Survey	The DASH diet may have beneficial effects on the alterations of BP, overweight and obesity in adolescence. However, adherence to this dietary pattern is still low.	The cross-sectional study found that higher DASH scores were associated with decreased body composition measurements; the other two did not associate between the DASH score, weight, and BP. the cohort study found that the DASH diet resulted in lower levels of diastolic BP and a lower body mass index gain of more than 10 years. One RCT showed that the DASH diet proved effective in increasing systolic blood pressure and another RCT observed a decrease in the prevalence of AH.
Suppression of hypertension in	Teenagers 13-15 years old	Cluster sample	Survey	Prevalence of high hypertension. behavioral	The prevalence of increased hypertension is

Title	Population / Sample	Method / Design	Intervention	Comparison	Outcome
adolescent schools will increase by 13-15 years in Assam **[13]**	In Assam 800 schools are taken in clusters and there are 16 clusters consisting of			risk factors such as tobacco, alcohol consumption, depression and sedentary lifestyles, extra salt intake, overweight and obesity are significant	influenced by behavioral risk factors of using tobacco, alcohol consumption, depression and sedentary lifestyle, extra salt intake, being overweight and obesity which are significantly associated with hypertension in adolescent school children.
Relationship of Genetic Factors with Blood Pressure in Adolescents**. [14]**	Malalayang 8th Middle School Students were from 80 students. Samples were students with good nutritional status who were enrolled in a particular school and given permission by their parents to participate in this study. There are 80 students	*Analytic observation*	Giving questionnaires and measuring blood pressure	inheritance pattern of hypertension in the family shows that hypertension genes are dominant. Even so according to Mendel's law, if only one parent suffers from hypertension, then the possibility of his child not suffering from hypertension is 50%. In this study, almost all children only had one parent who was hypertensive. So from that theory, it was	There is no relationship between genetic factors (parents of hypertension) and blood pressure in adolescents

Title	Population / Sample	Method / Design	Intervention	Comparison	Outcome
				concluded that most of the children with one of their parents were hypertensive who were not hypertensive, the dominant allele of hypertension was not inherited to them.	
Prevalence and incidence of hypertension in young girls **[15]**	2368 girls (49% Caucasians, 51% African-Americans) aged 9 or 10 years	*cross-sectional*	Observation Measurement of height. Weight and blood pressure	Obese girls have a higher prevalence (around 6 times higher) and occurrence (approximately 2 to 3 times higher) compared to girls of normal weight. A similar pattern is found for prehypertension, except that prehypertension occurs more in girls older than young girls.	Obese girls have a higher prevalence (around 6-fold higher) and incidence (approximately 2 to 3 times higher) compared to girls of normal weight. A similar pattern was found for prehypertension, except that prehypertension occurred more in girls older than young girls.
prevalence and predictor of pre-hypertension and hypertension among school going adolescents	Adolescents (14-19 years old) from Tripura, India 530 Tribal Tripuri and 363	*cross-sectional*	Anthropometric measurements, adiposity status, systolic blood pressure (SBP) and diastolic blood	Overweight or obese subjects were highly susceptible to pre-hypertension and hypertension. SBP showed a significant	Overweight or obese subjects are very vulnerable to pre-hypertension and hypertension.

(14-19 years)of Tripura, India **[16]**	Bengali teenagers from Tripura, India		pressure (DBP) subjects were evaluated	positive correlation with body mass index (BMI), waist-hip ratio (WHR), waist circumference (WC) and waist-height ratio (WHtR). While DBP correlated significantly with BMI, WHR and body fat of subjects.	
Prevalence of hypertension in Portuguese adolescents in Lisbon, Portugal **[1]**	Portuguese teenagers in Lisbon non-random samples from 234 adolescents of both sexes, aged between 16 and 19 years	*cross-sectional*	observation and measurement of blood pressure r	From right arm BPs were measured, whereas blood pressure may be different between the two arms and this could affect the results of the study. So, it would be better if BP was measured in both arms, the measurement were repeated (with at least 10-minute intervals) in the arm that has higher BP and the average of them were noted.	The prevalence of pre-HTN and HTN in the sample studied was high. Risk factors were evaluated, only gender, obesity and family history of HTN were significantly associated with BP values.
Protective Risks And Factors For Hypertension In American Indians And Native Teenagers And	Teenagers in American Indians and Alaskans from 20 teenagers. Teenagers aged	*cross-sectional*	Observation: (Measurement of blood pressure)	In adolescent and young adults, the risk of hypertension has only been associated with increasing body mass index and metabolic	In adolescents and young adults, the risk of hypertension has only been associated with an increase in body mass index and

Title	Population / Sample	Method / Design	Intervention	Comparison	Outcome
***Adults: A Systematic Review* [17]**	14-19 years			syndrome. In adults, the risk of hypertension increases with age and dietary consumption, low physical activity; tobacco use; overweight and obesity. In adolescents, the risk of hypertension increases with bad life style.	Metabolic syndrome. In older adults, the risk of hypertension increases with age and has been associated with consumption of foods high in red meat and sodium; Low Physical Activity; tobacco use and; Excess Weight And Obesity; diabetes status; Metabolic syndrome.

3.3 Characteristics of intervention

Anthropometric assessments were then performed (weight and height), followed by BP measurements. Weight and height were measured by subjects who were barefoot and lightly clothed. Weight is assessed using a calibrated scale, with the subject standing in the center of the platform and the weight distributed evenly between the legs. The height is measured on a wall mounted stadiometer with the subject's legs side by side, the head on the Frankfort plane and with the heels, buttocks, shoulder blades, and head touching the stadiometer. The weight is measured in kg and is rounded to the unit and the height of m is rounded to cm. Body mass index (BMI) was calculated as weight in kg divided by square of height in m, and subjects were classified according to the reference chart of the National Health Statistics Center for percentile age and gender specific as obesity (BMI ≥ P95), overweight (BMI between percentiles to -85 [P85] and P95) or normal weight (BMI <P85) [1].

Hypertension and prehypertension was significantly more in overweight and obese children compared to normal children indicating obesity as an important risk factor for hypertension. The prevalence of overweight and obesity is higher in urban than rural children. Recent changes in lifestyle in urban areas, like sedentary pursuits unhealthy dietary habits are the major culprits for this increasing trend in urban areas. So, early intervention strategies for promoting health, such as eating habits, physical activities and health education should be undertaken since school age to prevent morbidities of obesity such as hypertension. Adolescents need to pay attention to regular BP measurements, and more effort should be put into programs aimed at educating young people about healthy lifestyles, particularly the importance of regular exercise and a balanced diet.

4. Discussion

We conducted a systematic review using a cross sectional design to determine the factors that increase hypertension in adolescents. We included 16 studios that discussed the factors that influence hypertension in adolescents and will be discussed in full *Summary of findings* descendants, lifestyle behaviors, smoking, and alcohol.

Several studies have investigated whether parents' lifestyle behaviors are associated with hypertension in adolescents. There was no observed relationship between parents' lifestyle behaviors and blood pressure levels in adolescents. In a study conducted by Watt et al., No association was found between older people with higher sodium excretion rates and higher blood pressure levels in children. A different finding was reported by Simonetti et al., In Germany, it was found that children of parents who smoke were more likely to experience hypertension. The difference between results may be caused by different methodologies. For example, this study used an average of two measures of blood pressure and automatic oscillometric devices, while Simonetti et al. used three measurements and aneroid devices. In addition, the prevalence of smoking among parents in the study by Simonetti et al. was higher than that observed in our study: 28.5% of fathers and 20.7% of mothers reported smokers in Germany; in our study, 17.9% of fathers and 12.4% of mothers reported this behavior. Other factors may be the age of the individual. In a study by Simonetti et al., the population consisted of pre-schoolers who generally spent more time with their parents and were therefore more likely to be exposed to cigarette smoke and then develop higher blood pressure levels.

Our study population consists of adolescents, who are generally more independent and have other social relationships consisting mainly of their peers [18].

One of the new findings of this research is that it analyses whether the relationship of parents' health risk factors will increase the likelihood of hypertension in adolescents. This is not confirmed by fathers, but adolescents from mothers with four or more associated risk factors are 2.5 times more likely to have hypertension. In addition to genetic factors, which can affect the occurrence of hypertension in adolescents, especially due to several conditions during pregnancy, mothers tend to spend more time with their children than fathers and may have more influence on their behavior such as lifestyle, inactive physical activity, smoking, and alcohol consumption.

One limitation of this study is the assessment of self-reported hypertension among parents, which might contribute to the possibility of underestimation. No assessment of diabetes in this study should be considered a limitation because elderly diabetes may be a risk factor for high blood pressure in children. In addition, although we included adolescence, gender, and BMI in the statistical model as confounding as possible, others such as physical activity, sedentary behavior, and alcohol consumption by adolescents were not included, and this behavior might play an important role in the event.. Another factor is the cross-sectional design of the study, a feature that does not allow us to conclude the causal effects of the relationship of hypertension of parents and higher blood pressure values in adolescents [5]

4.1 Implication for research

The purpose of the systematics of this review is to find out the factors that influence hypertension in adolescents. Based on the results of the analysis there are many things that are known about the factors that influence the occurrence of hypertension in adolescents, namely heredity, weight, diet, alcohol, cigarettes, drugs and other disease factors. Lifestyle also affects the appearance of attacks of high blood pressure. Unhealthy habits such as an unbalanced diet with high cholesterol levels, salt, lack of exercise and a portion of rest to stress can affect the increase in blood pressure. Based on the review of the journal, it was found that observation of small blood pressure measurements until adolescents can detect or find out from the outset a person's blood pressure condition to get immediate treatment and avoid things that do not cause an increase in blood pressure.

4.2 Limitations of findings

The limitations of this study were: (1) the article was limited to published research, which may introduce publication publications, (2) what we consider to be the main results (gender, obesity, family history, lifestyle, age, weight, lifestyle, food consumption) were not always the same as in other studios.

5. Conclusion

From the results of the systematic study analysis, it is known that the most dominant factors affecting hypertension were smoking habits, body mass index (BMI), age and lack of physical activity. Based on the characteristics of the respondents, various hypertension studies showed age and family history as dominant risk factors for hypertension. As for the lifestyle of respondents, BMI factors and smoking habits were the highest risk factors identified in various studies of hypertension in various

countries. In future studies of hypertension should involve other variables besides factors of hypertension in adolescents.

ABSTRACT

Diabetes mellitus (DM) is a chronic disease which is characterized by hyperglycemia and glucose intolerance that occurs because the pancreas is unable to produce insulin adequately because the body cannot use the insulin that is produced effectively. This research aimed to understand the correlation of type 2 diabetes mellitus with the case of hypertension for patients of diabetes mellitus at working area of Public Health Center of Peterongan Sub District In Jombang District.The design of research used an analytic correlation with cross sectional approach. The population in this research was the patients of diabetes mellitus at outpatient of Public Health Center of Peterongan Sub district , in Jombang District as many as 74 people. The total of samples that was used as many as 62 respondents. The technique of sampling used convenience sampling. The technique of data collection used secondary data with statistical test analysis of Rank Spearman with $\alpha = 0.05$. The results of research showed that the majority (61.3%) of respondents suffered long from type 2 diabetes mellitus for 5-10 years as many as 38 people. the majority (53.2%) of respondents suffered moderate hypertension as many as 33 people. The result of Spearman rank test was obtained = 0,000 < = 0,05. The research concluded that there was the correlation of type 2 diabetes mellitus with the case of hypertension for patients of diabetes mellitus at working area of Public Health Center of Peterongan Sub District in Jombang District. Being expected this research results can be developed by the discussion of hypertension case for the patients of Diabetes Mellitus and it can be used as a reference for better prerequisite to community.

Keywords: type 2 diabetes mellitus, hypertension

1. Introduction

Diabetes mellitus (DM) is a chronic disease characterized by hyperglycemia and glucose intolerance that occurs because the pancreas gland cannot produce insulin adequately which or because the body cannot use insulin produced effectively or both. In recent years diabetes mellitus has increasingly attracted attention because of its increasing prevalence. There are 2 types of Diabetes Mellitus according to the causative factors namely type 1 diabetes mellitus caused by hereditary factors and viral infection and type 2 diabetes mellitus caused by factors of being overweight and lack of physical activity (WHO, 2014). Whereas explained by (Maulana, 2015) diabetes also triggers and complicates other diseases such as the heart to hypertension. Problems that arise in this disease until now one of the causes is the accumulation of free radicals or oxidants. Free radicals can destroy the tissue system and the integrity of DNA in our body, this condition stimulates the acceleration of

the aging process, as well as the destruction of the liver and causes other diseases such as the heart and cancer (Herlambang, 2013).

The number of people with diabetes, especially Diabetes Type 2, is increasing throughout the world, especially in developing countries. International Diabetes Federation (IDF) estimates that every year 4.9 million people in the world die from diabetes and as many as 179 million (49%) people do not realize that they have diabetes. Based on IDF data acquisition in 2014 the global prevalence rate of diabetics aged 20 - 79 years amounted to 387 million cases out of 4.6 billion world population, IDF estimates that in 2035 the number of incidents of diabetes will increase to 592 million (54%) cases . Diabetes mellitus in Indonesia has increased from 1.5% in 2013 to 2.1% in 2014 (Riskesdas, 2013), this is in line with the results of data obtained by IDF in 2014, that Indonesia has around 9.1 million cases of diabetes, this is the fifth largest number in the world, before in 2011, Indonesia ranked 10th for the highest diabetes cases in the world with 7.2 million sufferers and up in 2013 to 7th with the number of sufferers is 8.5 million.

Based on the data contained in the Profile of the Jombang District Health Office in 2014 there were 21,992 (20%) diabetes cases in Jombang Regency. One of the regions in Jombang with the highest incidence of DM was in the Pusongan Health Center with 2,686 cases of diabetes (50%) (Jombang Health Office, 2014). In January and February 2016 there were 213 cases of diabetes in Peterongan Health Center (Peterongan Health Center, 2016).

From the Preliminary Study conducted at the Peterongan Health Center in Peterongan District, Jombang Regency on March 2, 2016, of the 10 people with diabetes there were 6 people who experienced hypertension and 4 people did not experience hypertension.

Diabetes is the main factor that can experience hypertension which is controlled by angiotensin II or macrovascular substances. its relationship with type 2 Diabetes Mellitus is very complex, so hypertension can make cells not sensitive to insulin (insulin resistant). The factors that influence the occurrence of diabetes are heredity (genetic), autoimmune, viral or chemical substances, diet or left style (lifestyle), high cholesterol levels, lack of exercise, obesity or obesity, one of which affects diabetes is indicated by increase in high blood sugar levels.

In general, blood pressure is 120/80 mmHg. the blood pressure limit is still considered normal if the blood pressure is less 130/85 mmHg, if more than 140/90 mmHg is stated as hypertension and among them the value is categorized as normal high (the limit is for adult individuals over 18 years) (Herlambang, 2013)

In type 2 Diabetes Mellitus patients, the most effective management is to change a balanced diet or lifestyle (left style) and reduce foods that contain lots of protein, fat, sugar, and salt. While the handling of hypertension can be prevented by regulating a good diet and sufficient physical activity by avoiding other habits such as smoking and consuming alcohol can also affect the risk of hypertension (Herlambang, 2013). And based on the description, the researcher was interested in researching about "Relationship between Type 2 Diabetes Mellitus and the incidence of Hypertension in Diabetes Mellitus patients in the Work Area of Peterongan Health Center in Jombang Regency"

2. Method

The research design in this study is correlational with the approach used Cross Sectional which emphasizes the time of measurement or observation of independent and dependent variable data only once at a time. Independent and dependent variables are assessed stimulantly at a time.

The study population was patients with type 2 diabetes mellitus in outpatient care at Peterongan District Health Center in Jombang in 74 people in April. The sample is some patients with type 2 diabetes mellitus who are outpatient at the Peterongan Health Center in Jombang Regency as many as 62 people.

The sampling technique in this study is Convinience sampling is the selection of samples or the way in which samples are determined by looking for subjects on the basis of things that please researchers. The independent variable is Diabetes Mellitus and the dependent variable is hypertension. The researcher used the Rank Spearman statistical test, $p = 0.05$

This research will be conducted on April 15 - May 16, 2016 at the Peterongan Health Center in Jombang Regency

3. RESULTS

The research results are presented in the form of general data and special data. General data contains characteristics of age, gender and occupation. Whereas the specific data is Type 2 Diabetes Mellitus, the incidence of hypertension in patients with Diabetes Mellitus and the Relationship between the Long Suffering Type 2 Diabetes Mellitus and the incidence of Hypertension in Diabetes Mellitus patients in Peterongan District of Jombang :

General data

Table 1. Distribution of General Characteristics of respondents

No	General data	Total	%
1.	**Age**		
	40-45 years	2	3,2%
	46-50 years	16	25,8%
	51-60 years	44	71%
2	**Gender**		
	Male	14	22,6%
	Female	48	77,4%
3	**Work**		
	Does not work	0	0%
	Farmers / traders	32	51,6%
	PNS	8	12,9%
	Private / entrepreneurial	22	35,5%

Table.1 shows that most (71%) of respondents aged 51-60 years were 44 respondents, almost all (77.4%) of respondents were female of 48 respondents, and most (51.6%) of respondents worked as farmers / trader for 32 respondents

Special Data

Table 2. Distribution of cross tabulations between ages and incidence of hypertension

Age	Hypertension incidence								Total	
	Weight		Is being		Light		Normal			
	∑	%	∑	%	∑	%	∑	%	∑	%
40-45 years	0	0	1	1,6	1	1,6	0	0	2	3,2
46-50 years	1	1,6	10	16,1	5	8,1	0	0	16	25,8
51-60 years	2	3,2	22	35,5	18	29	2	3,2	44	71

Total	3	4,8	33	53,2	24	38,7	2	3,2	62	100

Based on table 2. shows that almost half (35.5%) of respondents aged 51-60 with the incidence of hypertension in DM patients with a moderate category of 22 respondents

Table 3. Distribution of cross tabulations between sexes with the incidence of hypertension

Gender	**Hypertension incidence in Diabetes mellitus patients**								**Total**	
	Weight		**Is being**		**Light**		**Normal**			
	∑	%	∑	%	∑	%	∑	%	∑	%
Male	1	1,6	9	14,5	4	14,5	0	0	14	22,6
Female	2	3,2	24	38,7	20	32,3	2	3,2	48	77,4
Total	3	4,8	33	53,2	24	38,7	2	3,2	62	100

Based on table 3. shows that almost half (38.7%) of female sex with the incidence of hypertension in DM patients with a moderate category of 24 respondents

Table 4. Distribution of cross tabulation between the relationship of diabetes mellitus and the incidence of hypertension

Long suffering from type 2 diabetes	**Hypertension incidence in Diabetes mellitus patients**								**Total**	
	Weight		**Is being**		**Light**		**Normal**			
	∑	**%**	**∑**	**%**	**∑**	**%**	**∑**	**%**	**∑**	**%**
>10 year	3	4,8	4	6,5	1	1,6	0	0	8	12,9
5-10 year	0	0	27	43,5	11	17,7	0	0	38	61,8
>4 month	0	0	2	3,2	12	19,4	2	3,2	16	25,8
Total	3	4,8	33	53,2	24	38,7	2	3,2	62	100
***Spearman Rank* = 0,602 ρ = 0,000 < α = 0,05**										

Based on table 4 shows that most (43.5%) of the old respondents suffer from hypertension 5-10 years with the incidence of hypertension in DM patients with a moderate category of 27 respondents, then the results of the Spearman rank test obtained a significant number or probability value (0,000) far lower than the significant standard of 0.05 or (r <α), then the data Ho was rejected and H1 was accepted which means there is a Relationship between Type 2 Diabetes Mellitus with the incidence of Hypertension in Diabetes Mellitus sufferers in the working area of Peterongan Health Center, Jombang Regency.

4. Discussion

Relationship long p with type 2 diabetes mellitus with hypertension events

Based on Table 4. above shows that 61.3% or 38 respondents suffered from type 2 DM for 5-10 years. Then 53.2% had moderate hypertension from 62 respondents. In table 5, the results of the Spearman rank test obtained a probability value (0,000) far lower than the significant standard 0.05 or (r < α), then H1 was accepted which means there is a relationship between Type 2 Diabetes Mellitus and the incidence of Hypertension in Diabetes Mellitus patients The working area of Peterongan Health Center in Jombang Regency.

Zimmet, (2009) explained that the duration of diabetes showed how long the patient had diabetes mellitus since the diagnosis of the disease. The duration of diabetes mellitus suffered is associated with the risk of several complications that arise afterwards. The main factor triggering complications in diabetes mellitus in addition to duration or duration of suffering is the severity of diabetes.

Complications of diabetes mellitus are metabolic disorders resulting in hyperglycemia which results in an increase in blood fat levels and damage to small blood vessels which in a long time will cause diabetic neuropathy and disorders of important organs in the body namely the heart, kidneys, brain, digestive tract, senses and so on (Sutedjo, 2010).

Related to these conditions, Mutmainah (2013) explained from the results of research that diabetes is a major factor that can lead to hypertension which is controlled by angiotensin II or macrovascular substances. its relationship with type 2 Diabetes Mellitus is very complex, so hypertension can make cells not sensitive to insulin (insulin resistant). Insulin plays a role in increasing glucose uptake in many cells and in this way it also regulates carbohydrate metabolism, so that if there is insulin resistance by cells, the blood sugar levels can also be disrupted.

In addition to the old condition of type 2 diabetes mellitus, the incidence of hypertension is strongly influenced by age factors, according to table 2, indicating that the majority (71%) of respondents aged 51-60 years were 44 respondents suffering from severe hypertension 3.2%, moderate 35.5 % and mild 29%. and normal 3.2%. Increasing age, the possibility of someone suffering from hypertension is also getting bigger. Hypertension is a disease that arises due to the interaction of as a risk factor for the onset of hypertension. The loss of atherosclerosis tissue elasticity and blood vessel dilation are the causes of hypertension in old age (Sutanto, 2010). this is because the more advanced a person will experience degenerative diseases such as hypertension. Besides eating patterns also affect the elderly occur hypertension, eating patterns that are wrong such as eating foods that contain lots of salt, eating fatty foods, drinking excessive coffee can lead to elderly people affected by hypertension.

Sex factors are also very possible for hypertension. Based on Table 1. shows that almost all (77.4%) of respondents were female of 48 respondents. Based on cross tabulation data between sexes and the incidence of hypertension in DM patients it is known that from 48 respondents almost half were female, the incidence of moderate hypertension was 24 people (38.7%).

The results of the 1995 household health survey showed that the prevalence of hypertension or high blood pressure in Indonesia was quite high, at 83 per 1,000 household members. Women> men at age> 50 years old men> women at age <50 years (Muhammadun, 2010). The role of estrogen hormone is to increase HDL levels which are protective factors in preventing the occurrence of the atherosclerosis process. The effect of protecting estrogen hormones is thought to be the presence of female immunity at premenopausal age (Kumar, 2009).

Referring to the data and theory above, the incidence of hypertension is strongly influenced by the old condition of suffering from type 2 diabetes mellitus, which generally has a long suffering from 5 years to more than 10 years. Then the condition is strongly influenced by age, where age is closely related to the body's degenerative system, especially the blood vessel system and the heart, so hypertension may occur in people with diabetes mellitus

Gender factors also play an important role in the occurrence of hypertension that gender is very closely related to the occurrence of hypertension, where in middle-aged hypertension is higher in women when a woman experiences menopause. Menopause is associated with an increase in blood

pressure, this occurs because menopausal women experience a decrease in the hormone estrogen, which has been protecting blood vessels from damage (Kusumawaty, et.al. 2016) this is also in accordance with the results of research by Min-Ju Kim, et.all. (2015) explained that there is a risk in people with diabetes mellitus more than 8 years of blood pressure. The prehypertension and hypertension were significantly associated with the development of diabetes, regardless of initial glucose status, gender and BMI

5. Conclusion

Based on the description of the results and discussion above, it can be concluded that; There is a relationship between Type 2 Diabetes Mellitus (5-10 years) and the incidence of Hypertension in Diabetes Mellitus patients in the Peterongan Health Center, Jombang Regency.

Email: primalova.septiavy.estiadewi-2017@fkp.unair.ac.id

ABSTRACT

Post-Traumatic Stress Disorder (PTSD) is highly prevalent in each person who have experienced trauma. No previous systematic review who have specifically investigated the effectiveness of psychological therapies of PTSD for survivors on natural disaster. Objectives of this review were to examine the effectiveness of psychological therapies in treating survivor on natural disaster who have been diagnosed with PTSD. A comprehensive search includes randomized controlled trials from the following bibliographic databases i.e Scopus, PubMed, Science Direct, ProQuest and Springerlink were used to search scientific contribution which is published between 2009-2019. Articles pre-identified by using relevant keywords. This systematic review in line with PRISMA guidelines. Twenty- five of about 486 articles both meet inclution and exclution criteria and were reviewed. The psychological therapies that found in these studies were Cognitive Behavioural Therapy (CBT), Narrative Exposure Therapy, Yoga, Trauma Stabilisation, Cognitive Hypnotherapy, Internet-CBT, Cognitive Processing Therapy, Supportive Counseling, Control-Focused Behavioral Treatment (C-FBT), Early Eye Movement Desensitisation and Reprocessing (EMDR) and meditation-relaxation. Most compared a psychological therapy to a control group. The psychological therapy for which there was the best evidence of effectiveness was CBT.

Keywords: phychological therapies, phychological treatment, post-traumatic stress disorder, natural disaster

1. Introduction

Natural disasters such as earthquakes, floods, and hurricanes may lead to a wide range of negative psychological consequences, including post-traumatic stress disorder (PTSD) [1]. The aftermath of a disaster is a time when survivors experience many psychosocial symptoms such as stress, grief, depression, and anxiety [2]. Furthermore, the life-threatening nature of the disaster, the loss of loved ones, and, in some cases, the irreversible physical impairment of affected individuals further contributes to the risk of developing mental health disorders, and such disorders might prevent victims from benefiting sustainably from material aid that is often provided as part of organized relief efforts [3]. A growing body of evidence demonstrates that major depressive disorder, PTSD, depression, and anxiety undesirably and forcefully [4]. PTSD as the most frequently occurring psychological disorder appearing after the experience of a natural disaster, with prevalence rates ranging from 5 to 60%, with higher rates in areas more severely affected by the disaster [3].

Epidemiological research suggests that 60–80% of individuals with acute stress disorder (ASD) develop PTSD and a third of subjects with acute PTSD symptoms remain symptomatic for six years or longer. Moreover, over 80% of individuals diagnosed with PTSD meet diagnostic criteria for at least one other disorder. A major depressive disorder is one of the most common comorbid disorders with PTSD [5]. Developing PTSD also is influenced by economic status, the extent of house and property damage, loss of beloved people, injury, anxiety levels during the disaster, and whether survivors are living in a shelter after the disaster [2]. There is increasing evidence that PTSD is associated with suicidal behavior and comorbidity with a mental and physical health condition [6]. As PTSD is highly comorbid with other mental disorders, aside from trauma exposure, what differentiates PTSD from other disorders is the re-experiencing of symptoms (for example, nightmares and flashbacks) and many of the other symptoms of PTSD, such as hyperarousal, avoidance, and numbing, overlap with other mental disorders, such as generalized anxiety disorder, panic disorder, and depression [6,7].

In relation to the treatment of PTSD, all psychotherapies, individual psychotherapy focused on trauma is the most effective, followed by stress management techniques and group cognitive-behavioral therapy [8]. A number of trauma-specific and generic psychological therapy approaches have been used in the treatment of PTSD for adults. Existing reviews have explored the effects of psychological therapies for the treatment of PTSD in children and adolescents [9]. A systematic review and synthesis of published group treatments for adults with symptoms associated with complex PTSD already known [10]. However, specific systematic reviews explore the effect of psychological therapies against PTSD among adult survivors of natural disasters have never been done. The objective of this article is to examine the effectiveness of psychological therapies in reducing PTSD in adult survivors of natural disasters.

2. Methods

2.1. Protocol

This systematic review using Procedures outlined in the Preferred Reporting Items for Systematic-Reviews (PRISMA) were followed [11,12].

2.2. Eligibility criteria

Journal articles published in English from January 2009 to January 2019. Searching strategy used the PICOS framework to identify the keywords.

2.2.1. Type of study design.

Only studies of completed randomized controlled trials published in peer-reviewed journals written in English were induced.

2.2.2. Type of participants.

Studies were included to all adult survivors (>18 years) of natural disasters with PTSD. Survivors with comorbid conditions such as depression, stress, and anxiety disorders were included.

2.2.3. Type of interventions.

Studies were included if the intervention comprised a psychological clinical framework, and may have comprised education, uni-or multidisciplinary rehabilitation (i.e., physician, physiotherapy, psychology,occupational therapy). Interventions must have sought to prevent the incidence, or reduce the severity and impact, of psychological conditions. All psychological therapies including CBT, NET, Yoga, EMDR, and IPT. Control as comparator intervention is treatment, as usual, waiting list controls or no treatment, another psychological therapy and other treatments.

2.2.4. Type of clinical outcomes.

Intervention studies had to include assessment of PTSD (i.e. overall levels of trauma symptomatology), anxiety and depression.

2.3. Information sources

Studies were identified by comprehensive searching of five databases namely Scopus, ScienceDirect, PubMed, Proquest, and SpringerLink.

2.4. Search

Search terms in the database using a combination of keywords (1) Psychological Therapies OR (2) Psychological Treatment AND (3) Post-Traumatic Stress Disorder OR (4) PTSD AND (5) Natural Disaster.

2.5. Study selection

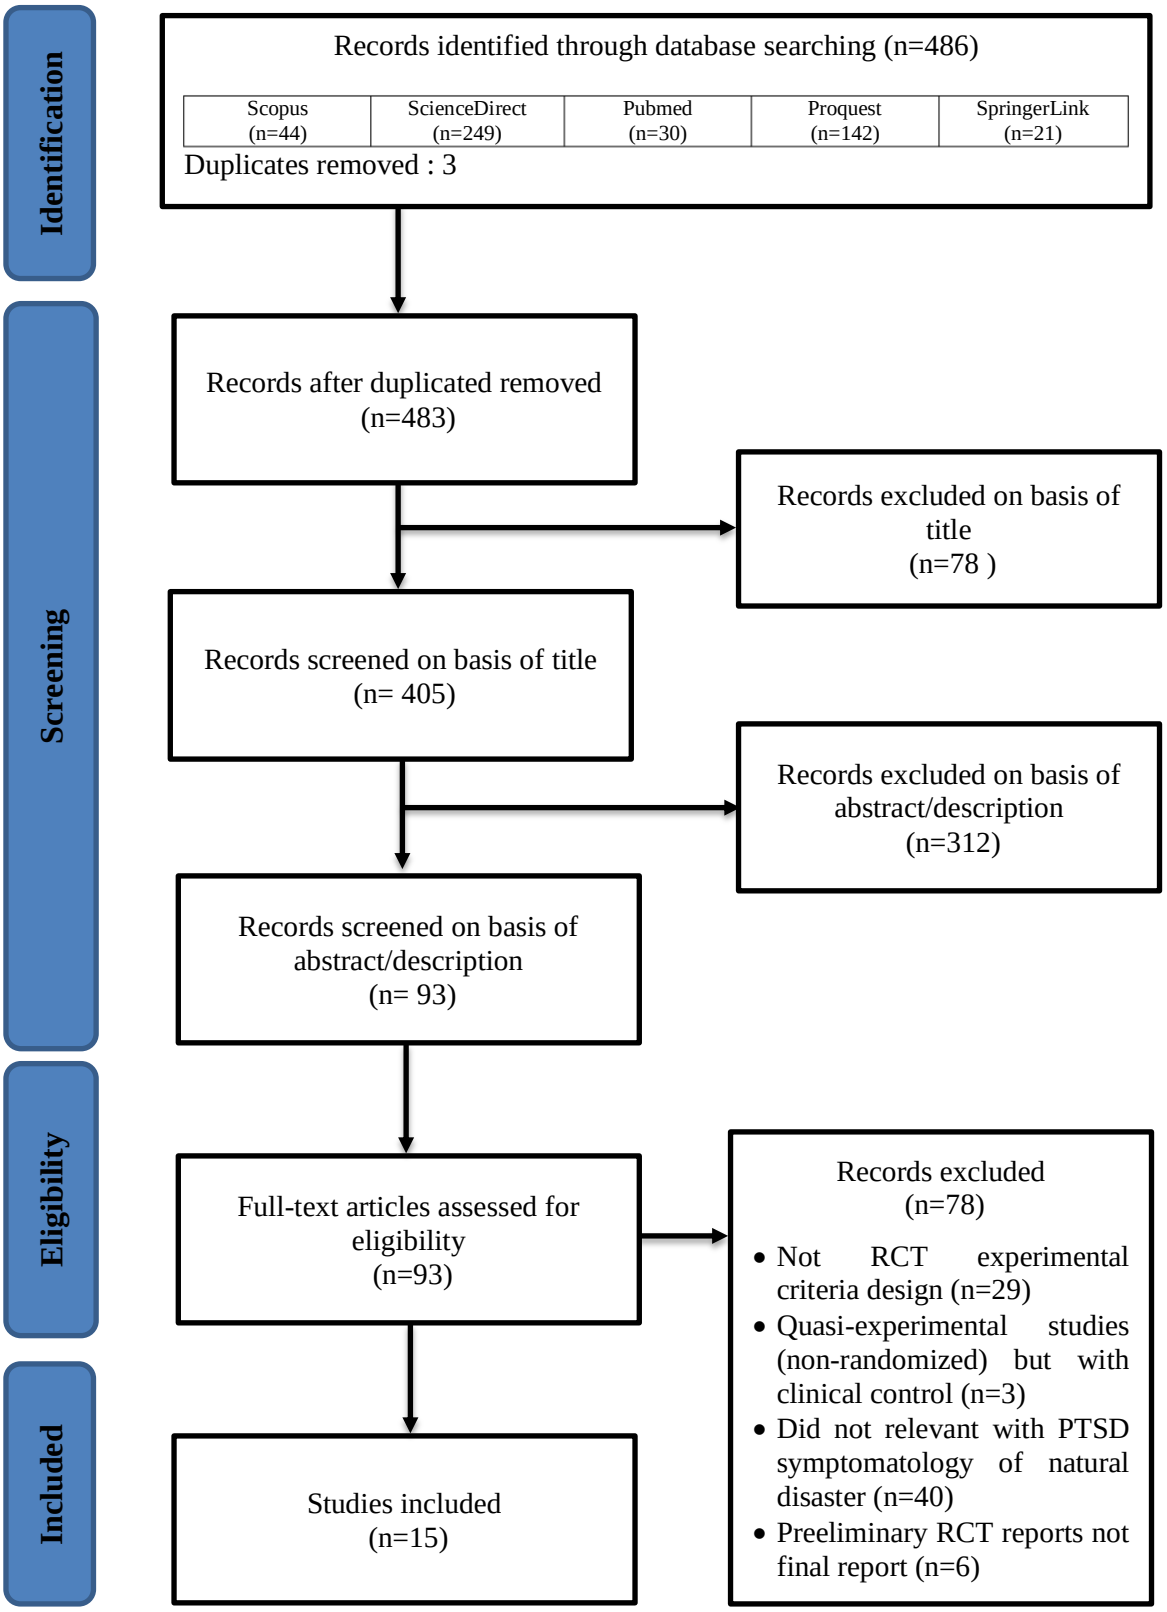
Titles and abstracts were independently screened by reviewers against the inclusion criteria. Reviewer assigned inclusion codes were yes, no or unsure. Full-text articles were then obtained and assessed for eligibility. The reviewers compared the screening results and discussed any disagreements regarding study eligibility.

2.6. Data collection process

The following data were extracted: the identity of studies, the setting of the study and the main results. Two authors (PSE and IKLTA) were involved in data extraction, and after organizing results in a table, the findings were discussed and reviewed again. One review author extracted the following data from included studies and the other checked the extracted data. Disagreement is resolved by discussion between authors.

2.7. Data items

Reviewers used a customized form to extract study information to enable the evaluation of study characteristics, heterogeneity, and likely population impact through reach, effectiveness, adoption and Implementation. The following data were extracted: (1) study country; (2) cohort characteristics (including therapy type, type trauma context, type natural disaster, gender distributions and sample size at recruitment and outcome assessment); (3) study inclusion and exclusion criteria; (4) study design; (5) characteristics of the intervention and control groups; (6) details of the intervention(s) including timing postinjury, discipline of therapy/therapists, modality (e.g., individualized, group) and intensity; (7) setting in which interventions were adopted; (8) who implemented the intervention (e.g., research staff or non-research clinicians); (9) timing of follow-up assessments; (10) primary and secondary outcomes; (11) measurement tools; and (12) intervention effects on outcomes.



1.1.1.1.2.1 **Figure 1.** Study inclusion based on the preferred reporting items for systematic reviews

2.8. Risk of bias in individual studies

As both randomized controlled trials (RCTs) studies were eligible for risk, bias assessment was undertaken using a tailored tool based on the respective Cochrane Collaboration guidelines [13]. Risk of bias was evaluated for the following domains: (1) selection bias (e.g., randomization and stratification); (2) performance bias (e.g., blinding of participants and personnel); (3) detection bias (e.g., missing data and appropriate confounders); and (4) reporting bias (e.g., selective reporting). Reviewer independently assessed each study for bias, which was coded as high, moderate, low or unclear/unknown. Where appropriate, the direction of bias was noted as favoring the intervention/control, or was unclear. The overall risk of bias ratings was determined qualitatively and some domains were weighted more heavily than others as recommended [13]. For example, trial performance and detection and analysis were given more weight as studies with a high risk of bias in these domains may be more likely to favor the intervention group. Each reviewer was blind to the assessment of the other reviewer. The reviewers crosschecked their final assessments and resolved any disagreements through discussion.

2.9. Data analysis

Studies were grouped according to the intervention used and the study population. Where possible, studies were thereafter grouped according to the time of follow-up and type of control group. All studies were individually rated for evidence level using the National Health and Medical Research Council (NHMRC) Hierarchy of evidence guidelines (IV-I, with I being the strongest level of evidence).

2.10. Meta-analysis

Meta-analysis was not possible as studies were too heterogeneous in the type of interventions, type of control group, outcomes measures used and the time of follow-up.

3. Results

3.1. Study selection

The search yielded 486 records. After the removal of 3 duplicates, 483 records remained, 78 did not meet the inclusion criteria after screening the titles, 312 did not meet the inclusion criteria after screening the abstract and description. Ninety-three full-text articles were assessed for eligibility, and 78 did not meet the inclusion criteria. Fifteen papers were included for data in systematic review[3,8,22–26,14–21]. Study characteristics, including cohort information, intervention details, and outcome measures are described in Appendix A.

3.2. Study characteristic

3.2.1 Type of participant.

About 15 included studies, four were conducted in Asia [14,16,22,25,27–32], eight in Europe [8,15,18–21,26,33], one in Africa [3,34], one in Australia [17]. Participants were predominantly recruited from the area of natural disaster. The included studies involved 1301 participants, with 332 (25%) men and 969 (75%) women. The majority of studies recruited participants aged 18 to 78 years old.

3.2.2 Type of study design.

All study adopted an RCT design, All other studies compared a single intervention to a waitlist, control or usual care group.

3.2.3 Type of interventions.

There were four key intervention designs: CBT [8,15,17,24]; NET [3,22]; yoga [14,21,25], EMDR [19,20,26,33], and IPT [16,18]. For most participants, interventions were initiated between 1-5 year post-disaster. The reported range of follow up start from one-month follow-up until 24-month follow-ups. Most interventions were delivered by a clinical psychologist, social worker or nurse who was trained and supervised to deliver the intervention. Further descriptions of the interventions, including timing and modality, are provided in Appendix 1.

3.2.4 Type of outcomes.

Each study examined PTSD symptomatology and depression outcomes. The timing of outcome assessments ranged from one month to 5 years post-disaster. In some studies, follow-up periods were specified relative to the time since commencing or completing the treatment. PTSD symptoms or diagnosis were reported as primary outcomes in all studies. Depression symptoms or diagnoses were secondary outcomes in seven studies.

Tools that used to measure PTSD symptoms was the Short Posttraumatic Stress Disorder Rating Interview (SPRINT-E) [8]; Short-Post Traumatic Stress Disorder Rating Review-Expanded [15]; Primary Outcome Measures PTSD [24]; Impact of Event Scale-Revised (IES-R) [17,20,22,24,26,33]; Clinician-Administrated PTSD Scale for DSM-IV [3,16–19]; PCL-17 [14]; Screening Questionnaire for Disaster Mental Health (SDQ) [25]; and PDS [21].

Depression and anxiety Generalized Anxiety Disorder, the PHQ-9 [17,24]; Hospital Anxiety and Depression Scale (HADS) [22]; The Beck Depression Inventory-Second Edition and The Beck Anxiety Inventory (BAI) [14,21].

3.3. Risk of bias assessments

Risk of bias judgments for each paper is summarized in Appendix B. Ten papers (66.7%) were considered to have a low risk of bias, four (26,7%) had a moderate risk of bias and one (6.6%) had a high risk of bias. Poor selection methods, lack of adjustment for confounding factors and inadequate analyses were the main sources of bias, see Fig. B2. While inadequate blinding of personnel was a key source of bias, we acknowledge that it is rarely possible to fully blind participants and clinicians to active psychological interventions.

3.4. Result of individual studies

There are various type of psychological interventions in the reviewers found, including CBT, NET, Yoga, EMDR, and IPT. Each intervention has been grouped and described separately related to its effect on the PTSD.

3.4.1. Cognitive behavioral therapy.

Cognitive-Behavioral psychotherapy that has demonstrated to be effective for PTSD treatment after a natural disaster is the cognitive-behavioral therapy for post-disaster distress (CBT-PD) that measured on four different occasions (referral, pretreatment, intermediate and post-treatment) [8]. CBT-PD is a short-term group therapy (10-12 sessions), whose objective is to identify and to intervene in the maladaptive beliefs related to the disaster and intervention which includes four

components: psychoeducation, breathing retraining, behavioral activation and cognitive restructuring [8]. CBT-PD is a manualized treatment that has a primary focus on identifying and challenging maladaptive disaster-related beliefs and it includes psychoeducation, breathing retraining, behavioral activation, and cognitive restructuring. Psychoeducation provided in the first session, psychoeducation aims to provide clients with an understanding of common reactions to disaster. Breathing Retraining and Behavioral Activation in session two clients are taught some immediate ways of managing their distress as well as skills for decreasing future distress. Breathing retraining is a skill for managing and decreasing anxiety. Behavioral activation is introduced as an effective way to combat depression and avoidance. Cognitive restructuring in session three mentioned clients are introduced to the concept that people's emotional reactions to events are determined by their interpretations of those events. In session four, clients are introduced to the cognitive distortions (called problematic thinking styles) that may result from basing current thinking on past traumatic experiences. The evaluation was minimal in the first pilots of the approach, but preliminary results were promising, and it appears that it can be rapidly disseminated to community-based clinicians [15].

Face-to-face CBT for PTSD typically involves 1–1.5 hours of treatment per week over 9–12 weeks, covering psycho-education, anxiety management, cognitive and exposure therapy, and relapse prevention [35]. However, this form of specialized treatment is unavailable to many sufferers due to a shortage of appropriately qualified professionals (especially in rural and regional communities), individual financial constraints, and the social stigma attached to seeing a mental health professional [36]. Therapist-assisted internet interventions have been found to be as effective as best practice face-to-face therapy. Both self-help and therapist-assisted internet-based treatments have been successfully delivered for a range of mental illnesses, including depression, panic, insomnia, and alcohol problems [17].

3.4.2. Narrative Exposure Therapy.

NET is a standardized short-term trauma-focused treatment approach developed to meet the needs of traumatized survivors. It is based on exposure therapy, CBT and testimony therapy. In contrast to other exposure treatments, the participant does not identify a single traumatic event as a target in therapy. Instead, NET involves constructing a narrative that covers the participant's entire life [22]. NET embeds the principles of testimony therapy, prolonged exposure therapy, cognitive-behavioral, and client-centered psychotherapy into recent findings of neurotraumatology [3]. Cognitive processing models suggest that PTSD symptoms are maintained through a distortion of explicit autobiographic memory about traumatic events and its detachment from the contents of implicit memory, which produces a fragmented narrative of the traumatic memories. Emotional processing theory states that the habituation of emotional responses through exposure leads to a decrease in post-traumatic symptoms.

NET stresses the importance of both approaches: the habituation of emotional responses to reminders of the traumatic event and the construction of a detailed narrative of the event and its consequences. NET is a strict manualized treatment. Sessions are usually 60–120 min in length and ideally occur in close succession. The person initially undergoes psychoeducation, then constructs a lifeline, with subsequent sessions dedicated to the narration of the person's life, with particular focus on and attention to the traumatic events, which are narrated in great detail, ensuring emotional engagement with the memory. The aim is to integrate the generally fragmented, gap-filled reports of traumatic experience into a coherent narrative and to bring about the habituation of emotional

responses to reminders of the traumatic event. Each session may focus on a single event, so people with multiple traumas need multiple sessions. Finally, the person and therapist have created a testimony of the person's life from birth to the present day, with a detailed narration of the traumatic events [3,22].

3.4.3. Yoga.

Yoga breath interventions could increase the symptoms of PTSD, depression, and anxiety. Multi-component mind-body programs, including breath practices postures (asanas) and movements, may alleviate symptoms of anxiety, depression, PTSD and schizophrenia. The Yoga intervention was taught as an 8-h program given in 2-h sessions over four consecutive days and included four breathing techniques: three-stage Ujjayi (Victorious Breath), Bhastrika (Bellows Breath), chanting 'OM' and Sudarshan Kriya (SK) (Clear Vision through Purifying Action). All breath forms are performed with the eyes and mouth closed while breathing through the nose. The intervention included some brief discussion about trauma reduction and life meaning. Ujjayi breathing employs a slight contraction of the laryngeal muscles and partial closure of the glottis (increasing airway resistance) while breathing through the nose. Bhastrika involves repeatedly raising the arms above the head and then bringing them down against the sides of the ribs, like the handles of a bellows, leading to vigorous exhalation through the nose Sudarshan Kriya (SK) uses a sequence of breathing at different rates starting slowly (4–6 breaths per minute), then at a moderate rate (10–12 breaths per minute), then briefly at a fast rate (80–100 breaths per minute). The sequence is repeated several times over a total period of approximately 10 min.

The yoga session was conducted in the morning between 06:00 and 07:00 hours. The yoga class included loosening exercises (sithilikarana vyayama) for ten minutes, physical postures (asanas) for twenty minutes and breathing techniques (pranayamas) for twenty-five minutes. These practices were followed by five minutes of guided relaxation in shavasana (corpse pose). Loosening exercises (sithilikarana vyayama) are a set of techniques which involve repetitive movements of all joints from the toes up to the neck to increase mobility and to prepare for the practice of yoga postures. The following yoga postures were practiced: standing posture (tadasana), lateral arc posture (ardhakaticakrasana), hand-to-foot posture (padahastasana), half wheel posture (ardhacakrasana), back-stretching posture (paschimottanasana), half lotus posture (ardha padmasana), moon posture (sasankasana), crocodile posture (makrasana), cobra posture (bhujangasana), locust posture (shalabhasana), shoulder stand posture (sarvangasana), and fish posture (matsyasana). The breathing techniques included high frequency yoga cleansing breathing (kapalabhati), alternate nostril yoga breathing (anulom-vilom pranayama), exhalation while making a humming sound like a bumble bee (brahmari pranayama) and exhalation with chanting of a syllable, OM (udgheeth pranayama). The breath rate for the high-frequency yoga cleansing breathing (kapalabhati) was approximately 60 breaths per minute. For alternate nostril breathing (anulom-vilom pranayama) the breathing rate was approximately 12 breaths per minute, whereas, for the breathing practices involving exhalation with a sound (e.g., brahmari and udgheeth pranayamas), the breath rate was lower, approximately 8 breaths per minute. The breath rates mentioned here are based on our unpublished data recorded in normal volunteers who were also novices to yoga and learned the techniques in the comparable time. This yoga program has been called Patanjali yoga as it is based on the teachings of Patanjali (circa 900 B.C.) [14,21,25].

3.4.4. Early Eye Movement Desensitization and Reprocessing.

EMDR is a structured psychotherapeutic method widely used to treat various psychopathologies and problems relating to traumatic events and emotionally stressful experiences and adopts as a theoretical base the AIP model (Adaptive Information Processing), which works on insufficiently worked-through memories. EMDR is particularly suitable for treating PTSD thanks to its applicability in emergency situations and its rapidity in achieving appreciable and lasting results [26]. The EMDR Integrative Group Protocol (EMDR-IGTP) takes about 90 min and foresees three sessions of intervention. Pointed out the advantages of EMDR in the emergency context typical of earthquake-affected populations who receive treatment in tent cities, compared to other strategies such as exposure-based cognitive behavioral therapies, or the techniques of "belief-restructuring" and "stress inoculation," strategies which are considered inappropriate and difficult to apply given the emergency situation and chaotic conditions of tent cities. Furthermore, the techniques based on exposure which center on the stressful details of the event are generally considered unsuitable for a population exposed to high levels of anxiety, suffering many bereavements and are under constant threat from the risks of further tremors [26,33].

The therapy followed a standard EMDR protocol and was composed of eight steps. The EMDR session began with the identification of patients' most disturbing memories of the traumatic event, as well as of any associated negative belief, disturbing emotion and its bodily location. Patients were then asked to focus on these traumatic events while following the bilateral finger movements performed by the therapist for about 30 seconds. After each set of horizontal movements, the patients were prompt to share any emotion/flashback/percept they have been noticing during the visual stimulation. When the patients reported no more erupting emotional burst or any other feeling related to the target memory, the therapist assessed the patient's ability to elaborate on the target with no emotional distress. The process was completed when the patient reported being able to think about the traumatic experience with no disturbing emotions or somatic reactions. Other targets were then selected and the same procedure (i.e., trauma identification, visual stimulation, assessment) was repeated. The EMDR treatment ended when patients were able to visualize themselves in a future scenario where they were able to face the re-elaborated targets while feeling no emotional discomfort. In the present sample, the EMDR required an average of 4 weeks (±2) of weekly sessions per patient. Each session lasted for approximately an hour. EMDR was performed by two certified EMDR therapists [19,20,26,33].

3.4.5. Interpersonal Therapy

IPT is 12-week structured psychotherapy established first-line treatment for depression in the U.S. IPT was delivered in one hour weekly individual sessions for 12 weeks. The goal of IPT is to examine and change current relationships and social support in order to improve mood and anxiety symptoms. IPT has been modified for other uses, including delivery by trained paraprofessionals in culturally distinct settings. Traditional IPT was modified slightly to address trauma-related mental disorders of the local population. IPT focuses on one of four areas, depending on the etiology of the patient's distress – interpersonal disputes, role transitions, grief/loss or interpersonal sensitivity/deficit. IPT protocol using a ten-point scale was used to assess the overall quality of the session (three items) and quality of key components for each of four phases (2–5 items), and two reverse coded items for off-protocol treatments, such as CBT [16,18].

4. Discussion

4.1. Summary of evidence

This systematic review explored the efficacy of interventions for the prevention and treatment of PTSD on natural disaster survivors. There are some important findings regarding the efficacy, or lack thereof, for several types of interventions, which will now be discussed in detail.

The results regarding the effect of CBT-PD show a significant reduction of PTSD in the group with severe symptoms and who received the original. The theory that supports CBT-PD can explain the effectiveness of the treatment and the role of clients (patients) and therapists. From the theoretical point of view, CBT-PD is based on the cognitive-behavioral model. In this model, the emphasis is on the creation of associations between symptoms with new ideas and rational thought to replace irrational beliefs about the traumatic event. These new associations require that the client gradually include new information to challenge these thoughts. Based on these principles, the therapy sessions are organized to give general information regarding the expected reactions after trauma until the cognitive restructuring necessary for processing the trauma. This whole process was accompanied by a change in symptoms, unpleasant feelings, behavior, and unpleasant reactions that were facilitated by breathing retraining and behavioral activation. In this way, the cognitive-behavioral psychotherapeutic model has proved to be very effective for the treatment of phobias, anxiety, quality of life, and depression; this, regardless whether the therapy is administered face to face or online.

The effect of survivors in the NET group suffered from severe symptoms of PTSD and depression and often experienced multiple traumatic experiences besides the natural disaster, including events related to the civil war. NET is a standardized form of TF psychotherapy, embedding trauma exposure in an autobiographical context. The section on NET depending on the number of traumatic events and treatment focuses on imaginary trauma exposure and on reorganizing memories. Memories of traumatic events are hypothesized to form multiple fear networks dominated by sensory–perceptual information and lacking autobiographical information. By connecting these anxiety-provoking implicit memories with episodic context, the autobiographic memory is rebuilt, allowing for reduction of anxiety. In NET, the therapist and the patient create a timeline of the patient's life, followed by chronologically elaborating this timeline in subsequent sessions [3]. At the end of therapy, the patient receives the written narrative as a documented testimony. Given its focus on the lifespan, NET is particularly suited to populations affected by multiple traumatic experiences. The PTSD and depression symptoms of participants less affected by trauma-related mental health disorders in the aftermath of the natural disaster also improved significantly over time. This result indicates that less severely affected individuals might not require a trauma-specific intervention but might benefit from spontaneous remission when they slowly regain the previous standard of living.

However, treatment survivor with PTSD of natural disaster with yoga can only be considered as an adjunct to other established treatments such as exposure therapy. If yoga is thought to be considered as a stand-alone intervention for PTSD, it should be empirically tested to an equal degree as established therapies. In line with this, the active components of yoga interventions remain unclear; dismantling studies would be needed to assess the individual effects of yoga postures, breathing exercises and meditation/relaxation. Regarding intervention types, the effects seem to be only applicable to yoga interventions which include physical postures but not to mainly breathing-based yoga intervention without physical postures. This studies demonstrate a small to medium-size effect of yoga and meditation on PTSD symptoms. In line with this, the active components of yoga interventions remain unclear, and are still needed to assess the individual effects of yoga postures,

breathing exercises and meditation/relaxation. So, there was low-quality evidence that yoga interventions including physical postures could be an effective, acceptable and safe intervention for PTSD.

This studies also evaluated the effects of EMDR provided to a large sample of individuals exposed to the earthquake. EMDR treatment was administered in the acute phase while tremors were still occurring, with severe aftershocks that went on for many months, preventing people from feeling safe at home or indoor. The results of our study mentioned that a group intervention with the EMDR G-TEP protocol can be used effectively with adults as an intervention during a period of significant on-going disruption and trauma, for screening and reducing symptoms of post-traumatic stress, self-reported distress and possibly for the reduction of depression. EMDR G-TEP is an efficient group model, in terms of time, cost and resources, even in a situation of the ongoing crisis, violence and war conditions with the effects maintained. A review of the literature showed that there are very few controlled studies on early interventions after large scale disasters.

Last, the psychological treatment IPT delivered by local personnel was not effective enough for reducing chronic PTSD and depression symptoms, as well as a full diagnosis of PTSD among earthquake survivors. IPT increased the overall quality of life, social support, and self-efficacy while reducing anger and receipt of violent victimization. Treatment gains were maintained three months following completion of the intervention with further spontaneous improvement, although additional follow up is necessary to assess maintenance of treatment gains. IPT had a long time and no significant effect against PTSD.

Overall, there is fair evidence for the role of psychological therapies in decreasing the number of adults who have PTSD. In addition, there is some evidence that psychological therapies can decrease the symptoms of anxiety and depression in an adult who diagnosed with PTSD. When each of the psychological therapies was compared to a control, the only therapy for which there was evidence of effectiveness was TF-CBT and EMDR. There was a greater improvement and decreased PTSD and depression effect in the CBT group compared to control for up to a year following treatment. In addition, CBT was shown to be superior to supportive therapy. Among the various alternatives, trauma-focused psychotherapeutic approaches such as trauma-focused cognitive behavioral therapy (TF-CBT), eye movement desensitization are the most widely used, with recent promising evidence also for mindfulness-based therapies. Despite differences in session-to-session patient management and behavioral techniques, TF-CBT, EMDR all focus on re-elaborating traumatic events or memories, favoring the emergence of new positive attitudes at the behavioral and cognitive level, leading to fear extinction and habituation. In particular, TF-CBT and EMDR further stress the cognitive component of the therapeutic process, strengthening top-down cognitive control. Specifically, TF-CBT helps patients to question and modify dysfunctional trauma-associated cognitions. Confrontation with trauma reminders helps patients to overcome their avoidance of trauma-related situations and thoughts, which leads to habituation and normalization of trauma memories. Besides habituation and conditioning, increased modulation of attentional processing and cognitive control are also associated with successful TF-CBT. Differently, during EMDR, patients mentally focus on a trauma-associated disturbing image, memory, emotion, or cognition. As a specific feature of EMDR, the exposure is usually short and intermixed with saccadic eye movements initiated by the therapist.

4.2. Limitations and future directions

Many studies had insufficient follow-up periods, with several studies only assessing outcomes

at one to four months post-treatment, which limits our capacity to determine the long-term impacts of psychological therapy. Finally, this review focused only on the effectiveness of psychological therapy on the adult survivor of natural disaster. Further studies that use population sampling methods are required to enable the comparison of outcomes with those of the broader population (sex, age and type of specific trauma).

5. Conclusions

This review cannot provide a definitive conclusion regarding the best form of psychological therapies. However, TF-CBT and EMDR were found to effectively increase PTSD adult survivor of natural disaster. TF-CBT and EMDR focus on re-elaborating traumatic events or memories, favoring the emergence of new positive attitudes at the behavioral and cognitive level, leading to fear of extinction and habituation. In particular, TF-CBT and EMDR further stress the cognitive component of the therapeutic process, strengthening top-down cognitive control. Specifically, TF-CBT helps patients to question and modify dysfunctional trauma-associated cognitions. More detailed and rigorous research is needed to strengthen the level of evidence supporting the benefits of psychological therapies against PTSD.

ABSTRACT

Schizophrenia has chronic symptoms and recurrence often occurs and causes cognitive decline. Antipsychotic medication is at the core of the treatment of schizophrenia, but needs to be supported from the family as care giver in treating patients. Some factors that can cause recurrence of clients include, knowledge, education, information, socio-economic, and family roles. This condition is aggravated by family attitudes that tend to isolate and exclude clients and even shut up. The understanding of some families who are still lacking about ODGJ care results in negative attitudes towards patients. Strategies to increase family knowledge by using video education are because it uses audiovisuals where the eyes are the main factor in channeling knowledge, besides that videos are more easily understood by recipients than cerama. This study aims to identify the effect of education using videos on caregiver's ability to meet ADL client needs, control client medication adherence, prevent recurrence and help client social interaction. Scopus, PubMed, and Science Direct databases from 2014-2018 search for relevant keywords. All studies included based access, randomized controlled trials, case control studies and Random. 17 of 1521 papers were included. The family education program using videos is effective in increasing caregiver's knowledge of treating schizophrenic patients.

Keyword: education, video, family centered nursing, ability, skizofrenia patients

1. Introduction

Mental disorders not only cause suffering for the individual sufferer but also for the person closest to them. Usually the family is most affected by the presence of mental disorders in their families. In addition to high care costs, patients also need more attention and support from the community, especially families, so that families lose productivity because they take care of patients, while treatment of mental disorders requires a relatively long time, if patients do not continue treatment, they will recur (Arif, 2006).

Some factors that can affect patient recurrence include knowledge, education, information, socio-economics, and family roles. Another factor that causes clients to experience

recurrence is because families don't know how to handle clients at home. According to Sullinger (1988) (Fitryasari, Yusuf, Dian, & Endang, 2018) and Carson / Ross (1987), clients diagnosed with schizophrenia are estimated to have a relapse of 50% in the first year, 70% in the second year and 100% in the fifth year after returning from hospital due to wrong treatment while at home or in society.

Based on research in the United Kingdom (Vaugh, 1976) and in the US Synder, 1981 (in Fitryasari et al., 2018) showed that families with high emotional expression with clients were estimated that clients would relapse within 9 months, the result was that 57% returned to care from families with high emotional expression and 17% returned to being treated from a family with a low emotional expression of the family. According to Hawari (in Wiyati, et al 2010), one of the obstacles in efforts to cure mental patients is knowledge of the community and family. Family and society consider mental disorders to be a shameful disease which bring shame to the family. This condition is aggravated by family attitudes that tend to isolate and exclude even patients. The understanding of some families are still lacking in ODGJ care results in a negative attitude towards patients. The negative attitude of the family towards the patient can be seen from the assumption that the disease experienced by the patient is a permanent disease and cannot be cured so that the family tends to let the original patient not interfere. Nearly all families appreciate that the patient is only a burden to the family because of their inability to care for oneself (Purwanti, 2017)

The high rate of recurrence can indicate that the family has not been able to care for family members who have schizophrenia. Sulistiowati (2012) in her research in the village of Pariangan Ponorogo said that 83.4% of families did not have the ability to care for schizophrenic patients properly, Suryaningrum (2013) also explained that 49.5% of families in hospitals had not been able to treat schizophrenic patients. The implementation of family duties in caring for family members who suffer from schizophrenia has not yet appeared, especially in making the right decisions when patients show symptoms of relapse and inability to modify a comfortable and conducive environment for schizophrenic patients. Stigma attached to patients and families, 37.5% of families still have negative perceptions of schizophrenia. Families feel embarrassed by the existence of schizophrenic patients so that families often isolate patients even to the point of being attached (El-mallakh, Yates, & Adkins, 2013). Educational programs for schizophrenic patients have been done well when patients undergo treatment at home. It hurts but does not have an impact if there is no support or role from the family. Education in the family is difficult because families rarely visit patients when hospitalized, and when the time control is very short, education is carried out in the soul poly. One effort to improve acceptance is coping strategies, through education or health education (Oshodi, Adeyemi, Alna & Umeh, 2012). Providing education is based on family social culture. One option to maximize family education by training family skills in caring for schizophrenic patients by using videos allows families to receive video education with the aim of increasing family knowledge and skills in caring for patients at home.

Contact with patients and families in mental nursing is very important, because the intervention and implementation of nursing care focuses directly on patients and families.

Online-based education is proven to be effective in managing symptoms and decreases recurrence rates and can improve family quality of life (Seo & Kim, 2010)

The implementation of education by using video is easier for the recipient to understand, because it uses audiovisuals, where the eyes are the main factor in channeling knowledge (75% to 87%) (Heri DJ, 2009, Kumboyono, 2011). Education using images or videos is easier for the recipient to understand than the lecture method. Education using technology has an important role in providing health education, so patients and families can report on the health of patients. The existence of video education applications can increase the independence, knowledge and coping of families in treating schizophrenic patients. This family strategy and coping process functions as a vital mechanism, through which processes and mechanisms family functions become apparent (Stuart, 2009).

2. Methods

Literature searches were conducted in major databases such as Scopus, PubMed, and Science Direct databases from 2014-2018 with relevant keywords by including the keywords education, family care, schizophrenia. Type and year of study, research design, sample size sample characteristics, interventions and results are presented.

The inclusion criteria that the authors set are: 1) Quantitative study design both observation and experimentation; 2) maximum time span of 7 years ago; 3) Male and female subjects (age 17 - 50 years) families who care for schizophrenic patients ≥ 1 year; 4) families living with patients 5) Interventions given are in the form of education about family duties; 6) the outcome parameter of the study is the ability of the family to care for schizophrenic patients while the exclusion criteria were: families with visual and hearing impairments, families that cannot be found before the study is complete

3. Results

Total of 126 journals were found from search databases namely Scopus (547) PubMed (526), and Science Direct (448) totaling 1521 journals. This systematic review reviewed 25 selected journals, all of which were from international journals. The designs used included: 8 journals using RCTs, 5 journals using Cross-sectional, 3 journals using quasi experiments, 1 journal using qualitative methods.

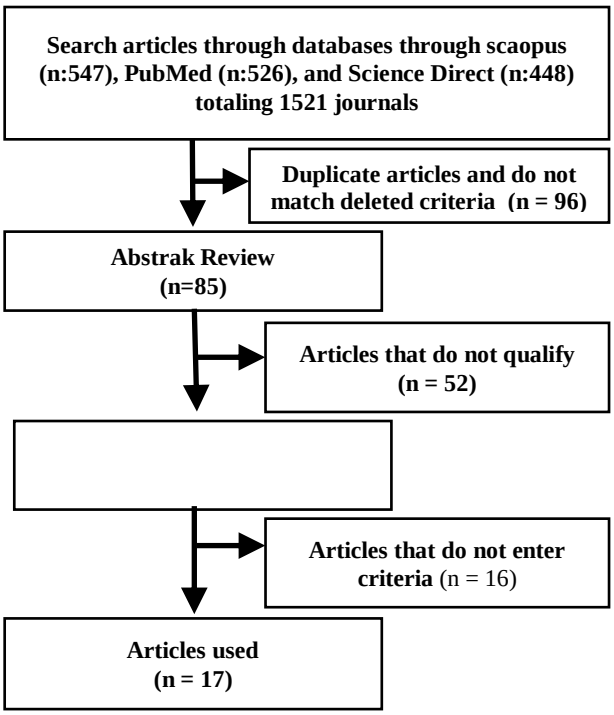

Figure 1. Flow of article selection used

3.1.Characteristics Of Participants

The journal used in the review was 17, the number of samples varied between 15-846 respondents. The respondents were taken in the psychiatric clinic, families of pediatric and adult patients suffering from schizophrenia, as a whole the control group used education that was in accordance with the standards in the hospital while the intervention group in addition to hospital education was also educated in the patient's family home using video which contains about how to treat schizophrenic patients who are assigned four times for one month. The duration of follow-up varied between 4 weeks to 5 years. This study used a Randomized Controlled Trial design, experimental Quasi, Cross-sectional, Qualitative. The total number of respondent was 4455. This research was conducted in various countries in Indonesia, Cairo, Iran, Japan, China and Hong Kong.

Table 1. Authenticity of the study of the influence of educational interventions with the Family Centered Nursing approach to the ability of families to care for schizophrenic patient

No	Title	Design	Sample	Variable	Instrument	Analysis	Results
1	Family members' perspective of family Resilience's risk factors in taking care of schizophrenia patients (Fitryasari, Yusuf, Dian, & Endang, 2018)	Qualitative design with an interpretive phenomenology approach	15 families	Variable independent : family Resilience's risk factors Variable dependent: burdens, stigma	Kuesioner	Collaizi technique	The burden of care felt by the family is confusion about illness, emotional burden, physical, time, financial and social, which causes a decrease in the quality of family life. Families also experience stigma
2	Evaluating the effectiveness of a culturally adapted behavioral family psycho-educational program for Egyptian patients with schizophrenia Article	RCT	30 patients with schizophrenia	Variable independent : psycho-education Variable dependent: cultural	Kuesioner	Chi-square test	Education in the control group showed a significant treatment effect because they experienced a reduction in psychotic symptoms, increased social function, and improved quality of life
3	Schizophrenia through the carers' eyes: results of a European cross-sectional survey A.(President et al., 2015)	A questionnaire-based cross-sectional	138 families		kuesioner	descriptive comparison	The guards recognized the importance of drugs to help patients get better (76%) and improve their quality of life (76%) and relationships (74%)
4	Effect of psycho-educational intervention for family members on caregiver burdens and psychiatric symptoms in patients with schizophrenia in Shiraz, Iran (Sharif, Shaygan, & Mani, 2012)	RCT	70 patient families schizophrenia	Variable independent : psycho-educational intervention variable dependent : caregiver burdens, psychiatric symptoms	kuesioner Family Burden	chi-squared test	psychoeducation significantly reduces symptom severity and caregiver burden both immediately after the intervention and one month later

5	Outpatient Follow-Up Care and Risk of Hospital Readmission in Schizophrenia and Bipolar Disorder (Shimada, Ohori, Inagaki, & Shimooka, 2018)	Retrospective **EPD-925**	Schizophrenia: 25401 people	Variable independent: Outpatient Follow-Up Care, Risk of Hospital Variable dependent: Schizophrenia, Bipolar Disorder	Schizophrenia, Bipolar Disorder using a diagnostic code, Outpatient Follow-Up Care and Risk: list of visits	cohort	significantly lower experience of hospitalization over a 90 day period (adjusted odds ratio [AOR] =. 88)
6	A multicenter, randomized controlled trial of individualized occupational therapy for patients with schizophrenia in Japan (Shimada et al., 2018)	randomized controlled trial	intervention of 66 schizophrenics Control: 63 schizophrenics	Variable independent: occupational therapy Variable dependent : schizophrenia	IOT program	linear mixed	Occupational therapy in schizophrenic patients significantly improves memory
7	Association of hospital stay and implementation of discharge planning in acute psychiatric inpatients in Japan Miharu (Nakanishi et al., 2015)	retrospective cross-sectional study	244 families of schizophrenic patients	Variable independent: hospital stay, implementation Variable dependent: discharge planning	questionnaires	Multilevel linear regression	The implementation of support for community care coordination did not show a significant relationship with these factors, which has been associated with an increased risk of re-accepting psychiatrists
8	Effectiveness of Needs-oriented Hospital Discharge Planning for Caregivers of Patients With Schizophrenia Li-En (Lin et al., 2017)	A quasi-experimental, non-parallel, two-group pretest and posttest	144 caregiver schizophrenia	Variable independent: oriented Hospital Discharge Planning Variable dependent:	Structured questionnaires	ANCOVA between the groups	Significant differences were found between the experimental group and the control group regarding the burden and health status of the caregiver (P <0.001). The caregivers of the burden and health status of the experimental group increased significantly compared to the control group. The repatriation planning process

		EPD-925		Caregivers Schizophrenia			involving caregivers developed in this study effectively reduces the burden placed on caregivers and improves their health status.
9	Suicide attempts in a national population of twins concordant for psychoses Stephen (Levine, Goldberg, Yoffe, Pugachova, & Reichenberg, 2014)	Experiment	116 psychotic twin pairs	Variable independent: Suicide Variable dependent : psychoses	Structured questionnaires	cohort	Age at the beginning of enrollment between 21 and 27 years is significant (po. 0.05) associated with an increased risk of suicide attempts at admission, and environmental factors 60% of causes of suicide
10	Length of stay of psychiatric admissions in a general hospital in Ethiopia: a retrospective study (Addisu, Wondafrash, Chemali, Dejene, & Tesfaye, 2015)	A retrospective study	846 schizophrenic patients	Variable independent: Length stay Variable dependent : general hospital	Long hospital stays (LOS)	Bivariate and multivariable logistic regression	The return of schizophrenic patients showed a 90.3% increase in results
11	A retrospective case comparison study of the relationship between an Integrated Care Pathway for people diagnosed with schizophrenia in acute mental health care and service users' length of stay, readmission rates and follow up within 7 days of discharge (J. Attfield PhD, 2017)	retrospective	400 caregiver schizophrenia	Variable independent : case comparison study, Integrated Care Pathway Variable dependent : schizophrenia in acute, service users' length of stay,	LOS	A cohort study	Statistical is not significant differences were observed at the rate of return or follow-up within 7 days after discharge
12	Telephone Intervention–Problem Solving (TIPS) for Schizophrenia	randomized controlled trial	185 caregiver for schizophrenic	Variable independent: Telephone	telephone	correlations, and Chi squares	Significantly related to problem reporting during TIPS (yes / no) (chi square = 8.55 df 2, p = 0.014).

	Spectrum Disorders: Responses of Stable OutpatientsOver NineMonths (L. Beebe et al., 2018)	**EPD-925**	patients	Intervention, Problem Solving Variable dependent: Schizophrenia Spectrum Disorders			
13	Telenursing Intervention Increases Psychiatric Medication Adherence in Schizophrenia Outpatients Lora (L. H. Beebe et al., 2008)	Quasy experiment	Control 69 schizophrenic caregiver Intervention of 74 schizophrenia caregivers	Variable independent: Telenursing Intervention, Variable dependent: Medication Adherence	Electronic monitoring system	ANOVA	People who receive TIPS have significantly higher medication adherence to psychiatric drugs during the study period, F (1, 20) = 5.47, p = 0.0298.
14	Mobile therapeutic attention for treatment-resistant schizophrenia (m-RESIST): a prospective multicenter feasibility study protocol in patients and their caregivers Anna (Alonso-solís et al., 2018)	RCT	45 schizophrenic patients	Variable independent: Mobile therapeutic, Variable dependent: treatment-resistant schizophrenia	mobile application	Qualitative and quantitative feedback	The results showed that 74% -86% of patients used web-based interventions efficiently, 75% -92% considered them as positive and useful, and 70% -86% of patients completed or were involved with intervention during follow-up
15	Using telehealth to augment an intensive case monitoring program in veterans with schizophrenia and suicidal ideation: A pilot trial John (Kasckow et al., 2016)	RCT	1628 schizophrenic patients hospitalized	Variable independent: telehealth Variable dependent : intensive case monitoring program	Mobile application	Qualitative and quantitative	Twenty of the 25 telehealth participants can set up the device. Monthly compliance for telehealth participants> 80%. A quantitative analysis of the endpoint survey showed that most participants had positive responses
16	Reduction of medical	RCT	51 patients at	Variable	telehealth	Mann-	Comparisons revealed that participants in

	hospitalizations in veterans with schizophrenia using home telehealth (Flaherty, Daniels, Luther, Haas, & Kasckow, 2017)	**EPD-925**	risk of suicide	independent : Reduction of medical Variable dependent: home telehealth		Whitney tests	the telehealth group had significantly fewer medical hospitalizations than the control group
17	A pilot comparative study of one-way versus two-way text message program to promote physical activity among people with severe mental illness (Chen, Chang, Kuo, & Yu, 2017)	RCT	15 participants	Variable independent : A pilot comparative study of one-way versus two-way text message Variable dependent : promote physical activity among people with severe mental illness	Mobile text message reminders	A pilot single-blinded comparative study	The two-way text message group showed a significant increase in the number of daily steps compared to baseline at weeks 6 and 11 (increasing by 21% and 32%, $p < 0.05$), respectively. No significant differences were found between groups or in one-way text message groups

4. Discussion

One strategy is to improve family knowledge and the ability to treat schizophrenic patients by providing routine education, so that family functions are real (Riley-McHugh, Brown, & Lindo, 2016). Educational programs for family members include information on the etiology of schizophrenia, current treatment modalities, interventions for behavioral problems, training in problem solving skills, effective communication, crisis management, and addressing life problems with family members suffering from schizophrenia. (Yusuf, PK, & Nihayati, 2015).

The results of the study (Pratt et al., 2015) on telehealth in depressed patients showed improvement in psychiatric symptoms, 82% decreased hospital visits (from 76 to 14 hospitalizations) and a 75% reduction in emergency room visits (from 63 to 16 visits). Improvements were observed in quality of life, severity of depressive symptoms and mental health status. Other studies say that patients and families who get treatment through telenursing experience an increase in knowledge and feel more comfortable with some contacts and advice on care through an application by nurses. This is felt because it is younger to access whatever the patient and family want to know immediately and generally are very liked (Ben-zeev et al., 2013).

The ability of families to care for schizophrenic patients is based on the role and function of the family in maintaining family health. Families play a role in fulfilling Activity Daily Living (ADL) and psychosocial fulfillment of schizophrenic patients (Pakenham & Kennet, 2012). ADL needs include meeting basic needs such as: eating, dressing, bathing and elimination (BAK / BAB). While the need for Daily Living Instrumental Activity (ADL) covers life support needs such as managing finances, work and treatment. Psychosocial fulfillment during treatment is also part of family duties by providing emotional support in an effort to prevent recurrence.

Research on educational interventions in families of schizophrenic patients has been shown to extend the relapse period of patients, improve medication adherence and improve the quality of patients and families (Ran, Chan, Ng, Guo, & Xiang, 2015) (Seo & Kim, 2010). Other studies of education can reduce psychotic symptoms (Randomized, 2015) (Rami et al., 2018) (L. H. Beebe et al., 2008) (President et al., 2015)

Educational interventions can reduce treatment days, reduce recurrence rates in psychosis (Kasckow et al., 2016) and increase family detention so families show positive responses to patients (Chen et al., 2017) (Alonso-solís et al., 2018) (Marcus et al., 2014). Education involves families in solving problems and helping families to modify the environment that supports patient health. Involving patients in daily activities is a therapy that can improve the memory of schizophrenic patients (Shimada et al., 2018) (Rotondi et al., 2005). Other studies on education can overcome family distress and provide education to improve family skills (Ghiggia et al., 2017). Through the application of education can involve the family in the care of patients both in the hospital or at home when outpatients, so that the family as an effective

source of support for patients.

5. Implications

Education using videos is an effective action in increasing family knowledge and skills in treating schizophrenic patients. Thus this research is expected to be used as a reference in educating families of schizophrenic patients in the community. This systematic review can be the basis of future researchers so that it can provide an advantage in reducing the recurrence of schizophrenic patients in the future.

6. Conclusion

Overall the results of the analysis of 17 journals on education in families of schizophrenic patients significantly reduced the rate of recurrence, leaving families in the care of schizophrenic patients compared to families who were not educated. Psychotic therapy combined with education

7. Recommendation

There needs to be ongoing research on the implementation of family education with other methods in the family and community environment to reduce the impact of stigma on psychiatric patients so as to reduce recurrence rates and improve the quality of life for patients and families. In addition, it can become a standard in the preparation of Standard Operating Procedures (SOP) in mental nursing services

ABSTRACT

Mental health includ social and emotional well-being the foundation of children and adolescent health development. Mental health difficult are increas drastic among the children and adolescents living in orphanages. Institutionaliz child and adolescent are at risk of experiencing greater psychological problem in their lives, such as the problem of coping mechanisms, adjustment, aggression, personality problem, self-esteem, self-confidence, anxiety, depression and stress. The purpose of this study is to find out risk factors of depression, anxiety, stress, self-esteem, and self-confidence adolescent live in orphanages. Methods of the study were systematic review of adolescent living in orphanage with study selection criteria using Scopus, Science Direct, and Pubmed database among 2014-2018, with PICOS approach. Of the 15 journals carried out and reviewed depression, anxiety, stress, self- esteem, and self-confidence are mental health risk factor for adolescents in orphanage. Actions to reduce risk factor for mental health and behavior problems among children and adolescent who live in orphanages by mental health promotion and early detection of developmental growth as appropriate preventive measures in the development phase.

Keywords: adolescent, mental health, risk factors,orphanage

1. Introduction

The development of children and adolescents was an important foundation for mental health and included social and emotional well-being. Teenagers with a feeling of mental health will have problem solving skills, social abilities and have goals or ideals [1]. These assets help them get back up from any setbacks for adolescent development that might occur in the face of a bad situation, so that teens can lead productive lives [2].

Loss of parents during childhood and living in orphanages can be stressful and have a negative impact on the psychological well-being of children and adolescents [3]. This loss leads to situations where children lack basic needs, lack of physical support, social and emotional support, decreased educational attainment, substance abuse, and the possibility of leading to sexual risk behavior [3]. In addition, adolescents who live in orphanages face various problems caused by a lack of parental roles that make them experience higher daily stress levels compared to those who live with parents [4][5]

Adolescents in institutional care centers have a higher level of mental disorder, compared to adolescents who live with their families [6]. Institutionalized children and adolescents run the risk of experiencing greater psychological problems in their lives, such as coping, adjustment, aggression,

personality problems, self-esteem, self-confidence, anxiety, depression and stress [5][7][8]. Adolescents who live in orphanages are at high risk of mental illness 48% depression, 25% PTSD, 27% suicide rate [9]. The high rate of mental illness and suicide shows the importance of addressing mental health problems within institutions [10]. It is recommended to develop institutional programs that foster peer relations [6][11].

Given some mental health and behavioral problems among adolescents who live in orphanages, early detection of mental health is important and can minimize mental health problems in adulthood [12]. Depression, anxiety, stress, self-esteem, how to relate to peers, identifying successes in the development cycle, and helping adolescents express emotions or behavioral problems in order to achieve more optimal levels of mental health [3]. Prevention and intervention programs have been developed to help institutionalized children and adolescents [13][14]. Orphanages are the therapeutic environment, shelter for displaced adolescents where they get guidance in the field of education, character building and adjustment in society. Mental health promotion and early detection of developmental growth is one of the mental health promotion efforts to help increase self-confidence [15].

2. Method

2.1 Research settings

The journal search strategy begins with asking research questions, namely "are depression, anxiety, stress, self-esteem, and self-confidence a risk factor for adolescents living in orphanages?". Searching the results of research in all published journals with the type of research Quasi experiment, Cross-sectional, Quantitative related to the mental health of adolescents who live in orphanages. The databases used for journal searches are the Scopus, PubMed, and Science Direct databases. The keywords used are adolescent, orphanages, mental health. Journals are limited to 2014-2018 publication years, with journals in nursing, medicine, and psychology, social and English-language journals.

2.2 Criteria and study options

Research inclusion criteria were 1) child and adolescent respondents living in orphanages, 2) 7-17 years old, 3) Loss of one or both parents due to death or abandonment, 4) Willing to participate as respondents.

3. Results

3.1 Results and Study Selection

The results were from the Scopus, PubMed, and ScienceDirect databases. The search results obtained as many as 339 journals. Scopus database obtained by 60 journals. PubMed database obtained by 7 journals and databases Science Direct gained as much as 272 journals. All journals that have been obtained are then screened according to the area of Medicine, Nursing, and Psychology until there are 301 journals. Then do the filtering in accordance with the mental health, youth and orphanages research found 158 journals accordingly. Then filtering regained much as 15 journals according

criteria inclusion and exclusion. All journals are Quasi-experimental, Cross-sectional, Quantitative focusing on depression, anxiety, stress, self-esteem, and adolescent self-esteem living in orphanages.

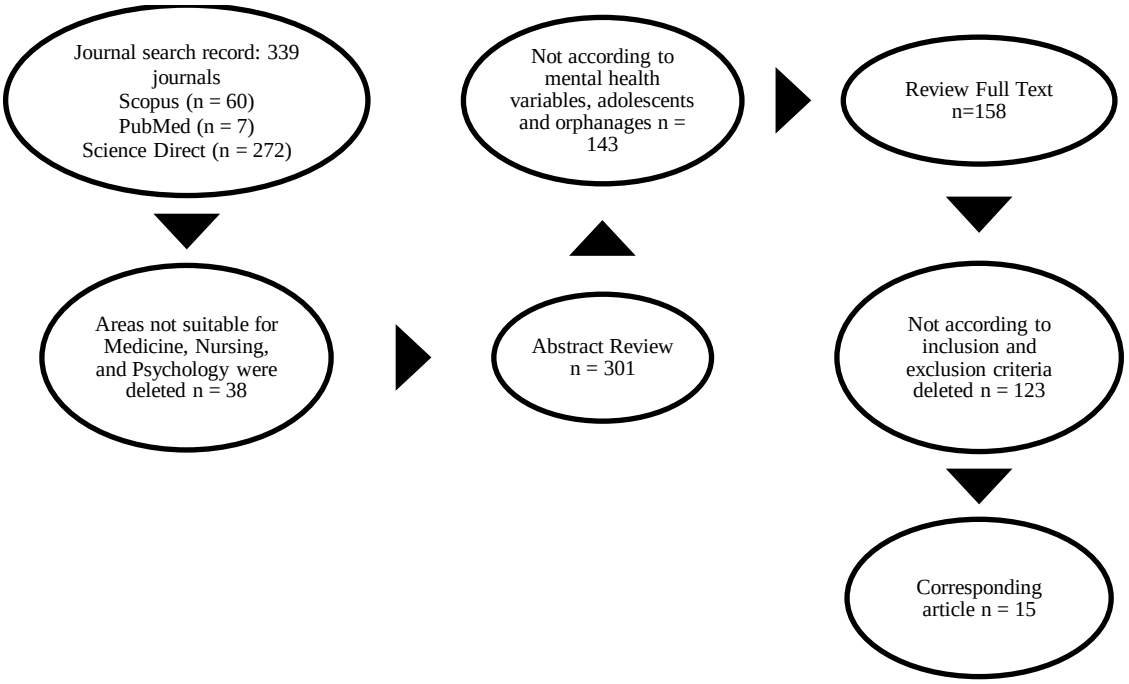

Figure 1. Search flow

3.2 Study Characteristics

The characteristics of the study are explained in picture 1. All journals obtained from the results of the study deal with the mental health problems of adolescents who live in care with depression, self-esteem, anxiety, stress, and self-confidence. Research from Malaysia as much as 3 journals, southern Africa as one of the journal, as one journal eastern Africa, Indonesia as one of the journals, USA as 6 journals, Japan by one journal, Germany by 2 journals. All studies have a minimum age rating of 7 years to 18 years. All studies of 15 study is a client who lives in an orphanage.

3.3 Limitations study

The keywords used are adolescent, orphanages, mental health. Journals are limited to 2014-2018 publication years, with journals in nursing, medicine, and psychology, social and English-language journals.

4. Discussion

Orphanages have an adverse effect on the personality development of orphans because the substitute family environment fails to replace the functions of the nuclear family [15]. Experiences of adolescents who lived in an orphanage as a child would have a negative impact on the long-term cognitive, emotional and social wellbeing[15]. Inability to accept things that are different from themselves making them vulnerable to psychological and behavioral problems. Self-acceptance is a psychological mechanism that allows individuals to survive and entertain themselves by recognizing and accepting their positive and negative traits in negative situations. Orphanages generally only

provide educational facilities and collective physical needs. While the emotional needs associated with psychological needs of foster children less considered [16].

This lack of function has an impact on passive, apathetic, withdrawal, easy despair, fear and anxious personality that makes it difficult for individuals to establish social relationships with others [7]. They also show negative behavior, fear of contacting others, feelings of hostility and selfishness, and preferences for being alone. Research conducted by [3] states that children who live in orphanages suffer from disturbances in emotional intelligence and their regulation. Mohammadzadeh et al., (2018)[4] states that there are many negative incidents in orphanages, unhealthy care will cause trauma that affects the formation of individual pathological personalities. Rules that are applied in orphanages should not obstruct the child's developmental tasks but vice versa, they need to adapt to conditions. Rules are used to harmonize life in an orphanage so that it can be harmonious. However, when the effect of the rules given has a detrimental effect, for example, it inhibits activities related to developing children's talents or social relations with the environment, it can cause damage to child development [15].

Experience while living in an orphanage with caregivers and more friends provide psychological experience, to determine an alternative choice to make certain decisions that guarantee the future. Parenting will affect independence, the formation of adolescent behavior and emotions [17]. Emotional support and social approval has a significant influence on self-esteem [18]. All of this is inseparable from the role that foster children receive from orphanage administrators as a substitute for their parents' role, which acts as a motivator to encourage children to continue learning. These studies link the poor psychological well-being of children placed in orphanages with a lack of social support, inadequate basic needs in orphanages, and the absence of problem solving skills and social skills in orphanage children. All of these factors is known as a risk factor for poor mental health in children. The research findings highlighted above indicate that placement in orphanages can have a negative impact on the psychological well-being of the orphan in question [3]. Positive findings associated with management factors are favorable in some orphanages which are run privately as well as the availability of basic needs and social support. Positive findings also indicate that the placement of the orphanage can improve psychological well-being of orphans [3]. Emotional support and social approval has a significant influence for self-esteem [18](Santrock, 2003). All of this is inseparable from the role that foster children receive from orphanage administrators as a substitute for their parents' role, which acts as a motivator to encourage children to continue learning.

Depression in orphans may be caused by the adverse effects associated with loss of parents (such as sadness, loss of care, separation from family members and social change) and poor conditions in orphanages, which include poor stimulation environments, poor care delivery, strict routines, often no care givers, stigma and administrative restrictions [3]. Anxiety is known to negatively predict the overall quality of life because it causes people to feel worse about themselves and thus aggravates their overall quality of life. Orphaned children show symptoms of anxiety are much higher, given that the loss of a parent is regarded as the most significant stressors that predict anxiety in children [3].

Given the increasing burden of orphan care, treatment and other support models have been developed to overcome the crisis of orphans who are growing, including institutional care (orphanages) and community-based care [19]. Community-based care refers to support programs that

are managed by non-governmental organizations, religious groups, or community-based organizations that usually allow children to remain in a family-based care environment [19]. The accuracy of institutional care for orphans has become a central question for international aid policies that affect many low- and middle-income countries [8].

Forms of nursing interventions that can be provided by providing counseling services, life skills training such as stress management and coping skills, formation and sustainability of healthy peer relationships, problem solving skills and decision making, and conflict management skills [3]. Thus, the variables of depression, anxiety, coping and overall quality of life can be overcome and reduce the risk factors for mental health of children and adolescents who live in orphanages.

Based on the research that has been done a study, it can be concluded that the results of these journals can be applied in Indonesia. Interventions can be done in terms of mental nursing department. This facilitates nurses in nursing care in a comprehensive manner. This facilitates nurses in full nursing care by providing counseling services to adolescents. The hope with the social support of nursing can reduce health risks in adolescents who live in orphanages.

The author would like to express his sincere gratitude to the leaders of the orphanage and caregivers of the orphanages for their very valuable cooperation. the authors also thank the Master of the Faculty of Nursing Supervisor Surabaya UNIVERSITY AIRLANGGA which gave right time to the perfection of my thesis.

5. Conclusion

From the results of a systematic review it was concluded that depression, anxiety, stress, self-esteem, and self-confidence were Risk Factors for Adolescent Mental Health Living in Orphanages

ABSTRACT

People with type 2 diabetes mellitus (type 2 DM) had a uniqueness to behave dietary adherence.The purpose of this study was to identify behaviour of dietary adherence to type 2 diabetes patients. A systematic review focused on qualitative research. A literature search resulted in 15 articles: 10 on the topic of dietary adherence behaviour. Searches were conducted in SAGE, PUBMED, Scopus and Google scholar using keyword "Qualitative study" AND "Type 2 Diabetes" AND "Dietary Adherence". Results were synthesised with the Enhancing Transparency in Reporting the Synthesis of Qualitative Research (ENTREQ) protocol. Result showed, overall behaviour dietary adherence practices were different. Some patients to dietary adherence behaviour influenced by knowlodge and clear information, family supports, social and cultural support and individual perception and motivation. Some factors acted as reinforces had an impact on patient adherence to nutrition care guidelines. These factors should be considered by diabetes educators, health practicioner including nutritionists, nurses and doctors, when planning dietary treatment for patients with type 2 diabetes mellitus.

Keywords: qualitative study, type 2 diabetes, dietary adherence

1. Introduction

Diet compliance sufferers with DM, up till now, have remained a health problem in the world. No compliance regarding diet means that, progressively, year by year, DM sufferers have increased. According to a report by the WHO in 2013, the average patient compliance toward diet and long-term therapy against chronic diseases such as DM in developed countries only amounted to 50% whereas in developing countries, the number was lower. It is estimated that 285 million people worldwide have diabetes mellitus, 90% of whom have type-2 diabetes mellitus[1]. The prevalence of diabetes for all ages worldwide was estimated to be 2.8% in 2000 and this is projected to be 4.4% in 2030.

The burden of this disease poses a serious public health threat. More recent studies have shown that the rate of undiagnosed diabetes in this region is also high and that these individuals are at great risk of chronic health complications[1]. DM requires intensive management to address them and long-term treatment. The management intended to control blood sugar levels in the normal range so then complications can be avoided. Lifelong treatment and diet affects the compliance of the patient [2].

The purpose of this study was to conduct a systematic review to identify the behavior of dietary adherence for type 2 diabetes patients. This study is expected to give ideas for further research to increase the control of attacks and the behavior of dietary adherence in patients with diabetes mellitus so then the quality of life of diabetes mellitus patients has increased.

2. Methods

2.1. Design

A systematic review of the qualitative studies was conducted involving the following steps:

a) Developing the review question
b) Developing the search strategy
c) Conducting a quality appraisal of selected papers that meet inclusion and exclusion criteria.
d) Extraction of themes
e) Synthesis of themes
f) Evaluation of confidence in the evidence

As described meta-syntheses are integrations that are more than the sum of parts, in that they offer novel interpretations of findings. These interpretations will not be found in any one research report but, rather, there are inferences that can be derived from taking all of the reports in the sample as a whole.

2.2. Search method

A literature search resulted in 15 articles on the topic of dietary adherence behavior. Searches were conducted in SAGE, PUBMED, Scopus and Google Scholar using the keyword “Qualitative study” AND “Type 2 Diabetes” AND “Dietary Adherence”. Reference lists of the papers identified by the online search were manually searched as well. The articles that met the inclusion/exclusion criteria that were eligible for quality appraisal also had their reference lists searched. Full-text articles were excluded for reasons such as not being in English language, not having a relevant study design and not having a relevant outcome

2.3. Assessment of relevance for inclusion

The full papers of the abstracts were described using a qualitative method and they focused on the dietary adherence behavior of type – 2 diabetes patients.

2.4. Data extraction

The initial search resulted in 120 citations. The first screening of the titles and abstracts according to the inclusion criteria resulted in a total of 38 studies. A secondary screening of the full text of each study resulted in 15 studies in the sample. A data extraction table (Table 1) was developed to summarize the information within each study. The criteria developed for the systematic review were used to measure the methodological quality of the systematic review: namely the study design, attrition, sample selection and instrument reliability. Each criterion was measured on a 4-point scale resulting in a maximum quality score of 13 and a minimum score of 0. The minimum methodological score accepted for this review was set at 3, a low number in order to be purposely inclusive.

Table 1. Characteristic study

Author	Participant	N	Aim	Method	Findings
[1]	Ethnic minority (non-Hispanic Black, Hispanic)	27	A descriptive qualitative study was used to explore hthe cognitive, behavioral, and psychosocial challenges associated with having and/or parenting an adolescent with pediatric type 2 diabetes (T2D) from the perspectives of ethnic minority parents and adolescents	Descriptive qualitative study	Six themes corresponding to 3 broad categories (cognitive, behavioral, and psychosocial challenges). cognitive challenges: 1. Learning about a new disease and dealing with misinformation/ myths 2. Managing youth knowledge deficits and/or superficial knowledge Behavioral challenges 3. Making and maintaining positive youth health behavior changes 4. Ensuring regimen adherence Psychosocial challenges 5. Managing youth emotions related to diabetes 6. Navigating social relationships with peers and other family members around the disclosure of T2D
[2]	Male participants aged 18 years and older. [12]	Diabetic patients for at least five years	13	To describe the self-care practices among individuals with type II diabetes in Addis Ababa, Ethiopia	Qualitative method	Most patients reported irregular self-monitoring of their blood sugar. Dietary and physical exercise recommendations were inadequately practiced by most of the participants. Most patients better adhered to medication prescriptions. Patients generally lack proper information/knowledge regarding the importance of self-care and how it should be implemented. Based on the reported behavior, we identified three main categories of patient; those who 'endeavor to be compliant', those who are 'confused' and those who are 'negligent'
[13]	Participants with type 2 diabetes, aged 68 to 85 years.	13	The project explored the experience of living with diabetes and the factors that facilitate or inhibit access to diabetes services	Qualitative method	The findings indicate five main themes, including (a) the value of health, (b) the impact of diabetes, (c) making changes, (d) managing diabetes, and (e) access to information and services
[14]	Participants who complied with the recommended attendance at nutritional counseling sessions and those who did not	12	To ascertain the role of the dietitian–patient relationship and the counseling approach in influencing individual patient decisions to adhere to counseling by persisting with the nutritional treatment.	Qualitative method	Four sub-themes, as follows: 1. Patients' perceptions of dietitians and the physician's role in shaping these perceptions. 2. How district dietitians understand the patients' perceptions of their profession. 3. Dietitians' perceptions of their profession. 4. Barriers to the long-term counseling process
[15]			To synthesize the recent research on depression and the adherence to dietary	Systematic review	Twenty-seven studies involving 7,266 participants were selected; participants were 54%

Author	Participant	N	Aim	Method	Findings
			and physical activity recommendations in persons with type 2 diabetes (T2DM).		female and 62 years of age, on average. When reported, depression prevalence in the study samples ranged from 4.5% to 74%. Six intervention studies targeted diabetes treatment, with or without depression treatment. No studies focused solely on treating depression. Twenty-one descriptive studies examined the relationship between depression and diet/physical activity adherence, finding there to be a negative association. Only 2 of the 6 intervention studies examined this relationship; findings were inconsistent.

3. Results

The analysis produced the following themes: knowledge and clear information, family support, social and health professional support, and individual perception and motivation.

3.1. Theme 1: knowledge and clear information

The participants described their limited dietary knowledge and their confusion regarding the mixed dietary messages pre-intervention. They reported feeling empowered and motivated by the information and strategies gained from their primary care nurses and the community education groups. Individualized, clear and achievable goals facilitated the initiation and continuation of dietary behavioral changes.

> 'It wasn't stop this, stop that. It was cut down on this, cut down, little steps...The favorite saying is "little steps". And that's probably one of the most helpful sayings I've ever heard...Not trying to do it in a week or two weeks, or two months or three months. It's over a period of time, you know?'

A particularly empowering achievement was learning to read food labels:

> 'Yeah, the label reading, that was excellent, that was really excellent.... I must admit that has changed my thoughts when I do go shopping. I think oh I'll just have a look at what the fat level is, or sugar, you know.'

Many of the participants commented that they were previously unaware of the extent of the hidden sugars, salt and fat in commonly consumed processed foods.

3.2. Theme 2: family supports

Support from their family and friends appeared to significantly support the participants' confidence and determination to improve their diet. Lack of adult support was detrimental to their resolve to make important lifestyle changes. The others felt that close adults in their daily lives were almost obstructive to their dietary efforts. Two women reported having to continue to cook unhealthy food for their family members because they did not want to change their diets, and others reported finding it difficult when their household members continued to eat unhealthy foods in their presence.

> 'You have stuff out to cook tea but you decide, no, you'll go and get takeaways because there's somebody else sitting there with takeaways.'

Although most of the participants had control over the household food purchasing and cooking, they found that the behavior of others undermined their ability to maintain healthy eating habits.

The decision to disclose T2D diagnosis to those within the adolescent's social network, including peers and other family members, varied within and across the parent- adolescent dyads. Some adolescents described being initially reluctant to disclose to their friends and the school faculty, yet their parents encouraged disclosure so then others would have knowledge of the diagnosis in case of a medical emergency. One adolescent mentioned disclosing to many of their classmates and she displayed a confident, self-assured attitude with her response: "Don't be [sorry], it's not like I'm dead, I just have diabetes," when others apologized upon finding out that she had T2D. Still, the other adolescents felt that disclosing their diagnosis could be used against them in the form of teasing or bullying.

3.3. Theme 3: social and health professional support

The importance of strong supportive relationships when attempting and maintaining healthy changes in eating behaviors was clearly evident. The participants drew on the support of others across the spectrum: health professionals, fellow participants with pre-diabetes, family and friends[1], [3]. Regular contact and a good relationship with a trusted health professional was considered to be especially helpful. Many of the participants were deeply grateful to their practice nurses and community education facilitators, and felt that the quality of these relationships was paramount.

> 'It's the way that she encouraged me, how she uplifted me. I'm so grateful...So I think having the right people at the forefront there, just to open you up, you know, and acknowledging where I am at.'

Feeling accountable to someone else motivated some to 'keep on track'. This feeling appeared to reflect the quality of the relationship and the value placed on that person's opinion:

> 'It was knowing that I was going to be checked up on [laughter]...If you're accountable to someone, you don't want to upset them, you know.'

Those who attended the community education sessions commented that they drew strength and inspiration from others with pre-diabetes. At a day-to-day level, friends and family were considered to be invaluable, particularly those in the household who understood the participant's need to make dietary changes. They encouraged them to do so.

> 'My family, they all know so they're all very helpful. You know, they'll say how are you going with your diabetes and so forth...They check to see how my diet is. My wife is very good. She'll make sure that I have the good stuff, you know.'

While it took personal commitment and effort to make the necessary dietary changes, this effort was not achieved in isolation but within the context of supportive relationships, clear information and manageable strategies[4].

3.4 Theme 4: individual perception and motivation

A few of the participants alluded to the fact that some of the members of their family may not understand what diabetes is and that this lack of understanding causes difficulty for them to follow the therapeutic diet[6,9].

4. Discussion

This review describes the systematic synthesis of the results from a variety of literature regarding the dietary compliance of type-2 DM sufferers. Knowledge is the result of human sensing. This is when someone knows the results of objects through the senses (eyes, nose, ears and so on)[1,2]. By itself, the knowledge produces a sensing that is strongly influenced the intensity of attention and perception towards the object[6]. Most of a person's knowledge is obtained through the sense of hearing (ear) and the sense of sight (eyes). Knowledge itself is influenced by several factors such as formal education, age and occupation. Level of education provides enough stock to allow someone to understand the information received, thereby providing sufficient understanding[7]. It will affect the attitude of someone in digesting the information received, including the knowledge of diet as related to DM.

Family support is the most important thing in a family due to the effects of the family support on health and welfare functions simultaneously. The role of the family in providing support will raise the coping methods of the other family members. The greater the support given to the diabetic patients, the higher the level of compliance with the diet given. Support is provided in the form of supervision and support when carrying out the recommended diet to make sure that the patient does not violate the diet given. The participants drew on the support of others across the spectrum: health professionals, fellow participants with pre-diabetes, family and friends. Regular contact and a good relationship with a trusted health professional was considered to be especially helpful. Family participation and decision making are common themes supporting the dietary management of diabetes[8]. Families that participate in meal planning and preparation facilitate understanding and healthier dietary habits for the diabetic family members, and in some cases, the entire family[9].

Finally, the patient is regarded as a decision maker and their compliance is a result of the process of decision making. In general, people who feel that they are receiving consolation, attention and the help they need from a person or group usually tend to more easily comply with medical advice than patients who get less social support.

5. Conclusion

Type 2 DM patients appear to want individualized treatment. In order to change patient eating patterns, the dietitian’s approach needs to be adapted to the patient’s individual and psychological needs, desires and narrative. This change in the profession should be communicated to the patient to encourage patient compliance. Further research may be necessary to determine whether a transformation in the field of dietetics has occurred and how the patients perceive it. Moreover, the scope of this research should be broadened to include additional countries and languages.

COMPLEMENTARY FEEDING WITH GENESIS STUNTING IN CHILDREN: A SYSTEMATIC REVIEW

Niswa Salamung[1], Joni Haryanto[2], and Florentina Sustini[3]
[1]Master Student, Faculty of Nursing, Universitas Airlangga, Surabaya
[2] Faculty of Nursing, Universitas Airlangga, Surabaya
[3] Faculty of Medical, Universitas Airlangga, Surabaya
Email: niswasalamung@gmail.com

ABSTRACT

Stunting is a problem of chronic malnutrition caused by insufficient nutrition in a long time due to feeding that is not in accordance with nutritional needs. One of the problems in feeding infants is the cessation of breastfeeding breastmilk and insufficient complementary feeding. The purpose study literature review is to identify the complementary feeding with the incidence of stunting in children. The authors conducted a relevant literature review in various data using the keywords "complementary feeding, stunting, child". Data based on SCOPUS, Science Direct, Proquest, Pubmed and Scholar. The criteria consisted of full text published in criteria were five years limit journal (2013-2018) use article using English. The Results as much as 2.090 articles found, and selected 15 article that suitable with criteria. On the process of the analysis of the articles showed that timely complementary foods, frequency of food and drinks, diversity of foods and drinks associated with the incidence of stunting. Good complementary feeding potential to improve children's nutritional status and can prevent stunting.

Keywords: complementary feeding, stunting, children

1. Introduction

Stunting is defined as a height that is more than two standard deviations below the World Health Organization's (WHO) child growth standard median [1]. Stunting is at issue in public health compilations of the prevalence of stunting in children greater than 40% [2]. Stunting is caused by poor nutrition and recurrent infectious diseases during the first 1000 days of life and will be irreversible [3]. The bad effects caused by stunted children in the short term include the disruption of brain development, intelligence, impaired physical growth, bodily metabolic disorders and a long-term decline in cognitive abilities and learning achievements. This also includes decreased immunity, a high risk for the emergence of diabetes, obesity and disability at the end of old age [4]

Stunting is caused by various factors such as parental status, socio-demography, economy, cultural and environmental practices and health [5]. Low parental education, family size and lag interval, a lack of sanitation, recurrent infections, not being given breast milk, low food intake and poor feeding practices are considered to be the main determinants of stunting [6]. Among all of the risk factors, the practice of feeding has the most direct impact on stunting. especially in appropriate interventions to modify feeding practices that have been proven to be effective [7].

Poor food intake is the cause of malnutrition [8]. Children aged 6-23 months are in a period of growth that is also a period of high risk because the fulfillment of nutrition cannot be fulfilled through

breast milk alone. However, children are not ready to consume the family food so early. The provision of complementary feeding refers to the introduction of nutritious solid foods in accordance with inclusions into the diet of other than breast milk [9]. The knowledge of parents or caregivers about the practice of providing complementary breast milk right (for example, offering a variety of nutritious solid foods, safe and developmental food preparation, the frequency of appropriate feeding and continuous breastfeeding) is an effective strategy to increase a child's intake [10].

Stunting occurs in many low and medium income countries during the period of complementary feeding (6-23 months), which is 500 days from the granting of exclusive breast milk before consuming a wide variety of food while breastfeeding. During the period of complementary feeding regarding breast milk, the children consumed little [11]. Therefore, ensuring the adequate intake of complementary foods and feeding for children aged 6-23 months is crucial to achieve the global target of reducing 40% of toddlers from being hampered, from around 171 million in 2010 to 100 million in the 2012 [12]. The study focus in this systematic review is "How can food companions affect the incidence rate of stunting in children?"

2. Methods

This systematic review was reported in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews) statement.

2.4 Data Sources and Searches

The databases searched were Scopus, Science Direct, Proquest, Pubmed and Google Scholar, which provided studies related to complementary feeding and stunting from 2013 to 2019.

2.5 Study Selection

The literature review was conducted using complementary feeding, stunting and child keywords. The selection of the articles was determined by the following inclusion criteria: full text published, articles published between 2013 and 2019, articles published in English, the age limit for the children being 0-59 months, and articles focusing on complementary feeding and stunting.

2.6 Data extraction and quality assessment

All citations retrieved from the electronic databases were imported into the Mendeley Program. Two reviewers (BU, SNK) independently analyzed the titles and abstracts of every study retrieved from the literature search to identify potential eligible studies. The full text of the remaining studies was obtain for further examination. The last review was conducted by the first reviewer (TPD).

The data of the included studies was independently extracted by the same two reviewers by including the first author's name, the year of publication, the study design, sample size, general characteristics of the participants, the research measurement tool and the main outcome of interest.

A descriptive analysis was done of the data obtained from the reviewed papers to include the information on complementray feeding and the incidence rate of stunting. Our hypothesis was that stunting was independent of complementary feeding in the 15 articles.

3. Results

3.1. Study Design

As many as 2,090 articles were found and the results came from five databases: 295 articles in Scopus, 287 articles in Science Direct, 687 articles in Proquest, 275 articles in Pubmed and 549 articles in Google Scholar. The results of the article selection were according to the inclusion criteria of the 15 articles. They were then given their serial number and we conducted article analysis to facilitate the review process. There were several inclusion criteria in this study, namely children of the age of 0-23 months, 0-59 months, 6-23 months, and 6-59 months. All studies had to use a 24-hour questionnaire and food recall. This study used a cross-sectional quasi-experimental study design, prospective cohort study and randomized controlled trial.

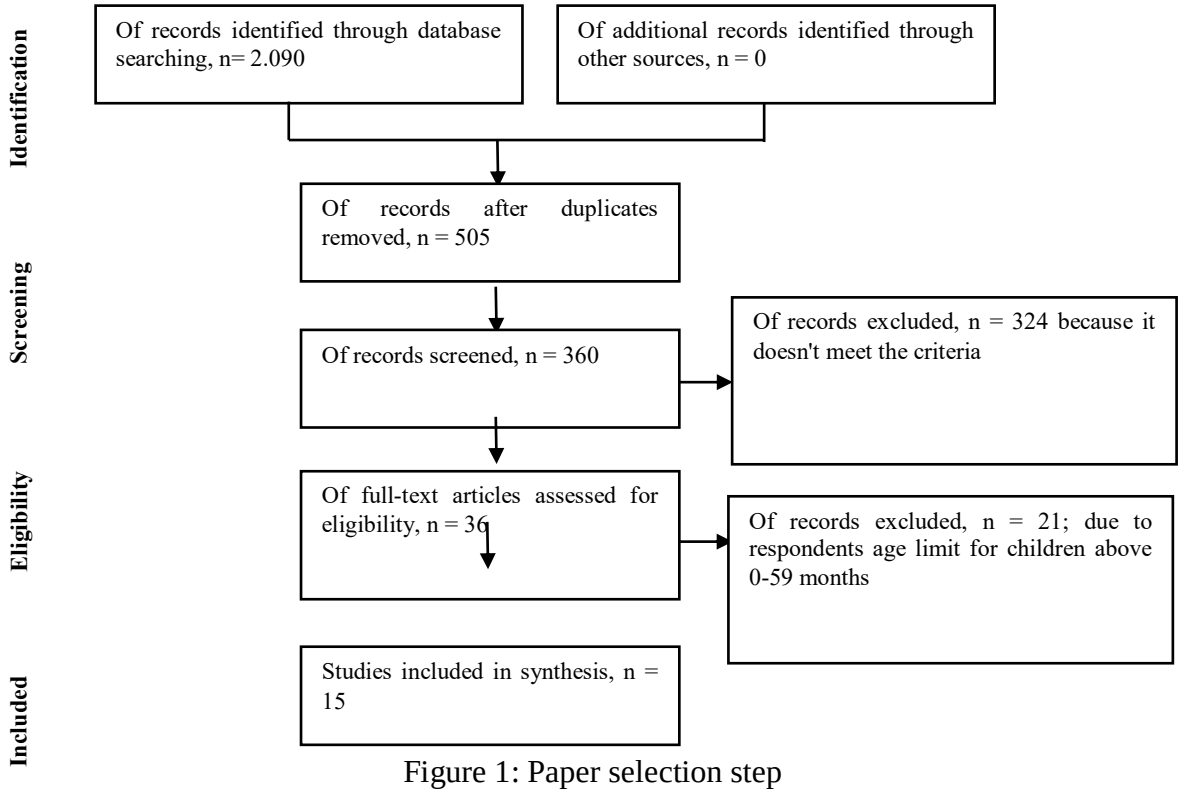

Figure 1: Paper selection step

3.2. Characteristics of Participant

In this systematic review of 15 studies, all of the population was older, with a varied sample of 120-74.548 for the age of the respondents namely the mother and the children aged 0-59 months. The research was carried out in various parts of the world including Asia, the Middle East, Europe, Australia, and the Americas.

3.3 Complementary Feeding of infants

Diet and feeding management in a timely and adequate manner escorts the children aged 6 months and above to a point where breast-feeding exclusively is not enough to meet the nutritional needs of the child. The parent's socio-economic situation also affects the diversity of the food, so 44.5% of the diversity of complementary foods do not meet the WHO recommended minimum food diversity guidelines (MDD). Alongside this, 17.8% of the overall rate of dwarfing exists in poor

countries in China's West. MDD found that stunting in childhood was inadequeately dealt with [13]. Stunting affects food diversity. Children who only consume foods rich in micronutrients are more likely to experience stunting, as the child who consumed foods rich in vitamin A and micronutrients are experiencing a reduction in the incidence rate of stunting [14]. Consuming animal food sources (ASF) such as eggs, meat and dairy 12.6% can inhibit the occurrence of child stunting [15].

In India, not reaching the minimum dietary diversity and an adequate minimum diet was found to be significantly related to the occurrence of stunting and wasting.The existence of wasting and stunting needs a more integrated intervention. That is, a program that aims to prevent (among low birth weight) Low Birth Weight and poor infant and young child feeding (IYCF) in order to prevent stunting. This program should be linked more effectively with the actions aimed at the management of the wasting [16].

.The frequency of eating the minimum associated with the nutritional status of the child [17]. Less than half (40%) of the kids 6-23 months old (n = 174) achieved a satisfactory feeding practices (frequency of eating food diversity and at a minimum minimum).The level of wasting (n = 180), dwarfing (n = 180) and underweight (n = 343) was 10%, 22.2% and 9.3% respectively [18].

4. Discussion

As a result of this systematic review, the analysis showed that feeding the right complementary food, having good food diversity, and having an appropriate frequency of food and drinkinfluences the incidence rate of stunting as found in 15 reviewed journals. The diet of the children is influenced by maternal socio-economic status [13]. Diet is also influenced by the age of the child. Those aged 6-11 months consuming animal foods and with food sources in the zero group were associated with a higher chance of being inhibited. There is a lack of difference in food recognition at that age [15]. Stunting is also influenced by exclusive breastfeeding when they are less than 6 months old, and if they are not given exclusive breastfeeding [24].

The provision of complementary food is not adequately affected by the reading and writing skills of the formal education of the mothers. They will be given literature in the process of gaining important information on inadequate child feeding and on the protection of malnourished children [18]. Knowledge of micronutrient-rich foods and parental education has a relationship with micronutrient food consumption [14]. In Ethiopia, stunting, thin and thin / fat rivals were 40%, 19.8%, 11.6% and 2.7% respectively. The prevalence of malnutrition was very high. Therefore, health professionals and health education officers must provide nutritional counseling about the frequency and diversity of food, about the environment and on personal hygiene by placing an emphasis on the mothers who do not have formal education [25]. The mother's knowledge is influenced by the level of education of the mothers in providing appropriate complementary breastfeeding foods that are appropriate for the variety of foods that children need to prevent stunting

The feeding of poor babies and children (IYCF) is very bad in malnourished children. In the feeding practices related to waste and stunting, many children in developing countries become stunted during infancy because of improper weaning practices and a poor diet. Feeding from a friend is not exactly related to malnutrition and stunting [17]. The fulfillment of nutrition in children during the stage of exclusive breastfeeding, through the use of supplementary food and the use of worm tablets has the potential to substantially reduce the incidence rate of stunting [19]. Preventing stunting does not only fulfill the provision of various additional foods. It is necessary to provide iron and

vitamin A-rich foods [26] as well as to increase exclusive breastfeeding [20]. According to the research conducted in Chile, the recommended breastfeeding adherence is 11.8 - 97.9% and the practice of supplementary feeding is 9.7 - 90.3% [22]. Compliance can improve the nutrition in children so then it can prevent the occurrence of stunting.

5. Conclusion

In this review, stunting is influenced by the accuracy of the complementary feeding, exclusive breastfeeding for 6 months, the frequency of eating and drinking, the diversity of iron and vitamin A-rich foods and the regular administration of worm medicine. Not only diet but also stunting were influenced by their socio-economic status, parental education, family size and environmental cleanliness. It is necessary to provide counseling routinely about fulfilling the nutrition for children so then it can prevent the occurrence of stunting.

Table 1. Description and Paper Analysis

Name, Country, and Years	Design	Population	Research Criteria	Research Measurement Tool	Outcomes
Fadare *et al* Negeria 2017 [14]	Cross-sectional study	The study included 419 children aged 6–59 months and 413 households	The targeted sampling technique was used in selecting farming households with children aged 0–59 months. The surveyed communities were predominantly divided between two ethnic communities, Nupe and Yoruba.	The intrahousehold food allocation patterns were assessed using Likert-scale questions. The caregivers were asked to rank the household members based on their food allocation in the order of 'more diverse' to 'least diverse'. These were separate questions assessing the diverse food allocation among male adults, the diverse food allocation among female adults and the diverse food allocation among children.	Owning small livestock and a refrigerator, knowledge of micronutrient-rich foods and higher parental education had strong associations with the households' micronutrient-rich food consumption. Children from households that consumed micronutrient-rich foods that received more diverse diets were less likely to experience stunting. The combined effect of micronutrient-rich food consumption and vitamin A supplementation was stronger on the likelihood of stunting reduction than the separate effect of each.
Krasevec *et al.* Nigeria 2016 [15]	Cross-sectional study	The sample size of children 6–23 months old in the pooled analysis was 74,548	The inclusion criteria for the surveys used in the analyses are the following: 1. Dataset available on the DHS website and this allowed for the generation of the seven food groups used in the dietary diversity measure (WHO, 2008)	They were assessed on the basis of the consumption of specific food items in the 24 hours prior to being surveyed. In the DHS survey, the mothers provided the food consumption data for their youngest child under 2 years of age using a	Those who did not consume any animal source food (ASF) the previous day had 1.436 higher odds of being stunted compared to children consuming all three types of ASF (egg, meat,

Name, Country, and Years	Design	Population	Research Criteria	Research Measurement Tool	Outcomes
			2. Child length measurements were part of the survey 3. All of the control variables were available in the dataset 4. Minimum of one (most recent) national level survey per country.	questionnaire assessing the previous days intake from a list of food items. These food items were then categorized into one of the following seven food groups as defined by the WHO for diet diversity.	and dairy). We estimated that 2,629 cases of stunting would have been averted (12.6% of those stunted). Outcomes by country-income grouping showed larger associations between diet diversity and ASF consumption for the upper and lower middle income countries compared to the low income countries. In summary, dietary diversity and ASF consumption were associated with stunting, with the association varying by the stratified groups
District *et al.* Nepal 2018 [17]	Cross-sectional	The sample size was 343 lactating women and their children. Out of 343 children, underweight was measured for all children while stunting and wasting were calculated for children whose age was above six months.	The inclusion of the participants in the study was determined by the mother's consent and the age of the child being between 0-23 months.	After taking verbal and written informed consent from the lactating woman of child, the data was collected regarding her dietary practices, child feeding practices and their nutritional status through using a pre-designed, pre-tested questionnaire in Pokhara Lekhnath Municipality, Nepal.	Less than half (40%) of 6-23 months od children (n=174) had achieved satisfactory feeding practices (minimum meal frequency and minimum dietary diversity). The rate of wasting (n=180), stunting (n=180) and underweight (n=343) was 10%, 22.2% and 9.3% respectively.

Name, Country, and Years	Design	Population	Research Criteria	Research Measurement Tool	Outcomes
					The feeding practices of the children were thus associated with wasting and stunting.
Ock *et al.* Rwanda 2019 [19]	Cross-sectional study	138 children 5 to 30 months in age	All households with a child 5 to 30 months of age had an equal chance of being asked to participate in the survey.	A structured questionnaire was used to collect information on the sociodemographic characteristics of each mother and child and breast-feeding and complementary feeding practices. Anthropometric status was assessed using height-for-age z- scores for the children and body mass index for the caregivers. Dietary intakes were estimated using a 24-h recall.	Interventions focusing on optimal nutrition during the complementary feeding stage, exclusive breastfeeding and the use of deworming tablets have the potential to substantially reduce stunting in children in the northern province of Rwanda.
Aguayo *et al* Bhutan [20]	Cross-sectional	441 children < 24 months	All <24 months old children in the study area participated in the study.	In each selected household, the interviewers administered a questionnaire about their household members, durable and productive asset ownership and the physical structure of the family's home, including access to improved water and sanitation facilities. A second questionnaire asking about pregnancy care and IYCF was administered only to the mother of the youngest child under age 2 years in the household. Length or height and weight were measured for all children under 5	Low rates of exclusive breastfeeding (EBF), given the possible protection of breastfeeding against being overweight and inadequate dietary diversity, offered evidence to guide future program interventions to improve the nutritional status of young children.

Name, Country, and Years	Design	Population	Research Criteria	Research Measurement Tool	Outcomes
				years living in selected households.	
Belén *et al.* Chile 2018 [22]	Cross-sectional study	Sample of 200 children.	Children younger than two years old whose parents agreed to participate and who signed the informed consent form were included. Children who required immediate care due to severe disease or with clinical dehydration were excluded. The excluded children were similar in age and sex to the final sample.	The questionnaire was used to collect information on the sociodemographic characteristics and 24 hours dietary recall, which was collected once per participant in a personal interview with each caregiver to assess portion size. The use of nutritional supplements was during the last week. Additional breastfeeding-related questions, including age at first breastfeeding, the duration of exclusive breastfeeding, age at introduction to solid foods, and age at weaning from breastfeeding were also taken.	Adherence to the recommended breastfeeding practices was 11.8–97.9%, and complementary feeding practices was 9.7–90.3%. Adherence was associated with a lower prevalence of malnutrition. Adherence to the WHO recommended feeding practices was associated with a better nutritional status.
Pediatría *et al.* Mexico 2018 [24]	Cross sectional	189 mother child dyad in children 1-24 months of age	The total group of children were divided into the following groups: 1. Breastfed children 2. Not breastfed children the day before, day or night. In breastfed children less than six months of age, maternal milk is exclusive when no other food or drink (including water) is offered. 3. Women who did not breastfeed their child or who combined it with formula.	A questionnaire to obtain the mother's data (age, education, occupation) and that of the the child (sex, birth date, and if they were born by cesarean section). Their socio-demographic data was applied.	One hundred and eighty-nine mother-child dyads were evaluated; 59.3% were breastfed and 40.7% were not. Stunting was found in 10.1% and it was identified starting in the fourth month of life. This was accompanied by early complementary feeding close to the third month (57.0%) and by a reduction in exclusive

Name, Country, and Years	Design	Population	Research Criteria	Research Measurement Tool	Outcomes
					breastfeeding during the second month of life to only 30%. The proportion of not breastfed children with stunting (27.5%) was almost twice that of breastfed children (12.0%) ($p < 0.03$). By age, the mean Z-scores for length for age (ZLA) was different from the trend showing that stunting increasing with age ($p < 0.05$): 1-6 months and 13-24 months.
Harding *et al.* South Asia 2019 [16]	Cross-sectional	62,509 children aged 0 to 59 months.	Each household sampled was from one of these sub-regions. Each country has a unique distinction for the sub-regions: 34 provinces in Afghanistan, 7 divisions in Bangladesh, 29 states in India, 6 geographic regions in the Maldives, 3 ecological zones in Nepal, and 6 provinces and regions in Pakistan	The DHS IYCF questionnaires were designed in such a way to build on these variables. The IYCF practices and indicators are (a) initiating breastfeeding with the first hour after birth, (b) breastfeeding exclusively for the first 6 months post-partum, (c) continuing to provide breast milk for at least 2 years post-partum, (d) introducing complementary foods at about 6 months, (e) meeting the minimum meal frequency (MMF) of receiving solid, semi-solid, or soft foods per day in children aged 6 to 23 months, and (f) meeting theMDDof	In India, not achieving minimum diet diversity and a minimum adequate diet were significantly associated with the co-occurrence of stunting and wasting. The co-occurrence of wasting and stunting requires more integrated interventions. That is, programmes aimed at preventing (between low birthweight) LBW and poor young child feeding (IYCF) to avert stunting should be linked more effectively with actions

Name, Country, and Years	Design	Population	Research Criteria	Research Measurement Tool	Outcomes
				consuming four or more of the seven food groups per day in children aged 6 to 23 months, and (g) meeting the MAD, an indicator that combines meeting the MDD and MMF among children aged 6 to 23 months.	aimed at the management of wasting.
Wang *et al.* China 2017 [13]	Cross-sectional	5196 children aged 6–23 months	All 6–23 months old children in the study area participated in the study.	A structured questionnaire for caregivers was provided in our survey. The items in the questionnaire were selected from the 'Multiple Indicator Cluster Survey' manual published by UNICEF. The dietary intake diversity assessment involved seven foods groups: (1) grains, roots and tubers, (2) legumes and nuts, (3) dairy products (milk, yogurt and cheese), (4) flesh foods (meat, fish, poultry and liver/organ meats), (5) eggs, (6) vitamin A rich fruits and vegetables and (7) other fruits and vegetables. The data on the dietary intake for the children 24h before the survey was obtained through the caregivers' recall.	Our study found that nearly 44·5% of the complementary feeding diversity did not met the WHO recommended minimum dietary diversity (MDD). An overall 17·8% stunting rate existed in the poor counties of Western China. Inadequate MDD was found to be positively associated with childhood stunting.
Demilew *et al.* Ethopia 2019 [25]	Cross-sectional study	A total of 841 mothers, with children who were 6–59 months old	All 6–59 months old children who resided in food-secure households in the study area who participated in the study.	The data was collected by interviewing the study participants using a pretested, structured questionnaire. The questionnaire consisted of socio	The prevalence of stunting, underweight, wasting and overweight/obesity was 40%, 19.8%, 11.6%, and 2.7%, respectively.

Name, Country, and Years	Design	Population	Research Criteria	Research Measurement Tool	Outcomes
				demographic and obstetric characteristics, environmental factors, anthropometry, child health and caring practices. The questionnaire was developed in English referring to the related literature.	The prevalence of under-nutrition was very high. Therefore, health professionals and health extension workers should give nutrition counseling about the frequency and diversity of meal content, environmental and personal hygiene by emphasizing this to mothers who have no formal education.
Wang J, *et al.* China 2017 [26]	Cross-sectional survey	832 children 6-23 months of age from 41 villages	All 6–59 month old children in the study area to participate in the study.	A questionnaire was designed to collect data on the basic characteristics of the children, their food consumption and their appetite for YYB and breastfeeding according to a 24-hour dietary intake (WHO IYCF).	The proportion of children fed a diverse diet and foods rich in iron or vitamin A increased ($P < 0.01$) in the follow-up study. The prevalence of stunting and underweight decreased ($P < 0.05$).
Geberselassie SB Northwest Ethiopia [3]	Cross-sectional survey	1287 children aged 6-59 months	1. Children aged 6-59 months who do not experience severe pain with spinal curvature. For example, kyphosis, scoliosis and kyphoscoliosis). 2. For households which had more than one eligible child.	Mothers or care givers were interviewed on their socio-demographic, economic, child health-related characteristics and environmental conditions with a pre-tested structured questionnaire.	The prevalence of stunting was high in the study area.We found that stunting was significantly correlated with child age, the occupational status of the household head, family size, and the fathers' education. Therefore, the intervention focused on supporting the housewives,

Name, Country, and Years	Design	Population	Research Criteria	Research Measurement Tool	Outcomes
					family planning, and education on child feeding and nutrition should be implemented.
Kubuga *et al* Africa 2019 [19]	Quasi-experimental study	Childbearing age women (15–49 years, intervention-Kassena NankanaWest district: n = 60; control-Builsa North district: n = 60) and their toddlers (6–24 months)	Inclusion criteria of having a functional borehole (water source) throughout the dry season, existing women's groups and access to Community-Based Health Planning and Services (CHPS) compounds ina sizeable number of mother and young children (6–23 months) dyads for a good sampling frames. The community health nurses were willing to work with researchers between May and August 2016.	Questionnaire on food intake frequency and a 24 h food intake recall was administered at the baseline and at the end of the study. At baseline, the information on the sociodemographic characteristics was also taken and the anthropometry of the participants' weights and heights were measured at the baseline, midpoint, and at the endpoint, according to the standard procedures.	Food parenting with the awarding of a iron-rich food source (Leaf Hibiscus sabdariffa) for three times a week for 12 weeks can prevent stunting in toddlers.
Malembaka EB, *et al.* Uganda 2019 [18]	Prospective cohort study	506 children who had adequate complementary feeding.		The main exposure variable was adequate complementary feeding (CF) measured using a parent questionnaire at 18 – 24 months of age.We defined adequate CF as having received animal food, cereals and fruit, juice and/or vegetables during the 24 hours preceding the interview. An adapted minimum acceptable diet was defined as having been given milk or milk products at least twice a day, having an adapted meal frequency of two and solid or semi-solid food	The predominantly rural population had a high prevalence of inadequate complementary feeding. Adequate complementary feeding between 18-24 months of age did not have a strong effect on the attained height in later childhood, though children adequately fed at 5–8 years of age tended to catch up with attained height better than those who were not.

Name, Country, and Years	Design	Population	Research Criteria	Research Measurement Tool	Outcomes
				meals from at least four food groups in a 24-hour dietary recall.	
Kinjo Y, *et al.* Africa 2018 [23]	Randomized controlled study	300 mother–child pairs visiting the University Hospital of Mother and Child Cotonou Lagoon.	The children were at the hospital to receive pediatric immunizations. The children targeted were those determined by the hospital nurse to be free of diarrhea, fever or other symptoms, and who were healthy enough to be immunized.	The mothers were interviewed using a structured questionnaire. The child's height/length and weight measurements were determined and their Z-scores were calculated using the 2006 World Health Organization Child Growth Standards. Children with a Z-score <2 were considered to have stunting or the status of being underweight.	Maternal safe food preparation behaviors can prevent child malnutrition, even after considering the biological and socioeconomic factors.

ABSTRACT

Stunting describes the condition of chronic malnutrition during the most critical period of growth and development at the beginning of life. Children are calssified as stunting if their height according to their age is below WHO standards. Factors that can affect stunting in developing countries include maternal education. The purpose of study literature review is to identify the education of mothers with the incidence of stunting in children. The authors conducted a relevant literature in various data using the keywords "maternal education, stunting, and children". Data based on Scopus, Google Scholar, Pubmed, Science Direct, Spingerlink, Ebscohost, and Sage. The criteria consisted of full text published in five years limit journal (2014-2019) using English. The result as much as 4.036 articles found and selected 15 article that suitable with criteria. On the process of the analysis, the articles showed that maternal education was a determinant of stunting in children. Higher maternal education reduces the likelihood of a child becoming stunting. Educated women are more likely to distinguish and practice appropriate child nutrition, hygiene, and health care that can greatly improve the nutritional status of their children.

Keywords: maternal education, stunting, children

1. Introduction

Stunting is a condition of chronic nutritional deficiency over the period of growth and development that is most critical at the beginning of life[1]. Children are classified as being stunted if their nutritional status based on height according to age is below the standard of the World Health Organization (WHO) with the value of the Z score being <-2 SD[2]. Stunting represents the failure of linear growth, both physically and cognitively, due to poor nutrition and infection both before and after birth[3]. Children who experience stunting worldwide amount to 90% in the African region and in Asia so it is important to be attentive in developing countries[4]. The latest data indicated that 38% of South Asia's under-fives are stunted[3].

The causes of stunting are multi-factorial. The WHO's conceptual framework on childhood stunting describes the complex interaction of household characteristics such as water, sanitation and hygiene, environmental issues, socioeconomic status, and cultural influences with childhood stunting [5]. The factors that may indirectly influence stunting levels among children in developing countries include socioeconomic status such as the mother's education and occupation, household income and

health expenditure. In addition, factors such as micronutrient deficiencies, inadequate protein intake, and infections may directly cause stunting[6].

The importance of a mother's education on child health and nutrition has been well demonstrated in a number of studies. The mother's education is associated with better child health and nutritional outcomes through improving the socioeconomic status of the mothers[7]. Maternal education has long been recognized as a key determinant of child nutrition through a number of pathways, such as better health and nutrition knowledge and practices, improved access to and use of information, and improved self-confidence and decision-making power. A number of studies showed that the importance of household wealth for child nutrition and health varies according to maternal education[8]. Based on the importance of maternal education in a number of studies and because there has been no specific literature review to discuss maternal education and its relationship to the incidence of stunting, this systematic review aims to find out the relationship between the education of mothers with stunting in children based on the collected research results.

2. Material and Methods

The design used in the present study was a systematic review. The research design was not limited to a particular research design from the start. The journals were browsed using online databases.

2.7 Data Sources And Searches

The databases searched were Scopus, Google Scholar, Pubmed, Science Direct, Spingerlink,Ebscohost and Sage. The studies were related to maternal education, stunting, and children from 2014 to 2019.

2.8 Study Selection

The literature review was conducted using maternal education, stunting and children as the focal points. The selection of the articles was determined using the following inclusion criteria: the full text was published, the articles were published between 2014 and 2019 and they were in the English language. All of the citations retrieved from the electronic databases were imported into the Mendeley Program. The reviewers independently analyzed the titles and abstracts of every studies retrieved from the literature search to identify potentially eligible studies. The full text of the remaining studies was obtained for further examination. The last review was conducted by the first reviewer. The data of the included studies was independently extracted by the same two reviewers by including the first author's name, the year of publication, the study design, the sample size, the general characteristics of the participants, the research measurement tool and the main outcome of interest. Descriptive analysis was conducted on the data obtained from the reviewed papers and this included maternal education with the incident rate of stunting.

3. Results

3.2 Literature Search

Four hundred and 36 journal articles were selected according to particular criteria from 7 databases: 233 articles from Scopus, 727 articles from Google Scholar, 457 articles from Pubmed, 494 articles

from Science Direct, 869 articles from Spingerlink, 78 articles from Ebscohost and 1.086 articles from Sage. The results of the article selection according to the inclusion criteria resulted in 15 articles.

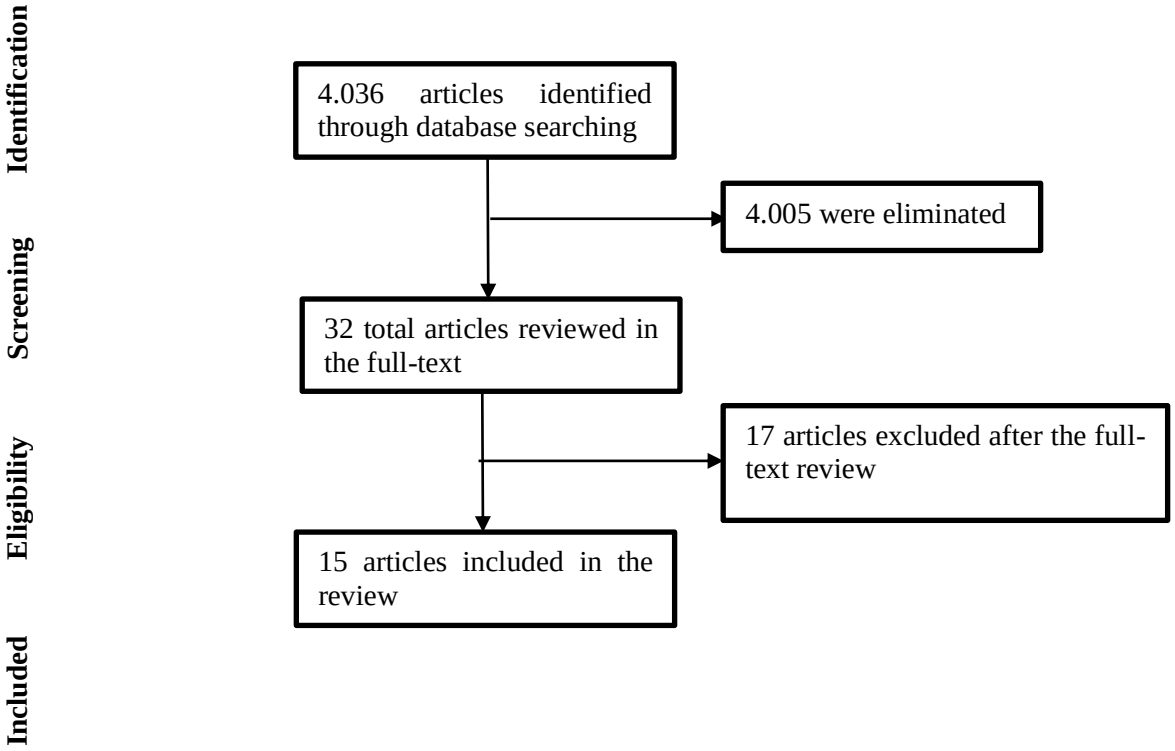

Figure 1. Flow diagram of the database search process

3.3 Respondents Characteristics

There were thirteen cross-sectional designs, one cohort study, and one case-control study reviewed. The respondents were drawn and recruited from the data under supervision, and the socio-demographic characteristics of each household and related information was collected from the mothers at antenatal clinics, from birth records and through face-to-face interviews with the caregiver. These studies were conducted in Asia, Africa, Australia and America. The studies in the sample used an average of more than a thousand children.

3.4 Measure Outcome

The results were measured by employing the following instruments: a semi-structured questionnaire, structured questionnaire, household questionnaire, women's and men's questionnaire, and the child's anthropometric Z-score using the WHO's growth reference standard.

3.5 Maternal education

The children whose mothers attended higher education reduced risk of their children being stunted by 90% compared to the mothers who could not read and/or write[1]. Stunting was significantly associated with the mother's education level in all three countries. Half of the children whose mothers had no education were stunted in Malawi, 45 % in Tanzania and 34 % in Zimbabwe. Child stunting was the lowest among children whose mothers had senior secondary education and above in the three countries[2]. HAZ did not increase with the wealth scores among the children whose mothers had not completed primary schooling, but the opposite was true for the children of mothers

with primary school or higher[3]. In another country, the result indicated that the children whose parents' attained secondary educations were less likely to be stunted compared to those whose parents had no formal education [4]. The prevalence of stunting decreased significantly with the increase in maternal education. A total of 38,7% of children whose mothers had no education were stunted, among children whose mothers had completed grade 5–9 and grade 10 or more [5].

4. Discussion

The results of this systematic review and analysis showed that maternal education was significantly associated with stunting in children (1-15,19). Maternal education appeared to strongly affect childhood stunting. Children born to mothers with higher education had a reduced risk of stunting compared to those born to illiterate mothers. This finding is in agreement with the study conducted in the Sidama zone that reported a higher risk of stunting among the children of uneducated mothers [1]. Maternal education appeared to be a protective factor for avoiding childhood stunting. Higher maternal education reduces the likelihood of a child becoming stunting. Educated women are more likely to distinguish and practice appropriate child nutrition, hygiene, and health care that can greatly improve the nutritional status of their children[17]. This study has highlighted three things related to education can affect the children's health, namely formal maternal education, which directly influences the health knowledge of prospective mothers. Second, the literacy and numeracy skills obtained by the women in schools improve their ability to recognize illness and to seek treatment for their children. In addition, they are better able to read the medical instructions for any treatment when the child is sick. Third, the length of time studying in school makes the women more receptive to modern treatment [18]. Children born to mothers with a higher level of education have reduced the risk of stunting compared to illiterate mothers. Highly educated mothers tend to distinguish and practice appropriate child nutrition practices, hygiene, and health care in terms of improving the nutritional status of their children[1]. Moreover, due to exposure to the media, they are likely to have better child and healthcare knowledge of nutrition, thus leading to better feeding practices[7]. The mother's education level is related to the ease of the mothers in receiving information about nutrition and health from outside. Mothers with a higher level of education will find it easier to receive information from outside than those with lower education. However, higher or lower education and even illiteracy have the same opportunity to obtain information from various media. The limitation of this systematic review is that it does not explain how the mothers obtain knowledge other than where the mothers are educated. This is because science can be found anywhere other than at school, namely through informal channels and technological advances.

5. Conclusion

In this review, maternal education was found to be significantly associated with stunting in children. Education is an important predictor of children's health and nutritional status. It has been estimated that the increase in women's education is responsible for nearly 43% of the total malnutrition, and that it is also related to the provision of specific supplementary foods. Higher educational attainment can increase the ability of the caregivers to understand the messages and to respond to the nutritional behavior. This results in the person being more receptive to alternative methods or recipes for food preparation, and for reading and interpreting food labels with ingredients.

THOUGHT STOPING AND GUIDED IMAGERY THERAPY EFFECTS ON ANXIETY LEVEL OF THIRD TRIMESTER PRIMIGRAVIDA PREGNANT WOMEN IN PUSKESMAS BASIRIH BARU AREA

Yuliani Budiyarti [1]; Magfirah [2]
[1]Universitas Muhammadiyah Banjarmasin
E-mail: yuliani@stikesmb.ac.id

ABSTRACT

The first pregnancy can cause psychological problems, namely anxiety, if left untreated it will have a negative impact on both the mother and the fetus. Actions to reduce anxiety include thought stopping and guided imagery. The purpose of this study was to analyze the effect of Tought Stopping and Guided Imagery therapy on the anxiety level of third trimester primgravida pregnant women in the New Basirih Health Center area. This type of research is quantitative with a non equivalent control group design pretest-posttest. The study population was all third trimester primigravida pregnant women in the Puskesmas Basirih Baru area in 2018. The research samples were 20 trimester primigravida pregnant women, divided into thought stopping intervention and guided imagery groups with total sampling technique. Instruments for measuring anxiety, namely HRS-A, Wilcoxon and Mann Whitney test analysis. The results of the study were thought stopping intervention with p-value = 0.005 so that thought stopping therapy had an effect on the anxiety level of pregnant women and guided imagery p-value = 0.007 so guided imagery therapy affected the anxiety level of pregnant women. It can be concluded that thought stopping and guided imagery can be used by pregnant women to reduce anxiety levels..

Keywords: anxiety level, guided imagery, primi-gravida trimester III, pregnant women, thought stopping

.

1. Preliminary

In general, pregnancy is a valuable experience for a woman, especially if the pregnancy is the first and most desirable pregnancy. The first pregnancy can give a very big emotional meaning such as feeling happy and hopeful, but can also cause anxiety caused by doubts about the ability to go

through various difficulties in terms of adjusting to the conditions that will be faced during pregnancy. Pregnancy is a natural process, where there will be changes in various physiological organs (Zuhrotunida, 2016).

These physiological changes include changes in physical and psychological aspects. In general, changes in physical aspects include changes in anatomy and organ function, while psychological changes that are often felt are changes that occur in the natural feeling and mood swing that causes the mother's emotions to become unstable, irritability, fear, discomfort and excessive anxiety (Anggarani et. al., 2013).

Anxiety is an individual response that occurs due to unpleasant conditions, which can be experienced by all living things when experiencing deep pressure and feelings (Shodiqoh, 2014).

Anxiety can also be felt during pregnancy, which can occur throughout the pregnancy process but with different levels, ranging from mild anxiety to panic. The inability of pregnant women to deal with anxiety constructively is the main cause of pathological behavior that will continue until the postpartum period. In the first trimester (1-3 months gestational age) anxiety is often associated with the incidence of morning sickness and the risk of abortion. Trimester II (4-6 months of gestation) anxiety will be felt a little reduced because physiologically the pregnant woman has begun to be able to adapt to the changes that occur and start enjoying her pregnancy. In the third trimester (7-9 months of gestation) anxiety will be felt to increase again, which is often caused by excessive thinking about the smooth delivery, physical condition of the prospective baby, pain that will be felt and so forth (Maimunah, 2009). This description is supported by the results of a study by Astria (2009) who obtained data that the increase in majority anxiety occurred in mothers who had pregnancy in the third trimester.

The World Health Organization (WHO, 2017) outlines the global prevalence of anxiety that occurred in 2015 as many as 3.6% of pregnant women, the Ministry of Health of Republic of Indonesia (MOH) also explained that in 2016 there were approximately 377,000,000 people experiencing anxiety and of the 377,000,000 pregnant women obtained as many as 107,000,000 people experienced an increase in anxiety in the third trimester. There are a lot of negative impacts that occur when during pregnancy, mothers experience anxiety including risk of weakening uterine muscle contractions, inhibiting cervical dilatation, slowing labor, increasing the risk of emotional imbalance after childbirth, baby blues and postpartum depression and weak bonding attachments between mothers with baby.

In addition to having a negative impact on pregnant women, babies conceived are also at risk of developing growth disorders, low birth weight (LBW) and increased hypothalamic activity Adrenal Pituitary (HHA) which causes changes in steroid hormone production, damage to social behavior and a high risk of infertility as adults (Shahhosseini, 2015). The description above is supported by research conducted by Maimunah, S. (2009) with the results of mothers who experience anxiety during pregnancy, most of whom experience premature birth and give birth to babies with LBW.

In order to avoid negative impacts on pregnant women and babies who are conceived, measures must be taken to overcome these anxieties. There are 2 types of therapy that can be used, namely pharmacological therapy and non-pharmacological therapy. Pharmacological therapy can be done by administering anti-anxiety drugs, but it has an adverse effect, especially for pregnant women because it can cause a high risk of drug dependence, giving birth to babies with low weight and preterm birth, so it is advisable to use non-pharmacological therapy for reasons of therapy it is simpler and easier to do. Some literature also states effective and minimal side effects. Many types of non-pharmacological therapies are currently being developed with the aim of relaxing pregnant women including thought stopping and guided imagery therapy.

Therapeutic thought stoppping is one of the behavioral therapies used to help pregnant women change the thinking process. Positive thinking habits can form positive behavior too. Thought stopping therapy can also cause changes in brain wave activity (the pre frontal cortex, limbic system, and hypothalamus) which are capable of increasing regulation of emotions and sympathetic nerve activity thereby increasing relaxation conditions, increasing neurotransmitters (melatonin, sirotonin, beta endorphin and acetycholine) that affect positive emotional conditions that depress

neurotransmitters (norepinephrine and cortisol) which can increase anxiety (Agustarika, 2009).

In addition to thought stopping, another therapy that is recommended is guided imagery therapy, which is a relaxation technique using directed imagination to reduce anxiety. This therapy can stimulate the emergence of chemical substances similar to beta blockers in the peripheral nerves that can close the sympathetic nerve nodes which are useful for lowering blood pressure, reducing tension which has an impact on reducing anxiety levels (Mayasari, 2015)

The results of a preliminary study conducted at the New Basirih Community Health Center showed that of the 10 primigravida trimester III pregnant women, 50% of pregnant women experienced moderate anxiety and 10% experienced severe anxiety. In general, the impact of perceived anxiety include mothers feeling restless, easy to cry, disrupted rest and sleep patterns that have an impact on daily living activities. Based on the description above, the purpose of this study is to analyze the effect of Tought Stopping and Guided Imagery therapy on the anxiety level of third trimester primgravida pregnant women in the New Basirih Health Center area.

2. Research Methods

This research is a quantitative research with a quasi experiment non equivalent control group (pretest-posttest) design. The entire population in the study was taken as a sample of the third trimester primigravida pregnant women in the work area of the New Basirih Health Center in 2018 with 20 people divided into 2 groups, namely 10 thought stopping intervention groups and 10 guided imagery intervention groups. The thought stopping intervention was carried out after giving the pretest to the sample. If the sample is stated to have anxiety, the intervention is carried out. In the thought stopping intervention group, the intervention was carried out for 10 times with a frequency of 1 time in 1 day with the duration of implementation of the 30-minute work phase every 1 intervention, as well as the same actions carried out in the guided imagery intervention group. After the intervention was completed in the 2 groups, then on the 10th day posttest will be conducted to assess the level of anxiety by using the same measuring instrument as the pretest.

The instrument used to measure anxiety levels are standard questionnaire Hamilton Rating for Anxiety (HRS-A) and non-verbal observation sheets to measure anxiety levels. The sampling technique used was consecutive sampling. The analysis test used in this study was the Wilcoxon signed rank test used to test the differences in the value of anxiety levels before and after intervention both in thought stopping intervention groups and in guided imagery intervention and Mann Whitney test to determine the differences in the effects of thought stopping and guided therapy imagery of the anxiety level of primigravidian pregnant women.

3. Research Result

1. *Frequency distribution of age of third trimester primigravida pregnant women based on anxiety level.*

Table 1. The frequency distribution of age in third trimester primigravida pregnant women based on anxiety level

Ages	Anxiety Level			f	%
	Low	Mid,	High		
	f (%)	f (%)	f (%)		
< **20 yo.**	4 (20)	3 (15)	4 (20)	11	55
21 – 35 yo.	4 (20)	5 (15)	0	9	45
≥ **35 yo.**	0	0	0	0	0
Jumlah	8 (40)	8 (40)	4	20	100

Table 1 shows that most pregnant women aged less than 20 years experience moderate levels of anxiety as many as 3 people (15%) and experience anxiety levels of as many as 4 people (20%)

2. *Frequency distribution of education level in third trimester primigravida pregnant women based on anxiety level*

Table 2. Frequency distribution of education level for third trimester primigravida pregnant women based on anxiety level

No	Education Level	Anxiety Level			f (%)
		Low	Mid	High

2	**Unemployee**	6 (30)	5 (25)	4 (20)	15 (75)
	Jumlah	11	5	4	20(100)

Table 3 shows that the majority of pregnant women who are not working experience moderate

levels of anxiety as many as 5 people (25%) and anxiety levels as heavy as 4 people (20%)

4. *Frequency of gestational age of primigravida trimester III mothers based on anxiety level*

Table 4. Frequency of gestational age for primigravida third trimester mothers based on anxiety level

No	Usia Kehamilan	Anxiety Level			F (%)
		Ringan (%)	Sedang (%)	Berat (%)	
1	**28-32 minggu**	5 (25)	4 (20)	1 (5)	10 (50)
2	**33-36 minggu**	4 (20)	3 (15)	3 (15)	10 (50)
3	**37-40 minggu**	0	0	0	0
	Jumlah	9	7	4	20

Table 4 shows that most mothers who enter gestational age 33-36 weeks experience moderate levels of anxiety as many as 3 people (15%) and anxiety levels as heavy as 3 people (15%)

5. *The difference in the significance value of the anxiety level of third trimester primigravida pregnant women before and after given thought stopping intervention*

Table 5. The difference in the significance value of anxiety levels of third trimester primigravida pregnant women before and after administration thought stopping intervention

No	Anxiety Level	Group Thought Stopping			
		Pretest		Posttest	
		F	(%)	F	(%)
1	**Low**	5	50	8	80
2	**Medium**	3	30	2	20
3	**High**	2	20	0	0
4	**Very High**	0	0	0	0
	Total	10	100	10	100
***Wilcoxon Signed Rank Test p* = 0,005, *α*= 0,05**					

Table 5 shows that the Wilcoxon Signed Rank Test test results obtained p = 0.005 and α = 0.05, it can be concluded that there are differences in the anxiety level of primigravida pregnant women in the third trimester before and after thought stopping therapy.

6. *Differences in the significance value of anxiety level of third trimester primigravida pregnant women before and after guided imagery intervention*

Table 6. The difference in the significance value of the anxiety level of third trimester primigravida pregnant women before and after being given guided imagery intervention

No	Anxiety Level	Kelompok *Guided Imagery*			
		Pretest		***Posttest***	
		F	**(%)**	**F**	**(%)**
1	**Low**	5	50	8	80
2	**Medium**	3	30	2	20
3	**High**	2	20	0	0
4	**Very High**	0	0	0	0
	Total	10	100	10	100
***Wilcoxon Signed Rank Test p* = 0,007, α= 0,05**					

Table 6 shows that the Wilcoxon Signed Rank Test test results obtained p = 0.007 and α = 0.05, it can be concluded that there are differences in anxiety levels of third trimester primigravida pregnant women before and after guided imagery therapy.

7. *Differences in mean values between thought stopping intervention groups and guided imagery intervention groups*

Table 7. Mean Value Differences between thought stopping intervention groups and intervention groups guided imagery

Tingkat Kecemasan (Kelompok N=20)	*Wilcoxon Signed Rank* *ρ value*
Intervention Group *Thought Stopping* *Pretest* *Posttest*	0,005
Intervention Group *Guided Imagery* *Pretest* *Posttest*	0,007
Mann whitney p = 0,007 α= 0,05	

Table 7 describes the results of the Mann Witney test, p = 0.007 and α = 0.05, then p <α. so that it can be concluded that there is the effect of giving thought stopping and guided imagery therapy to the anxiety level of third trimester primigravida pregnant women

4. Discussion

The frequency distribution of age in third trimester primigravida pregnant women based on anxiety level.

The results showed that most pregnant women aged less than 20 years experience moderate anxiety and experience severe anxiety. The age of the mother during pregnancy is very influential on the process of pregnancy itself. This is related to the readiness of the physical and psychological aspects of the mother, where if the pregnancy occurs at a young age (less than 20 years) then the reproductive organs are still immature and not ready to perform their functions properly related to pregnancy so they are at risk of complications, disability and even maternal death and fetus.

In addition, during pregnancy, the physiological levels of the hormone progesterone will experience an increase which results in the mother becoming more irritable, easily experiencing changes in feelings and experiencing a mood swing which results in increased susceptibility to higher levels of anxiety, which in this study proved to be the mother pregnant who are less than 20 years old mostly experience moderate and severe anxiety. An increase in the grade of anxiety that is felt also occurs due to undergoing the first pregnancy (primigravida) where the mother still does not have sufficient experience so that the ability to adapt to changes that occur is also lacking, which results in the emergence of excessive anxiety,

If viewed from the psychological aspect where pregnancy itself causes physiological and emotional stress simultaneously, which is aggravated by emotional instability, maturity in the thinking process and problem solving perspective is not yet adaptive, this will result in the mother being more at risk of anxiety with a more severe level.

.The above description is supported by the results of the study of Astria et al. (2009) where the majority of pregnant women with young age experience anxiety when compared to reproductive age pregnant women. The above description is in line with the results of Zamriati's research (2013) where the age of the mother during pregnancy affects the emergence of feelings of fear and anxiety. If pregnancy occurs at less than 20 years of age, the tendency of the mother is not ready to adapt adaptively to the physical and psychological changes that occur due to pregnancy and has not yet experienced emotional maturity, making it very easy to experience anxiety.

Frequency distribution of education level for third trimester primigravida pregnant women based on anxiety level

The results showed that the majority of pregnant women with only elementary education (SD-SMP) mostly experienced moderate level anxiety and severe anxiety. Notoatmodjo (2013), describes that education is one of the basic human needs that is very necessary for self-development and increased intellectual maturity. This intellectual maturity influences one's insight and way of thinking, both in actions that can be seen as well as in the way decisions are made. Intellectual maturity is very necessary for pregnant women to be able to undergo the pregnancy process normally.

During the pregnancy process, there are many changes that occur in the physical and psychological aspects. If pregnant women do not have intellectual maturity in this case, they are insights and good thinking skills, they will have difficulty not even being able to adapt to these changes so that they are susceptible to disorders such as anxiety. In order for pregnant women to

adapt well, intellectual maturity is needed, one of which is obtained from education. The results of Hawari's study (2008) describe that the level of education is related to a person's ability to adapt to anxiety.

The description above is in line with the results of this study, where most pregnant women with elementary education (SD & SMP) experience moderate and severe anxiety. Low education for pregnant women is one of the things that causes intellectual maturity (insight, ways of thinking and the ability to adapt) become less so that anxiety occurs at moderate and severe levels.

The frequency distribution of work in third trimester primigravida pregnant women based on anxiety level

The results showed that most pregnant women who did not work experienced moderate anxiety and severe anxiety. Working generally is an activity that can take time and focus attention so that there is a shift in focus from things that can cause interference.

According to Said (2015) work can divert someone's attention from something that is felt like anxious feelings, because dense activity is very time consuming so that a person does not have the opportunity to focus more on perceived anxiety. Likewise the case with pregnant women who have jobs will be more active outside the home and will interact more with other people so they do not have the chance and a lot of time just thinking about something that is felt. Working outside the home can also be used as an activity to refresh thoughts and feelings because they can see and find new experiences so that they are not only fixated on routines, things are monotonous and there are no changes. This description confirms that pregnant women who have jobs rarely experience higher levels of anxiety when compared to pregnant women who do not have jobs.

The above description is in line with the results of this study, where the third trimester primigravida pregnant women who do not have work (housewives) mostly experience moderate and severe levels of anxiety. Pregnant women who do not have jobs have more free time so they will be more focused on thinking about things that make them feel anxious, lack the opportunity to interact with other people and not get the opportunity to see and have new experiences, so that one of the impacts is limited information -New information and help to overcome the anxiety that is felt, which if left to drag it will fall into a more severe state. namely moderate and severe anxiety.

Frequency of gestational age for primigravida third trimester mothers based on anxiety level

The results showed that most mothers who entered gestational age 33-36 weeks experienced moderate level anxiety and severe anxiety. The gestational age approaching labor is one of the causes of anxiety that occurs in third trimester pregnant women. Anxiety will be felt to increase again because too much thinking about various things such as the smooth delivery, physical condition of the prospective baby and pain that is felt during labor. Anxiety is felt to increase in level (moderate and severe anxiety) when the mother does not have previous experience through labor. The results of this study are supported by Maya, et. al (2017) where mothers with gestational age> 33 weeks the majority experience anxiety which is higher in level when compared to mothers whose gestational age is less than 29 weeks.

Value difference Significance of anxiety level of third trimester primigravida pregnant women before and after thought stopping intervention.

The results of the study showed that before being given thought stopping therapy, most pregnant women experienced moderate anxiety and severe anxiety. Anxiety is an unpleasant feeling characterized by concern, concern and fear that is sometimes experienced at different levels. The higher the level of anxiety that is felt, the greater the risk of harm that will be obtained by the individual. In this case, anxiety can be experienced by all individuals including women who are undergoing pregnancy. Anxiety that occurs in the mother during pregnancy can occur throughout the pregnancy period (from the first trimester to the third trimester), but when the pregnancy enters the third trimester, anxiety will be felt more because it will face the labor process.

Mothers who experience prolonged anxiety are more likely to experience difficulties during labor and are at risk of giving birth to abnormal babies compared to mothers who are relatively calm (Desmita, 2010).

In this study before being given thought stopping therapy, most primigravida pregnant women who entered pregnancy in the third trimester experienced moderate levels of anxiety and severe levels of anxiety, which if not treated immediately would provide a very detrimental risk to the mother and baby contained, including increasing the risk of baby blues, postpartum depression, weak bonding attachments, developmental disorders in infants, LBW, damage to social behavior and a high risk of infertility in adulthood. In order to avoid the adverse risks above, action must be taken to overcome these anxieties. One simple and safe action is thought stopping therapy.

The results of Malfasari's study (2017) showed a significant decrease in anxiety rates in patients who received thought stopping therapy. This is also in line with the theory of Nursalim (2013), where thought stopping therapy is one example of therapy that uses cognitive psychotherapy techniques. behavior that can be used to help and improve the ability of pregnant women to control their thoughts and images of themselves by suppressing or eliminating negative awareness.

In this study, after being given thought stopping therapy, pregnant women who experienced moderate levels of anxiety decreased because there was a decrease in anxiety levels and those who experienced severe anxiety decreased to moderate levels of anxiety, so it can be concluded there were differences in anxiety levels of third trimester primigravida pregnant women before and after thought stopping therapy.

This research result is in line with Naikare VR, Kale P, Kanade A. B., Mankar S., Pund S, and Khatake S (2015) research which adresses intervention thought stopping has significant influence of anxiety level decrease. Based on the data above, the thought stopping is one of the non-pharmacological therapies that have been shown that reduces anxiety levels in pregnant woman and help stop thoughts that cause anxiety, then replace those thoughts by choosing alternative positive thoughts.

The difference in the significance value of the anxiety level of third trimester primigravida pregnant women before and after being given guided imagery intervention

The results showed that before being given guided imagery therapy most pregnant women experienced moderate anxiety and severe anxiety. Moderate level anxiety and severe anxiety is a very detrimental situation for pregnant women, because when the anxiety is felt by pregnant women

unable to think positively about things that are real, the concentration level deteriorates and is unable to solve problems effectively. This situation must be addressed immediately in order to reduce the adverse risks that might occur.

According to Mayasari (2015) guided imagery is one of the non-pharmacological interventions that has been shown to be effective in reducing anxiety. This is also in accordance with the study of Bastani (2014) which describes that relaxation exercises in pregnant women can improve the psychological health of the mother by reducing perceived anxiety. Relaxation can stimulate the emergence of chemicals similar to beta blockers in the peripheral nerves that can close the sympathetic nerve nodes which are useful for lowering blood pressure and reducing tension

The results of this study also showed that after being given guided imagery therapy, pregnant women who had moderate levels of anxiety decreased to mild levels of anxiety and those who experienced severe anxiety decreased to moderate levels, so it can be concluded that there *Wilcoxon Signed Rank* ere differences in anxiety levels of third trimester primigravida pregnant women before and after guided imagery therapy.

Jall0 N. (2014) proved that the guided imagry theraphy have influence in improving the anxiety level decrease. The above can occur because guided imagery therapy teaches someone who experiences anxiety to focus more on positive imagination that can lead to a relaxed state (Nguyen, 2012). When the body is relaxed and parasympathetic it will work to stimulate the appearance of chemicals similar to beta blockers in the peripheral nerves to suppress or close the sympathetic nerve nodes which are useful for lowering blood pressure and reducing tension so that the body and mind can be relaxed. Based on the data above, the guided imagery are able to decrease anxiety levels in pregnant woman twice as great than who were only treated by general nursing intervention.

Effect of thought stopping therapy and guided imagery therapy on anxiety levels in third trimester primigravida pregnant women

The results of the study describe that the provision of thought stopping and guided imagery therapy affected the anxiety level of the third trimester primigravida pregnant women. Thought stopping therapy is a form of behavioral therapy that is used to help pregnant women change the thinking process. Changing the thinking process of pregnant women who experience anxiety is very important so that behavioral changes that are expected to be very bad are expected to become adaptive behavior.

Thought stopping therapy in addition to being able to change the thinking process that is all negative to positive, this therapy also causes changes in brain wave activity (cortex, pre-prontal, limbic and hypothalamus systems) which increase emotional regulation, increase parasympathetic activity and increase heart rate relaxation conditions, improve neurotransmitters that affect positive emotional conditions such as melatonin, serotonin, beta endorphin, and acetylcholine so as to reduce neurotransmitters (norepinephrine and cortisol) which have an increased anxiety (Parmadi, 2015)

In this study for the implementation of thought stopping therapy the pregnant women were directed to do attention so that it would be easier to do each thought stopping therapy session. In session 1, pregnant women are asked to identify and disconnect threatening thoughts or cause anxiety. This is done because when a pregnant woman realizes and can identify negative thoughts

that appear to accompany an event that demands self-adjustment, pregnant women will more easily overcome the problem, which in this case is anxiety. During session 2 of thought stopping therapy, pregnant women practiced to decide their thoughts by using the recording of the word "STOP" and if it was successful the recording would be replaced with a whisper and imagine hearing the word "STOP", and finally changing the voice "STOP" using rubber bracelet, pinch yourself or press finger nails so that negative thoughts can be removed immediately and replaced with positive thoughts. In session 3 pregnant women practiced deciding negative thoughts automatically. This therapy is done 10 times with a frequency of 1 time in 1 day with a duration of approximately 65 minutes. This study found that thought stopping therapy can reduce the anxiety level of pregnant women.

The results of this study are supported by Laela (2010) where pregnant women who get thought stopping therapy experience decreased levels of anxiety. This is also in accordance with Rafati et al. (2017) 's research, where thought stopping therapy is an effective therapy to stop negative thoughts. And then this research result is in line with Bakker M., Ross D. M (2009) research which adresses thought stopping theraphy is effective to change and control negative thoughts in someone who has anxiety, depression and especially in someone who has obsessive compulsive disorder. Changing the thinking process is an action that must be done immediately so that the mechanism of destructive behavior change will change into constructive behavior.

This therapy is proven to be effective in reducing anxiety, issuing negative thoughts and suggesting oneself with positive thoughts. By thinking positively indirectly can make a person become calmer and relaxed.

In addition to thought stopping therapy, the results of this study also prove that guided imagery therapy is effective in reducing anxiety levels in pregnant women. Guided imagery is a relaxation technique that uses directed imagination from yourself by imagining pleasant things so that the body's condition will relax which results in a reduction in anxiety levels.

Someone who is in a state of anxiety often focuses only on negative thoughts and because of the above causes a feeling of fear and excessive worry about things that will happen in the future without being accompanied by rational reasons. Pomerantz (2014) supports a description of someone who is in a state of psychological disorders such as depression and anxiety psychologically due to a reaction to his own thoughts so that an action is needed to relax physical and psychological conditions.

Relaxing conditions in the body will inhibit the increase in sympathetic nerves, so that the hormones that cause body dysregulation can be reduced in number. The parasympathetic nervous system that has work functions that are opposite the sympathetic nerves will slow or weaken the workings of the body's internal organs. The result is a decrease in heart rate, rhythm of breath, blood pressure, muscle tension, metabolic rate and production of stress-causing hormones. With the regulation above, pregnant women will feel relaxed along with the decrease in anxiety symptoms.

In guided imagery therapy, pregnant women who are used as research participants are directed to focus on pleasant experiences, while also involving all the senses of the body to share the comfort and beauty of the experience, such as being able to see, smell, feel and experience fun that has been experienced before so that there is interaction between cognitive and affective centers in the brain which can lead to psychomotor changes that can lead to relaxed conditions in the body and mind. This therapy is done 10 times with a frequency of 1 time in 1 day with a duration of approximately 65 minutes. This study found that guided imagery therapy can reduce the anxiety level of pregnant

women.

This is supported by Naparstek (2007) by imagining time, place and events in all sensory comforts and beauty - sights, sounds, smells, feelings can produce a positive emotional response as a pleasant distraction to divert thoughts and attention from an inconvenience such as anxiety.

The above description is in line with Resmaniasih (2014) where guided imagery therapy is effective in reducing tension by stimulating the emergence of chemicals similar to beta blockers in the peripheral nerves that can close the sympathetic nerve nodes which are useful for lowering blood pressure and reducing tension. Based on the data above, the thought stopping and guided imagery is one of the choice non-pharmacological therapies that have been shown to reduce anxiety levels in pregnant woman.

5. Implication

The results of this study have implications for the choice of safe (non-pharmacological) actions that nurses can make when implementing nursing in pregnant women to reduce anxiety levels and the development of nursing science regarding nursing actions especially handling anxiety in pregnant women.

6. Conclusion

There are differences in anxiety levels of third trimester primigravida pregnant women before and after thought stopping therapy. There are differences in anxiety levels of third trimester primigravida pregnant women before and after guided imagery therapy. There is an effect of giving thought stopping and guided imagery therapy to the anxiety level of third trimester primigravida pregnant women.

7. Acknowledgement

ABSTRACT

Patients with Diabetes Mellitus should have skills for managing their disease to prevent complications and to increase their quality of life. One of that skills is to do health life behaviour, especially diet. Dietary adherence was being the most important foundation for Type 2 DM Management. This study aims to collect evidence based by previous research about factors that influence dietary adherence in Type 2 DM patients. The article was searched through electronic data base such as: Scopus, ProQuest and Google Scholar using keyword "dietary adherence" AND "diabetes mellitus patients" AND "qualitative study". There were 372 studies found and 16 studies were selected based on inclusion criteria to reviewed. Result showed that dietary adherence difficult to do because some factors: culture, individual factors, knowledge, perceptions about diet, motivation, social supports, barriers to do dietary behaviour, and menu of diet. These review result could be a reference for health workers to plan alternative intervention which more suitable to applied for improving dietary adherence of Type 2 DM patients.

Keywords: dietary adherence, type 2 diabetes mellitus, qualitative study, systematic review

1. Introduction

Type 2 Diabetes Mellitus (T2DM) continues to be a major threat to public health in many countries[1]. According to the Global Status Report on Non-Communicable Diseases by the World Health Organization, the global prevalence of diabetes in 2014 was estimated to be 9% among adults aged 18 years old and over. In Indonesia, The International Diabetes Federation (IDF) estimated that the increase in the number of people with Diabetes Mellitus went from 9.1 million in 2014 to 14.1 million in 2035 [2].

Self-care is an important component in the management of type 2 diabetes mellitus. Self-care management focuses on lifestyle adaptations (diet and physical activity), blood glucose monitoring, medication use, and foot and eye care[3]. Dietary management is central to effective diabetes care as it is considered vital for improving and maintaining blood glucose control and promoting weight loss in those who are overweight/obese. The diet recommended to people with type 2 diabetes is the same "healthy", balanced diet that the general public is encouraged to follow, being low in fat, sugar and salt. Specific recommendations highlight the importance of replacing fat-rich foods and other dietary sources of fat with starchy carbohydrate foods (e.g. those that are cereal based) and fruit and vegetables. Where weight management is required, people are encouraged to reduce their overall

energy content, rather than the bulk of what they consume, as it is considered to be important to continue to consume a 'sufficient volume for satiety' [4].

The World Health Organization in 2003 stated that the research results in several countries stated that the non-adherence of DM patients had reached 40-50%, which in developed countries was 50% and in developing countries, the number was even lower. Other study results showed that only a few patients (2,4%) adhered to the diet program, while 20,9% did not follow any diet and 61,8% ate a diet that was self-made (not according to the program)[5]. Another researcher also found that non-adherent patients with a diet made up 44,8% and the effect was that they had a low quality of life[6]. Other data showed that the dietary adherence rates for Type 1 and Type 2 Diabetes were only 39% and 37% respectively [7].

Adherence is the level of patient behavior which is directed at the instructions given in the form of prescribed therapies, whether they be focused on diet, exercise, treatment, or keeping up with the doctor's appointments [8]. Research conducted at Puskesmas Krian in Sidoarjo found that diabetic patients had low adherence, with some among of them stating that it was difficult to adhere to a diet program and that they often ate carelessly. Patients who have been suffering from diabetes for a long time said that they were bored, that they did not stick to the diet because their blood sugar had dropped, and that they had taken the medication. Others also said that it was difficult to go on a diet because they were travelling and while attending parties. All of these were the reasons for the difficulties encountered while dieting. In the new patients, difficulties were found because they were unfamiliar and found it difficult to change the habits that were contrary to the diet programs, in addition to a lack of support and information[9].

The purpose of this study was to collect evidence based on previous research results about the factors that influence dietary adherence in Type 2 Diabetes Mellitus adult patients using the systematic review method.

2. Research Methods

The method used in this paper was a systematic review. The article search was conducted using electronic databases: Scopus, ProQuest and Google Scholar. The keywords used in the article search were "dietary adherence" AND "diabetes mellitus patient" AND "qualitative study". The article search was limited from 2004 to 2018. The inclusion criteria for the study selection ere (1) explaining dietary adherence, (2) type 2 diabetes mellitus patients, (3) study design was qualitative and (4) adult patients.

The study excluded what didn't focus on factor influence adherence for diabetes patients, diabetes mellitus patients caused by gestational conditions and the diagnosis not being the focus (due to having other diseases besides DM), child patients and quantitative studies.

From Scopus, ProQuest, and Google Scholar, there were 372 studies identified. From the 372 articles identified, 86 articles did not have the full text available, 120 articles were not suitable according to the topic, 13 articles were duplicated and then the remaining 153 articles were re-selected using the inclusion and exclusion criteria. Finally, 16 studies were found that were suitable for review.

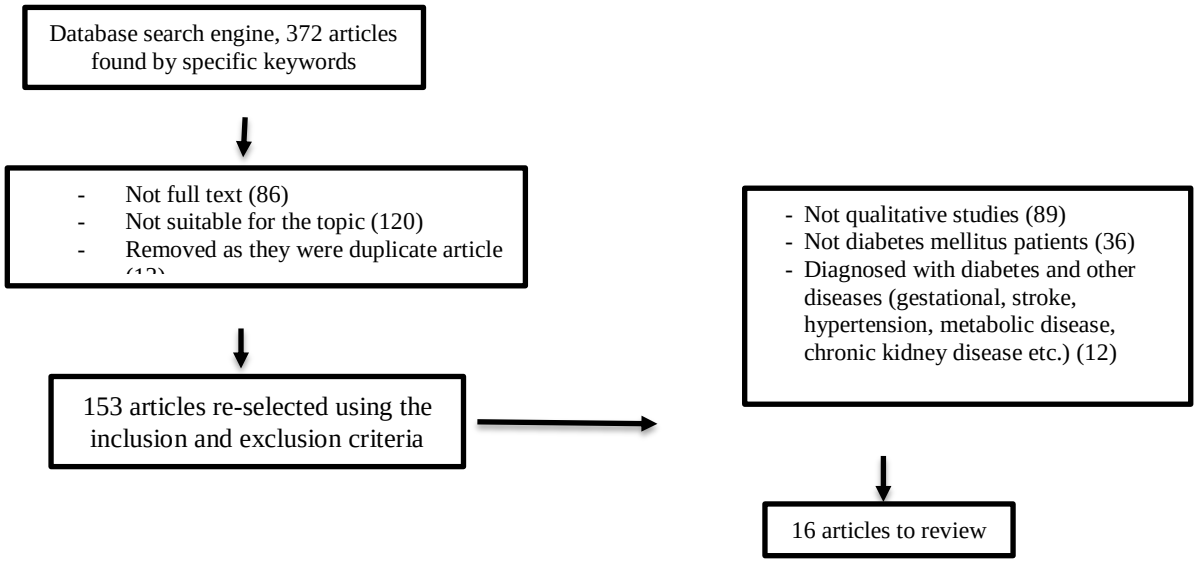

Figure 1. Article Search Scheme.

3. Results

Table A.1 Summary of the Evidence Studies

Title	References	Study Design	Variable	Results
Challenges to Healthy Eating Practices: A Qualitative Study of Non-Hispanic Black Men Living with Diabetes	Lee *et al.* (2016)	Qualitative study	Dietary practices, perceived barriers to healthy eating	The participants' self- reported eating practices did not always relate to hunger. Internal cues to eat included habit and as a response to emotions, and the external cues to eat included media messaging, medication regimen and work schedule. Men identified multiple barriers to healthy eating including hard breaking habits, limited resources, and the availability of food at home and in the neighborhood grocery stores, and perceived

				poor communication with health care professionals.
Factors influencing adherence to dietary guidelines: a qualitative study on the experiences of patients with type 2 Diabetes attending a clinic in Cape Town	Ebrahim *et al.* (2014)	Qualitative study using semi-structured interviews	Lived experiences of Type 2 Diabetic Patients, Diet Adherence	The main identified factors at the individual level were motivation, individual knowledge, the perceptions of moderation, self-responsibility, taste concept or cravings, and temptations. At the small group (family and friends) level, the family relations with the patients were identified as the main support system used to manage diabetes. At the organizational or health systems level, long waiting times and the theme of seeing different doctors emerged as problematic factors, but overall, the patients were satisfied with the clinic service. At the community and policy level, culture and the cost of food were identified as the key influential factors with regard to adherence to nutrition care guidelines.
Knowledge and perceptions about diet	Ranasinghe *et al.*	Qualitative Study using	Knowledge and	All were aware of the importance

and physical activity among Sri Lankan adults with diabetes mellitus : a qualitative study	(2015)	FGD and verbatim recorded	perceptions about diet and physical Activity for diabetes patients	of diet in the management of DM. But most had difficulty in incorporating this knowledge into their lives, mostly due to their social circumstances. The majority described a list of ‘good foods’ and ‘bad foods’ for DM. They believed that ‘good’ foods can be consumed at all times, irrespective of quantity and that ‘bad’ foods should be completely avoided. Many believed that fruits were bad for diabetes, while vegetables were considered to be a healthy food choice. The majority thought that there were ‘special’ foods that could help to control blood glucose, with the most common being curry leaves and bitter-gourd. Most of the study participants were aware of the importance of being physical active. However, there was lack of consensus and clarity with regards to the type, duration, timing and

				frequency of physical activity.
Dietary Pattern of self care among Asian and Caucasian diabetic patients	Meeto (2004)	Qualitative study using semi-structured interviews and a 7-day health diary to explored self care activities	Self care, Self help group, Nutrition and diet	Diet-related health actions are influenced by a host of interrelated factors, which include individual differences, social and cultural influences and the nature and experience of diabetes itself. Efforts to promote self-care must take into account the breadth of these factors and encompass both individual and sociocultural initiatives.
Support systems for and barriers against diabetes management in South Asians and White Europeans in the UK	Singh*et al.* (2012)	Qualitative study using semi-structured interviews with an interpretative phenomenology analysis	Support system and the barriers to diabetes managemen t	Both South Asian and White participants emphasized adherence to dietary recommendations as being the most difficult aspect of living with diabetes. In addition, the social stigma attached to diabetes was a prominent concern among South Asian participants that seemed to have a significant negative impact on their diabetes control and overall management. Given the South

				Asian patients' reliance on their family for the management of their condition, intervention targeting to improve the diabetes outcomes in this population may prove more successful if they are designed to involve significant family members.
Pengalaman Ketidakpatuhan Pasien terhadap Penatalaksanaan Diabetes Mellitus	Purba *et al.* (2008)	Qualitative Study : Studi Fenomenologi	Non-adherence, diabetes managemen t	There were seven themes of non-adherence in diabetes management: unpleasant diet foods, not understanding the benefits of the diet, not understanding the benefits of physical exercise, age, limited physical exercise, mistaken understanding about the benefits of the drugs and failing to take the medication for economic reasons.
"I've made this my lifestyle now": a prospective qualitative study of motivation for life style change among people with newly diagnosed type two diabetes mellitus	Sebire *et al.* (2018)	Qualitative study	Motivation, behavior change, intervention	The findings revealed the diversity in motivation quality both between and within individuals over time and that patients with newly diagnosed diabetes have multifaceted and often competing

				motivations for lifestyle behavior changes. Motivation for lifestyle change following diagnosis with type two diabetes is complex and can be relatively low in self determination. To achieve patient empowerment regarding the aspirations of the current national health care plans, intervention developers and clinicians would do well to consider the quality and not just quantity of their patient's motivation.
"We should change our selves, but we can't" - accounts of food and eating practices amongst British Pakistanis and Indians with type 2 diabetes	Lawton *et al.* (2008)	Qualitative interview study	Food, diet, identity, Pakistani, Indian	Despite considerable diversity in the dietary advice received, the respondents offered similar accounts of their food and eating practices following diagnosis. Most had continued to consume South Asian food, especially in the evenings, despite their perceived to concerns that these foods could be "dangerous" and detrimental to their diabetes control. One respondent described such food as "strength-

				giving', and highlighted a cultural expectation to participate in acts of commensality with family/community members. The male respondents often reported limited input into food preparations. Many of the respondents attempted to balance the perceived risks of eating South Asian foodstuffs against that of alienating themselves from their culture and community by eating such food in smaller amounts. This strategy could lead to a lack of satiation and it is not recommended in the current dietary guidelines.
Perceived impact of Nepalese food and food culture in diabetes	Sapkota *et al.* (2017)	Qualitative study	Diet management, food culture, perceptions, Nepalese, behavior	Perceived dietary restriction requirements created social and emotional discomfort in the patients. Meals high in carbohydrates, limited food choices, and food preparations

				methods were identified as barriers, particularly in Nepal. In Australia, the participants reported greater availability and easier access to appropriate food and healthier cooking options. The socio-cultural aspects of food behavior, mainly food practices during social events, were identified as significant barriers.
Patients' perspective of disease and medication adherence for type 2 diabetes in an urban area in Bangladesh: a qualitative study	Islam *et al.* (2017)	Qualitative study	Medication adherence, compliance, perception, glycemic control, Bangladesh	The data analysis generated rich information on the participants' knowledge and perception of diabetes. They also reported numerous misconceptions about the disease. Knowledge on diabetes medication, its appropriate use and its side effects were rather poor. The

				respondents also reported non-compliance to the dietary and physical activity advice by their physicians and concern with diabetes diabetes-induced psychological stress.
A qualitative study to explore the perceptions and behavior of patients toward diabetes management with physical disability	Gillani *et al*. (2017)	Qualitative study	Patient education, disease understanding, counseling	When the participants were asked in their opinion what was the preferred method of recording the blood glucose test, several participants with a low socioeconomic status and who were either divorced or widowed denied adapting to telemonitoring, instead preferring to record manually. There were mixed responses about the barriers to controlling diet/calories. Even patients with a high

				economic status, who were of middle age (35-50) and who had a diabetes history of 5-10 years were influenced towards alternative treatments.
Determinanketidakpatuhan diet penderita Diabetes Mellitus Tipe 2	Al Tera (2011)	Qualitative study	Dietary adherence, diabetes mellitus	The results of 13 studies showed that there were no respondents who made the appropriate eating arrangements concerning the amount of energy, the type of food, and scheduled meals as recommended. Predisposing factors are a lack of knowledge, a lack of confidence about the effectiveness of their diet, and misperceptions about the seriousness of the disease. The enabling factors are the lack of availability and affordability of nutrition

				education and counseling facilities. The reinforcing factors are a friend's suggestions, a lack of family support and a lack of education and counseling support from health workers.
Considerations affecting the dietary behavior of immigrants with type 2 diabetes: a qualitative study among Surinamese in the Netherlands	Kohinor *et al.* (2011)	Qualitative study	Dietary behavior, Suriname ethnic minority, type 2 diabetes	Suriname food was eaten regularly by all of the respondents. Most of the participants were aware of the need to change their diet but they reported difficulty with changing their dietary behavior to meet the dietary guidelines. Many perceived these guidelines to be based on Dutch eating habits, making it difficult to reconcile them with Suriname cooking and eating practices. Firstly, the respondents

				indicated that they did not choose foods based on their nutritional qualities. Instead, the choices were based on Surinamese beliefs regarding "good" (e.g. bitter vegetables) or "bad" (e.g. spicy dishes) foods for diabetes. Secondly, the respondents often perceived recommendations such as eating at fixed time as extremely important since the respondents perceived these to be a core element of their identity as Surinamese
Understanding the experiences of participating in a weight loss lifestyle intervention trial; evaluation of South Asians at high risk of diabetes.	Morrison *et al.* (2014)	Qualitative study	Dietary adherence, life style modification intervention, diabetes mellitus	Many of the participants were motivated to participate because of a known family history of diabetes and the desire to better understand diabetes-related risks to their

own and their family's health. They wanted to know the ways to mitigate the risks and to benefit from personalized monitoring. Home-based interventions, communication in the participant's chosen language(s) and continuity in the dietitians support were made a part of their continuing engagement with the trial. Adaptations in terms of food choices were initially accommodated by the participants, although social and faith-based responsibilities were reported as being important barriers to persevering with agreed dietary goals. Many of the participants reported that increasing their

				level of physical activity was difficult given their long working hours, physically demanding employment and domestic commitments. This being compounded by Scotland's challenging climate and a related reluctance to exercise in the outdoors.
Diabetic patient's compliance to the recommended treatment: a qualitative study in Greece	Krepia *et al.* (2011)	Qualitative study	Dietary program, compliance, diabetic patients	Passivity, un-readiness, weakness to accepting the disease, ignorance about the illness and its complications, poor doctor-relations, insufficient family support, the environment, an insufficient variety of tasty foods, chronic exhaustion, and the complexity of the illness were shown to be detrimental toward the patient's progress. Health

				education can help diabetic patients to address issues such as diet or exercise, and it can recommend a healthy dietary program which regulates the glucose levels and avoids complications.
Patient Perspective on Factors Contributing to Non-adherence to Dietary Therapy: A qualitative study in Multicultural Population of Kedah, Malaysia	Mohd *et al.* (2018)	Qualitative study	Non-adherence, diet therapy, DM type 2	The main factors that affected the diabetic patients' dietary adherence were "individual preference", "family support" and "social and cultural activities". It is difficult to change the exciting meals, there is poor family support, there is the practice of eating out, and social culture gatherings were among the factors that influenced the diabetes patients' adherence toward dietary therapy. Most challenges were

	related to the social role of food in the multicultural population. Therefore, in addition to family and community involvement, dietary therapy should be individualized to improve patient adherence.

\both the participants and their cultures. One study was conducted on 34 non-Hispanic black men in Birmingham in the Alabama area [10] and another study was conducted on 50 adults suffering from diabetes in the National Hospital of Sri Lanka [11]. In another study, it described the selection of the participants who had two differences in their cultural characteristics, in which there were 25 Asians and 25 Caucasians. Asians were defined as those with an Indian sub-continent background while Caucasians referred to anyone who was White European. One of the factors considered to be important in the sampling was the influence of ethnicity on adherence to diet since the incidence rate of diabetes has shown a dramatic rise among Asian populations. This pattern is reflected in other ethnic communities[12].

Some of these studies indicate being *culturally influenced* as one of the factors that made adhering to the diet as difficult to do. Research conducted by [13] described that most had continued to consume South Asians food especially in the evenings, despite their perceived concerns that these foods could be "dangerous" and detrimental to their diabetes control. One respondent described such food as "strength-giving', and highlighted a cultural expectation to participate in acts of commensality with family/community members. The male respondents often reported having a limited input in food preparations. Many of the respondents attempted to balance the perceived risks of eating South Asian foodstuffs against those of alienating themselves from their culture and community by eating such food in smaller amounts. This strategy could lead to a lack of satiation and it is not recommended in the current dietary guidelines. Another study also found that social culture gatherings were among the factors that influenced the diabetes patients' adherence toward dietary therapy. Most of the challenges were related to the social role of food in a multicultural population[1].

The results from this systematic review also found that both South Asian and White participants emphasized adherence to dietary recommendations as the most difficult aspect of living with diabetes[14]. In Australia, the participants reported greater availability and easier access to appropriate food and healthier cooking options. The socio-cultural aspects of food behavior, mainly food practices during social events, were identified as significant barriers[15]. Another study

conducted by [16], which explored the dietary behavior among the Surinamese in the Netherlands, showed that most of the participants were aware of the need to change their diet but they reported difficulty when it caem to changing their dietary behavior to meet their dietary guidelines. Many perceived these guidelines to be based on Dutch eating habits, making it difficult to reconcile them with Suriname cooking and eating practices. Firstly, the respondents indicated that they did not choose foods based on their nutritional qualities. Instead, the choices were based on Surinamese beliefs regarding "good" (e.g. bitter vegetables) or "bad" (e.g. spicy dishes) foods for diabetes. Secondly, the respondents often perceived recommendations such as eating at a fixed time as extremely important since the respondents perceived these to be a core element of their identity as Surinamese.

Besides the cultural factors, dietary adherence behavior is also influenced by *individual factors*. Many of the participants were motivated to participate because of a known family history of diabetes and the desire to better understand diabetes-related risks to their own and their family's health[17]. A study conducted by [12] found that diet-related health actions are influenced by a host of interrelated factors, which include individual differences, social and cultural influences and the nature and experience of diabetes itself. Another study also showed that other individual characteristics like marital status, age, social economic, and the time period during which they had been suffering from diabetes also influenced the patients when they did diabetes self-management, including dietary adherence[18]. Even patients with a high economic status who were middle aged (35-50 years old) and who had a diabetes history of 5-10 years were influenced towards alternative treatments. A study which was conducted in an urban area in Bangladesh also found that individual psychological stress which was stimulated by their concern with diabetes could influence non-adherence to the dietary and physical activity advice given by their physicians[19]. This finding is in accordance with the study which found that passivity, un-readiness, weakness when it came to accepting the disease, ignorance about the illness and its complications were influencing dietary program compliance. These factors come from the individual's characteristics[20].

The third factor that also influenced the diabetes patient when it came to adhering to the dietary management was *knowledge*. This was found in a study conducted focused on type 2 DM patients at the Groote Schuur Hospital Diabetes Clinic in Cape town[21]. In the study and among the adults with diabetes in Sri Lanka, it was found that all of the participants were aware of the importance of diet in the management of DM. Most had difficulty incorporating this knowledge into their daiy lives mostly due to social circumstances[11].The data analysis generated rich information on the participants' knowledge and perception of diabetes. They also reported numerous misconceptions about the disease. The knowledge of diabetes medication, their appropriate use and the side effects was rather poor[19].

Another factor that influenced dietary adherence was perceptions *about diet*. Perceived dietary restriction requirements created social and emotional discomfort in the patients [15]. A study conducted in Indonesia also found that predisposing factors to dietary adherence besides knowledge include a lack of confidence about the effectiveness of the diet, and misperceptions about the seriousness of the disease[22]. Patients who do not understanding the benefits of the diet were also an influence toward the patient's dietary adherence [23].

The fifth factor that influenced dietary adherence was *motivation*. The findings revealed the diversity in motivation quality both between and within individuals over time and that patients with

newly diagnosed diabetes have multifaceted and often competing motivations for their lifestyle behavior changes. The motivation for lifestyle change following the diagnosis of type two diabetes is complex and can be relatively low in self-determination[24]. The motivational descriptions of individuals who had been newly diagnosed with type 2 DM patients in this study were amotivation, external motivation, identified motivation, integrated motivation, and intrinsic motivation.

The sixth factor which also influenced dietary adherence was social support. Sources of social supports can be obtained from one's family, friends, health workers, other patients and other communities with diabetes. At the small group (family and friends) level, family relations with the patients were identified as the main support system used to manage diabetes[21]. At the organizational and health systems level, long waiting times and the theme of seeing different doctors emerged as the problematic factors but overall, the patients were satisfied with the clinic's services. This is in accordance with the study conducted[22], which also found that the enabling factors for dietary adherence are the lack of availability and the affordability of nutrition education and counseling facilities. The reinforcing factors are a friend's suggestions, a lack of family support, a lack of education and counseling supports from the health workers, just like in [20],[1]which found that poor doctor-relations, insufficient family support and the environment as the social support had impact on dietary adherence among type 2 diabetes patients.

The barriers to dietary behavior was the next factor that influenced dietary adherence. Some of these barriers were unpleasant diet foods [23], taste concept or cravings and temptations[21], hard to break habits, limited resources, the availability of food at home and in neighborhood grocery stores, the perceived poor communication with health care professionals[10], meals high in carbohydrates, limited food choices, and food preparations methods s, particularly in Nepal[15]. The internal cues to eat include habits and as a response to emotions, and the external cues to eat included media messaging, a medication regimen, and their work schedule[10].

The menu of the diet was the last factors found in the studies reviewed in the systematic review. The majority described a list of 'good foods' and 'bad foods' for DM. They believed that 'good' foods can be consumed at all times, irrespective of their quantity and that 'bad' foods should be completely avoided. Many believed that fruits were bad for diabetes while vegetables were considered to be a healthy food choice. The majority thought that there were 'special' foods that help to control blood glucose, with the most common being curry leaves and bitter-gourd [11].The results also showed that an insufficient variety of tasty food had an impact for dietary adherence[20]. The other was the difficulty of changing from exciting meals [1].

4. Discussion

Based on the journals that have been reviewed in this systematic review, it can be seen that cultural factors are one of the important types of factors that can influence the compliance of diabetics undergoing a diet. This is because there are certain cultures that have certain beliefs related to foods, the selection of foods, and how to process food, such as the belief in "good" food and "bad" food[16], "dangerous" foods and food as being "strength giving" [13]. The relations of foods with culture is also associated with the community and the typical habits in that community, like the perceptions of South Asian foodstuffs necessarily being comprised of "risky" options. It is perceived that the dietary guidelines are made based on "Dutch" habits or another culture, so the people - for example, like the Suriname people with diabetes - do not want to follow the dietary guidelines because they are of the

belief that their habits of cooking and eating practices are related to deeply rooted cultural beliefs and values.

The patients preferences or individual factors including age, social economic, marital status, psychological stress, diabetic history and the family history of diabetes have an influence on the dietary adherence of diabetic patients. This is because individual factors relate to the patient's awareness, ability and responsibility when it comes to adhering to the dietary program and understanding the concept of calorie counting in the diet modification plan. The majority of the participants with an age that was >40 years and with a diabetes history >11 years showed concern about financial conflicts. However, the patients age >60 years were either dependent on another caregiver for their blood glucose monitoring or they were usually reluctant to self-monitor with a limited experience of diabetes-related symptoms[18]. The psychological stress associated with diabetes often negatively affects the patient's ability to maintain the rigors of the recommended treatment and care. The respondents often lamented on the restrictions imposed by diabetes on their food habits [19].

As knowledge and the perception of diet are interconnected, where and when the knowledge gained by diabetic patients is good, their perceptions about diet become appropriate. Purba, Sitorus and Afiyanti (2008) described the association between the misperception of diet and the wrong knowledge level where the diabetic patients think that the benefit of diet is to reduce the level of sugar. They also think that the dietary limitations can be violated occasionally, that the diet is about reducing sweet foods or only lessen the sugar. Snacks can be included in the diet as long as it is low, the portion in the diet is not known well, and the patients could take cookies as a snack as long as they did not use sugar as an ingredient.

Diagnosis with T2DM provokes a range of emotional responses, including the close scrutiny of the patients' lifestyle, the threat to people's social life and personal identity and the need to construct a new identity representation. It is not surprising therefore that many of the participants' motivation for change was controlled or not self-regulated. The external motivation for diet or physical activity change was experienced as the participants complied with what they perceived to be restrictive dietary advice through a fear of non-compliance (i.e., "lapses") being identified in the appointments and assessments [24]. This was supported in the findings, stating that the participants often experienced these motivations concurrently, by complying with recommendations and labeling themselves as "good" or "naughty" and their behavior as "right" or "wrong" based on the extent to which their behavior change was successful. However, there is a when the diabetic patients are in an amotivation condition, which is defined as being reluctant to change and it is articulated as a passivity towards any changes reported. Ignoring one's diabetes, feeling helpless, not being able to change or being resigned to one's current way of life and not believing the health benefits of recommended treatments could be barriers to dietary adherence.

The social life of diabetic patients is one of the most important factors [20]. The most prevalent reasons behind the diabetic patients' dietary non-compliance are feelings of shame, feeling tired of the need to explain their condition to others and feeling deprived of foods that others enjoy in front of them[20]. The support needed by the patients with this condition can be obtained from their family friends, or health workers. A lack of family support is because the family thought that the patients understood how to manage their meals. Friends also having a role in the spreading of terms and perceptions that are not true about DM, and the lack of support from the health workers is because

of the limited amount of health workers that are available to give nutrition counseling and health education [22]

The others factors associated with the taste concept are habit, how to create the right menu of diet including how to get good ingredients for making foods, managing the patients' time due to their activities and their adherence to their diet. Findings from the other studies have [10]highlighted the importance of integrating a culture-specific menu and meal planning and promoting the foods to eat more of, as opposed to a negative focus on the foods to restrict. It is important to discuss the socio-economic barriers to healthy eating as the diabetes-self management strategies are often designed, as it was found that African American areas in Louisiana have more convenience stores than supermarkets, potentially limiting access to foods such as fresh fruits and vegetables while increasing the availability of snack foods. Other barriers may result from a combination of external factors (e.g. jobs, school and family) and there is the perception that prepared healthful meals are excessively time-consuming. The participants' perception of limited access to healthy foods may thus be related to a lack of access to convenient, easy-to-prepare forms of healthy food (e.g. prepackaged prepared and inexpensive foods) as well as to a lack of knowledge about how to quickly prepare foods using available healthy ingredients. Several interviewed patients feel that changes in meal pattern and reducing the meal portions were not suitable for them. Some of the common quotes from them suggest that the dietary advice recommended was not tailored to the local culture and their personal preferences[1]

The limitations of this systematic review are that all of the studies used in this study are not focused on diet. They also involve other things related to diabetes patients, such as motivation, self-care and other components of diabetes management (medication adherence, physical activity etc. as seen in the appendix). A deeper discussion about non-adherence to diet and the factors that influence it is very limited. The most notable differences in this study are that there were studies that purely discussed the dietary inhibitors as related to the cultural factors only such as the research conducted [13], [15], [16], while there were also studies that discussed the factors that originate in individual patients such as knowledge and the perceptions of diet, motivation and the individual factors carried out by [11], [21], [1] Other studies have also discussed the factors outside of the individual, especially support during the diet and dietary barriers (see appendix).

5. Conclusion

Diet is one diabetes management strategies used to reach a point of good blood glucose control for type 2 diabetic patients. To reach this goal, the patients cannot reach this aim by themselves. They are in need of support from their social life and support from policy makers is also needed, especially when it comes to making a dietary program for diabetic patients that is suitable and in line with the recommendations. This is because although the current dietary program has enough promotion from the health workers to the diabetic patients, their adherence is still low. There are some factors related to this: culture, individual factors, knowledge, perceptions about diet, motivation, social supports, barriers to dieting, and the menu of their diet. The most influential factor is culture.

These factors make it difficult for type 2 diabetic patients to adhere to their responsibility of following the dietary program, meaning that blood glucose control becomes unachieved. From the sixteen journals reviewed, a dietary program needs to consider all of these factors, especially those

related to culture and the habits of the diabetic patient's community. As the American Diabetes Association has suggested, dietary therapy should be individualized according to personal preference (tradition, culture, region, health beliefs) and their metabolic goals. These findings could be a reference for health workers to plan an alternative intervention that is more suitable to applied to improve the dietary adherence of Type 2 DM patients.

Further studies should be able to explore more of the non-adherence that is culture-based concerning the diets of different individuals and their respective backgrounds, because the results of the studies of this systematic review indicate that cultural differences and individual characteristics give different results for understanding diet and dietary behavior. The nursing practical implications from the results of this review include and incorporate the discovery of the various factors that influence dietary adherence in Type 2 DM patients. This can be some of the input for further research to explore this in greater depth and with more focus for each of the themes.

USE OF THE TERM RESILIENCE IN ADULT CANCER PATIENTS: A SYSTEMATIC REVIEW OF QUALITATIVE STUDY

ABSTRACT

Resilience is a dynamic process of positive adaptation to adversity, including cancer. While the term is used frequently by researchers, controversy exists over its conceptualisation and little is known if and how cancer patients use the term resilience. We examined qualitative studies exploring cancer patient experiences of resilience to understand: (a) definitions of resilience as identified by patients and researchers and (b) the themes relating to attributes of resilience as identified by patients. The literature review was conducted through SCOPUS, MEDLINE, PsycINFO, and CINAHL databases were searched from database inception to November 2017, identifying qualitative studies of adult cancer patients/survivors. Thematic analysis was used to code studies and generate analytical themes, and a single author identified definitions of resilience within the studies. After reviewing 573 citations there were only 32 studies that were suitable. Four thematic categories emerged; coping strategies, social support, spirituality, and growth. Eight researcher definitions and no patient definitions of resilience were identified. This review does not find a definition of cancer resilience. Patients and cancer patients rarely use the term resilience directly, rather than identifying coping strategies, social support, growth, and spirituality as attributes related to resilience.

Keywords: resilience; qualitative; coping strategies; social support; spirituality; growth

1. Introduction

Resilience, a dynamic process of positive adaptation within the context of significant adversity [1], has been linked to various positive health outcomes, including reduced psychological distress, protection from depression, and improved quality of life [2,3]. However, despite the vast body of literature regarding resilience, significant controversy exists about its conceptualization and there is a lack of consistency regarding how the term resilience is used and defined [1].

While some researchers use the term resilience to describe pre-existing personality traits, others regard it as a dynamic process of adaptation that develops over time, while a third perspective argues for resilience as a psychosocial outcome [1,4]. An integrated biopsychosocial approach to resilience harmonizes all of the prior definitions by the concept of resilience being the psychological equivalent of a somatic immune system, protecting against adversity through multi-level defense mechanisms [5]. Thus while some resilience mechanisms may be innate/pre-existing, others may be developed through individual adaptation, or through external influences. Furthermore, when exposed to adversity, resilience may grow in effectiveness through behavioral immunization, allowing for a more effective response to that specific adversity in the future [6].

The concept of resilience has attracted considerable interest in cancer. A diagnosis of cancer represents substantial adversity and it is often associated with significant physical and emotional distress, at times resulting in mental health conditions such as depression and anxiety [1]. Resilience promoting interventions would seem to be advantageous for cancer patients but at present, evidence for such interventions is limited in the cancer setting, with individual results ranging from no statistically significant change in quality of life, to reduced distress and improved quality of life [5]. One reason for this may be a lack of consistency in how the term resilience is used and defined within the oncology setting.

To date, there have been two reviews of resilience in adult cancer care. Eicher and their colleagues undertook a review of 11 quantitative papers with the aim of describing the current scientific perspectives of resilience in adult cancer care and their implications for cancer nursing [3]. They defined resilience as a dynamic process of facing adversity related to cancer and confirmed the association of resilience with improved health outcomes, recommending the development of a conceptual framework for nursing interventions and the refinement of scales/instruments to measure resilience [3].

Molina and their colleagues reviewed 57 papers to describe the ways in which elements of resilience have been defined and studied at each phase of the cancer continuum from risk assessment/screening through to survivorship and end of life. They concluded that as the stress and adaptation required at each phase may be different, each phase of the cancer experience has unique as well as shared aspects of resilience. In all phases of the cancer continuum, the resilience attributes included baseline characteristics, mechanisms of adaptation and psychosocial outcomes [6]. In the statement of the limitations of their reviews, Molina acknowledged the diversity of the definitions, literature, and study design, while Eicher acknowledged the exclusion of qualitative studies on resilience.

Reviewing the qualitative literature that focuses on patient usage of the term resilience may add to the conceptual definitions of resilience but to date, no systematic literature review has synthesized the qualitative research in adult cancer care examining how patients use the term resilience in their day-today life. To address this gap, the aim of the present review is to enhance the understanding of cancer patients' use of resilience with a focus on the following questions: [1] 'What are the definitions of resilience as identified by patients and researchers/study authors?' and [2] 'What are the themes relating to the attributes of resilience as identified by the patients?'

2. Research Methods

This review followed the guidelines from the Enhancing Transparency in Reporting the Synthesis of Qualitative Research (ENTREQ) statement [7].

2.1 Inclusion and exclusion criteria

To meet the inclusion criteria, the studies needed to have a qualitative design, to be printed in English and to include patients or survivors over the age of 18 with any type or stage of cancer. Qualitative studies were defined as using qualitative methods of data collection, such as interviews and focus groups and using qualitative data analysis methods such as thematic analysis or discourse analysis. The studies needed to include "resilience" and "cancer" (or a derivative) in their title,

abstract, or keywords and in the full text. Studies were excluded if resilience was not a theme or outcome, if it was studied primarily from the perspective of non-patient members (family members or caregivers), or if it was defined in the context of a group rather than an individual (i.e. family resilience).

2.2 Search strategies

A pre-planned comprehensive search of four electronic databases (SCOPUS, MEDLINE, PsycINFO, and CINAHL) was conducted to identify all of the relevant studies between database inception and the the end of November 2017. The search strategy (initially created in MEDLINE then accurately translated for the other databases) involved using database-specific controlled terms (where available) and the key words "resilience" and "cancer" (or derivatives such as melanoma), as well as Boolean operators in the title and abstract and medical subject headings. Qualitative studies were identified by using the keyword "qualitative" and searching for studies using qualitative methodology, such as phenomenology or qualitative analysis methods. A single author screened the study titles and abstracts to identify the studies for a full-text review. An example of the search strategies used has been provided in Figure 1.

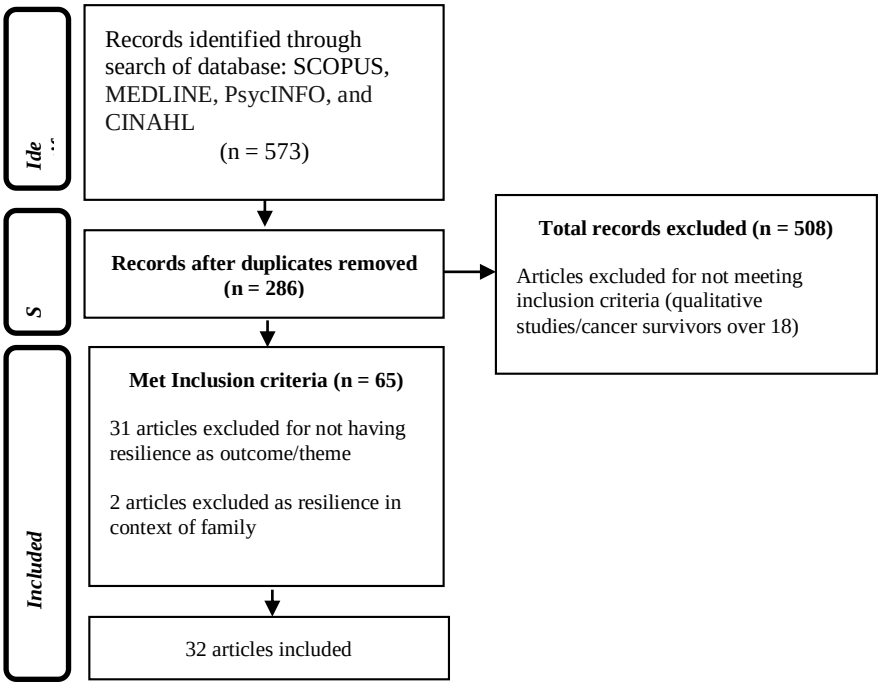

Figure 1. Diagram summarizing the search of the literature

3. Results

3.1 Definitions of resilience

No patient definitions of resilience were identified within the reviewed studies, and the patient's usage of the term resilience was only reported in a single study [8]. Resilience was explicitly defined eight times by the researchers in the included studies with varying definitions as shown in

Table 1. Four definitions described a process of adaptation to adversity or threats [9], with one study explicitly noting the adaptation as being positive [10]. Two definitions described resilience as a phenomenon of maintained or recovered psychological health after adversity [10,11], with one study adding the concept of physical changes and suggesting the notion of "growing past" [10]. One study defined resilience as "a comprehensive process, including existential meaning making, selection and optimization (of goals) and growth" [8], and the final study defined resilience as having three main components: social embeddedness, positive life perspective, and personal resourcefulness [12].

3.2 Themes of resilience

Figure 2 depicts the conceptual map of the themes identified in the thematic analysis. A full list of themes can be found in the supplementary material. Seventy-nine unique themes of resilience were initially identified as used by the authors of individual studies, which were then combined based on similarity. Studies contributed between one and four individual themes, with each study contributing a mean of three individual themes. Four overarching thematic categories emerged and they were ordered according to prevalence: (1) coping, (2) social support, (3) spirituality, and (4) growth. Fourteen studies identified resilience themes within only one category, fifteen studies identified themes within two categories, two studies identified resilience themes across three main categories, and one study identified themes across all four categories. Spirituality, growth, and social support were commonly grouped with coping strategies due to the plethora of coping strategies raised as a theme, and spirituality was associated with coping in all but one study [8]. No other clusters of themes were evident within the analyzed studies.

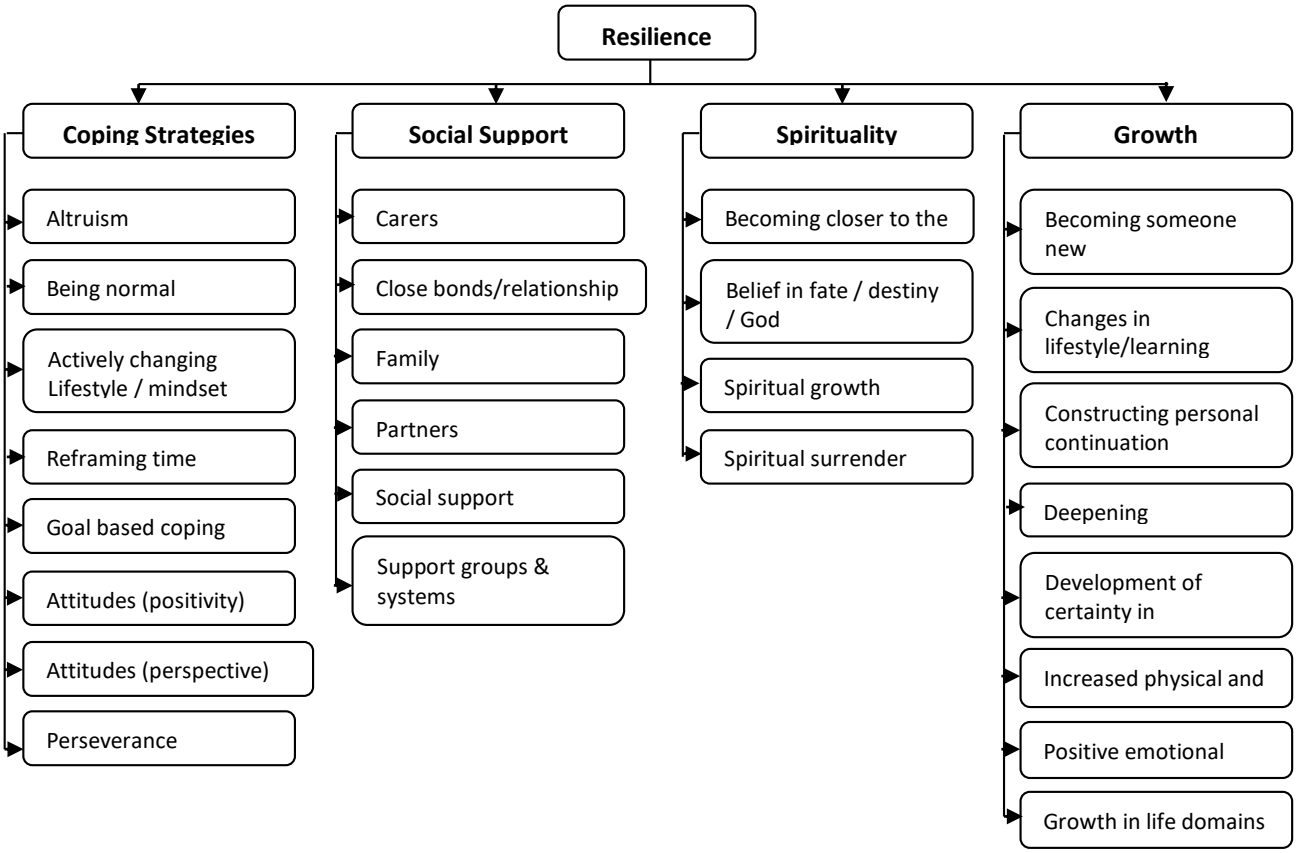

Figure 2. Conceptual map of themes of resilience

Coping

The thematic category most commonly associated with resilience was coping with the stressors of the cancer experience, which was identified in all but one study [13]. Themes related to coping emerged 55 times across all studies and they were further summarized under the following eight subordinate themes: positivity, perspectives, perseverance, being normal/denial, actively changing lifestyle and mindset, reframing time, altruism, and goal-based coping, as summarized in detail below.

Maintaining a positive attitude was a frequently discussed coping strategy, succinctly expressed in one study as "if I was a negative person, I wouldn't be sitting here with you today". Variations of positivity as a theme of resilience included thinking positively and remaining positive [14], having the right mindset [15], being grateful [10], and seeing the bright side [2,10,14,15]. The perspectives of the patient helped to shape their coping strategies, with studies describing this theme as acceptance of their diagnosis, being self-reliant [9], or identifying the meaning of life and the situation [12]. Being pragmatic and seeing things in perspective were variants of this theme [14,16].

The concept of persevering through cancer-related stress is another coping strategy that the patients used frequently. One study identified this theme as "doing what has to be done" [9], and another patient recounted her experience of perseverance as "these are challenging times and may be rough times, but keep on" [26]. Others described this theme as inner strength [17], not giving up [10] or stoicism [18]. Perseverance was described in one study as the process of handling decline and loss, where the patients endure tough treatment periods to have a life prolonging effect [9]. In contrast, the concept of "toxic" resilience was raised, where the patient's drive to stay resilient eventually becomes problematic and counterproductive to quality of life in the participants [18].

Another coping strategy displayed was the concept of being "normal", with one patient stating "I think what I wanted to preserve was the absolute preciousness of normality" [19]. This was achieved through methods such

as minimizing the impact of cancer [20], avoiding conventional sick roles [14], maintaining normal life [9], and coping through distractions, such as work [5,12]. Some of the patients sought to cope by actively changing one's mindset and lifestyle, with variations of this theme including being more flexible [16], dealing with adversity [17], embracing paradoxes [21], existential meaning making through selection and the optimization of goals [8], finding ways to keep going [21], and having a voice in their treatment [13]. Reframing time was another common mechanism of coping [21], with another related strategy being living in the present [21]. Other coping strategies included helping others/altruism [22], the assimilation or accommodation of cancer through goal-based coping [18,19], and surrendering to life impermanence and circumstances [23].

Social support

Resilience was commonly described in relation to a background of receiving support from friends, family, the community and health care workers, and this was described 10 times as a theme of resilience. A study conducted in the USA on 13 older adult patients with lung, prostate, or digestive system cancers stated that social support contributed to resilience and that it held symbolic and literal

meaning for patients, suggesting that this was one aspect of resilience which allowed them to maintain and grow past their previous level of functioning. Conversely, the participants characterized as non-resilient were described as being remarkable in their lack of social support [10]. Similarly, another patient described the support that her family provided as "My family never left me alone … if it was not for them, I do not know what I would have done" [5]. The importance of supportive relationships was further shown in another study when women resilient to distress had stable, supportive families, while the sole participant with a lack of family support displayed distress [24]. Other social supports discussed included partners and ex-partners [3,25], children, friends, religious and social groups and healthcare professionals [17].

Growth

Growth, described as growth in one or more life domains following exposure to cancer-related stressors, was raised as a theme of resilience nine times across all of the identified studies. Patients resilient to distress often demonstrated growth in at least one domain including changes in worldview, faith, and family relations [9]. Growth as a theme was identified as becoming someone new, with new values, causing the patients to become more resilient [20]. One study described the process as the deepening of connections with others and spiritual forces, stating that cancer "prompted everyone to connect with someone bigger" [23]. Another study discussed the development and growth of personal strength as a consequence of cancer, with one patient stating "I don't think there's any way I'd be so positive or determined. I think that totally came from that experience" [26]. Growth was not limited to cancer-related growth; mental/physical growth and improved self-esteem occurred in patients with cancer who practiced yoga [13].

Spirituality

Spirituality and religion were a theme of resilience in several of the studies, occurring nine times across all identified studies as a theme of resilience with eight unique themes. The idea of entrusting one's self to fate and destiny was expressed by one patient who stated "I believe nothing can happen without His (God) will … my prayers helped me and gave me strength" [22]. Other patients discussed cancer as being an opportunity to become closer to the Lord and they emphasized the importance of religion to their coping with cancer [15]. Spirituality was characterized in one study in the context of a "belief frame" ranging from traditional Christian faith to atheism, in which the participants experienced as something positive and contributory to resilience [8]. Spirituality-faith was similarly described in another study as expressing feelings of gratitude and being blessed. Patients who demonstrated spirituality were characterized by a general lack of fear [10]. A comparable concept was characterized as "spiritual surrender", which is a form of spiritual awakening which enables the patients to find inner peace and comfort by surrendering to impermanence [27].

4. Discussion

This systematic literature review aimed to determine the definitions of resilience as identified by researchers/study authors in examining patient experiences of resilience and to determine the themes relating to the attributes of resilience as identified by the patients. Our review showed that

the use of the term resilience by patients was rare. No studies included a patient definition of resilience, and only one study [9] included a patient using the term resilience. Whether this is because the patients did not use the word or because the researchers did not include the patient usage of the term is unclear. However, none of the studies included questions on what the term resilience meant to subjects. In fact, one of the included studies [10] explicitly stated that the usage of the term resilience was actively avoided by the researchers while formulating questions and that the term was never brought up during any of the interviews. Researcher definitions of resilience were lacking in the 32 studies included in the review. Only eight studies provided an explicit in-text definition of the term resilience. The most common definition to emerge from the included studies described a process of adaptation in response to threats or adversity. However, the definitions used varied widely, thus supporting the idea that resilience is poorly defined and potentially poorly understood. This may be one of the factors contributing to the varying effects of resilience as reported in the extant literature.

Although the term resilience was not commonly used by either the researchers or the patients, coping strategies, social support, growth, and spirituality were the most commonly identified attributes of resilience. Coping strategies were the most common theme, being represented in nearly every study, and it appeared as a stand-alone theme in more than half of the studies. Coping strategies included concepts such as positivity, perspectives, perseverance, being normal/denial, actively changing their lifestyle and mindset, reframing time, altruism, and goal-based coping. Social support was the next most common theme and it involves individuals receiving support from external sources, such as their friends, family, healthcare workers, and cancer support groups. Growth was another theme of resilience, with individuals exhibiting growth in various life domains. Spirituality emerged as the final theme, with the beliefs of the individuals contributing towards resilience. Coping strategies were the main theme most commonly grouped with other main themes, and spirituality was grouped with coping in all but one study [28], thus suggesting that spirituality may act as a coping mechanism as well as a main theme. Additionally, only the psychosocial aspects of resilience were identified as themes of resilience, suggesting that other aspects of resilience such as physical resilience were either not discussed by the patients, or not reported by the researchers.

One finding of interest was how growth was conceptualized as a theme of resilience. Although growth has been included in some definitions of resilience [10], most definitions refer to a return to baseline functioning [10]. This finding suggests that researchers may use the term resilience interchangeably with post-traumatic growth. Although a similar construct to resilience, post-traumatic growth is described as a “positive psychological change experienced as a result of the struggle with highly challenging life circumstances”, implying that individuals achieve a higher level of functioning than before the trauma [29]. This has been both positively and negatively associated with resilience [4]. While this does not discount growth as a theme of resilience, further research should be undertaken to investigate whether resilience is conflated with post-traumatic growth. It is unclear from the analysis of the studies whether the attributes of resilience were used to describe resilience as a process of adaptation, as an innate trait associated with resilient behaviors or as an outcome. Many of the individuals who appeared to be resilient displayed similar attributes such as positive or stoic attitudes and with good social support. Similarly, Lam et al. and Pentz [10,12] described individuals lacking in resilience as lacking social support, suggesting that resilience has characteristics of both a trait and a process facilitated by personal factors and resources, such as social

support. As this review was unable to determine whether resilience is best characterized as a trait, process, outcome, or as a combination of these descriptions, a longitudinal approach may be more appropriate to examine how resilience changes over time and thus to clarify its construct definition.

The current review has notable limitations. As many of the identified articles did not focus on resilience as a primary goal of analysis, the patient's usage and definitions of the term may not have arisen during the course of each study or they may have been omitted. Similarly, researchers may not have found it necessary to include their operational definitions of resilience if this was not a focus of their study, thus limiting the number of definitions found. Grey literature, such as dissertations, case reports, and non-published studies, were excluded. By not examining sources outside of traditional publishing channels, the review may have missed important sources of information which may have contributed to the understanding of resilience. Given the complexity of qualitative data, single author coding/analysis may lead to a loss of alternate interpretations of the data, and thus potential themes may have been excluded, although we have attempted to minimize this through a collaborative discussion of the dataset with other study authors.

Previous research have suggested that resilience is a developmental process unfolding over time and circumstances, with the determinants of resilience differing depending on global, cultural, and contextually specific aspects and challenges [6]. As the data was drawn from a global population of diverse sociocultural backgrounds with different cancer types and disease burdens, the relevance of our findings to specific cancer populations is limited. Additionally, the term "resilience" may not be used in non-English speaking backgrounds. Nine of the included studies were from countries where English is not the official language and another study explicitly sought participants who did not speak English as their first language. When translated into English, subtle cultural nuances of the term resilience may be lost.

5. Conclusion

This review found that patients are seldom quoted as using the term resilience, and that no cancer patient definitions of resilience were identified. Furthermore, the usage and definitions of the term resilience by researchers are notably inconsistent. While patients do not use the term resilience, they identify various coping strategies, spirituality and growth, and social support as important attributes commonly associated with resilience. Further research specifically identifying how cancer patients understand and use the term "resilience" is needed.

ABSTRACT

Hemodialysis (HD) is a kidney replacement therapy that aims to support kidney function for the care of individuals end-stage renal disease (ESRD), kidney function is replaced by an external dialyzer to filter blood so it is necessary to limit diet and fluid intake and manage medicines. Compliance with fluid and dietary restrictions needs a complex adaptation process because hemodialysis patients must try to change their diet, lifestyle, and culture. The purpose of this systematic review is to summarize the experience of hemodialysis patients in limiting diet and fluids. This systematic review is a synthesis of qualitative studies. Data is collected with a vulnerable time of 10 years from 2008-2018. An electronic database used to search for relevant keywords; Scopus, Medline, Proquest, and Science Direct. There are 16 best qualitative study articles found, qualitative research methods include, phenomenology, ethnography, grounded theory, mixed method, descriptive explanatory, and thematic analysis. There are 4 themes that often arise from each study identified: Understanding about dietary and fluid restriction, Experience of support, Experience of psychology, Experience of behavioral and Experience of financial. The experience of hemodialysis patients in restricting diet and fluids is faced with a variety of efforts and barriers, various experiences of hemodialysis patients can have implications in practice in the field in providing interventions to improve adherence to hemodialysis patients in diet and fluid restrictions.

Keywords: experience, hemodialysis patients, diet and fluid restriction

1. Introduction

Hemodialysis (HD) is a kidney replacement therapy that aims to support kidney function for the care of individuals with end-stage renal disease (ESRD), where the kidney function is replaced by an external dialyzer to filter the blood [1,2]. Dialysis therapy continues throughout life because dialysis does not cure ESRD but it does prolong their life, therefore limiting their diet and fluid intake and managing their medication needs to be done [3,4].

Restrictions on diet and fluids are the biggest challenges for hemodialysis patients. Fluid imbalances will cause an increase in their interdialytic weight gain (IDWG), which can be associated with increased blood pressure and increased cardiovascular risk. Dietary non-compliance will cause malnourishment, an increase in potassium and an increase in phosphorus in the body (E. Leigh Gibson et al., 2016). Compliance with the fluid and dietary restrictions requires a complex adaptation process because hemodialysis patients must strive to change their diet, lifestyle, and culture [6,7].

Non-adherence to fluids and diet in hemodialysis patients is quite high, with the non-compliance with fluid restrictions being 9,8-75,3% and 2-81,4% for diet [8]. Compliance with diet and fluid restrictions is a multidimensional phenomenon. There are six factors that influence the compliance of hemodialysis patients in terms of restrictions on their diet and fluids, namely knowledge, self-assessment, and th psychological, social, physical and environmental factors. The factors that are most commonly felt by hemodialysis patients when limiting their fluid and diet are the psychological factors. The psychological factors that are often felt by the patients are feeling boredom, discomfort, distress, and other emotional responses when limiting their diet and fluids [9–12]. The knowledge factor (education) is a supporter of adherence, as it is a component of knowledge that is effective and cognitive that affects the psychomotor responses (behavior). Providing education to hemodialysis patients about heir and fluid restrictions can effectively affect their behavior and compliance measures [13,14].

The aim of this systematic review was to summarize the experience of hemodialysis patients who were limiting their diet and fluids by synthesizing the existing qualitative studies to inform them of the hemodialysis facilitators and clinical research.

2. Methods

2.1 Design

The design of this study was a systematic review of qualitative study approach that was formulated to review the relevant qualitative studies and to put forward a comprehensive analysis. This systematic goal was developed based on the PICO (Patient, Intervention, Comparison, and Outcome) framework model [15]. *This systematic reporting structure used PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) [16].*

2.2 Inclusion and exclusion criteria

This systematic review established an inclusion and exclusion criteria that focused on qualitative studies and mixed method studies that partly used a qualitative approach. A feasibility study was conducted to describe the experience of hemodialysis patients in limiting their diet and fluids tie into the language eligibility criteria with minimal abstracts using English. The year of publication was limited to the last 10 years from 2008 to 2018. Further criteria for the inclusion group were the live experience research concept and the research into adult hemodialysis patients. The exclusion criteria were peritoneal dialysis patients,

hemodialysis patients who were children, the health workers associated with hemodialysis (nurse, doctor, and nutritionists), family, and caregivers.

2.3 Search strategy

A systematic search of the PICO database electronic data framework was carried out according to the PICO framework [15]. For the first step, we looked on the electronic databases of Scopus, Medline, Proquest, and Science Direct in order to identify key articles and to identify keywords by adjusting the key concepts: 1. patients undergoing hemodialysis, 2. life experience 3. diet and fluid restriction and 4. qualitative studies. Our keywords were used to look for quotes and full articles, including the title, abstract, text and reference information. The second step was translating the keywords into English to find the relevant articles in the chosen electronic databases. The third step was to filter using the PICO framework to determine which articles passed for further review according to the topic. The search strategies were limited to the last 10 years between 2008 and 2018.

2.4 Quality *of appraisal*

The quality assessment of articles will be reviewed using a qualitative Critical Appraisal Skills Program (CASP) study tool. There are 10 different questions that consider the results of qualitative studies, the validity of studies, and their uses [17]..

CASP is a tool for evaluating the quality and utility of research reports [18]. The 10 questions in CASP were answered by selecting "yes", "no" or "not now" for each question. The allocation of the scores on a scale of 10 for each article reviewed was based on how many "yes" answers were in the score. A score that is above 7 refers to the quality of the article being very good. The purpose of this quality assessment was not to distinguish between the different qualities within the studies but instead to conduct a systematic process. The standard process can provide high-quality reviews based on the existing topics.

3. Results

3.1 Study selection

The search strategy was carried out by generating a total of 561 citations, in which 248 citations were deleted 248. In addition, 270 existing items of literature were deleted during the first screening because the title and/or abstract did not match with the specified eligibility criteria. Then, 43 complete articles were found in the second phase of screening and 10 articles obtained were retained for review. Following this, 6 additional articles were obtained from the reference screening stage and thus the last session included 16 articles based on the experience of fluid restriction and diet in hemodialysis patients.

3.2 Study characteristics

A total of 16 studies were reviewed. They were published between 2008 and 2018 were conducted in 13 countries: the USA, Italy, South Korea, Japan, Singapore, Turkey, New Zealand, London, China, Chile, the Netherlands, and Australia,. The qualitative research

methods included phenomenology, ethnography, grounded theory, mixed method and a descriptive explanation.

3.3 Result of synthesis

The literature search identified 16 journals that described the experience of fluid and dietary restrictions in hemodialysis patients. Finally, the 5 main theme findings of the synthesis were summarized briefly: the understanding of the dietary and fluid restrictions, the experience of support, the experience of psychology, the experience of behavior and the experience of the financial factors.

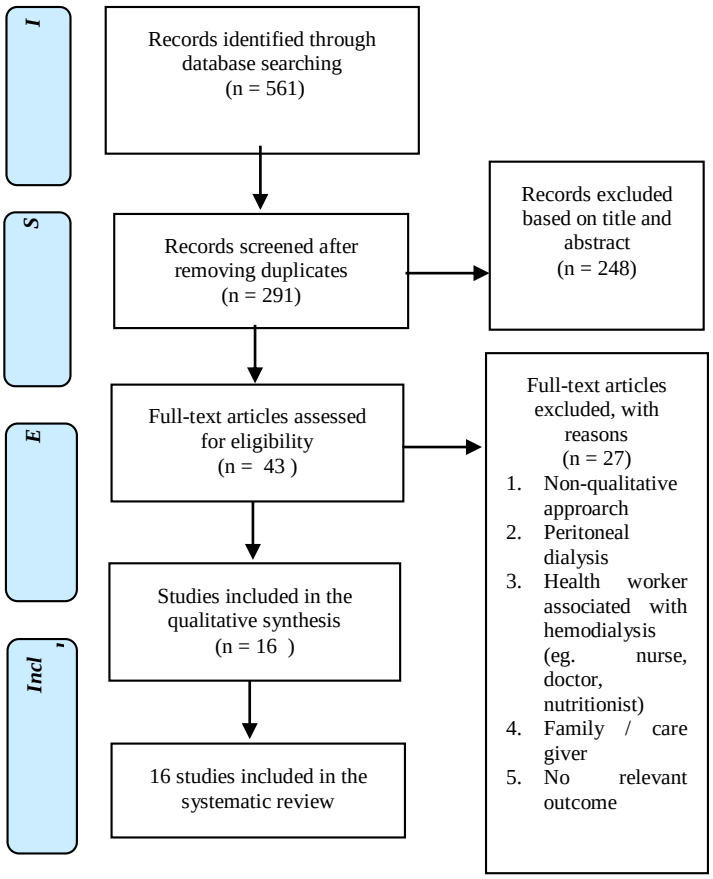

Figure 1. Flow Diagram

3.3.1 *Understanding dietary and fluid restrictions.*

Compliance with the diet and fluid restrictions is important for hemodialysis patients, and they must understand the dietary and fluid restrictions in order to comply. A lack of adherence to the dietary and fluid restrictions is due to the limited patient education such as a lack of understanding and purpose, self-educateion and the consequences of fluid and dietary restrictions [14].

Hemodialysis patients claim that it is difficult to control their diet and fluids because they are unable to resist their thirst and because they are hesitant to consume the recommended foods. This is as the foods that are recommended seem bland to consume. They know that limiting their diet and fluid intake to maintain their health is the best thing to do because their kidneys are not functioning [19,20]. Based on [21] and [6], patients consciously ignore the dietary and fluid restrictions intentionally because they consider it to be less important and unreasonable. However, the fluids and food are a necessity and they are an element that is needed by the body to carry out activities. However, most patients have knowledge of the effects and complications of non-compliance with their diet and fluid restrictions but they do not adhere to them because they do not feel the negative effects [9].

A few patients who do carry out diet and fluid restrictions do so due to not wanting to be hospitalized. The patient must accept their new identity as a hemodialysis patient and cultivate their mind to accept the limits that they need to apply to their food and drink [12].

3.3.2 Experience of support. Changes in the lifestyle of hemodialysis patients in terms of regulating their food and drink intake must be done because of the decline in the function of their kidneys. The patients need support from the people around them.

Family support was identified as a support system for the hemodialysis patients so as to improve patient self-management. The role of the family reminded the patients of what to do and they actively participated in limiting their drinks, and regulating and providing the patient's diet. However, the form of family support differs between the sexes; male patients get direct support from their partners regarding diet and fluid preparation by regulating their diet and limiting the ingredients, while the female patients receive support from their family members and they prepare their own food menu [7,9,22–24].

Support from fellow hemodialysis patients is done by sharing experiences focused on carrying out fluid restrictions, and the impact that is experienced also increases their compliance [19,22]. Health professional support strengthens the patient's self-control when it comes to fluid retention. The form of support given by the health professionals (nutritionists) is counseling done routinely to regulate the dietary restrictions. This includes the explanation of the food, what can be consumed and what to avoid, and how to cook food so then the potassium is not too high and demonstrations by the nutritionists to make the patients motivated. The frequency of the contact with the health professionals makes the patients feel valued and cared for in regulating their dietary and fluid restrictions [3,7,19,25]. However, the lack of family support and that of the health professionals was where they reported that they did not measure their intake of fluid objectively. They remembered what they drank because they were uninformed

about measuring their fluid and food intake, so they searched for their own information regarding fluid restrictions through the internet [14,24]. The patients reported lacking social support (environment/friends), they ate and drank normally when they were in social situations because they had difficulty controlling themselves and when they were unable to explain their condition to others, especially when visiting. There were also special events to take into account such as eating at restaurants, parties and meeting others while on vacation [6,14].

3.3.3 Experience of the psychological factors. The most common obstacle for hemodialysis patients in terms of restricting diet and fluids is psychological. The stress and frustration experienced by the hemodialysis patients when their lifestyle changes includes the limits in terms of the recommended fluid and diet. Ignoring their thirst when it is hot and eating the same food all of the time makes them suffer and get bored. According to them, the technique of limiting their fluid intake and diet is not effective. The patient does not feel that there is an effect on him when they are consuming excess liquid or sodium. The patient has the belief that the person who knows his condition best is himself and that the patient understands the fluid needs of their body [9,11,12,14,23].

Frustration when carrying out diet and fluid restrictions is felt by the hemodialysis patients ho reported that they psychologically perceived their desired food and thirst as their enemy that they can no longer perceive as pleasure. Psychological management is done because they do not want to be hospitalized and because they do not want any complications to occur [12].

3.3.4 Experience of the behavioural factors. The efforts of the hemodialysis patients when it comes to limiting their diet and fluids involve a self-assessment. Self-assessments include measuring their urine production and weighing themselves every day. They control the fluid entering but do not assess the overall status of the fluid and they often do not objectively measure the volume of fluid entering their body. They control the desire of wanting something and avoid direct contact with the food that they want because they don't want to be hospitalized and lose a lot of energy when taking fluids at the hemodialysis session [2,12,14].

However, hemodialysis patients who carry out the diet and fluid restrictions cheat for many years. They eat and drink freely like they were before they were sick, but they measure their food and drink intake. They consume based on their intuition and trial and error, so the patients understand their limits and how much they eat without causing negative effects to their bodies [6,7,13].

3.3.5 Experience of the financial factors. Finances are one of the obstacles to adhering to diet restrictions. The restricting of the diet for hemodialysis patients is "expensive" diet. The financial factors are a barrier factor for making kidney diet recommendations. The diet menu settings are that they should not consume meat that contains salt, so more money is needed to adjust to the kidney diet and dietary recommendations. These are sometimes not done because of adjusting to their new financial condition [3,11].

Going on a kidney-specific diet adjusts their income. This is because they have sufficient

income for their current lives but they find it difficult to deal with the cost of the disease. This is because everything is measured and when they want something that is in accordance with the kidney recommendations, the money to buy it is often not enough [20].

4. Discussion

This systematic review was prepared to explore the experience of hemodialysis patients in limiting their diet and fluids. We identified of 16 articles where the objectives were consistent with the systematic review.

Diets depend on the approval of the therapy regimen, one of which requires fluids and a balanced diet [8]. The understanding of the patients is needed to carry out their fluid and dietary agreements. Their fluid intake is noted every time and their diet is managed by consuming foods that are low in phosphorus, potassium and sodium, and maintaining their protein intake [14]. However, the decision to refuse the management of fluids and diet was not followed due to an increased interdialytic weight (IDWG), cardiovascular morbidity and mortality. Increased phosphorus levels are directly related to the risk of death and ventricular arrhythmias if there is an excess of potassium [8].

Support for the hemodialysis patients comes from the health professionals, their family, and their fellow patients. Family support involves someone who can motivate them directly to carry out fluid and diet management [22].

The psychological problems (stress and frustration) that occur in general hemodialysis patients are because of problems related to prevailing lifestyle changes regarding the patients associated with risks and a diet that is needed to improve health and to maintain bodily functions [9].

The lifestyle of the hemodialysis patients persists, providing boredom in relation to the therapy, depending on the compatibility and any trial problems with fluids and diet [7].

The setting of menus for hemodialysis patients in accordance with the dietary recommendations of kidney patients requires a large amount of money, and some families also have difficulty as the menu of hemodialysis patients to be shared by other family members [11,20].

5. Conclusions

Various studies have provided informed perspectives on the life experiences of hemodialysis patients in carrying out diet and fluid restrictions. This research is related to the life experience of hemodialysis patients in terms of diet and fluids. In this review, we have discussed diet and fluids, the support experience, the psychological experience, the behavioral experience and the financial experience.

Further research is very important, especially related to the meeting in the perspective of supporting hemodialysis patients in a community. In addition, the research must determine whether the research on fluids is the same between patients whether they join the community or not. There is also whether and how the frequency of hemodialysis and comorbidity makes it difficult to improve diet and fluids to consider. Clinically speaking, understanding fluids and

the importance of social, psychological, and economic support, including those used in increasing approval of fluids and diet, is important.

THE ACCURACY OF CURCUMIN AS A DIAGNOSIS MEASUREMENT PREMATURE RUPTURE OF MEMBRANES

Ika Pratiwi[1], Melyana Nurul Widyawati[1], and Suryono Suryono[2]

ABSTRACT

Reduced infant mortality began from antenatal care and continues with good intranatal treatment. Enforcing an accurate diagnosis of premature rupture of membranes could prevent further complications for mother and fetus. The gold standard for diagnosing premature rupture of membranes used litmus paper. But unfortunately, the availability of litmus paper was not always ready in primary health care. This research proposes a diagnosis of premature rupture of membranes measurement used curcumin. Initially, characterization of change color at curcumin carried out to find a type of liquid based on pH value. This measurement basis was validated by measuring the change of color on underpad curcumin during delivery care or amniotomy from 30 respondent. Results show that change of color in the underpad has significant linear relation (R = 0.9434). curcumin can be used to measure premature rupture of membranes with a high accuracy of up to 91.4%.

Keywords: curcumin, change of color, accuracy, premature rupture of membranes

1. Introduction

Amniotic fluid is one of the most important aspects of pregnancy. It protects the baby from trauma, provides space for growth and prevents the cord from experiencing outside compression[1,2]. Amniotic fluid also has bacteriostatic properties that serves as a barrier to protect the fetus from infection[3,4]. However, amniotic fluid that comes out before the onset of labor results in several effects including intrauterine infection and cord compression. It is also directly related to fetomaternal morbidity[5,6]. Establishing an accurate diagnosis of premature membrane rupture is the key to effective management in order to improve fetomaternal well-being [7]. This will also help to increase the success of vaginal delivery [8].

Premature membrane rupture occurs in 10% of pregnancy, 7% of aterm pregnancy and 3% of preterm pregnancy [9]. Premature membrane rupture incidence in China in 2015 was at 2.7% - 7%, while in North America, it was 5 - 15% [10]. Meanwhile, Indonesia witnessed an incidence of premature membrane rupture in 12% of pregnancies[11]. Premature membrane rupture is not a direct cause of death but it can trigger infection that may result in both maternal and perinatal mortality as well as morbidity. One third of women with premature membrane rupture in a less-term pregnancy experience results in more severe infections for the babies instead of the mothers [12]. Up to 47.9% of infants die from the complications of infection after premature membrane rupture [13]. Infection ranked third as the direct cause of maternal death in Indonesia in 2015 [14].

The diagnosis for premature membrane rupture usually uses litmus paper [15,16] as it can

easily be performed using the remaining amniotic fluid that is held in gloved hands. The interpretation is also simple in that it only requires the observation of the litmus paper discoloration. Amniotic resistance is detected when the litmus paper turns blue (alkaline) [17]. However, this visual observation is prone to subjectivity.

Another drawback is that litmus paper is not always available in primary health care facilities, especially in rural areas. This is why there is the need to use a locally available organic material such as leaf extract, flowers and some medicinal plants as natural pH indicators to replace synthetic litmus paper [18][8]. This approach is also gaining momentum as such natural ingredients are widely available in Indonesia and they are cost effective [19][20]. One of the natural pH indicators that have been developed focuses on the color pigments of turmeric [21].

Turmeric contains curcuminoid. This substance is yellow in color, soluble in oil, insoluble in ether, and sensitive to acidic or base conditions. The pattern of discoloration of the turmeric crystals is more conspicuous than in litmus [22]. Curcumin provides clear and fast color changes (in less than 5 seconds) and shows different color changes at each pH level[23].

Nonetheless, the proposed substitution titration must be able to explain the effective performance of the substance using objective methods[24]. Digital image processing can accurately detect the color changes of amniotic fluid [25]. Image processing allows for the interpretation of the Red, Green and Blue (RGB) elements, based on sensitivity and resolution [26]. This study aims to test the accuracy of curcumin to diagnose premature membrane rupture.

2. Methods

This was an experimental study with a post-test only control design. The population was intrapartum mothers who were treated at RSUD Ungaran (Regional General Hospital of Ungaran) and Klinik Bersalin Esti Husada (Esti Husada Maternity Clinic) in Semarang, Indonesia, from February 1 to 28 February 2019. Ethical clearance was obtained from the Ethics Committee of Universitas Sultan Agung Semarang number 013 / B.1-KEPK / SA-FKG / I / 2019. It was also in accordance with the 7 points of the WHO Ethical Standard for Research with Human Beings of 2011, which includes: 1) Social Value, 2) Scientific Value, 3) Fair Valuation and Benefits, 4) Risk, 5) Persuasion, 6) and 7) Informed Consent. It also referenced the 2016 CIOMS Guidelines as indicated by the fulfillment of the indicators of each standard.

This study was initialized by characterizing the color changes of curcumin. The curcumin extract used was put on pantyliners which were then exposed to amniotic fluid. The measured amniotic pH from the panty liners was then compared with the values of the color elements on the pantyliners captured using a camera. Red, Green and Blue were the default colors. The camera was 3500 pixels x 4700 pixels. It comes with a focal distance of 3.87 mm and 500 lux of lighting, which is standard hospital lighting. The color changes of the pantyliners were validated with content validation using the Spearman-Brown coefficient. Pantyliner accuracy tends to be expressed in sensitivity values. The procedure for measuring the Red, Green and Blue color values has been shown in Fig. 1.

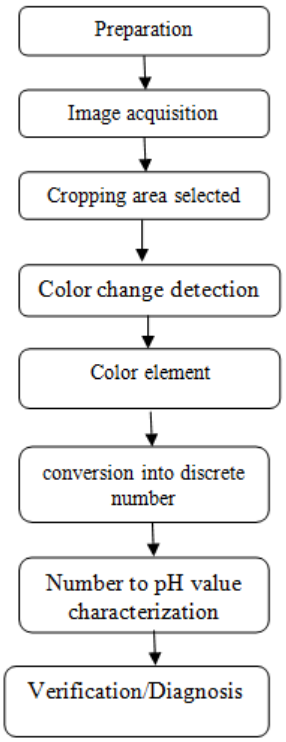

Figure 1. Procedure of amniotic fluid diagnosis using digital image processing

The data was taken from February 1 to 28 2019 involving as many as 44 amniotic samples of first-time pregnant women who underwent an amniotomy or those having their remaining amniotic water on delivery onset. Out of the 44 amniotic samples obtained, one pantyliner could not be used due to exposure to maternal urine and feces, 2 panty liners were too contaminated with delivery blood and 1 underpad sample was contaminated with meconium. The remaining 40 respondents who met the inclusion criteria were then divided into 2 groups. They were the amniotic treatment group tested using curcumin and the amniotic control group tested using litmus paper.

The color changes observed in both groups were then converted into pH standard values using MatLab. The respondent characteristics are shown in Table 1.

Table 1. Respondent characteristics

Characteristics	Curcumin Group	Litmus Group
Mean Age (year)	24.3	25.7
Mean Parity	165	1.02
Age of Pregnancy (week)	38.5	39.3
Premature membrane rupture, n	18	15
Amniotomy, n	2	5
Meconium in amniotic fluid	2	1

The curcuminin this study was extracted using 70% ethanol and 90% glacial acetate acid that was macerated for 3 days and concentrated using a rotary vacuum evaporator at 70˚C. The results of the extraction test using several treatments are as shown in Fig.2.

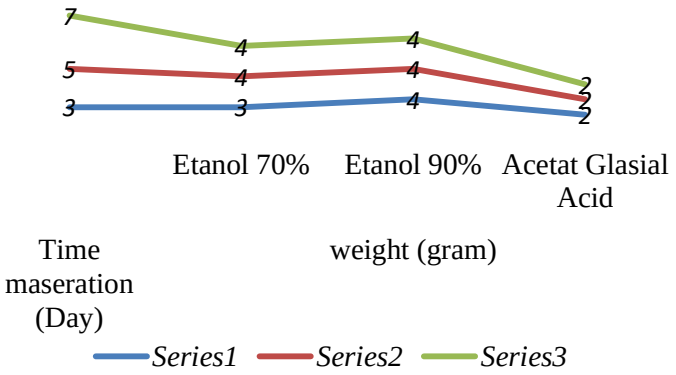

Figure 2. Maceration process of curcumin

The best performance for the curcumin was obtained from dried turmeric rhizome maceration using 70% ethanol for 3 days. The extraction products were put on the pantyliners, along with the design of the panty liner as shown in Fig. 3.

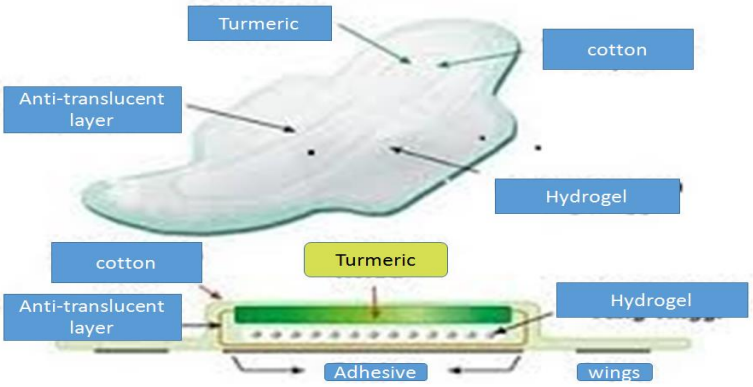

Figure 3. Product design of the pantyliner

3. Results

3.1 Characteristics of color change

Discoloration of the curcumin by liquid with a concentration of pH 4.0 - 10.0 produced 10 different color change images. The naked eye observation of the color changes in the panty liners are as shown in Fig. 4.

1 2 3 4 5

Figure 4. Color change of curcumin

Pantyliner color changes from left to right are as follows: image1 shows pH 5.0, image 2 shows pH

6.0, Image 3 shows pH 7.0, image 4 shows pH 8.0 and image5 shows pH 9.0. The duration that it took for curcumin to change color as observed by the naked eye was 0.75 seconds with good absorption. The exposure and application of the curcumin to a mixture of pH concentrations showed a unique pattern of color change that formed color blocks in line with the particle catches on concentrated liquid. The segments that absorbed the base changed color to brownish red but those that that absorbed the yellow acid tended to fade.

3.2 Conversion of curcumin color changes

A normal and clean vagina has a pH range of 4.5 - 5.5 with acidic characteristics. This property can be obtained using simulation fluids of HCL with pH concentrations in the range of 4.5 - 5.5. Prior to the simulation, the fluid was measured using a pH meter. The simulation did not show any color change in the curcumin. Urine, having a pH value of 6-7, is equivalent to a neutral pH with a slight shift to weak acidic properties. The liquid used for simulation was purified water mixed with a few drops of HCL until the same concentration as that of urine was reached with urine. Subsequent visual observations did not show any significant color change. The color was bright yellow, as original curcumin is.

Amniotic has alkaline properties with a pH range of 7.5-8.5. The liquid used here was NaOH 0.001 M. At this pH range, curcumin showed a quick and clear color change in less than 10 seconds. The color change that occurred was yellow to brick red. This simulation fluid was then measured using a digital pH meter with a pH value of 4.0 until 10.0. Each liquid was exposed to 10 curcumin pantyliners. The resulting color changes in curcumin were captured using the camera. The comparison of the average RGB values against the standard pH is as shown in Fig. 5.

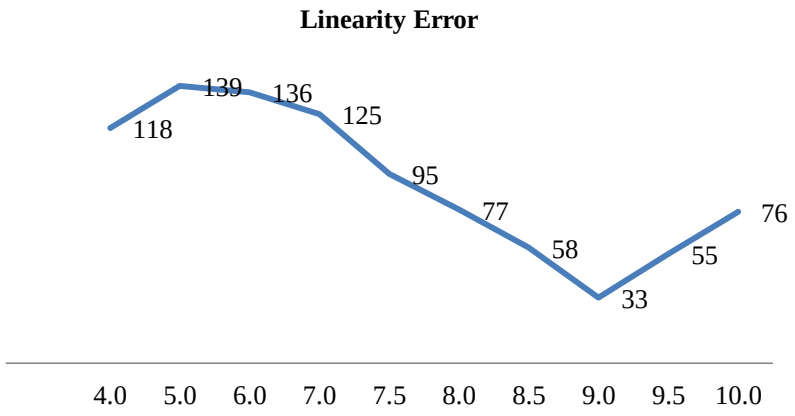

Figure 5. Comparison of the average Red, Green and Blue values with the pH standard

3.3 Linearity test between the color elements and the standard pH of amniotic fluid

Visual observation is prone to subjectivity, hence why an objective alternative is required to assess the level of consistency in the color changes of curcumin. This consistency assessment made use of image processing to explain the discrete numbers that can be justified [28]. The calculation results of the average Red, Green and Blue values shows poor linearity (R = 0.51). The measurement of the linearity of curcumin is as shown in Fig.6.

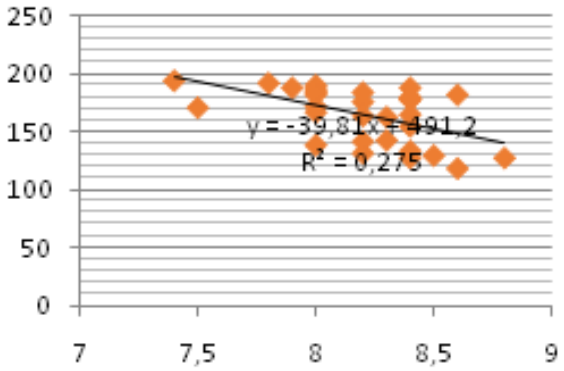

Figure 6. Significant linear relationship

3.4 Validity and reliability of curcumin

The content validity test was conducted by Dr. Adil Zulkarnain, SpOG (K), Head of the Secondary Mortgage Facility (SMF) for Obstetrics and Gynecology at RSUD Ungaran in Semarang. This expert judgment suggests that turmeric could be used as a pH detector for amniotic fluid. Curcumin reliability, according to the Spearman-Brown coefficient formula, was 0.78, which means that it has a high level of consistency.

3.5 Accuracy of curcumin

In order to be accurate, the diagnosis method using curcumin must produce small false positive and false negative group categories. There are two things that must be considered; how well the curcumin screening test identifies women positively diagnosed with premature membrane rupture and how precisely the tests classify women with normal pregnancy, albeit with negative curcumin test results or known sensitivity. This study has a sensitivity value of 95%, as shown in Table 2.

Table 2. Sensitivity of curcumin pantyliners

Positive	Positive	Negative
Curcumin Pantyliner	True Positive (19)	False Positive (1)
Negative	False Negative (0)	True Negative (0)

4. Conclusion

Amniotic fluid can be tested using curcumin with the concept of changing pH. Appropriate diagnostic information can be provided by the sensitivity values. In the intrapartum condition, getting amniotic fluid with good characteristics without blood and meconium contamination is not easy. The presence of other fluids during labor will affect the titration results. There is no standard measurement that can be used as the gold titration standard so as to ensure zero errors in the final diagnosis. Nonetheless, seeing a significant color jump is quite an effective pH detector for amniotic fluid. Other methods to improve the accuracy of the premature membrane rupture diagnoses must be developed in further studies.

INFORMATION TECHNOLOGY AND EDUCATION ENHANCE DIETARY ADHERENCE AMONG HEMODIALYSIS PATIENTS: A SYSTEMATIC REVIEW

Rochma Adelia[1], Kusnanto[1],Suprajitno[2]
1 Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
2 Department of Nursing, Politeknik Kesehatan Kemenkes, Malang, East Java, Indonesia
Email: adelia.rochma-2017@fkp.unair.ac.id

ABSTRACT

Dietary adherence has become the fundamental component of effective healthcare as the treatment regimen itself among Chronic Kidney Disease (CKD) receives Hemodialysis (HD). It becomes the key to reduce morbidity and mortality. Education using pamphlets or video is common method to enhance patient dietary adherence. Information technology (IT) has offered new tools to facilitate communication and monitor patient's dietary consumption. This systematic review aims to know the effectiveness of education and IT using in dietary adherence among HD patients. Literature obtained through Science Direct and Scopus data bases. This literature is restricted from 2011 until 2017. Based on a study of 15 selected journals, obtained some types of education and IT that is used to enhance dietary adherence in HD patients. The education can be group or individually using pamphlets, video or flip chart, the technologies include mobile phone applications, SMS, and web-based. This systematic review shows that education and IT are effective to enhance dietary adherence among HD patients. Information from this systematic review can be used to design future research combining Education and IT on enhancing dietary adherence among patients who receive HD therapy.

Keywords: education, information technology, dietary adherence, hemodialysis

1. Introduction

Lack of adherence to treatment is common in hemodialysis patients. Patients with end-stage renal disease, care goals focus on optimal control of mineral markers and fluid management to reduce the risk of complications and mortality [1]. Besides dialytic procedures, patient self-management or patient ability and the willingness to change and then maintain appropriate behaviors regarding diet, fluid intake and medicines, is critical to maximizing good clinical outcomes [2]. Adherence to this complex regimen is poor, with non-adherence estimates of 2% to 57% for diet, 10% to 60% for fluid intake, and 12.5% to 98.8% for medication, contributing to morbidity, avoidable hospitalization, and death [1]

Self-efficacy education facilitates the patients' acquisition of knowledge and skills to improve disease management and it has been reported to improve health outcomes across a range of chronic diseases [3]. Education using pamphlets or video is a common method to enhance patient dietary adherence. Besides that, education materials that usually are used include brochures, fact sheets, lists of foods to avoid, referral to Internet sites, and ongoing counseling [4].

Education can be an effective tool used to increase adherence but in order to facilitate dietary and fluid self-management in daily living, nurses and other health professionals are challenged to make information available at a time that is convenient for the patients, thus providing information tailored to their individual needs, cultures, and food preferences. It must also complement patient decision-making with useful feedback (5). They tried using information technology (IT) [6]. Dietary

Intake Monitoring Application (DIMA) was one of the examples of IT, based on mobile technology to facilitate self-monitoring [7].

These findings suggest that both education and electronic dietary intake self-monitoring using IT has the potential for persons receiving HD [7]. But to our knowledge, there has been no conclusion about using education and IT at the same time to increase dietary adherence with patient hemodialysis. So this systematic review aims to know the effectiveness of education and mobile application using in dietary adherence and self-efficacy among HD patients.

2. Research Methods

2.1 Search Strategy

This Systematic review uses a guide based on the Preferred Reporting Item for Systematic review and Meta-Analysis (PRISMA). The literature was obtained through the ScienceDirect and Scopus databases. This literature is restricted from 2011 until 2017. The reviewer assessed all of the articles for rigor, key research methods, credibility and relevance. Search terms using a combination of keywords mobile application AND education AND dietary adherence AND self-efficacy AND hemodialysis.

2.2 Inclusion and exclusion criteria

All of the studies used in this systematic review were experimental studies that studied mobile application and education effectiveness on enhancing dietary adherence and self-efficacy among HD patients.

2.3 Analysis

The analysis method in this systematic review refers to the PRISMA guidelines. The studies were specified according to the hypotheses before conducting the analysis. The validity of the studies included in this systematic review was assessed by random allocation, the blinding of the study, the outcome and involving of the health care provider. After determining their validity, we analyzed the studies included by following the PRISMA guidelines.

3. Result

3.1 Literature search and study selection

A total of 15 articles were identified to be included in the systematic review. The search was done through the Science Direct, Scopus, PubMed, ProQuest and CINAHL databases. After duplication screening, there were 625 articles left. Searching for full-text articles allowed for the identification and elimination of as many as 10 articles. The 15 articles included in this systematic review were made up of randomized control trials published in English.

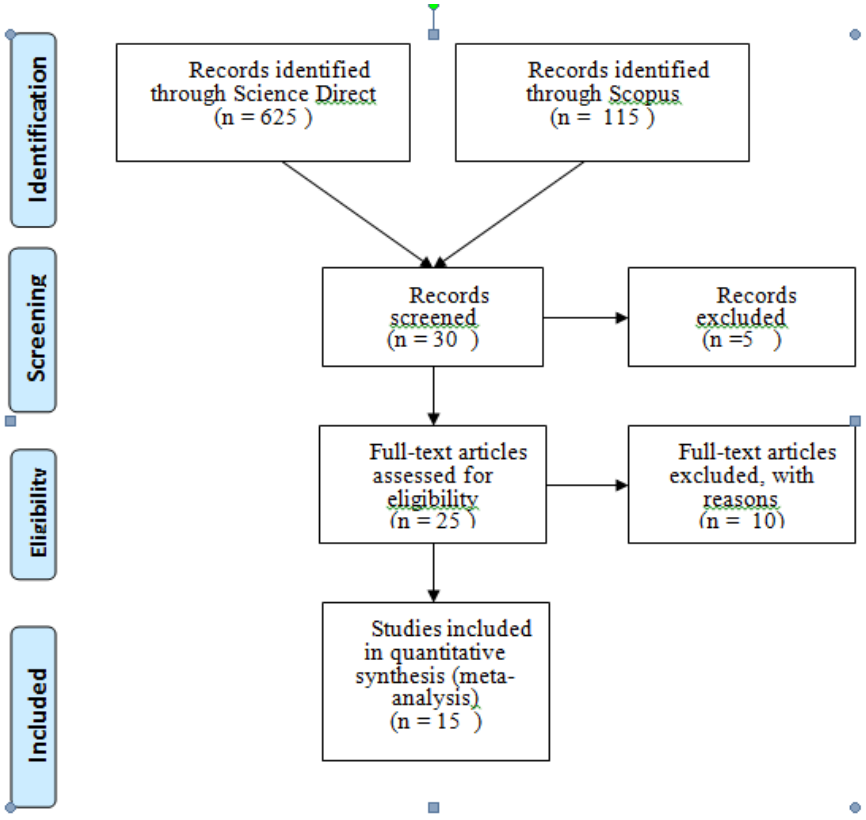

Figure 1. Flow Diagram

3.2 Mobile application and education enhancing dietary adherence and self-efficacy

Mobile applications and education are effective at enhancing the dietary adherence and self-efficacy of the HD patients. From the 15 articles, it can be concluded that the education given through nursing using many different kinds of education intervention are effective at enhancing dietary adherence. The education methods that can be used include psychological interventions (nursing as a facilitator in group discussion making a comforting environment and giving motivation to patients), systematic nursing instructors, targeted interventions by the nursing staff, direct education through nursing and using technology like smartphones or game education.

Self-efficacy is the personal judgment of their ability to manage their health. Effective education helps the patient to live healthier and for them to be more independent through self-efficacy enhancement[8]. The nurses can help the patients to increase their knowledge, positive perception, skills and achievement through a support group. This can increase patient self-efficacy and help the patient to manage their health, including dietary management.

The mobile application facilitates the user in monitoring their daily food intake. Some applications allow the user to count their daily calories, fluid or protein intake. In order to maximize the application's functions, the mobile application should be designed to present daily food recommendations. Both education and the mobile application can increase the dietary adherence by increasing fluid management, lowering the dietary phosphorus, increasing self-management and controlling BMI.

4. Discussion

Health education is an important external factor that influences self-management behavior, although a further study found that self-management education that simply provided information only produced a slight improvement in the self-management behavior of the patients [1]. The present study showed that, despite receiving health education, the behaviors associated with poor self-management continued to be observed in the patients [8]. Patients with good self-management knew what they should and should not do. This would thus increase the adherence to the diet of the patients with hemodialysis.

On the results of this study, the intervention giving to the patient was for five week to maintain good motivation. The strong motivation to maintain good health was the key to the patients realizing the benefits and necessity of the treatment, thereby improving their overall self-management[7,9].

Education has the definition of giving knowledge to others. Knowledge is essential for effecting changes in behavior. Individuals can obtain knowledge and skills through learning [3]. Accordingly, patients and their families need to actively receive knowledge, which can lead to the gradual development of healthy beliefs and attitudes that are reinforced with the adoption of healthy behaviors [3].

The mobile application used can increase dietary adherence. These findings suggest that the level of self-efficacy might improve if technology was used more. The trend for improved self-efficacy in those who used the application more often was consistent with the theoretical assertion that performance attainment is an influential source of efficacy information [7].

5. Conclusion

Adults receiving HD have difficulty implementing the complex, restrictive diet and fluid regimen in their daily living. The results of this study indicate that both IT and education are effective at increasing the dietary adherence of HD patients. The data from this study can be used to inform the development of future intervention studies designed to combine IT and education used to increase the adherence to the prescribed dietary and fluid intake regimen among the adults receiving HD.

ABSTRACT

Limited research is known about self-care management among patients with diabetes in Asian populations. Understanding the factors contributing to diabetes self-care-management (DSCM) in these populations based on literature can guide interventions aimed at improving self-care practices, achieving glycaemic control and preventing diabetes complications. This study aims to identify self-management barrier and strategies for diabetes in Asia. Literatures are obtained through Scopus and Science Direct data bases. The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) model for reporting integrated reviews was used for this systematic review. The result of this review, there are 7 articles (N=
147) included in this systematic review. The range of the sample sizes from the articles is 14 to 40. The range of ages is 28 to 70 years. Four major finding of self-management strategies are self-monitoring practice, social support, knowledge, and faith. Asian with diabetes experience barriers to self-care including lack of resources, stress, lack of social support, stigma, and depression. The conclusion of this review is Asian is at high risk for developing diabetes because of their race, gender, and lifestyle. Although there are many barriers to self- management, such as stress and depression, there are many positive self-management behaviours exhibited.

Keywords: self-management, diabetes mellitus type 2, qualitative

1. Introduction

Diabetes is a complex chronic illness that requires performing multiple daily self-management behaviors [1]. People with diabetes often face challenges related to diet, physical activity [2], taking medications and stress management. Such factors may be barriers to achieving optimal glycemic outcomes [3].

The prevalence of diabetes mellitus type 2 in Asian countries is high [4]. The most common version of the disease, Type 2 Diabetes Mellitus (T2DM), is a growing health concern in Asian countries such as India or China where approximately 62 million citizens have the disease [5,6]. India has the highest disease burden of T2DM among the Asian countries with the prevalence rates increasing steadily over the past 40 years [6]. Yet, besides conducting research on the diabetes risk factors [7], limited research is known about the self-care management among the patients with

diabetes in Asian populations. Understanding the factors contributing to diabetes self-care management (DSCM) in these populations can guide the interventions aimed at improving self-care practices, achieving glycemic control and preventing diabetes complications [8].

DSCM is considered to be a cornerstone for glycemic control and it is a key aspect of care [9]. According to some estimates, DSCM comprises as much as 95% of diabetes care. However, a healthy diet, regular exercise, blood glucose self-monitoring (BGSM), medication adherence and foot care adherence can be challenging [10]. They require lifestyle changes for many patients with diabetes, as well as the monitoring of a variety of daily behaviors [11].

While considerable research effort has gone into trying to understand why people do not achieve good control over their diabetes, we know little about the experiences and management practices of the minority who do [12]. A study conducted using Leventhal's Common-sense model to inform the qualitative analysis of the interview data illustrated the value of appropriately supported blood glucose monitoring in achieving an understanding of blood glucose levels [1]. To our knowledge, there has been no conclusion about self-management strategies and barriers among an Asian population. It is important to assess the self-management strategies [13] and barrier among Asians due to the differences with other regions. The purpose of this study was [1] to identify the self-management strategies used for diabetes in Asia and [2] to identify the barriers to the self-management of diabetes in Asia as well.

2. Methods

The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) model for reporting on integrated reviews was used for this systematic review. Scopus, ScienceDirect, PubMed, CINAHL and Google Scholar were the databases used to search the literature about diabetes mellitus type 2 management in Asia. The search terms used were as follows: self-management, diabetes mellitus and qualitative (see Figure 1). Initially, 52 articles about diabetes mellitus were found. After removing the duplicates, the titles and abstracts were examined according to the inclusion and exclusion criteria. The full articles were reviewed for goodness of fit. Articles that discussed self-management strategies were included. Secondary data analysis, reviews, non–peer-reviewed articles and qualitative studies on the caregivers of persons with other conditions were excluded. In addition, all of the qualitative studies in which the sample population was not fully Asian were excluded in order to focus on the cultural and social experience that is unique to Asians. Of the 62 articles retrieved from Scopus about diabetes, 7 met the inclusion criteria.

The reviewer assessed all of the articles for rigor, key research methods, credibility and relevance. The assessment was made using the Critical Appraisal Skills Progam (CASP's), which consists of 10 questions for qualitative research. This tool includes 10 essential appraisal questions with individual sub-prompts to guide the critical analysis and data extraction. While there were small variations of strength and weaknesses between sections of the articles, all had a clear statement of the aims and they provided convincing evidence for why a qualitative methodology was appropriate for their study; 7 articles withstood critical appraisal via the CASP tool by the reviewer and they were thus deemed valid and worthy of inclusion in the qualitative literature review. Finally, the data was

extracted into a table for review. The data fields included the study purpose, study design, sample and setting and any major findings. The data was examined to identify the major themes and any unexpected findings, particularly on the self-management of diabetes mellitus type 2 and the associated barriers.

3. Results

There were 8 articles (N=147) included in this systematic review (Table 1). The range of the sample sizes was 14 to 40. The range in age was 28 to 70 years old. The years for the articles being published dated from 2013 - 2019. The participants in this literature were Malaysian, Indian, Chinese, Vietnamese, Thai, Korean and Singaporean that contained the Chinese, Indian and Malaysian races.

3.1. Self-management strategies for diabetes mellitus type 2

The 4 major findings of self-management strategies are self-monitoring practices, social support, knowledge and faith. Almost all articles discuss these strategies as patients with both a low and high economic status do self-management practices. Patients with a high economic status keep their records with technology while patients with a low economic status keep manual records [14]. The patients used trial and error to find out the effects of the food that they ate, including taking notes and remembering and avoiding foods that cause blood sugar spikes [15].

Social support is very helpful for women in terms of self-management; 4 articles discussed social support. Women have the role of being the main support provider in their families. They want someone to help them to cook and to help them get to their doctor's appointment [16]. In addition, women also explained about their family members and friends helping them with their daily routines related to self-care and problem solving. When the support in society in the community is low, they consider it to be a barrier to agreeing to adhere to the diet and self-management of diabetes [17].

Knowledge is something that is important in the management diabetes [14]. The participants in 4 articles were interested in getting new knowledge with the initiative of attending a diabetes seminar. They came to the seminar that was organized by the local clinics to gain knowledge in order to better manage their disease. They also gained knowledge by asking healthcare professionals for information on diabetes management and diabetes care, including their family doctors, medical specialists, diabetes educators, podiatrists, ophthalmologists and dieticians [15,16].

Belief is the last theme that was discussed in all articles. Believing in their health is a very important thing and it is more essential to life than financial wealth [15]. Faith in God’s help, coupled with the fear of the consequences of diabetes, motivated them to engage in self-care practices [18].

3.2 Barriers to Diabetes Self Care

Asians with diabetes experience barriers to self-care, including a lack of resources, stress, a lack of social support, stigma, and depression. Many of the participants reported that they worried about diabetes complications, which added to their stress. Other factors that increased stress included shift work, multiple jobs and a lack of empathy from their family members [19].

The caregiving role, which caused added pressure, was reported many times by the women and not men [20]. They reported that they felt frustrated by their family obligations and responsibilities. Many Asians in these studies reported that the barriers were the most important self-care activities for diabetes: healthful eating and physical activity [17,19]. They said that a lack of motivation and a lack of time were the barriers to exercise. Similarly, many Asians reported that they struggled to make healthful food choices. In the study by Tan, it reported on the role of food as a source of comfort and stress and that trying to make healthy decisions became a source of shame for the participants. Their perception of a diet low in carbohydrates was associated with deprivation rather than building skills and strategies to successfully use food as a tool to manage their blood glucose and diabetes [17,19,20]. On the other hand, they said that they were hesitant to completely change their diets in order to maintain a healthy relationship with their family members [14].

Also evident in the research of Ansari et al was that many women felt that their family did not understand their life with diabetes well enough to assist them in meaningful ways. They believed that "their energy output was much greater than their energy input." They experienced the demand of caring for others yet they experienced very little energy flowing from others into their own lives. Almost all of the articles in the study described dissatisfaction with their health care providers as well as a lack of communication and understanding about their illness. Their physicians often rushed through their appointments and thus, they did not feel comfortable asking questions. General information and diabetes education were respected and used by the participants. However, many reported difficulties in adapting the information to their particular needs [18].

Stigma occurs in almost all countries in Asia. There is the stigma that diabetes is a disease that affects themselves. In Korea, the stigma occurs in themselves where the patients develop negative thoughts in themselves about their illness. This can ultimately disrupt their self-esteem and self-efficacy. In addition, the patients tend to avoid conversations that lead to discussing their illness and they simultaneously withdraw socially (21). In Pakistan, stigma occurs more extremely in men than women, where almost all men don't let other people know that they have diabetes. This happens in both rural and urban areas. They assume that other people will start looking down on them because of mistakes made in their past [17].

4. Discussion

The important role of diabetes management is self-care practices including the self-monitoring of blood glucose (SMBG) [14,22]. There is a relationship between knowledge and self-care practices including physical activity and adherence to diet, as shown in several studies [17,23]. Functional knowledge about the disease is reflective on the patient's behavior (SMBG) [14].

Making a behavior change in relation to the self-monitoring of blood glucose (SMBG) needs to include aspects of the process of self-management such as structuring the situation and activating resources [self-perception], accepting the options for actions [self-reflection] and believing in self-efficacy [self-regulation]. This leads to a change in the metabolic profile of the patients using blood glucose self-monitoring [24]. SMBG with structured brief counseling provided the patients with a tool for taking on more self-control resulted in an improved outlook on life [25]. Therefore, the care

plan must include the elements of disease knowledge, the potential determents that influence the treatment course and the patient's participation in treatment planning [14]. This type of care plan makes it easier to do during fasting where there is a decrease in blood sugar by up to 8.61 mg / dl [26]. Care plan can be a lifestyle intervention that has been proven effective in Muslims with diabetes [27].

Family and support systems are also something that are of a high value, although their support systems seem to play a complex role [16]. Many of them viewed caregiving as both a barrier and a facilitator of self-care. Almost all of the participants said that they had many responsibilities to others that compromised the amount of time that they had to care for themselves. They were also motivated to manage their condition so then they could be there for their family in the future. A major theme that emerged was that they felt the need to take care of others. The need of take care others made the patients stressed and it became a stigma [28]. Besides this, dietary behaviors and the perceptions are linked to culture and tradition may contribute to problems with balancing the dietary guidelines for diabetes and cultural traditions [29].

Believe in God/spirituality and believe in themselves was a major facilitator of self-care for those with diabetes [18]. Many Asians highly value their religious and spiritual beliefs, as expressed in these qualitative studies. This spirituality continues to be an important part of managing their condition [30]. They turn to God to pray and they are very active in their church, including volunteering and sometimes singing in the choir. Practicing their spirituality was a major facilitator of self-care behavior [18,30].

In contrast to caring for others, self-reliant behaviors were also important for women, as they facilitated their independence and increased their self-worth [15]. Many of the self-care behaviors that were identified, including indulgent self-care such as shopping and maintaining their favorite hairstyles, allowed the women to be more self-reliant. Attending support groups with others affected by their conditions was also a major facilitator of self-care [31]. They enjoyed the sense of belonging that they felt when they met others who were going through similar experiences. This decreased their sense of loneliness related to their condition [16].

Asian reported there to be a lack of understanding from their family and negative experiences with health care professionals [15]. Health care is an important aspect of diabetes management related to the support of individual efforts to modify their habits and to adopt a healthier lifestyle [32]. The families did not seem to understand the implications of their condition or what their life was like while living with diabetes [14]. It is thus more because of the low knowledge of their family[33]. These conditions were associated with negative experiences with health care providers, such as feeling rushed during appointments or feeling that the health care provider exercised a negative attitude toward them. For many participants, stress made it difficult to emotionally and physically manage their diabetes [18]. It is important for nurses to continuously evaluate the patient's psychological reaction to disease management because changes associated with the diagnosis of diabetes may lead to psychological effects such as depression and a negative coping style [34].

The stigma in Asia also needs to pay attention to culture. Culturally appropriate diabetes education, with specific attention to cultural beliefs about diabetes, is essential because it consistently

contributes to improved diabetes knowledge and glycemic control [35]. In San Jose Tecoh, it is particularly important to address the traditional Mayan–Yucatecan understanding of the deep relationship between the body, nature, the emotional self and society with regard to physical health [36].

Stigma and cultural barriers also exist for people living with T2DM in Mexico and the biomedical approach to disease management (i.e., acute care of T2DM symptoms and conditions) may not adequately consider these determinants of health [37]. Access to health care services may be limited due to financial constraints [38]. For example, individual financial concerns may be related to the high cost of medications, exams and healthy foods. Even when the health services are covered by public insurance, individuals may be required to pay for extra services. Culturally constructed perceptions of T2DM's causes and treatments, such as the relationship between stress and disease, may affect the individual understanding of proper diabetes management [39].

Asians with diabetes experience similar daily barriers like the patients in other countries, such as a lack of financial resources, health insurance, transportation, a flexible work schedule and the need to take daily medication and to maintain an exercise schedule and healthy diet [25,40]. As both conditions require maintaining self-care behaviors, these barriers can lead to the inefficient maintenance of self-management strategies [15]. Nurses need to consider patient co-morbidity in the compilation of skills and self-management needs. There should be a review of all patients who have management expertise that can be used in their diabetes management. They should also assess patients who have problems with social support to facilitate them accessing social support. Nurses also need to examine whether they needs to be supported to look for social support related to stigma, such as support groups or mosque communities (if appropriate).

5. Findings

Asians are at high risk of developing diabetes because of their race, gender and lifestyle. Although there are many barriers to self-management such as stress, depression and stigma, there are many positive self-management behaviors shown by Asian patients. The uniqueness of Asia is that people's trust in a God is still high. Both culture and stigma are something important to them. Both of these features can be important aspects of good self-management or not. In addition, the role of the health care providers is to listen to their patients' needs and to provide support when needed, which can affect the health of the community.

Table 1. Studies of the Self-Management of Diabetes Mellitus in Asia

Author(s) (Year)	Design and Purpose of study	Sample and Setting	Major Findings
Gillani et al 2017 (14)	Descriptive analysis To determine the used self-monitoring practices and to determine the awareness of dietary modifications and the barriers to medication adherence among the physically disabled type 2 diabetes mellitus patients	N= 21 Age range: 35-67 years old Setting: Clinic in Penang General Hospital, Malaysia	**Self-monitoring practice:** Those with a low economic status denied adopting technology and kept manual record. However, the participants from moderate or high economic status and who were either single or married showed a positive perception/willingness to adapt to technology-based monitoring. **Barrier Self-care practices**: The majority of participants were aged >40 years and had a diabetes history >11 years. They showed concern about financial conflicts. **Awareness towards diet management:** All of the participants didn't know about food management. **Barrier to diet:** A reduction in food intake in terms of carbohydrate seems to be ineffective. They may also be hesitant to change their diet because of a large number of family members eating it. **Behavior to medication**: The majority said that it was not important and that it didn't relate to diabetes management. **Improved Knowledge**: The patient usually attended a seminar to increase their knowledge
Carloan-Olah et al 2013 (15)	Phenomenology To gain a deeper understanding of the difficulties that Vietnamese patients experience when accessing services and managing their type 2 diabetes	N= 15 Age range: 60-70 years old Setting: Inner Northwest, Melbourne Region	**The value of being healthy:** The participants in this study rated their health as very important and more essential to life than financial wealth. **Controlling Disease:** The participants were proactive at controlling their disease, which included modifying their diet, restricting their consumption of certain foods, exercising and seeking advice on the best way to control

Author(s) (Year)	Design and Purpose of study	Sample and Setting	Major Findings
			their blood sugar levels. Many used a trial and error approach to work out the effect of certain foods and in the future, they avoided foods that caused a spike in their blood sugar. Other strategies included being prepared for hypoglycemic episodes and making the most of the doctors' visits to ask questions and to make sense of their medication. **Information Access**: In the final theme, the issues related to service and information access were explored. The participants attended a number of healthcare professionals for their diabetes care, including family doctors, medical specialists, diabetes educators, podiatrists, ophthalmologists and dieticians. **Barrier**: The participants mostly didn't understand when the doctor spoke too fast.
Lunberg et all (2017) (16)	Phenomenology explorative qualitative To explore the self-care management of Thai Buddhists and Muslims with type 2 diabetes	N= 27 Age range: 28-70 years old Setting: Thailand	**Becoming a self-care management practice:** They discussed practical approaches to self-care with a focus on the reduction of their blood glucose levels. **Changing daily self-care:** This theme refers to the participants' behavior in their daily lives. They worked hard to follow their plans and advice from their doctors and nurses. **Support from family and other:** Diabetes self-care is a part of family life and social life in general. The participants described that their family members and friends helped them with their daily routines when it came to self-care and problem-solving. **Barrier:** Diet was the most difficult problem, and economic difficulties, incorrect knowledge, and misleading beliefs were also barriers.
Saidi et al (2018) (18)	Phenomenology explorative qualitative To explore the self-care	N= 27 Age range: 28-69 years	**Fatalism:** Patients were fatalistic about developing diabetes – they perceived it as inevitable because it is so common in Malaysia.

Author(s) (Year)	Design and Purpose of study	Sample and Setting	Major Findings
	and self-care support of patients with type 2 diabetes in urban Malaysia	old Setting: Malaysia	**Faith**: Faith in God, coupled with fear of the consequences of diabetes, motivated them to engage in self-care practices. **Fear:** Fear was largely induced by the diabetes health care professionals working in overcrowded clinics stretched thinly across the service. They used a direct and uncompromising approach to instill the importance of self-care in order to avoid severe long term complications.
Tan et al (2017) (20)	Descriptive qualitative To explore the experiences of older Singaporeans with Type 2 diabetes in diabetes self-care management in order to understand their perceived needs, expectations and the barriers associated with their diabetes self-care management	N=14 Age range: 50-71 years old Setting: Singapore	**Diabetes is genetic, destined, and not serious; complications, let it come:** It is a family genetic condition and not cancer. Complications let them came. **I don't know diabetes**: There was a widespread expression of frustration and unhappiness over the inadequacy of health information and their lack of understanding about diabetes converging in all of the participants. **Doctor and nurses are important facilitators of self-care management:** There was a convergence of the perception that a doctor and/or nurse is the best alternative for patient who seek advice related to self-management. **Barrier:** **Diabetes self-care is difficult:** Eating is meaningless and cultural. There is no time for physical exercise and they often forget the medicine.
Ansari et al (2018) (17)	Phenomenology, qualitative To explore the patients' perceptions and the experience of the self-management of diabetes in the rural area of Pakistan and to better	N=30 Age range: 40-60 years old Setting: a medical center at	**Stigma attached to the disease:** Diabetes is considered to be "self-inflicted disease" in Pakistan – there is a moral aspect to self-management of diabetes. **Self-management in context:** In Pakistan, women often subjugated their own needs to those of other family members, usually their

Author(s) (Year)	Design and Purpose of study	Sample and Setting	Major Findings
	understand differences in diabetes self-management among men and women living with type 2 diabetes mellitus. This is as well as the barriers and challenges related to the self-management of diabetes	Al-Rehman hospital in Abbottabad, Pakistan.	husbands and children, who preferred non-diabetic foods. **The patient-doctor relationship:** The diabetic patients need to engage with a range of health professionals in order to develop and participate in self-management activities. **Adherence to diet and exercise:** It appears that the aspect of self-management is almost missing from the population. In particular, the concept of diet and exercise was not there, although some participants mentioned walking in the evening but not regularly. This was evident from the culture, tradition and lifestyle behavior of the people in the rural area of Pakistan where the eating patterns and physical activity pose a lot of difficulties for the middle-aged population in the self-management of diabetes. **Access to diabetes resources:** In Pakistan, the diabetes management program in the community health clinics is not equipped well enough to help and support the patients with diabetes. The health services in the community are not adequate. **Social support:** The lack of social support in the community in the rural area of Pakistan was very much evident from the discussions with the patients, particularly with their friends and family **Barrier:** There is a shortage of community doctors and expensive consultations with private doctors pose many problems for patients.
Medagama et al (2017) (19)	Descriptive qualitative To explore the contextual reasons that limited physical activity among the type 2 diabetic patients living in a rural community	N=40 Age range: 40-60 years old Setting: the Diabetes	**Engaging in physical activity:** None of the participants engaged in a regular regimented exercise program, and any significant PA that was performed was a part of their lifestyle. **Barriers to physical activity:** health-related, time and lifestyle

Author(s) (Year)	Design and Purpose of study	Sample and Setting	Major Findings
		Clinic at the Teaching Hospital, Peradeniya Srilanka	management, environmental, social and cultural.
Kawoun Seo (2019) (21)	Concept analysis To conduct a concept analysis of self-stigma among patients with diabetes and to introduce an operational definition of self stigma	N= 9	**Barrier to self management:** The meaning of self stigma in patients with diabetes is a state in which the persons develop negative self-feelings as they deal with the disease. This can cause low self esteem or self-efficacy or both. Then there is the tendency to avoid disclosing the illness along with social withdrawal.

THE EFFECT SPIRITUAL STORY TELLING TO DECREASE STRESS LEVELS OF CHILDREN TREATED AT SULTAN AGUNG ISLAMIC HOSPITAL

Wahyu Endang Setyowati[1], Markus
[1] Lecturer Nursing Faculty, Islamic Sultan Agung University, Semarang, Indonesia
wahyu.endang@unissula.ac.id

ABSTRACT

Hospitalization create a good condition for children and their family. However, children's perceptions of illness vary. This was caused by the stages of development of the age of the children, previous experience of sickness, supporting factors that exist, and the ability to overcome a problem. Children will feel uneasy because they cannot play like when they were healthy. This study aimed to determine the effect of spiritual storytelling on stress levels of children admitted to hospitals.The design of the study was a design model used in conducting research. The type of this study was observational quantitative research. It used the One Group Pre and post-test with control design. The results of statistical tests of stress levels in the intervention group obtained p-value of 0.000, which means there was a significant difference between stress levels before and after treatment because the p value was <0.005. The use of spiritual story telling therapy as a non- pharmacological effort to reduce stress should be carried out in the application of nursing science.

Keywords: hospitalization, stress, spiritual story telling

1. Introduction

Being ill is a condition that can occur in anyone, especially children. During their growth and development, children who get ill can bring in stress responses both to the children themselves and to their families. The hospitalization of children increases the stress felt by the children and their families (Widayat, 2017).

According to Wahyuningsih, hospitalization is when the condition of a person in relation to their bodily functioning decreases and they are admitted to health care facilities or to a hospital. The hospitalization reactions shown by children include feeling uneasy, being unwilling to be approached by the health workers, fear and crying, feeling anxious, uncooperative and even having a temper tantrum (Wahyuningsih, 2012).

When a child gets sick, there tends to be a stress response in both the child and their family. Hospitalization creates a good condition for the children and their family. However, a child's perception of illness varies. This is caused by the stages of development depending on the age of the children, their previous experience when sick, any supporting factors that exist and the ability to overcome a problem. Children will feel uneasy because they cannot play like when they are healthy (Wong, 2009).

According to Achmad's research, (2015), storytelling has the effect of reducing the degree of stress felt by 8 year old children with leukemia who are hospitalized. This was characterized by changes in behavior before and after the intervention was given. Nurses must be able to understand the stressors and behavior of children during unhealthy conditions and when they are admitted to the hospital according to their developmental stage. Nurses are expected to provide nursing care and to be able to meet the psychological needs such as play and spirituality of the children who have experienced hospitalization (Masulili, 2013).

Previous research has shown that story telling reduces anxiety and pain. Fairy tale therapy can also address sleep disorders in children. Arad (2004) revealed that story telling with the parents helps children with Attention Deficit / Hyperactivity Disorder (ADHD). It helps the children with this disease to stay in school and to practice concentrating when they are receiving lessons. Arad said that story telling helps the children receive lessons with their parents and teachers in a state of concentration and happiness (Banarto, 2017).

Interventions to improve the ability to control stress are by teaching techniques to express their problems experienced physically, verbally, socially and spiritually. Previous research has proven that story telling effectively heals a person post-trauma. The results of the story telling and managing trauma research focused on health and spirituality at work concluded that telling stories is able to help the child to heal from trauma as a result of disasters. It also helps the therapists to do cathartic communication, which can help someone to express the burden of feelings that they do not want to be conveyed (Ruesch, 2017).

Playing is an activity that is favored by children. When playing, children directly apply various kinds of activities such as communicating and achieving satisfaction during the process of socialization with others. In vulnerable children, they need full attention from their parents and the environment around them. If the children’s needs are psychologically not fulfilled, then it can cause the children to easily experience stress. (Russell, 2017)

Therefore, the emotions of children can be directed and also trained by telling stories. By telling stories, the children can be directed to feel various things. Children can be directed on how-to live in a state of sadness and happiness. Storytelling is a good children's coping mechanism to divert the stress that they feel about their illness. Through storytelling, a feeling or emotion is trained well and it will be able to make the children feel and live with various types of roles in their life. Moreover, by telling stories, the children will be able to let go of their fear, anxiety and pain directed towards the illness, and they may be able to express anger and hostility (Gubrium, 2017).

The results of a preliminary study survey conducted at the Sultan Agung Islamic Hospital in Semarang City showed that there were around 30 pediatric patients in 2017. The percentage of children cared for, by more than 60%, was made up of pre-school age children. Of the 30 patients, 23 of them showed maladaptive behavioral changes to care. Maladaptive behavioral characteristics such as rejection, fear, sadness, no acceptance and crying when being taken care of were some of their. This happens because the child does not understand or know the health worker, the type of care and

the new environment. This creates stress in the patient. Child psychology is strongly affected by stress conditions and it can also affect the programs provided by health care workers.

Based on the description of the problems found, the researchers were interested in conducting a study on the effect of spiritual storytelling on the stress levels in the children treated at Sultan Agung Islamic Hospital.

2. Methods

The research design was a design model used in conducting research (Hidayat, 2007). This study was an observational quantitative research study. The design of this study was a one group pre-test-post-test with a control design. Therefore, the sample consisted of two groups, i.e. the control and the intervention group (Hidayat, 2014). The study aimed to determine the effect of spiritual storytelling on the stress levels of children treated in hospitals.

The population was all of the subjects with the characteristics that will be examined (Hidayat, 2007). The population in the study was 30 children treated in the hospital. The sample was part of the population to be studied (Hidayat, 2007). The sample in this study was part of the total population which can represent the children who experience increased stress. The sample was taken using the total random sampling technique. The random sampling (18 control and 18 intervention) was taken by taking the entire population to be used as samples (Hidayat, 2007). The criteria for the sample taken were the inclusion criteria resulting in an affordable target population. They were examined according to the general characteristics of the research subject (Nursalam, 2013). The inclusion criteria in the research were as follows: children who were willing to become participants in the research gave their consent verbally and this was permitted by their parents by them filling out the informed consent form. The children were aged 6 - 12 years old and they were treated for at least 3 days at Sultan Agung Islamic Hospital Semarang. The exclusion criteria resulted in removing the subjects who did not meet the inclusion criteria from the study according to the problems experienced by the children while they were being hospitalized (Nursalam, 2013).

The exclusion criteria in the study were children with special needs such as autistic children, children with hydrocephalus disease, hyperactive children and children who were in isolation rooms. This was in addition to the patients taking anxiety or stress medication.

The research was conducted at Sultan Agung Islamic Hospital, Semarang beginning in November 2017.

3. Results

The results of the study on the effect of spiritual story telling on the stress level of children treated at the hospital can be explained as follows.

The study was conducted over 4 weeks from December 3rd 2017 to January 5th 2018. The number of samples obtained was based on the following criteria, i.e., 30 respondents divided into 15 respondents as the control and intervention group. The results of the study obtained data on the characteristics of the respondents according to age, education, disease and their length of time in the

hospital under care. This is as shown in the below table.

Table 4.1. Characteristics of the Children Who Experience Stress in the Hospital

Variable	Category	Control Group N=15		Intervention Group N=15	
		N	%	N	%
Age	6 Y.O.	3	10.00	3	10.0
	7 Y.O.	4	13.35	4	13.35
	8 Y.O.	3	10.00	3	10.00
	9 Y.O	4	13.35	4	13.35
	12 Y.O	1	3.35	1	3.35
	Total	15	100	15	100
Education	1st Graders	3	10.00	3	10.00
	2nd Graders	4	13.35	4	13.35
	3rd Graders	3	10.00	3	10.00
	4th Graders	4	13.35	4	13.35
	5th Graders	0	0	0	0
	6th Graders	1	3.35	1	3.35
	Total	15	100	15	100
	Total	15	100	15	100
Diseases	DBD	2	6,35	2	6.35
	Debris	9	30,00	9	30.00
	Typhoid	4	13,35	4	13.35
	Total	15	100	15	100
Length of Hospitalization	3 Days	7	23,35	7	23.35
	4 Days	6	20,00	6	20.00
	5 Days	2	6,65	2	6.65
	Total	15	100	15	100

Based on Table 4.1, it shows that in the treatment group, most of the children were aged 7 and 9 years old, totaling 4 children (13.35%). Education on the average was in the 2nd and 4th grade of elementary school. The disease suffered from was debris for 9 children (30%) and the length of hospitalization was, on average, 3 days for 7 children (23.35%). The control group was mostly the same as the treatment group.

Univariate analysis in this study illustrated the results of the analysis on the age of respondents, in addition to the frequency distribution of the respondents' characteristics including education, disease, length of stay and their stress levels before and after the story telling treatment.

Table 4.2. Stress Level Before and After Treatment in the Control Group

Variable	Before Treatment	Percentage (%)	After Treatment	Percentage (%)
Normal	0	0	5	16,7
Mild Stress	5	16,7	10	33,3
Moderate Stress	10	33,3	0	0
Severe Stress	0	0	0	0
Chronic Stress	0	0	0	0
Total	15	100	15	100

Based on Table 4.2, the data shows that in the control group, the stress level before treatment was in the moderate stress category with 10 respondents (33.3%) and after treatment, this turned into the mild stress category with 10 respondents (33.3%).

Table 4.3. Stress Level Before and After Treatment in the Intervention Group

Variable	Before Treatment	Percentage (%)	After treatment	Percentage (%)
Normal	0	0	15	50
Mild Stress	5	16,7	0	0
Moderate Stress	10	33,3	0	0
Severe Stress	0	0	0	0
Chronic stress	0	0	0	0
Total	15	100	15	100

Based on Table 4.3, the data showed that in the treatment group before the treatment, there were 5 mild stressors (16.7%). After the intervention, it became normal (0%). For moderate stress, it was experienced by 10 people (33.3%). After the intervention, the stress levels became normal in 15 people (50%).

Bivariate analysis was carried out to determine the effect of the spiritual storytelling program on the stress level of children treated in the hospital using the Kolmogrov-Smirnov test analysis. The results of the bivariate analysis are as follows.

Results of the Marginal Homogenety Test on the Stress Levels Before and After Treatment in the Control Group

Based on Table 4.4, it was found that the stress level of the respondents before therapy was that 5 respondents in the normal category and after treatment, there were 20 respondents in the normal category. Some of the respondents who were in the same category both before and after therapy experienced an increase in stress. As for the results of the marginal homogeneity test, the p-value was 1.000 which means that Ho is rejected. Therefore, there is no difference before and after the administration of therapy in the control group.

Results of the Marginal Homogenety on the Stress Levels Before and After Treatment in the Intervention group

Based on the results of the test, it was found that the stress level of the respondents before therapy was that 5 respondents were in the mild stress level category and 10 respondents were in the moderate stress level category. After therapy, the stress level of the 15 respondents was in the normal stress level category. Some of the respondents who were in the same category before and after therapy experienced an increase in average points. As for the results of the marginal homogeneity test, the p-value was 0.000, which means that Ho was accepted. Thus, it can be seen that there is a difference before and after the treatment in the treatment group.

Table 4.4. Results of the Kolmogrov-Smirnov Test on Stress Levels after Treatment in the Intervention and Control Groups

	Stress										Total	P
	Normal		Mild		Moderate		Severe		Chronic			
	n	%	N	%	N	%	n	%	N	%		
No Treatment (Control)	0	0	5	16,7	10	33,3	0	0	0	0	15	0,000
With Treatment (Intervention)	15	50	0	0	0	0	0	0	0	0	15	

Based on the results of the Kolmogrov-Smirnov test in Table 4.6, it was found that the value of p was 0.000 (p > 0.005). This means there were differences in stress after being given therapy in both the control and intervention groups. Therefore, it can be concluded that there is an effect from spiritual story telling on stress.

4. Discussion

a. Stress levels before and after treatment in the control group

The results of the study in the control group showed that the 15 respondents generally experienced a decline; 10 respondents were in the moderate stress category and 5 respondents (16.7%) were in the mild stress category. Statistically, the majority of respondents experienced stress in the moderate stress category, totaling 10 respondents (33.3%).

In the control group, an assessment of the increase in stress levels was first performed. After that, none of the intervention was given by the researcher until the intervention process in the treatment group was completed. After 4 weeks, their stress levels were assessed. Based on the analysis of the marginal homogeneity in Table 4.5, the p value was 1.000 where p > 0.005. This means that there was no difference in stress level in the control group before and after the intervention in the treatment group.

The control group in this study did not get the spiritual story telling treatment during the study and the results showed that their general statistics showed a decrease in stress levels. This is very interesting to analyze. A behavior process is something that threatens and that can also affect the individual responses to an event on the physiological, emotional, cognitive and behavioral levels. In addition, according to Lazarus and Folkman (2012), stress is an individual condition that is influenced by the environment. The condition of spirituality in children is influenced by the existence of programs that have been made by the hospital including therapy such as playing puzzles and efforts to always pray before and after taking nursing care.

It can be concluded that even though the control group did not get spiritual storytelling therapy, in general, the decrease in stress that occurred may be due to the spiritual conditions otherwise. Thus it is important to include aspects of spirituality in each intervention.

b. Stress levels before and after treatment in the intervention group

In the intervention group, an assessment of the increase in stress levels was first carried out. After that, the treatment was given by the researcher until it was completed. After 4 weeks, the assessment of the child's stress levels was carried out. The results of the study focused on the treatment group of respondents before therapy were that 5 respondents (16.7%) were in the mild stress level category and 10 respondents (33.3%) were in the moderate stress level category. After therapy, the stress level showed that all 15 respondents (50%) were in the normal stress level category.

Based on the marginal homogeneity analysis test in the previous table, the value of p was 0.000 where $p > 0.005$. This means that there is a difference in the stress felt by the control group before and after treatment as in the intervention group.

Based on this, it can be concluded that the intervention group that received spiritual storytelling therapy saw a general decrease in stress. Therefore, it is important to administer play therapy to deal with the stress in the form of spiritual storytelling therapy that makes them motivated, causing their stress levels to decline.

c. Comparison of stress after treatment in the control and intervention groups

Stress in the control and intervention group, according to the results of the study, showed that there were differences after giving the treatment in the intervention group. This can be seen in the table on the measurement of the child's stress levels. In the intervention group, the results showed that all of the respondents experienced a decrease in stress levels and categories down to normal. Meanwhile in the control group, there were some respondents who showed a decrease from the moderate stress level category to having a mild stress level.

The results of the Kolmogrov-Smirnov statistical test found that the p - value was 0.000 ($p > 0.005$). Therefore it can be concluded that play therapy had an effect on changing the stress levels of children treated in a hospital.

There was a decrease in stress levels from moderate to mild, and even down to no stress. The emotions of children can be directed and trained by telling stories. This is because it can direct the children to feel various human feelings. Children can be directed on how to live with both sadness and happiness. Storytelling is a good child's coping method to divert stress in a child about their illness. Through story telling, a feeling or emotion can be trained to feel and live well in the context of various types of role in their life. Moreover, by telling stories, the children will be able to let go of fear, anxiety and pain felt towards disease, as well as being able to express anger and hostility (Gubrium, 2017).

According to Achmad's research (2015), story telling has an effect on reducing the level of stress in 8 year old children suffering from leukemia. This is characterized by changes in behavior before and after the intervention. Nurses should be able to understand the stressors and the child's behavior during the time when they are unhealthy and admitted to the hospital according to the stage of the child's development. Nurses are expected to be able to provide nursing care and to meet the child's psychological needs, such as play and spirituality, when they experience hospitalization (Masulili , 2013).

Previous research has showed that story telling decreases anxiety and pain. Fairy tale therapy has also been used to address sleep disorders in children. Arad (2004) revealed that story telling with the parents helps children with Attention Deficit Hyperactivity Disorder (ADHD). It helps the children with this disease stay in school and to practice concentrating when receiving lessons. Arad said that story telling helps the children receive lessons with their parents and teachers in a state of concentration and happiness (Banarto, 2017). Spirituality is a good choice to mix with story telling. People are more easily accepting of moral messages that they want to convey when they are packaged into the values of spiritualism. The combination of the two results in new concepts and ways, namely spiritual story telling, is done by utilizing the values and stories of religiosity so then their spiritual elements modify the fairy tale. (Yuniarti et al., 2017). The results of the statistical tests on the stress levels in the intervention group obtained a p value of 0.000, which means that there is a significant difference between the stress levels before and after therapy because the p value is <0.05.

5. Conclusion

The characteristics of the respondents in this study were 7 and 9 year old children totaling as many as 4 (13.35). The results obtained showed that all of the respondents experienced a decrease in stress with a percentage of 100%. In the treatment group, the stress levels before the treatment showed the result that the number of respondents who experienced mild stress was 16.7% and those who experienced stress at a moderate level was 33.3% . In the control group, the stress levels after the intervention showed the result that the number of respondents with moderate stress was 15 respondents or 100% . The results of the statistical tests on the stress levels in the intervention group obtained a p value of 0.000, which means that there is a significant difference between the stress levels before and after therapy. This is because the p value is <0.005.

The patients and wider society can use spiritual storytelling to relieve stress. For the health service institution, it is expected to apply spiritual storytelling therapy as a non-pharmacological therapy to reduce stress conditions in accordance with the operational standards that have been set. For educational institutions, the actual use of spiritual story telling therapy as a non-pharmacological effort to reduce stress should be carried out in the application of nursing science. For further research, it is expected that further research on stress control can be done through other methods (for example, writing therapy techniques and batik techniques).

ABSTRACT

Hyperglycemia is one of problem that happened to clients Diabetes Mellitus is a difficult problem to controled, pharmacological interference to DM Patient has not been able to guarantee control blood sugar. There is a need to discover new therapies to controling the seriusly desease, use of complementary therapy is one of the effective alternatives to reduce blood sugar levels, like a use Nigella sativa oil extract, pomegranate seed oil, Black truffle extract, and Corn silk (Zea mays L). Herbal medicine or complementary therapy the benefit very low side effects, low price, therapeuticaly potent, and easy availability. Eleven best articles were foundusing PECOT framework in some databases; Science Direct, EBSCO, Scopus, ProQuest, Pub Med, and Spinger Link. Those articles have been chosen based on some criteria. Complementer theraphy has been avective to decrease blood glucose for patient DM. Complementer theraphy was recommended for patient with DM.

Keywords : Diabetes Melitus, complementer theraphy, hyperglycemia

1. Introduction

Diabetes mellitus is a metabolic disorder that results in the pancreas not producing enough insulin, and this can affect other major organs such as the heart, kidneys, and liver [1]. The condition in DM is characterized by hyperglycemia and glucose intolerance due to decreased insulin production and or insulin not produced at all or both. [2].

Mortality and disability in clients with DM is very high, in the world diabetes mellitus is a chronic disease that affects about 5 - 10% of the world population. The estimated global estimate for diabetes is 171 million in 2000 and will increase to 366 million by 2030 [3]. diabetes mellitus is the most degenerative disease with 102,399 cases, this is based on the annual report of the East Java Health Office in 2012.

Diabetes has become a serious threat to public health and an increasing burden on the global economy [4]. One effort to reduce DM prevalence rates is for experts to carry out research and development of herbal medicines as complementary therapies or other complementary therapies, in research conducted by Ahangarpour et al., 2017 800 species of plants have the potential for diabetes. Herbal plants that can be used as anti-diabetes include Nigella sativa oil extract (black cumin), pomegranate seed oil, black truffle (mushroom), and corn silk (Zea mays L) and many others.

From research conducted by experts, it was found that herbal plants containing anti-

inflammatory and high anti-oxidants were very good for the treatment of diabetes such as Nigella sativa extract and pomegranate seed oil, and black truffles. Whereas in the corn silk plant, the research conducted by Kristover Koloay, Gayatri Citraningtyas, 2015 besides having high antioxidants, antidiabetic, and antihyperlipidemic and contains flavonoids [6]. Corn silk has been believed to be a treatment for diabetes in China for several centuries [7]. We can find corn plants easily, cheap prices, and safe for consumption [1]

The purpose of this study is to conduct a literature review to determine the effectiveness of several herbal plants that are used as non-pharmacological therapies or complementary therapies for the treatment of DM. Of the several herbs that have been studied, corn silk (Zea mays L) has more value compared to other herbs, besides being easy to get, economical, and has enormous benefits as a form of alternative herbal therapy that can reduce blood glucose levels in patients with diabetes mellitus. This study is expected to be able to provide further research ideas in the provision of interventions for alternative herbal treatments in patients with diabetes millions so as to improve the quality of life of patients with diabetes mellitus [1].

2. Methods

2.1.*Design*

The design of this study uses systematic reviews of quantitative study approaches formulated to review relevant quantitative studies and comprehensive analysis. This systematic goal was developed based on the PICO (Patient, Intervention, Comparison, and Outcome) framework model [8]. This systematic reporting structure uses PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) [9].

2.2.*Inclusion and exclusion criteria*

This systematic review establishes the inclusion and exclusion criteria that focus on quantitative studies. The feasibility study is used to describe the provision of complementary therapy to reduce blood sugar in DM patients with language eligibility criteria with minimal abstracts using English. The year of publication is limited to the last 10 years from 2008-2018. The criteria for further inclusion groups are research on the use of complementary therapy/use of herbal therapies to reduce blood sugar in DM, while the exclusion criteria are the use of pharmacological therapy in DM patients.

2.3.*Search strategy*

A systematic search was carried out using the PICO electronic data framework and was conducted in accordance with the PICO framework [8]. The first step: searching for the electronic databases of Science Direct, EBSCO, Scopus, ProQuest, Pub Med, and Springer Link to identify key articles and identify keywords by adjusting key concepts: 1. Extracts to reduce glucose in DM 2. Complementary herbs 3. Complimentary for DM 4. Diabetes mellitus. And 5 quantitative studies. Keywords to find complete quotes and articles, including title, abstract, text, and reference information. The next step was to translate keywords in English to find relevant articles in electronic databases. After that, the filter used the PICO framework to determine which articles have been passed to be reviewed according to the topic. Complete search strategies are limited to the last 10 years between 2008-2018.

2.4.*Quality of appraisal*

The quality assessment of articles was reviewed using a quantitative Critical Appraisal Skills Program (CASP) study tool. There are 10 different questions that consider the results of qualitative studies, the validity of studies, and uses (Critical Appraisal Skills Programme, 2018).

CASP is a tool for evaluating the quality and utility of research reports (Exactly Katrak et al., 2004). 10 questions in CASP by selecting "yes", "no" or "no now" from each question. Each document was assessed independently by 3 reviewers (YD, TS, and EF). Existing judgments are combined with other reviewers in one file and if there are differences of opinion among reviewers then it will be completed in the next discussion phase. The allocation of scores on a scale of 10 for each article reviewed is based on how many "yes" answers in the score and score yes above 7 or more refers to the quality of the article that is very good. The purpose of this quality assessment is not to distinguish between quality but in a systematic process and the standard process can provide high-quality reviews based on existing topics.

3. Result

3.1.*Selection of study*

The search strategy produced a total of 112 citations, deleted 53 duplicates, 27 in the existing literature were deleted during the first screening because the title and/or abstract did not match the specified eligibility criteria. 15 full articles from the second screening phase and 8 articles obtained were retained for review, 4 additional articles were obtained from the reference screening stage and thus the last session included 12 articles on complementary therapy to reduce glucose levels in DM patients.

3.2.*Study characteristic*

A total of 12 studies reviewed in 2008-2018 were conducted in 10 countries: Thailand, Iran, China, Hong Kong, Nigeria, Turkey, Pakistan, Sudan, Indonesia, and India. Quantitative research methods consist of true laboratory experiments and quasi-experimental studies.

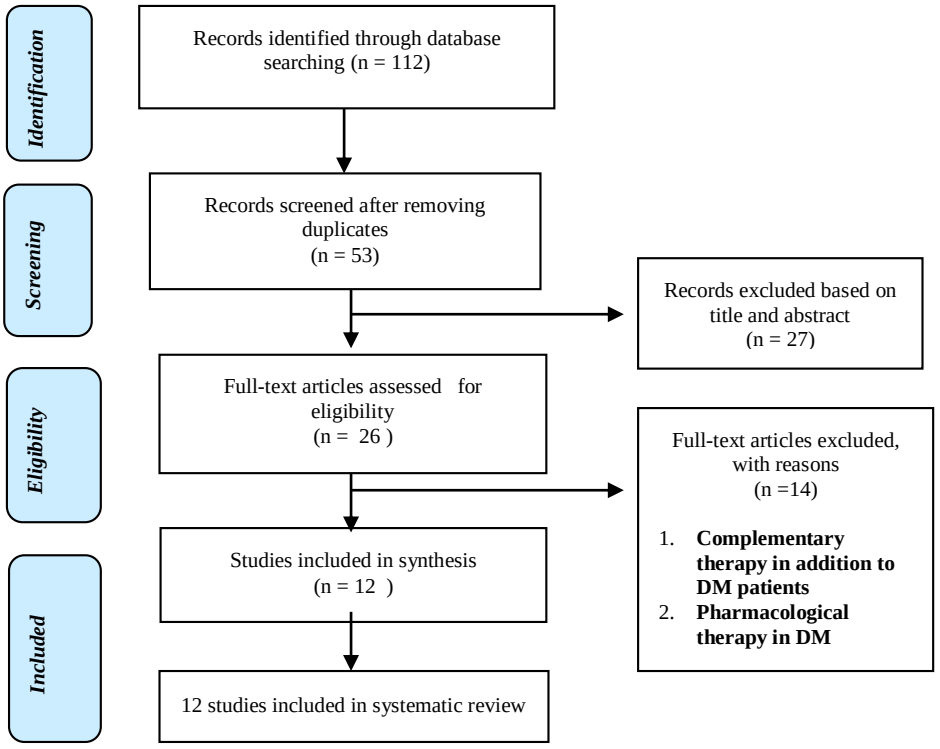

Figure 1. Flow Diagram

3.3.*Result of intervention*

Search literature identifies 12 journals that describe complementary therapy can reduce glucose levels in patients with DM. There are several advantages to using herbal ingredients as complementary therapies including:

3.3.1. Extract nigella sativa. In the research conducted by [10], it was found that administration of Nigella sativa extracts in rat experiments significantly reduced inflammation and was a good antioxidant.

3.3.2. Pomegranate seed oil. Giving pomegranate seed oil to ingredients has been shown to reduce insulin resistance by reducing inflammatory cytokines, modulating glucose homeostasis, and is antioxidant. And is one of the complementary therapies recommended for patients with DM [4].

3.3.3. Black truffle extract. Reports from [11] it was found that the administration of black truffle extract is very good for reducing inflammation and can reduce hyperglycemia.

3.3.4. Betaine treatment. Is one of the complementary therapies that can reduce HbA1c levels, and serum glucose and fat and peroxides in the liver and kidneys [12].

3.3.5. Corn silk (Zea mays L). In a study conducted by [15] corn hair (Zea Mays L) is also one of the complementary therapies that can be used as a good anti-inflammatory and anti-immunologic benefits. Research results from [11] how that in modern pharmacological studies, corn silk extract can be used as a companion drug for people with hyperglycemia, and beta cell regeneration and insulin repair. In China, corn silk has often been used as a herbal medicine [12]. Corn silk is very suitable when used as a complementary therapy in Indonesia because we can get corn plants easily, economical prices, therapeutic potential and no side effects [1].

4. Discussion

Nigella sativa extract in this study, nigella sativa extract significantly decreased fasting blood glucose significantly in the intervention condition compared with the placebo group [13]. ***Pomegranate seed oil*** in this study it was found that PA provides antidiabetic effects through various mechanisms, such as reducing inflammatory cytokines, modulating glucose homeostasis, and antioxidant properties in type 2 diabetes [4]. In Indonesia pomegranate plants are now rarely found, pomegranates are imported from abroad and are expensive. ***Black truffle***, the results of research on this study found that black truffle is one of the herbs that can reduce oxidative stress and how to regulate antioxidant synthesis at the molecular level, and can reduce the occurrence of inflammation in STZ-induced mice [10]. Black truffle is one type of plant that is less familiar, especially in Indonesia, and is only available in special places. So that it is less effective for all groups, especially middle and lower economic circles. ***Betaine treatment*** in this research study comparing two agents was compared, namely giving betain and metformin to STZ-induced DM rats. And it was produced that betain has an effect similar to metformin which can reduce blood HbA1c, serum glucose and lipid levels, and urinary protein excretion and reduce prooxidant status in the liver and kidney tissue of DM rats. However, it does not improve liver and kidney function tests in serum and histopathological findings in the liver or kidneys. In conclusion, all the findings mentioned above indicate that betain can be a supplement candidate in the treatment of DM and prevention of its complications [14]. ***Corn silk (Zea mays L)*** Corn silk is very potential to be used as an herbal plant for complementary therapy. Corn silk can be used as a good anti-inflammatory and also as an anti-oxidant. within a few decades this plant was believed in China as a hyperglycemic drug, beta cell regeneration and insulin repair [11]. Corn silk is very easy to get in Indonesia. Corn plants are spread in the provinces of Lampung, Bengkulu, East Kalimantan, West Java, West Nusa Tenggara (NTB), and East Java.

From various complementary herbal therapies of Nigella sativa extract , pomegranate seed oil, black truffle extract, betain treatment , and corn silk, it was concluded that the use of corn silk (Zea mays L) was very potential to be carried out in Indonesia, the average area of agriculture and plants corn is very easy to get in Indonesia with low prices, many benefits for therapy, no side effects [1]

5. Conclusion

Review of journals that have been done found that therapy using herbal or complementary is very significant in lowering blood glucose levels in animals try (mice) and human. Therapy the benefit very low side effects, low price, therapeutically potent, and easy availability.

Appendices

Table 1. Summary of studies

No	Title, Authors, & Time	Variable	n	Design	Result
1	**Black truffle aqueous extract attenuates oxidative stress and inflammation in STZ-induced hyperglycemic rats via Nrf2 and NF-kB pathways [10]**	Independent: extract black truffle Dependent: oxidative stress and inflammation	-	True experiment	Reducing inflammation and reducing hyperglycemia
2	**A potential compound of pomegranate seed oil in Type2 diabetes mellitus management [4]**	Independent: pomegranate seed oil Dependent: Type2 diabetes mellitus management	-	Quasi experiment	inflammatory cytokines, modulating glucose homeostasis, and antioxidant properties
3	**Betaine treatment decreased serum glucose and lipid levels, hepatic and renal oxidative stress in streptozotocin-induced diabetic rats [14]**	Independent: Betaine treatment Dependent: decreased serum glucose and lipid levels, hepatic and renal oxidative stress		True experiment	Effective in decreasing STZ-induced high levels of blood HbA1c, and serum glucose and lipid levels and prooxidant status in liver and kidney tissues.
4	**Effect of Nigella sativa oil extract on inflammatory cytokine response and oxidative stress among people with type 2 diabetes mellitus: a randomized, double-blind, placebo-controlled trial [13]**	Independent: Nigella sativa oil extract Dependent: inflammatory cytokine response and oxidative stress among people with type 2 diabetes mellitus	Sample: 43 participants divided into 2 groups, namely 1. group controls 23 participants 2. groups of 20 participants	Quasi-experiment	Potential anti-inflammatory and anti-oxidant substance

5	**Corn Silk (Zea mays L), a Source of natural antioxidants with α-amylase, α-glucosidase, advanced glycation and antidiabetic nephropathy inhibitory [2]**	Independent: Corn Silk (Zea mays L) Dependent: α-amylase, α-glucosidase, advanced glycation and antidiabetic nephropathy inhibitory	-	True experiment	Anti-inflammatory and anti-immunologic benefits
6	**Comparison of Anti-Diabetic Effects of Polysaccharides From Corn Silk On Normal And Hyperglycemia Rats [15]**	Independent: Polysaccharides Corn Silk Dependent: Normal And Hyperglycemia Rats	The 20 samples were made into 6 groups. The first group of the control group and group two were divided into 5 treatment groups	True experiment	In diabetic rats that have been given therapeutic treatment using corn-based distilled water at a dose of 100 - 500 mg / g per body weight, it significantly reduces blood gular levels, and can even reduce the total serum lipid cholesterol (TC) and total triglycerides (TG).
7	**Therapeutic Potential of Herbs Against diabetes [1]**	Independent: Therapeutic Potential of Herbs Dependent: decreased blood sugar levels and weight loss	Samples were carried out on rat experiments but the amount was not mentioned in detail	True experiment	Corn hair extract can significantly reduce blood sugar levels ($p < 0.01$) Giving extract of corn hair affects weight loss in experimental animals
8	**Hypoglycemic and Hypolipidemic Effect of Methanol Extract of Corn Silk (Zea mays) In Streptozotocin-Induced Diabetic Rats [16]**	Independent: Hypoglycemic and Hypolipidemic Effect of Methanol Extract of Corn Silk Dependent: decrease in blood sugar, blood urea, and cholesterol	24 rats were divided into 3 groups, each of which consisted of 8 rats	True experiment	The effect of methanol extract from corn in induced hyper blood glucose silk on Glycemic rat. In type II diabetes the dose of 200 mg/kg showed the highest effect of glucose reduction at 2 hours ($p < 0.001$) compared to the control group. Followed by a dose of 400 mg/kg which reduced blood glucose significantly

					(p <0.05) during the trial. Whileglibenclamide. showed a significant decrease in the second h (p <0.001) and 4 hours (p <0.05). Effect of methanol extract from corn silk In streptozotocin (type I) diabetic mice both extract doses reduced blood glucose other than blood urea (p <0.05) and the effect of cholesterol reduction was significant (p <0.001)
9	**Uji Efektivitas Ekstrak Etanol Rambut Jagung (Zea Mays L .) Terhadap Penurunan Kadar Gula Darah. Pharmacon Jurnal Ilmiah Farmasi [5]**	Independent: efektivitas ekstrak etanol rambut jagung Dependent: penurunan gula darah	15 rats were divided into 2 groups: 1. control group A (positive dick (+) 2. control group (negative control group (-)	True experiment	Based on research that corn hair ethanol extract has the effect to reduce blood glucose levels with the most effective dose is 2.25g / kgBB
10	**Corn Silk- A Medicinal Boon [11]**	Independent: rambut jagung Dependent: penurunan gula darah dan regenerasi sel beta,dan perbaikan insulin.	Using mice but not stated in detail	True experiment	Corn hair extract can be used as a medicine for hyperglycemia, and beta cell regeneration and insulin repair
11	**The ethyl acetate fraction of corn silk exhibits dual antioxidant and anti-glycation activities and protects insulin-secreting cells from glucotoxicity [17]**	Independent: The ethyl acetate fraction of corn silk exhibits dual antioxidant and anti-glycation activities Dependent: anti-glycation activities and protects insulin-secreting cells from	Separate speckle samples sprayed with anisaldehyde spray reagents and detected after ultraviolet absorption at 254 nm and 365 nm	True experiment	Corn silk can be developed as a dieting agent to protect beta cell function against pathological oxidative stress and protein breakdown in diabetes.

		glucotoxicity			
12	**Physicochemical properties and antidiabetic effects of a polysaccharide from corn silk in high-fat diet and streptozotocin-induced diabetic mice [12]**	Independent: Physicochemical properties and antidiabetic effects of a polysaccharide from corn silk Dependent: high-fat diet and streptozotocin-induced diabetic mice	48 rats were divided into 5 groups, namely: 1. Control the diabetic group 2. Positive control group 3. Group of mice with PCS1 200mg / dl 4. Groups of mice with PCS2 500mg / dl 5. Groups of mice with PCS3 800mg / dl	True experiment	PCS2 has stronger antioxidant activity and a relatively high inhibitory effect (Zhao et al., 2012) high in amylase compared to PCS1 and PCS3

DIET IN PREVENTION OF HYPERTENSION : A SYSTEMATIC REVIEW

A P Sar , S Ramadhan , B F Hidayat

Master Student, Faculty of Nursing, Universitas Airlangga, Surabaya
Email: agoesta.pralita.sari-2018@fkp.unair.ac.id

ABSTRACT

Hypertension is a major public health problem throughout the world and is closely related to the risk of morbidity and mortality in cardiovascular and kidney disease. The purpose of this study was to determine the relationship between dietary patterns to prevent an increase in blood pressure in hypertension patient. The method used in preparing this systematic review begins with searching articles on Scopus, Science Direct and Proquest databases. Articles identified using search terms or keywords ('diet' OR 'dietary' OR 'pattern') AND ('patient' OR 'blood' OR 'pressure' OR 'hypertension') published in the last 5 years (2014-2018). The criteria for the articles used in preparing this systematic review are : cross-sectional research and / or cohort; dietary patterns related to blood pressure in hypertensive patients and / or diagnosed with hypertension; the population in the study were hypertensive patients. There were 15 journals that met the criteria to be analyzed related to diets in hypertensive patients. Food has an influence on the risk of hypertension. Nitrite diets, phenolic acid diets, high- polyphenol diets, whole grains and nuts, cereals and vegetable diets are some examples of diet or foods that can reduce the risk of hypertension.

Keywords: Hypertension; Diet; Blood pressure

1. Introduction

At present the main public health problems around the world are related to the risk of morbidity and mortality in cardiovascular and kidney disease. Hypertension according to the American College of Cardiology is defined as blood pressure above 130/80 mmHg [12].

The incidence of the number of people with hypertension increased from 600 million in 1980 to 1 billion in 2008 and is expected to increase again to 1.5 billion, accounting for a third of the world's population. The prevalence of hypertension is 46% in adults aged 25 years and over in Africa, and about 31% of US adults aged 18 years suffer from hypertension. Hypertensive complications are 9.4 million deaths annually worldwide, and at least 45% of deaths from heart disease and 51% of deaths are related to hypertension [13].

Where, the occurrence of high blood pressure (hypertension) can be used by the body for years before symptoms develop. If not controlled, sufferers can end up with disabilities, poor quality of life or even a fatal heart attack. About half of people with hypertension die of heart disease associated with poor blood flow and death from stroke due to hypertension [7].

The American Heart Association and the National Institute of Health in the United States recommend diet foods to control blood pressure and protect heart health [14]. This literature review study aims to compare what dietary patterns are, which are better at lowering blood pressure.

2. Methods

2.1 Article search strategy

The method used in preparing this systematic review begins with searching articles on Scopus, Science Direct and Proquest databases. Articles identified using search terms or keywords ('diet' OR 'dietary' OR 'pattern') AND ('patient' OR 'blood' OR 'pressure' OR 'hypertension') published in the last 5 years (2014-2018).

A total of 450 articles were found using selected keywords. There are 64 articles that are relevant to the topic, 49 articles were eliminated due to research design mismatches. So there are 15 articles chosen to be reviewed in this systematic review.

2.2 Article selection criteria

The criteria for the articles used in preparing this systematic review are : 1) cross-sectional research and / or cohort; 2) dietary patterns related to blood pressure in hypertensive patients and / or diagnosed with hypertension; 3) the population in the study were hypertensive patients and / or diagnosed with hypertension. This Systematic review was made with the aim of knowing the relationship between dietary patterns to prevent increased blood pressure in hypertensive patients.

3. Results

There are 15 journals that meet the criteria to be analyzed related to diets in patients with hypertension. From the journal, the total respondents in this discussion were 70,808 respondents who suffered from hypertension and needed the right nutrition diet to reduce or stabilize their blood pressure which consisted of ages 11 years to> 60 years. With 12 cross sectional design studies, and 3 cohort studies. From the results of this analysis it was found that food / nutrition / diet intake in patients with hypertension with several complications, such as obesity can affect the occurrence of hypertension in both children, adults, and the elderly. The diet in question is a low-acid diet, a lunch pattern, a nitrite diet, a phenotic acid diet, a diet high in polyphenols, a cereal and vegetable diet, and a grain diet. Where after concluding, only foods that contain fiber are good for lowering blood pressure or hypertension.

4. Discussion

Some studies explain the right diet to be consumed by hypertensive patients, including low-acid diets, low calcium, high-nitrite high-potassium diets, high polyphenols, fiber diets, diet of seeds and nuts. Research [6] showed that high acid consumption was directly proportional to the high systolic blood pressure and the high prevalence of hypertension in the adult population living in Germany.

In their study explained that there was no significant relationship between low calcium dietary habits and the risk of hypertension in Chinese adults [8]. The results of these studies are supported by the results of which explained that short-term interventions from calcium supplements with a daily dose of hundreds of milligrams were reported to be effective in reducing blood pressure compared to dietary calcium habits directly from food sources.

Other studies on diets recommended for hypertensive patients [4]. The results of the study explained that consuming foods containing polyphenols can reduce the risk of hypertension especially in women compared to men. Poliphenol is found in tea, beans, coffee and olive oil. Polyphenols have five main components, including flavonoids, phenolic acids, stilbenes, lignans, and others.

Phenolic acid as part of polyphenols has been shown to reduce hypertension. Explained that by consuming phenolic acid, approximately> 400 mg / day, people who experience hypertension get results with reduced high blood pressure they experience [2].

Research explained that a diet with fiber can reduce hypertension. According to the study, when people consumed 0.35 g / kg / day of fiber the risk of hypertension was reduced to 53%. The study proved that the intake of total fiber, cereals, and vegetables, but not fruit fiber, was associated with a reduced risk of hypertension in adults in the United States [13].

In line with the results who conducted a study in Korea on gender differences in the relationship between diet and the incidence of hypertension. The results showed that a diet rich in whole grains and beans was inversely proportional to the risk of hypertension in Korean women. This shows that there are gender differences in the relationship between diet and hypertension [12].

Research also explained related diets for hypertensive patients. The study explained that a diet high in nitrites can reduce the occurrence of hypertension and kidney failure. Many nitrite contained in white rice, chicken, yogurt, tomatoes, cucumber, and others. Suggestions for consumption of nitrite according to the study are 1.0 to 1.4 mg / day [1].

Describes research related to potassium diets for hypertension in adults in Germany. The study found that potassium intake had a direct lowering effect on blood pressure through lower sympathetic activity, altered baroreceptor activity, and reduced renin production and increased renal natriuresis. The potassium intake recommended by the study to reduce hypertension was 0.8 grams / day [6].

Other treatments for hypertensive patients are dietary approach to stop hypertension (DASH). As explained [14] that DASH is associated with a reduction in hypertension in people in the Philippines. The study also explained that individuals who were older, cautious, did not consume alcohol and engage in regular physical activity could have a higher DASH score. But research [5] explained that patients with hypertension were not suitable to follow the DASH guidelines. The study explained that individuals diagnosed with hypertension showed less adherence to the DASH diet than those not diagnosed with hypertension, so the diagnosis of hypertension did not seem to provide incentives to engage in healthy dietary behavior. Research on other DASH was conducted which explained that there was no significant relationship between adherence to the DASH diet and the overall incidence of obesity.

Other studies on diet related to hypertension were carried out [10] who examined the relationship of diet patterns to the incidence of hypertension in adults in Korea. The study explained that consuming alcohol and foods that contain lots of salt increases the risk of hypertension. The results of these studies provide knowledge that improving healthy lifestyles and regular exercise can reduce the risk of hypertension.

Another study on diet explained that high diet quality was measured using a dietary guidline index (DGI) associated with low incidence of hypertension. DGI is a food-based score designed to reflect the quality of the subject's diet in accordance with ADG 2013 compliance for adults in

Australia. Scores of various foods based on various foods consumed are grouped into five core food parts: fruit, vegetables, meat or alternative meat, milk and cereals [9].

Research on the Australian diet is examined [7] the study explained that there was a relationship between the frequency of eating snacks and blood pressure in men and the "later lunch" pattern associated with increased blood pressure in women.

Research[15] explained that diet and main food patterns had a relationship with the incidence of hypertension in the elderly population in China. The main food that gets attention is fast food. According to the research there is a role of the government in setting rules and policies that encourage healthy diets by using healthy foods originating locally and regionally in the prevention of hypertension. Fibrous vegetables, sprouts, soybeans, peas, and green bean sprouts are products that can be used to prevent hypertension.

5. Clinical Implication Nitrite Diets, Phenolic Acid Diets, High-Polyphenol Diets, Whole Grains and Nuts, Cereals and Vegetable Diets

Some dietary patterns that have been studied can be used as promotive, preventive, curative and rehabilitative efforts to increase blood pressure in hypertensive patients, both newly diagnosed and with a history of hypertension. So that it can minimize or eliminate complications that can occur later.

6. Conclusion

Food has an influence on the risk of hypertension. By doing dietary patterns can affect the risk factors for hypertension. Nitrite diets, phenolic acid diets, high-polyphenol diets, whole grains and nuts, cereals and vegetable diets are some examples of diet or foods that can reduce the risk of hypertension. But for a low calcium diet the results showed not so significant for lowering blood pressure. But the need for further research is done to find out the long-term side effects of dietary patterns that have been studied above.

HEALTH EDUCATION PROGRAMS TO IMPROVE SELF CARE BEHAVIOR AMONG PEOPLE WITH DIABETIC FOOT ULCERS: A SYSTEMATIC REVIEW

Dewi Sanda Prima[1], Kusnanto[2], Wahyuni Erna Dwi[2]
[1] Master Student, Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
[2] Lecturer, Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
Email: sanda.prima.dewi-2017@fkp.unair.ac.id

ABSTRACT

Self-care behavior is useful for preventing diabetic foot ulcers (DFUs) and is an important part of education that needs to be conveyed to patients. Providing an effective health education program can improve self-care behavior so that complications in the form of DFUs can be avoided. This study aims to assess health education programs to improve self-care behavior among people with DFUs. We are looking for evidence about health education programs to improve self-care behavior through the Science Direct, EBSCO and Scopus databases. We chose randomized controlled trials (RCTs) and quasi-experimental studies and searches based on inclusion criteria and keywords including 'foot', 'care' and 'diabetes'. Seven studies were assessed and reviewed in the final stages. The results showed that health education programs involving media such as videos, telephone texts, android applications and others were more effective and potential to be developed in this millennium era. However, there are certain methodological concerns in the articles reviewed, indicating the need for further evaluation.

Keywords: health education programs, self care behavior, diabetic foot ulcers.

1. Introduction

Foot care is a part of the standard practice guidelines for diabetic self-care. Continuous foot care can prevent ulcers and amputations. Compliance with DM patients in performing foot care will reduce the risk of ulcers and amputations. Efforts to change a continuous healthcare behavior need a health education. Several organizations such as the World Health Organization, International Diabetes Federation and American Diabetes Association have emphasized the importance of foot care education for DM patients (Ahmad Sharoni, Minhat, Mohd Zulkefli, & Baharom, 2016). Education and efforts to increase motivation are needed to achieve successful behavior change (PERKENI, 2015).

In the millennial era like today, the delivery of education is closely related to the use of technology. Technology is an important means of conveying information because it is more interactive and easily accessible to the public. One technology that is now developing very rapidly is mobile information and communication technology using smart-phones (Castro-López, Chávez-Mayol, Rodríguez-Piñeyro, Melendez-Mier, & Cervantes-Molina, 2017). Other method also developed to increase the foot care behavior among people with diabetes type 2 to following the update in this era.

Objective of this systematic review is to assess the health education programs to improve foot care behavior among people with diabetic foot ulcers.

2. Method

2.1.Search strategy

This Systematic review uses a guide based on the Preferred Reporting Item for Systematic review and Meta-Analysis (PRISMA) [1]. Articles identified through the Science Direct, EBSCO and Scopus databases. We chose randomized controlled trials (RCTs) and quasi-experimental studies and searches based on inclusion criteria and keywords including 'foot', 'care' and 'diabetes'.

Inclusion and exclusion criteria

2.2.Study design

All of these studies were experimental studies that studied the effectiveness of health education programs to improve self-care behavior among people with diabetic foot ulcers.

2.3.Population

Studies reviewed included people with diabetic foot ulcers, aged > 40 years.

2.4.Intervention

All types of health education programs to improve self-care behavior among people with diabetic foot ulcers.

2.5.Study selection

The protocol standard for selecting research studies is suggested in the PRISMA method for systematic review followed by screening by removing duplicates, then reviewers selecting titles, abstracts, and keywords, then deleting irrelevant text according to the selection criteria.

3. Result

3.1.Literature search and study selection

A total of 7 articles were identified to be included in this systematic review. Searching through Science Direct, EBSCO and Scopus, found 296 articles. After duplication screening, there are 268 articles left. Of these, 251 articles were eliminated because of irrelevant topics. The full text article identifies and eliminates as many as 17 articles on the grounds that it is a review article, publication is not in English, research design is not experimental and the outcome is irrelevant. See flow diagram Figure 1.

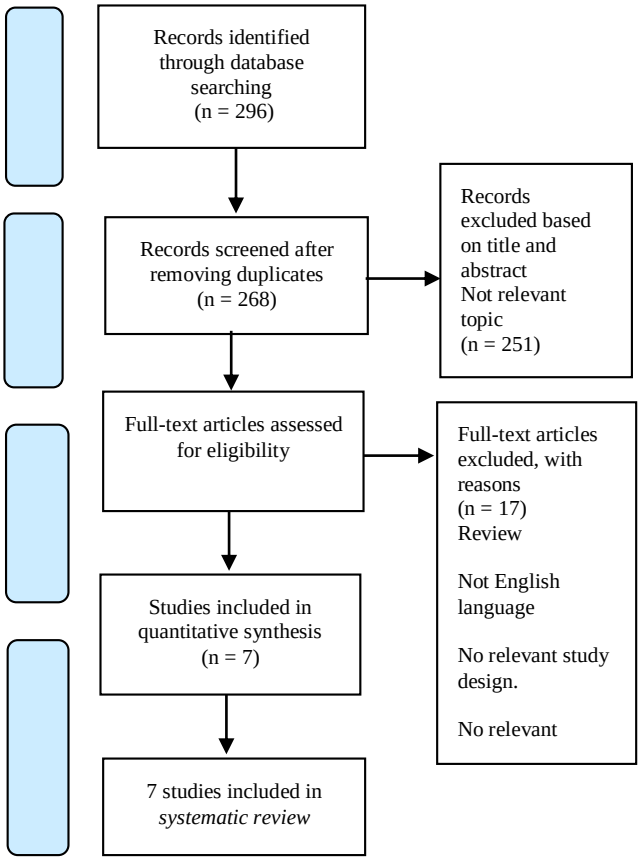

Figure 1: Flow Diagram

3.2.Type of studies

7 studies finally selected for review were three randomized controlled trial, and four quasi-experimental design.

3.3.Population

The included studies involved 977 participants. The sample size of the included studies range from 52 - 225 participants, involving people with diabetic foot ulcers.

3.4.Interventions characteristics

The interventions in this study include health education programs in an educational course, family involvement, instruction and practice program, tele homecare, mobile phone text message and written education.

3.5.Clinical outcomes measures

Studies reported foot self-care behavior, foot self-efficacy (efficacy-expectation), foot care expectation, knowledge, quality of life, fasting blood sugar, leg condition, HbA1C reduction, knowledge, foot care practices and the presence of new injuries.

3.6.Analysis of intervention

Each intervention has been explained related to its influence on the self-care behavior among people with diabetic foot ulcers.

3.7.Educational course

Brand, Musgrove, Jeffcoate, & Lincoln (2016) reported there were changes (positive to negative) STONES and NERDS occurred in 42 (84%) patients from the intervention group and 21 (42%) patients in the control group (P = 0.001). Reduction in the 60-second Diabetic Foot Screen Score was 34 (68%) for the intervention group and 24 (48%) in the control group (P = 0.03). So it was stated that the use of an integrative intervention education program was effective in reducing the danger in patients with diabetic wounds, which would lead to a decrease in infection and better dynamic conditions.

3.8.Family involvement

Marchand et al. (2018) reported that patients in the treatment group had better preventive behavior. The results of the study reinforce the importance of the duration of time and the involvement of the family to increase patients' understanding of the disease & improve the behavior of foot ulcer prevention..

3.9.Instruction and practice program

Mohammad & Khresheh (2018) reported that the implementation of educational programs developed by means of instruction and practice showed a significant increase in the level of knowledge of patients, the ability of patients to carry out their own foot care and the level of patient awareness after the implementation of the program.

3.10. Mobile phone text message

Hassan (2017) reported that knowledge and practice of patient foot care increased significantly after treatment. Providing education with Mobile phone text messages related to DFUs knowledge and prevention practices is an economical, feasible, and effective way to increase diabetic self-care, especially in developing countries.

4. Discussion

4.1.Summary of findings

This systematic review investigated the health education programs to improve foot care behavior among people with diabetic foot ulcers. The included trials were very heterogeneous, differing in outcome measures, types of intervention, types of control group and the duration of follow-up.

4.2.Limitations and future directions

There are some potential limitations related to this systematic review. (1) Heterogeneity of study design. (2) What we considered as primary outcomes (self-care behavior) was not always the same as in the original study.

5. Conclusions

This systematic review explains that health education programs to improve foot care behavior among people with diabetic foot ulcers included educational course, family involvement, instruction and practice program, tele homecare, mobile phone text message and written education.

WHAT'S THE CORE QUALITY OF NURSES ON DIGITAL ERA: A SYSTEMATIC REVIEW

Priscylia Maria Sandehang and Dora Irene Purimahua
Faculty of Nursing, Universitas Pelita Harapan, Karawaci, Tangerang
Email: priscylia.sandehang@uph.edu

ABSTRACT

Nowadays, there is a rapid changing in term of technology that lead to the transformation including nursing services. Nursing as a profession has to maintain the unique characteristic for remaining exist in this era. The purpose of this study was to find out the main quality of nurses in the digital era. This research used a systematic review design, analysed 10 articles from databases were CINAHL, Proquest, EBSCO, Web of Science, Scopus, and Wiley; and was limited to articles published in English between November 2009 and 2019. The researchers applied the Preferred Reporting Items for Systematic Reviews & Meta-Analyses (PRISMA) reporting guidelines as applicable. In this study, nurses have to adapt with all aspect of transformation without losing the main character that is humanities aspect, was formed from caring, cultural sensitivity and ethics-moral value. This systematic review provided the scientific evidence for nurses to improve humanities skill as a principle and main commodity of nurses' job which could not exchange with any form of skill for survive on the radical changing caused by technology development. Future studies are suggested to investigate driving factors leading to healthcare transformation in being a fully contributing member of the interprofessional healthcare team on the 4.0 industrial revolution.

Keywords: core quality, digital era, caring, nurses' role, transformational

1. Introduction

The 4.0 Industrial revolution has introduced the development of mass technology production which are able to operate independently or coordinate with humans. The 4.0 industrial revolution is used on three interrelated factors namely; 1) digitization and economic interaction with simple techniques towards economic networks with complex techniques; 2) digitizing products and services; and 3) new market models [1]. Furthermore, Deloitte (2015) stated that there are four characteristic on 4.0 industrial such as (1) *The vertical networking of smart production systems, (2) Horizontal integration by means of a new generation of global value-creation networks, (3) Through-engineering throughout the entire value chain, and (4) Acceleration through exponential technologies.*

The digital era brings various impacts from several aspects that are affected including those occurring in the fields of health, government, economy, and society. Nursing as one of the cornerstones of health services and the largest health workers, is one of the areas affected by this industrial revolution. Technological advances, rapid data exchange, robotic use has become a growing trend in health services in this digital era. As the evidence of technology usage in nursing, in United States of America, there are 66% nursing student and 71 % nurses use smart mobile

devices at their work. Jeleč, Sukalić, & Friganović, (2016) explained that technology can help nurses do their work like using 3D cameras, laser imaging device, and video with high definition. They also said that nurses need to manage their skills and get challenges to adapt with this new era of technology.

Technology can make nurses work more safe and fast in several things, such as perevention of medication error, speed up disease diagnosis and the treatment, prevent hospitals infection, and so on. In practice, Sommor et al. describe that using technology also impact adverse events by using devices like foley catheter (57%), arterial catheter (17%), peripheral central catheter (7% of cases), and central venous catheter (17%). These data show that possible in the next 5 years, technology will develop dramatically in nursing practice [4].

Facing this rapid and huge changing in technology development, nursing workforce need to adapt within. The millenial nurses or young nurses will not take a long period for following this digital development. However, the senior nurses especially in the rural area are going to do extra struggling for adapt with this newest technology. Besides that, nursing workforce has to be shine and perform the main quality of nursing profession. However, amid the developments that occur, nurses are also required not to lose their professional identity. Along with the demands of technological developments, many nurses are busy carrying out non-nursing tasks oriented to the use of technology facilities. Nursing workforce need to perform the uniqeness of its profession in the midst of disruption era.

The use of technology may change practice. For that, it is necessary to develop strategies and programs in dealing with this situation. The use of technology has proven to have a large impact on the system in hospitals, so that nurses' competence in the use of technology must be ensured to be adequate so that the provision of nursing care is safe and accordance with international standards. This is because nurses are at the forefront of changes on healthcare system in hospital.

In facing this era, the most important thing is the aspect of humanity. The human approach reprsent the existence of art in nursing where nurses are actively involved in the use of technology. One of the important challenges that nurses must face in the coming decade is how nurses can achieve balance between benefits of using technology and not override the human element. That is why, the purpose of this study was to find out the main quality of nurses in the digital era.

2. Method

A systematic literature review was conducted for five months. This review was used for identifying studies that describe the diverse types of nurse manager competencies in a clinical setting during a certain time period. This paper focuses on a competence-based approach for leaders and managers, instead of merely the profession-centred view of point, even though the profession-centred approach dominates previous studies. Searches have probed systematic reviews published in the journal. A review of literature published over the past 10 years uses databases: CINAHL, Proquest, EBSCO, Web of Science, Scopus, Wiley, and PubMed. The search period spanned between 2009 and 2019 because there are dramatically increasing amount of the literature regarding

the main quality of nursing profession in the digital eral during this period.

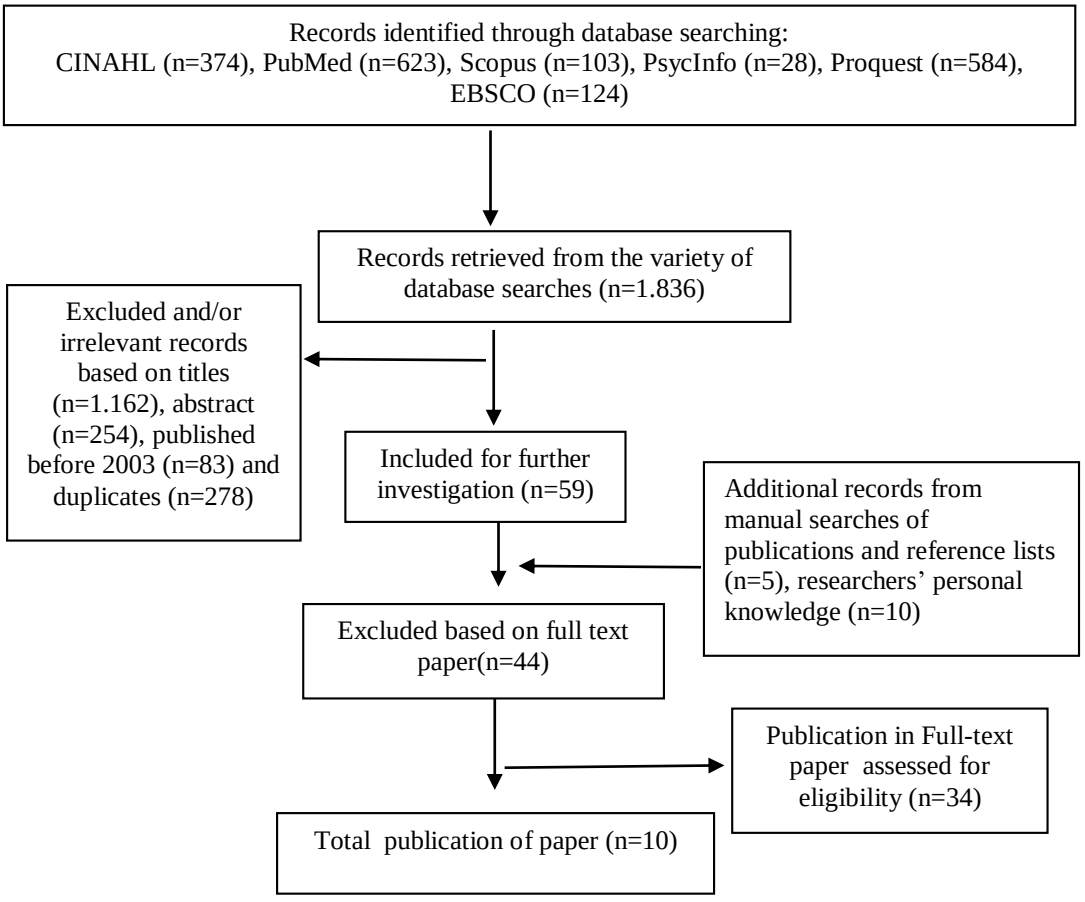
The literature was searched using these keywords: core quality, digital era, caring, nurses' role, and transformational. These words were searched for in combination and individually. The inclusion criteria for the articles were as follow: (1) full paper was publication in English; (2) focus on a nurse manager; (3) focus on a competence and its predictors or determinants, both in all research methods of literature reviews; and (4) a full-text paper. The criteria for exclusion were as follow: (1) the study was not published as a full paper, (2) lack of reliable or valid testing and (3) publication more than 10 years. After evaluating studies with relevant titles and abstracts, the researchers identified 10 relevant articles targeting competence and nurse managers. The metodological quality of each study were review. Both of authors (PMS, DP) directly filters the titles, abstracts and complete and relevant articles. Then, the researchers independently review each 5 articles and consensus was reached through discussion.

3. Result

3.1 Study Characteristics

The systematic review involved 10 studies, which were mainly quantitative and conducted in municipal care, hospitals and all healthcare settings. All humanities dimension of nurses in digital era were analysed in all studies. Figure 1 explains the steps according to which databases were searched.

Figure 1. Flow of Data Search



3.2 Study Findings

The findings of this study are summarised in Table 1 in the appendix. Table 1 was extracted from 10 publications printed from 2009 to 2019.

			technology
[12]	Telenurse's Skills	Qualitative	The qualities of a telehealth nurse can be grouped into 4 categories: (a) Interpersonal communication skills (b) Collaboration skills (c) Clinical assessment skills (d) Technology-related kkills.
[13]	The Effect of Nursing Participation in the Design of a Critical Care Information System: A Case Study in a Chinese Hospital	Qualitative: Case study	1. Digital nursing documentation can significantly improve quality and efficiency. 2. Nurses spent more time on direct patient care after the introduction of the ICIS. 3. there has been significant progress in team formation, communication, increasing individual skills, capacity and skills in intensive care nursing in five years

In this study, nurses have to adapt with all aspect of transformation without losing the main character that is humanities aspect, was formed from caring, cultural sensitivity and ethics-moral value. Each dimension consisted of a nursing core qualities on digital age concerning related explanations.

Caring. This is the soul of the nursing profession and brand of the nursing services. Caring involves a deepest meaning of compassion and empathy. A trully nurses always perform this qualitiy without considering time, person, race, or culture of patient who they serve.

Cultural sensitivity. Nurses has to perform the compassion to all people who they serve without making a discrimintation. Race, nationality, culture and religion are not a consideration for nurses in giving their services. On contrary, that things has to be considered by nurses in choosing the nursing care model for every patient. Finally, the patient are going to feel trully human and be treated properly.

Ethics-moral value. The nursing workforce have to display competence with laws and ethics to protect nursing services and nursing staff and to safely serve patients. The ability to display legal and ethical competence, such as in decision making, is guided by ethical values, ensuring patient and staff rights, understanding the legal aspect of nursing services, maintaining a nursing code of ethics and staying current with nursing and healthcare policies.

4. Discussion

Globalisation and science-tech development are causing huge changes in the world. Nursing services is an integrative part which is not separate from these changing needs. Thus, this field must undergo improvement and innovation so it does not get left behind. Based on that perspective, nursing organisations must change and review their management models to improve the quality of their service. The nurse has played an important role in health services, since this professional is

responsible for managing nursing services and for taking measures that include administration, the delivery of care and teaching–research [14].

Nowadays, nurse need to has the informatic and technology competencies due to development on the digital era. When the nursing workforce perform the caring, it can lead to a development of a quality and safety mindset. It is reflection of the nursing practice which can develops professional matury to continue develop knowledge, constantly maintain patient safety, ensuring the quality improvement, renewal and supporting of the human spirit. The challenging in 4.0 industrial revolution is a large number of nurses in practice little is aware about this disruption era and they have a lack of competencies required for an touching patient' life. Most of them is lack in humanities skill because of this digital world changing. Four leading challenges of integration of new technologies as (1) balancing human element to technology, (2) balancing cost and benefits, (3) training provided technical workforce and ensuring competence, (4) ensuring that the use of technology in accordance with the code of ethics[15].

In nursing, caring is an important element that is used as a moral, theoretical and philosophical foundation. In the last decade a practice model has been developed that pays attention to aspects of caring and healing as the core aspects of professional nursing. Its application has also been carried out along with the many challenges in professional nursing. Nurses in practice are aware of the lack of nurses, the hopelessness of the demands of the system, and the lack of awareness to care for nurse professionals that trigger changes in nursing. On the other hand, it cannot be denied that nurses have challenges which is divided between human concern and the 'calling' that makes them interested in becoming nurses, task-oriented biomedical practices and institutional demands, high workloads, and outdated patterns of practice.[16].

In the transformation era, the main component that nurses and health practitioners must have are competent, compassionate, knowledgabele even in hospital setting or in clinical agencies. Nurses and practitioners must be able to maintain relationships with the public with love, kindness, attention, and meaningful things. This makes the public see that nurses play a role in seeking wholeness and spiritual connections for their wellbeing, interventional medical technology, and human-to-human caring relationship.

Legal-ethics is close with the responsibility of nurses to keep the data privacy of patient. The law guarantees the confidentiality of data and patient privacy so that nurses have a responsibility to safeguard this. However, carrying out this responsibility is not easy in the era of technology where information can be accessed anywhere and anytime. This becomes a challenge to face together. Nurses in practice require confidential information about patients and then must be passed on between nurses as long as it becomes a nursing process. Despite the fact that routine confidential information is shared, nurses have the privilege of accessing this information. This should not be taken for granted, Nurses but must be carried out with responsibility for moral values according to human needs, behavior, and individual feelings in making decisions.

However, nursing staff need support from other health workers when using new technology both in practice in hospitals and the community. This means that the use of new technology needs to be regulated for multidisciplinary health care. In technological transformation, special attention needs to be given to the characteristics of the technology itself. Nurses must recognize their important role as part of the benefits of transforming technology towards multidisciplinary, leading, and using technology in all care settings. Thus, it is important to ensure nurses' understanding of

technology, and its use for each individual in the nursing care process.

However, there are pro and contra about using technology in health services. Smartphones and applications related to health have the potential to improve care, but if not regulated, there will be difficulties in use. It is important to ensure that the technology used is safe, easy to use, reliable, and accurate. In the UK study, it was mentioned that there was a shortage of smartphone use among nurses in the UK. But from day to day there is a rapid development in the provision of health care applications so nurses have many choices about which applications are suitable for use in practice. Therefore, it is necessary to pay attention to aspects of effectiveness, conformity and efficacy in the use of technology before finally the technology is used. On the other hand, there are concerns about the dependence of nurses on the use of technology. Nurses are feared unable to calculate drug dosages, tubal mass index, or early warning scores without applications and smartphones. In addition, technology is also feared to have a detrimental effect on nurse-patient interactions. [17]

Culture is a set of shared mental assumptions that guide the way we think, act, and behave in the workplace. Those who do things in the "proper" way will lead to the success of competencies. Those who chose not to do things in the proper way do not last long with an organization. However, the organizational culture is closely associated with senior managers. Every top manager has different expressions and understandings in influencing the culture of the organization. Leadership competencies influence the motivation and performance of nurses. The important competence that nurse managers must gain is managing ethical and legal issues. The support of manager and all healthcare team give a positive impact for nurses to improve their skill on the digital age. Reinforcing the skills of nurses, especially their ethical competency, could be a solution to reduce moral stress, as Kälvemark-Sporrong et al. declared.

At the end, the 4.0 industrial revolution, the changes is not only what we do but also our identity. This is going to affect our identity and all the problems connected with it: a sense of privacy, understanding of ownership, our behave of consumption, the time to work and relaxing time, and how we arrange and improve our careers, grow our competencies, meet people, and maintain networking. That quote also explains that the 4.0 industrial revolution also affects each individual. One of the biggest individual challenges put forward by emerging technology is privacy. The discussion about vital issues such as the impact on our inner lives of the loss of control over our data will only increase in the coming years. Likewise, the revolution that occurs in biotechnology and artificial intelligence, which redefines what it means to be truly human by pushing back the threshold of life, cognition, health, and current competencies, will support us to redesign and redefine our moral and ethical concern.

5. Conclusion

Primely???, true transformation of health care has to come from a shift in consciousness and intentional actions of the nursing workforce themselves, changing health care from the inside out. On the digital era, nurses has to improve humanities skill as a principle and main commodity of nurses' job which could not exchange with any form of skill for survive on the radical changing caused by technology development. Future studies are suggested to investigate driving factors leading to healthcare transformation in being a fully contributing member of the interprofessional healthcare team on the 4.0 industrial revolution.

Email: saadrianty@gmail.com

ABSTRACT

In Indonesia, the government regulated how nurses should carry out their duty which stated in Indonesian Law Act number 38-year 2014. There are many cases where nurse is charged with criminal accusation. In some studies, it was mention that most patients experience sexual hallucinations under the influence of drugs. Thus, the main point of this paper is to question the legal protection for nurses who reportedly committed acts of sexual abuse to patient whom under the influence of anesthesia. This study used a normative juridical approach that is descriptive analysis with the study of literature and regulations relating to legal protection of nurses and attempt to find to what extent of Indonesian law act number 38- year 2014 can protect nurses and resolve legal problems that occur. Used secondary data that was collected thorugh literature study and document study, the collected data were analyzed qualitatively. The study stated that sexual hallucination have been reported since the introduction of Chloroform. Some practitioners have been the victims of allegations resulting from the hallucinogenic effect of these drugs. The results of the study showed that some patients experienced sexual hallucinations and most did not prove to be sexually abused.

Keyword: legal protection, nurses, anesthesia

1. Introduction

Nurses are professionals whose provision concerns carrying out their duties. The profession in Indonesia is regulated in Law No. 38 of 2014 about Nursing Personnel. Therefore there must be legal protection for the nurses when they are carrying out their duties. This study was specifically regarding the medical actions performed by the nurses related to the patients after anesthesia. Gream, in his book entitled “Chloroform”, expressed that in 1849, a woman admitted that she was sexually assaulted after she had given birth. After the investigation, the woman was found to be under the influence of hallucinations after undergoing treatment with an anesthetic; chloroform. A dentist was once accused by a female patient. She felt that her breast was touched during the treatment, and the dentist had used 30mg Midazolam and 10mg Diazepam IV[1]. In 1989, a patient accused a nurse of assault in the dressing room. She was convinced that she was being stripped naked and that the nurse held her breast. It was proven that it was just a hallucination caused by the drug diazepam.

There is a limit to the extent to which Law Number 38 of 2014 concerning Nursing Personnel

can protect nurses and resolve any legal problems that occur. The journal of Balasubramaniam and Park with the title "Sexual Hallucination During and After Sedation and Anesthesia" showed that sexual hallucinations have been reported since the introduction of chloroform. Some practitioners have been the victim of allegations of the resulting hallucinogenic effects of the drugs. There are at least 3 other journals which became our research reference sources.

An example is a case that occurred in Surabaya in 2017 at the National Hospital. A nurse who iwas an anesthetist's assistant was faced with a patient's demands. The patient claimed that he was a victim of sexual abuse by the nurse. The patient had just come out of surgery, meaning that the patient had just become aware of the effects of the anesthetic.

2. Research Methods

This study used a normative juridical approach as according to Sardjono Soekanto. This research was a descriptive analysis with the conducting of a study of the literature and regulations relating to the legal protection of nurses. The study used secondary data collected through literature / document studies. The data that was collected was analyzed qualitatively, which emphasis the depth of the data obtained by the researcher[2].

3. Result and Discussion

3.1. Legal Protection in General

According to Satjipto Rahardjo, the function of law is to protect one's interests by allocating a power to him to act in the context of those interests. The allocation of this activity is carried out in a measurable manner, in the sense that it is determined by its level and depth[3]. Protection is defined as the act of giving a guarantee or security, well-being, and peace from the protector to the protected from all of the dangers or risks that threaten him.

Legal protection is an absolute right for every citizen and it is an obligation that must be fulfilled by the government, considering that Indonesia is known as a legal state. Legal protection, as explained by Philipus M. Hadjon[4],[4]can be divided into 2 types.

a. *Preventive* legal protection implies a form of legal protection whereby the people are given the opportunity to raise objections or opinions before a government decree gets a definitive form which aims to prevent disputes.
b. *Repressive* Legal Protection is a form of legal protection which is more aimed at resolving disputes.

3.2. Definition of the Nurse Profession

According to the Minister of Health Regulation Number: HK.02.02 / Menkes / 1481/2010 concerning Permits and the Implementation of Nursing Practice, Article 1 point 1, a nurse is someone who has passed through nursing education both at home and abroad in accordance with the applicable legislation.

A nurse is someone who plays a role in caring for and maintaining, helping, and protecting someone because of illness, injury and the aging process (Harlley, 1997). According to the Republic of Indonesia Law Number 38 of 2014 concerning Nursing, nursing is the activity of providing care to individuals, families, groups or communities, both in a sick and healthy condition.

Nurses are defined as someone who has passed through nursing education, both at home and abroad, which is recognized by the government in accordance with the provisions of the legislation[5]. According to the International Council of Nurses (1965), nurses are someone who has completed a nursing education program, who is authorized in the country concerned to provide nursing services and who is responsible for improving care, preventing disease, and being in service to patients.

3.3. Nurse's Rights

In terms of international standards, the Indonesian nursing profession still very weak because the International Council of Nurses (ICN) regulations have not been set out to be related to national regulations. The legal protection available to the nurses has not been regulated specifically in international law. The International Council of Nurses' (ICN) code of ethics for nurses regulates the standard ethics profession and yet it still has not regulated preventive or repressive legal protection yet.

Article 36-38 of Law Number 38 of 2014 states that the Nurses' Rights are:

a. Obtain legal protection as long as they are carrying out duties in accordance with the standards of service, professional standards, standard operating procedures and the provision of legislation;
b. Obtain correct, clear and honest information from the Clients and / or their families;
c. Receive compensation for the Nursing Services that have been given;
d. Refuse the wishes of the Client or other parties that are contrary to the code of ethics, service standards, professional standards, standard operating procedures or the provisions of the Laws and Regulations;
e. Obtain work facilities according to the aforementioned standards.

The role of the nurse is actually determined by the conditions faced by the client. Nurses and clients both have goals. A client in certain situations has a purpose. The nurse, in certain situations, has a specific goal. There are several things that underlie the relationship between nurses and clients, including the following:

a. Value
b. Human dignity
c. Development of trust,
d. Measurement of problem solving
e. Collaboration[6]

3.4. Nursing Code of Ethics

Nursing ethics act as a basic reference for nurses when carrying out their profession, both related to the use of nursing technology and their nursing knowledge. Increasing the technological factors an developing the science therein requires evolving nursing principles and ethics. This includes considerations concerning values, human rights and professional responsibilities. A nurse must be able to maintain and appreciate, practice and develop these values through the nursing code of ethics. The pressure point of the principles of the nursing code of ethics is service based on the belief that the nurse will do the right thing that is needed and that will benefit the client and his health[6].

3.5. Some Cases of Hallucinations due to Anesthesia

One of the most damaging allegations that a doctor or nurse can face is one of sexual misconduct involving patients. Most of the information is based on case reports in the medical or legal literature. Gream reported several instances in 1849 where women used obscene language under chloroform anesthesia. As a result, its use was opposed in obstetrics[1].[8] Simpson repudiated these allegations by stating that chloroform had been in use in Edinburgh for 15 months and that he had not heard similar reports. However, he cited a French prostitute who had reported lascivious dreams after inhaling ether during her confinement. Simpson concluded 'but surely it was to say the least very unbecoming that most English women should have sexual dreams (like the French prostitute) when under the influence of chloroform[7]'.

In 1984, a male dental surgeon was charged with sexually assaulting two of his female patients. Both had been sedated with 30mg diazepam and 10mg midazolam intravenously. After they were sedated, the dentist was alone with the patients for long periods during which the alleged assaults occurred. Despite the dentist's defense being based on sexual hallucinations being caused by the drugs, he was convicted of indecent assault[8]. In 1986, a doctor in an emergency department near Ottawa, Canada, was accused of placing his penis in the hands of a patient recovering from an intravenous dose of benzodiazepine[9]. The doctor mentioned that he had been testing her ability to respond to a command by asking her to squeeze two fingers of his hand. He was acquitted at the criminal trial. However, the College of Physicians and Surgeon of Ontario found him guilty of disgraceful and unprofessional conduct and he lost his license to practice. In 1990, a dentist was acquitted of assaulting seven women who had been given diazepam as a sedation[10].The Judge directed the jury to return a verdict of not guilty on the basis of Dundee's finding that 1 in 200 women given large doses of benzodiazepines experience sexual fantasies.

In another case in 1990, a Manchester dentist was investigated by the police following a complaint of sexual misconduct[11]. During the investigation, a further three complaints were discovered. He was prosecuted for allegedly assaulting four women while they were sedated using midazolam. The dentist was convicted on two counts on a majority verdict. In the judge's summary of the evidence, there was no mention of a sedative dose. Following this, there were another 15 reports in the medical and dental literature of sexual hallucinations. Some of these were reports made by patients. None of them were reported to the police nor were they the subject of a formal complaint.

There were reports made by dentists in the medical and dental setting of sexual hallucinations after a Manchester dentist was convicted of sexual assault by two patients. None of the following were reported to the police or formed part of a formal complaint. In the tables below, M= Male and F=Female[11]

Table 1. Observations by dental surgeons

Sex of Patient	Sex of Dentist	Age of Patient	Drug	Observation by Dentist
M	F	20	Diazepam	Masturbation
F	M	Unknown	Diazepam and pentazocine	Grabbed Dentist
F	M	30	Nitrous oxide	Sexual Excitement
M	F	9	Nitrous Oxide and Halothane	Acted like a baby and sexual comments
M	M	48	Diazepam	Masturbation
M	F	25	Diazepam	Masturbation
M	F	30	Diazepam	Masturbation
M	M	20	Midazolam	Masturbation
F	M	22	Midazolam	Masturbation

Table 2. Observation by the patient or relative

Sex of Patient	Sex of Dentist	Age of Patient	Drug	Complaint by the Patient or Relative
F	M	18	Nitrous oxide	Saw dentist naked
F	M	42	Diazepam	Increased sexual appetite
F	M	30	Diazepam	Felt breasts kissed and fondled
F	M	Unknown	Brietal, Nitrous Oxide and halothane	Rape
F	M	18	Brietal and atropine	Sexual dream
F	M	25	General anesthetic	Sexual affair

Most of the serious hallucinations that resulted in an investigation involved women patients and male dentist or anesthetists. However, male patients also have similar, albeit less frequent, hallucinations. Many of the reports of hallucinations have originated from northern European countries with a few from southern Europe, perhaps representing a cultural difference. All hallucinations must be taken seriously. The patient is likely to be distressed. A full explanation of the cause must be offered, along with the reassurance that there was a chaperone present. Despite this, the patient often find this difficult to accept because of the very real nature of the hallucinations. Sexual hallucinations do occur with many of the hypnotic drugs used by anesthetists and others. To the patient, they are real and frightening. They may be reported to the authorities that may then investigate the anesthetists. Even though the events may eventually be shown to be hallucinations, they may be damaging both to the patient and to the doctor and others who are involved. Unfortunately, some doctors use these drugs to sexually assault their patients. This makes it difficult for external authorities to determine exactly what happened [12].

From a number of the examples in the above cases, it is appropriate that where there are similar cases that incur accusations against both the doctors and nurses, they need to be further investigated. It could be that these patients experience hallucinations after the use of certain anesthetic drugs. As with the case at the Surabaya National Hospital, which is currently underway, it is better if it is reviewed regarding the effects of the drug's use on patients.

4. Legal protection for nurses

Legal protection for the nursing profession in Indonesia has actually been contained in several laws and regulations. In the case of a nurse who performs anesthesia on a patient, they can be protected by law if the nurse acts according to his authority and if that authority can be proved normatively.

If the anesthesia nurse then encounters the case of a patient who is likely to experience hallucinations after anesthetic action, then any legal protection that can be done is proof that the anesthetic action performed is in accordance with the authority and procedure, thus proving that the sexual action that the patient has accused the nurse of is not real.

Regarding the authority of nurses in conducting medical actions, Article 63 paragraph (4) of Law Number 36 of 2009 concerning Health explicitly states that:"The implementation of treatment and / or treatment based on medical science and / or nursing science can only be done by health workers who have the expertise and authority for it."

Article 27 paragraph (1) states that:

> "Health workers have the right to get compensation and to obtain legal protection when carrying out their duties in accordance with their profession."

Article 24 paragraph (1) states that:

> "Health workers as referred to in Article 23 must meet the provisions of the code of ethics, professional standards, the rights of the users of health services, minimum service standards and standard operating procedures."

More specifically, the Regulation on Nurse Anesthesia in Indonesia is now regulated in the Minister of Health Regulation No. 18 of 2016 concerning the Permitting and Implementation of Anesthesia Practice Practices (hereinafter abbreviated as "PMK No. 18 of 2016"). In Article 13, the regulation states that anesthetist nurses can receive a mandatory delegation of authority from an anesthesiologist or another doctor in order to assist in the anesthesia service which includes:[13][15]

a. implementation of anesthesia in accordance with the instructions of the anesthesiologist;
b. installation of non-invasive monitoring devices;
c. installing invasive monitoring devices;
d. administration of anesthesia;
e. overcome any difficulties that arise;
f. airway maintenance;
g. installation of mechanical ventilation equipment;
h. installation of nebulization equipment;
i. termination of anesthesia
j. documentation on medical records.

The authority delegated by the doctors to the anesthesia nurses, especially in terms of the installation of medical devices, is sometimes misunderstood by some patients who are under the influence of anesthesia as a sexual act. It is important for the patients to be given the knowledge related to all medical actions involved in their care so as not to cause misunderstandings.

In addition, formal proofing is also important to be done by the nurse to refute the allegations that were brought to him. Article 183 of the Criminal Procedure Code *(KUHAP)* confirms that "the Judge

may not impose a sentence on a person except if with at least two valid evidences he obtains the conviction that a criminal act actually occurred and that the accused is guilty of doing so."

In Article 184 of the Criminal Procedure Code, it sets out the following:

(1) Valid evidence includes:
   a. Witness testimony
   b. Information from experts
   c. Letters
   d. Clues
   e. Testimony of the defendant

(2) Things that are generally known do not need to be proven.

In this case, the anesthesia nurse who performs the medic action in accordance with his authority can at least have two items of evidence to protect himself, namely the Administrator's Permit for Anesthesia and witness information that can be obtained through the doctor who gives them authority and through the other witnesses who may be at the crime scene.

Regarding the Permit for Anesthesia Arrangement Practice, this understanding is regulated in Article 1 number 4 of PMK Number 18 Year 2016, "Anesthesia Regulator Practice License (hereinafter abbreviated as SIPPA) is written evidence granting authority to carry out professional practice of Anesthesia Administrators in Health Service Facilities".

5. Conclusion

Legal protection for the nurses who care for patients who have received anesthesia in the face of cases of patients who are likely to experience hallucinations after anesthesia is a form of repressive legal protection, namely by proving that the anesthetic action performed is in accordance with the authority and procedure. In Law Number 36 of 2009 concerning Health, Article 24 paragraph (1) in junction with Article 27 paragraph (1) explains that nurses who carry out their duties in accordance with the code of ethics, professional standards and standard operating procedures have the right to obtain legal protection when carrying out assignments according to their profession. If there is a claim against them, the nurse who performs the anesthetic action in accordance with their authority must at least have two items of evidence to protect themselves in the form of an Administrator Practice Permit and witness information that can be obtained through the doctor who gives them authority and from other witnesses who may have been at the crime scene.

Universal regulations are needed that can be used to protect the nurses when they are carrying out their duties. The need for rules governing the gender of nurses that should be equated with the gender of the patients. This step is considered to be necessary as part of a preventive effort related to the occurrence of sexual abuse among nurses. There is the need for patients to be accompanied by a guardian after the anesthesia process is carried out. This is so then other people can be witnesses so that when the anesthesia is carried out, there is no abuse of authority on the part of the nurse.

ABSTRACT

A hospital is a place for the implementation of the health services to give the health services performed by the medical practitioners who work in the hospital. To perform the medical, and diagnostic intervention, doctors try as maximally as possible to perform their duty and obligation to cure patients based on their knowledge, ability and competence which they possess. The research was aimed to know how yuridical observation to the forms (standard formats) of medical action agreements was. The research used the normative yuridical analysis method with the law approach (conceptual approach and statute appraoch). The reseach used the primary law material consisting of legislation, official document or treatise in making legislation, and court verdict. The secondary law material consisted of the all publication of the law which was not offical document. It consisted of books, law dictionary, law journals and comments on court verdict. The result of the research could be concluded that in general, the informed consent forms, which were provided, complied main element included in the informed consent. The informed consent format and its application must have agreed with the present legislation.

Keywords: legal relations, standard contract, informed consent

1. Introduction

The rapid progress in medical science and technology, coupled with the increase in consumerism, has changed the paradigm of the existence of health care institutions, which in this case is a hospital. It has changed from a social institution to a socio-economic institution in the sense that an institution must prioritize social norms when carrying out its duties and also at the same time, it must pay attention to the economic norms so then the existence of a hospital can be guaranteed.

The health workers who work in hospitals have direct contact with patients; they are doctors and nurses. In terms of taking medical action, when something that is diagnostic/therapeutic (that determines the type of disease/healing) is done to the patients, the doctors will do their best to carry out their duties and obligations to provide healing assistance to the patients based on their knowledge, abilities and competencies.

The development of science and technology in all fields has influenced the paradigm of thinking of society, especially the relationship between doctors and patients where all this time, the relationship is only a place to express feelings on the basis of mere trust. Now the relationship has turned into a radical relationship. Trust is not a benchmark for the relationship because there are

many cases where the patient is clearly suing and demanding that the doctor must be responsible for his legal rights.

According to Springer, in America and specifically health workers, they are now facing confrontations from the social and legal fields that have never been experienced before. Practitioners of the medical profession, for a variety of causes that lie in history, have not been prepared for this attack. At the same time, the community becomes more critical. Respect for and any expectations placed on the medicine changes throughout the country. The population now generally has hopes more and it is impatient when it comes to listening to the explanations that try to explain why the provision of high quality medical services cannot be provided at a reasonable cost at this time. [1]

This situation has been accommodated by Act 29 2004 about medical practices which, in its explanation, specifically states that in paragraph five, the reduced public trust in doctors and dentists and the rampant lawsuits in today's society are often identified by the failure of healing done by doctors and dentists.[2]

The decisions about the medical care that a person will receive, if any, are to be made in a collaborative manner between the patient and physician.[3] The medical actions performed by a doctor without legal approval are because of uncompleted and incorrect information, as the doctor can be sued in court.

In today's medical world, information is a patient's right because based on that information, the patient can make decisions about a medical act. On the other hand, giving information correctly to the patients is the basic obligation of a doctor carrying out his profession. Besides relating to legal issues, this information is also related to ethics, morals and the norms in society.

Informed consent may not be an obstacle or a barrier to the conduct of a medical action on a patient in a forced or emergency situation. In this case, a doctor can do what is best according to him. In a situation like this, the patient can provide a form of consent called implied consent that is an agreement that is considered to be given by the patient without being stated explicitly, but it can be used to draw conclusions from the attitudes and actions of the patient concerning what is implied in the agreement.

Based on the description of the background above, the problem can be formulated as follows: ‘What is the judicial review of the form (standard format) of hospital medical approval in Indonesia that has fulfilled the legal requirements of the agreement with the Civil Code?’

2. Research Methods

This research was carried out by referring to, using and processing the secondary data and literature review legislation governing health laws in Indonesia, as well as the books and writings of experts relating to the problems that are to be studied.

The type of research used in this writing was legal research. There was no need to use the term normative research because the term ‘legal research’ is always normative. Legal research is carried out to solve the legal issues faced. It needs the ability to identify legal problems, to do legal reasoning, to analyze the problems faced and then to provide solutions to the problems. [4]

3. Discussion

2.1. Juridical Review of the Form (Standard Format) Approval of Medical Action

The informed consent form that is available and provided in a hospital is in the form of a standard agreement whose form and contents have been determined by the hospital. The doctor may not change it. This is done to facilitate and maintain the fulfillment of the standard of informed consent, so it becomes strong evidence when a dispute arises. The doctor cannot change the form that is specified by the hospital.

Specifically, informed consent is of particular concern. In this matter, the patient's right to consent came after the information hit the Indonesian medical world after the appearance of Muchjidin, Sukabumi (1984). What if informed consent is associated with approval for operations? It must be known in advance that the matter of liability (*aanspaakelykheid*) for doctors applies to the general validity of the initial regulation. Civil provisions, among other things, are valid 'regarding engagement' provisions and they are highly related to professional responsibility regarding matters of care and therapeutic agreements.

The civil aspect of informed consent, when associated with Civil Law in the Civil Code / BW Article 1320, contains 4 legal requirements for an agreement, namely that there is an agreement between the parties that is free from coercion, error and fraud. The parties involved are those who are capable of acting. There is also the existence of a certain thing that was promised and a lawful reason that is justified, that is not prohibited by law and that is reasonable to fulfill. [5]

Before the doctor takes a medical action, the doctor is obliged to provide information about the type of illness suffered by the patient and on the medical actions that are to be taken to save the patient. The risks that may arise from the medical treatment related to the patients and their families and the risks may arise from the medical treatment to the patients and their families also tie into it. A fixed procedure for returning permanent and binding medical actions is the patient's approval for the medical action. The acceptance from the patients is stated in the agreement of them taking medical action (informed consent). This medical action approval form has generally been arranged in such a way that the doctor / hospital and the patient fill in the form and an oral explanation is given to the patient and their family.

2.2. Legal Relationship Between the Doctor and Patient

The legal relationship between doctors and patients today is changing. Initially, the position of the patient is not equal to the doctor because the doctor is considered to be the most aware of his patients. In this case, the position of the patient is very passive and dependent on the doctor. But in the development of the relationship between doctors and patients, the pattern has changed, where the patients are now considered to be in an equal position to the doctor. All medical actions performed by a doctor on the patients must have the patient's consent, after the patient has had a sufficient explanation of the disease and the medical treatment. [6]

The position of the relationship between the doctor and the patient, even if has developed, but in general the relationship until now is still paternalistic, where the doctor still has a higher and respectable position as a treatment from patients who are unfavorable or sick. [7]

The changes in the pattern of legal relations between the doctors and patients occur because of several factors which, among others, are[8] that trust is no longer focused on personal doctors but on the ability of health science and technology. Society considers that the doctor's duty is not only to

cure, but also to emphasize care. There is a tendency to state that health is no longer a condition without a disease, but it also refers to physical, mental and social welfare. The increasing number of regulations giving legal protection to the patients is so then the patients know and understand their rights in relation to those of the doctor. The level of community intelligence regarding health is increasing and able to conduct assessments.

According to the principles of applicable law in Indonesia, the relationship between doctors and patients is based on a relationship of balance, justice, benefits, protection and the patient's safety. Based on Act 29 of 2004 concerning medical practices, the provisions of Article 2 explain that "the implementation of medical practice is carried out based on Pancasila and it is based on scientific values, benefits, justice, humanity, balance, protection and patient safety."

The relationship between a doctor and a patient in terms of criminal law is based on the actions taken by the doctor, which is an action that will cause there to be a legal relationship. On one hand, it raises their rights and on the other, it requires the fulfillment of obligations, namely in the form of claims of responsibility due to the medical actions carried out by the doctor, whether done intentionally or whether done with negligence. [9]

The noble aspects of the doctor's duty are as a helper when viewed from a health point of view. In principle, personally, institutionally and professionally, the relationship between the doctors and patients is more than an obligation where everyone needs help.

Based on Hermein Hadiati Koeswadji[10], the relation between a doctor and a patient is one of 2 types. There is the system of paternally vertical relation and contractually horizontal relation. In the vertical relation, the position between the doctors as the givers of health care are not equal to the patients as the users of healthcare. In the system of contractually horizontal relations, the position between the health care users and the health care givers is of an equal position.

2.3. Right and Obligation between Doctors and Patient

Someone's rights and obligations are determined and inherent based on their duties and authority. Duties and authority are not only interpreted in relation to the work environment in an institution, but they can also be interpreted as existing and being attached to a person as a creature created by God.

In simple terms, right is authorized to do and not to do. However, in relation to medical services, the doctor's action involves reasons and measures according to his professional standards to avoid the misuse of their rights (*misbruik van recht*) for doctors. Rights are always paired with obligations so then obligations are often said to be a burden or task that must be carried out. Actually, rights and obligations are the demands of the authority inherent in a person, the demands on which the parties fulfill their achievements and on the other hand, they are for demanding achievements.

The rights owned by the patients as stipulated in Act 29 of 2004 about medical practices, are as follows in Article 52: the right to live, the right to his own body, and the right to die naturally. The right to obtain human medical services is in accordance with the standards of the medical profession, there is the right to obtain an explanation of the diagnosis and therapy from the doctor who treats them, there is the right to reject planned diagnostic and therapeutic procedures, and even to withdraw therapeutic contract, there is the right to obtain an explanation of the medical research that he will participate in and to reject or accept his participation in the medical research. There is also the right to be referred to a specialist if necessary and returned to the doctor who refers him after the

completion of the consultation or treatment to get treatment or a follow up. There is also the right to confidentiality or personal medical records, the right to obtain an explanation of the hospital regulations, the right to relate to one's family, counselor or clergy and others as needed during the hospital treatment and finally, the right to obtain an explanation of the details of the costs of hospitalization, including medication, laboratory examinations, x-ray examinations, ultrasound, CT scan and magnetic imaging, including the cost of the rooms, operating rooms, delivery rooms and the compensation for their medical services.

2.4. The Agreement of Medical Action / Informed Consent

In Indonesia, the progress of "informed consent" in formal jurisdiction is marked by the existence of the Indonesian Physicians Association (IDI) about "Informed Consent" through *SK PB-IDI No.319/PB/ A.4/88*of 1988. This is confirmed again with the Regulation of The Health Minister No. 585 in 1989 about the "approval of medical action or Informed Consent". This does not mean that doctors and health workers in Indonesia do not know and implement "informed consent". Long before that, there had been a habit of carrying out operations where the doctor always asks for written approval from the patients or their family before surgery is carried out.

Literally, being informed can be interpreted as being notified after it has been submitted or after they have been informed. Consent is the agreement given by someone to do something. Thus informed consent is the agreement given by the patient to the medical practitioners after being given an explanation. Informed consent is formulated as an agreement or as the agreement of the patient toward the medical practitioners regarding the medical efforts that can be done to help them, accompanied by information about all of the risks that may occur. [11]

Informed consent starts because of the relationship between the doctors and patients through therapeutic transactions that generate the respective rights and obligations of each party. For both service providers (medical providers) and service recipients (medical receivers), it is binding and must be respected by both parties involved in the therapeutic contract [12].

Informed consent can be defined as follows. Consent refers to approval, while informed refers to being informed, so informed consent refers to an agreement on the basis of information. Another term that is often used is the approval of medical action [13]. According to the Regulation of The Health Minister No 585 in 1989, the approval of medical action is the agreement given by the patient or his family on the basis of an explanation of the medical actions to be taken against the patient.

Referring to informed consent, Komalasari expressed his opinion, namely that[14] "informed consent is a tool used to enable the self-determination of the patients and patient's rights or the information has been fulfilled in the practice of doctors."

The function of informed consent is[15] the promotion of individual autonomy rights, to provide protection from both the patients and subjects, to prevent fraud and coercion to stimulate the medical profession to conduct introspection, to promote rational decisions and to encourage community involvement in advancing economic principles as a social value and conducting supervision in biomedical investigations.

The purpose of informed consent according to [16]is to protect the patients against all medical actions carried out without the patient's knowledge, to provide legal protection for the doctors against unexpected and negative consequences (for example, against the risk of treatment that cannot be

avoided even though the doctors have tried as much as possible and acted very carefully and thoroughly).

The absence of informed consent can lead to the action of malpractice, especially if there is a loss or intervention in reference to the patient's body. Commonly, laws in various countries state that the consequences of the absence of informed consent are in line with negligence. However, in some cases, the absence of informed consent is equivalent to an intentional action, so the degree of thedoctor's error in the context of the action is higher.

Before the doctor takes medical action, the doctor is obliged to provide information about the type of illness suffered by the patient and the medical actions that are to be taken to save the patient's life, including the risks that may arise from the medical action to the patient and his family. The fixed procedure in taking medical action that is permanent and binding is the approval of the patient to take medical action. The acceptance of these patients is set out in the form of an agreement to take medical action (informed consent). The medical action approval form has generally been arranged so that the doctor / hospital and the patient only need to fill in the fields provided for it after an oral explanation has been given to the patient or the patient's family. Because informed consent is an agreement to take medical action, the existence of informed consent is very important for the parties who make the health service agreements. It can thus be seen that the existence of informed consent is very important and necessary in hospitals.

In the implementation of the approval of medical actions according to the Regulation of The Health Minister No. 585 1989 Article 4 Section (3), it mentions that:

In reality in the community, there were many violations of informed consent according to the Regulation of The Health Minister No. 585 1989 Article 4 Section (3). For example, there are no witnesses at the time that the agreement is made or it is someone who is not capable or who must be forced to do the legal action because of a certain matter.

2.5. Informed Consent according to Burgerlijk Wetboek[17]

The informed consent form that is available and provided in the hospital takes the form of a standard agreement in which the form and contents have been made by the hospital; the doctor may not change it. This is done to facilitate the filling in of the form and to keep the standard of informed consent fulfilled. It can thus be strong evidence when a dispute arises. Doctors cannot change the forms set by the hospital.

Although the informed consent form that is available and provided by the hospital is in the form of a standard agreement whose form and content has been determined by the hospital, the implementation of the informed consent must not deviate from Article 1320 BW regarding the legal terms of the agreement.

For the relationship between informed consent and the medical action to be performed by the doctor, it can be said that informed consent is the main component supporting the existence of medical action. The agreement being given voluntarily by the patient by signing an informed consent is one of the subjective conditions for the validity of the agreement, namely “agree to bind themselves”. In this case, the agreement in question is an agreement to conduct medical actions between the doctor and the patient.

Informed consent and Article 1320 BW:

2.5.1. Agreement to those who bound themselves. The signing of an informed consent form is basically the affirmation of an oral agreement that has been done before, namely after the patient gets complete information from the doctor regarding the patient's disease and the medical actions that are to be taken. In the informed consent form provided, there was statement from the patient that the agreement was made with full awareness and without coercion. This shows that there was an agreement between the parties who signed the informed consent.

2.5.2. Able to make an agreement. Informed consent should be signed / approved by the patient or the patient's family. But in general, not all parties mentioned above have fulfilled the capable conditions for carrying out legal actions, in which case the informed consent is included in the act of reaching an agreement. The party who agrees must meet the age required to conduct legal action, namely 21 years old. In practice, there are many who agree that the informed consent individual of focus is a person who is not capable of carrying out legal actions. This is not in accordance with the Regulation of The Health Minister No. 585 1989 concerning Approval of Medical Action Article 8 Section (2) and Keputusan Direktur Pelayan Medik Nomor: HK. 00.06.3.5.1866.

2.5.3. A certain thing. As known from the foregoing description, the object of the agreement is in the form of professional medical actions characterized by giving help. In this case, the doctor gives an achievement in the form of an effort to take medical action to achieve maximum patient recovery. The patients themselves provide achievements in the form of payment and the provision of information about the disease to the doctor. Therefore, it can be concluded that the achievements given by the parties are clear, thus enabling the implementation of the rights and obligations of both parties.

2.5.4. A reason that is lawful. The contents of the medical action agreement are about the agreement of the parties to take medical action to achieve patient recovery. This is not something that is contrary to the Law, public order and morality.

4. Conclusion

Informed Consent is carried out prior to medical action, even though the existing Informed Consent form provided at the Hospital is in the form of a standard agreement whose form and content has been determined by the Hospital. The implementation of the Informed Consent should not deviate from Article 1320 BW regarding the validity of the full agreement. The hospital must carry out the agreement in accordance with the correct procedure that is carried out in agreement with the family members of the patients who are capable of carrying out legal action even though, in an emergency, the hospital must be able to condition the informed consent agreement in accordance with the applicable regulations.

In implementing the informed consent form, one must pay attention to Article 1320 BW, which is the most important as it states that the subject who gives their informed consent must be a capable subject who can carry out legal actions. Although in general the form already meets juridical provisions, there is a need for additional siblings in the format of a signatory status and the information that the intended father / mother is the biological father / mother in order to comply with the provisions of the applicable legislation. In addition, in the form provided, it is necessary to

mention who is entitled to be a witness. The presence of witnesses, one of whom is a nurse or another paramedic from the HHospital, is necessary to strengthen the testimony in the court if a dispute occurs with the patient.

EFFECT OF TRANSFORMATIONAL LEADERSHIP STYLE ON MOTIVATION, COMMITMENT, SATISFACTORY PERFORMANCE AND DECREASE IN BURNOUT NURSE: A SYSTEMATIC REVIEW

B Y Weu, F Pattaru, F S Handini and Heryyanoor
Master Student, Faculty of Nursing Airlangga University, Surabaya, Indonesia
Email: basilius.yosepfus.weu-2018@fkp.unair.ac.id

ABSTRACT

Embodiments of optimal health care quality nursing care is required. Quality nursing care is not far from a good organization, effective leadership. methods with emphasis on leadership style will affect the performance of the staff were underneath. The purpose of this study was to review the effect of transformational leadership on motivation, commitment, satisfactory performance and decrease burnout. For the systematic review a literature out of the 14.954 retrived articles namely Scopus, Science direct, and Proquest. Total of 15 articles was selected between 2016-2018, the keywords used to search the literature; nurse leadership style, motivation, commitment, satisfaction performance, and nurse burnout. The results discuss leadership style where transformational leadership style more positive impact on the performance of nurses, including increased motivation, commitment, innovation, nurse satisfaction and decrease burnout. Six for 15 articles indicate that the influence of transformational leadership style on job satisfaction. Conclusion: In this systematic review indicate that the influence of transformational leadership style on job satisfaction, motivation, nursing management, innovation and decrease burnout in nurses.

Keywords: leadership, transformational leadership style, nursing

1. Introduction

People's demands for quality health services, especially nursing services, will always follow the diversity of the health problems that occur in the community[1]. Professional health services needed to improve public health. In order to realize optimal health care and the nursing service quality required, considering the degree of organization and the methods of effective leadership with a focus on the leadership styles that affect the performance of the subordinates in carrying out their nursing actions needs to be done[2].

The concept of leadership has much to do with the study of different theoretical approaches and dynamic as a development over time. Some of these studies found no leadership style that was implemented in a pure form, but it had instead been modified according to different leadership styles[3], It is intended to create a working environment that encourages the commitment of the staff and the organization of nursing[4].

Transformational leadership was first conceptualized by Burns and then further developed by Bass. The term tends to refer to Bass's transformational leadership theory. According to Bass, there are four characteristicss of transformational leaders. The first characteristic, individualized consideration, suggests that transformational leaders support the development of their subordinate's

skills and that they will assist ther subordinates in achieving the desired outcomes. Such leaders not only offer coaching and advice but they also give the employees attention and treat them as individuals. Second, transformational leadership includes intellectual stimulation, whereby the leaders promote a culture in which the employees will develop their intelligence and rational thinking. Intellectual stimulation, in turn, fosters independent problem-solving by the employees. Inspiration is the third element of transformational leadership. In this regard, the leaders communicate high expectations and encourage the employees to focus their efforts on achieving the established goals. Finally, transformational leaders are regarded as charismatic leaders who offer a vision and mission to their employees. Such leaders will try to instill pride, respect and trust in their employees so then the organization can achieve the required outcomes[5]. The nurses surveyed reported a lower level of AC relative to NC and CC, suggesting that these nurses do not feel a strong sense of belonging or attachment to their organization. Leadership style and psychological empowerment significantly affect commitment levels, with transformational style having a marginal effect [4]. Supervisor support has a dramatic influence on employee job satisfaction compared to the other factors. Supervisor support was one of the job characteristics highly associated with transformational behavior. Supervisor support is a core transformational behavior and it increases the job satisfaction of a nurse [10]. The increased development of transformational leadership behaviors increases the nurses' job satisfaction and thus contributes to the increased retention of nurses [13]. The effective role of transformational leadership helps to improve nursing management and reduce burnout among nurses because this style of leadership enhances creativity and motivation among the nurses [7].

The transformational style has a positive impact on stimulating motivation, assuring job satisfaction and consolidating teamwork among the health workers compared with those who demonstrated transactional skills or laissez-faire styles[6]. Transformational leadership style, which is mostly correlated with satisfaction (Idealized influence attributed) which the staff nurses perceived as respect, caring for others, professional development and appreciation, was rarely practiced by the managers studied [15]. Job satisfaction can be manifested as employee commitment that results from an increased sense of meaningfulness at work and improved accomplishments. Job satisfaction is a valuable indicator that management can use to assess the overall employee development within an organization. Most satisfied employee developments tend to very highly self-confident, which boosts their performance[5].

2. Methods

2.1 Search Strategies, Data Source

The searching of the literature materials for this systematic review was limited to articles in English performed between 2014 until 2018 which was accessible from an Internet search. The databases searched were Scopus, ScienceDirect and Proquest. The sources of the research data were derived from the literature, and were mainly published scientific articles from national and international journals. Seven articles indicated that there was an influence from transformational leadership style on job satisfaction, while two articles were on motivation, two articles were on commitment and one was on the decrease in burnout among nurses. The keywords used to search the literature were "nurse leadership style, motivation, commitment, satisfaction performance, and nurse burnout".

2.2 Inclusion Criteria

An article was included if it met the following criteria: 1) it included the transformational leadership style in nursing; 2) it was an original research; 3) it included nurses as the study subjects and 4) it involved satisfaction, performance, the burnout of nurses and articles published in the years between 2014 and 2018. An article was excluded if it met the following criteria: 1) subjects of the study were not nurses; 2) not a primary study; 3) not about transformational leadership style and 4) no outcomes of interest.

2.3 Design

The systematic review was organized using several stages based on the preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA), namely (1) identifying the intervention in the literature, (2) identifying the relevant literature by topic and title, (3) getting the literature in full-text form, and (4) analyzing the results of the various interventions in the literature.

2.4 Data Extraction

The components involved in the extraction of the data include the author, journal, state, objectives and the research questions, theoretical framework, research design, research subjects, methods, instruments, reliability and validity, the analysis of the results of the leadership and whether the results were significant or insignificant. The data was extracted by one of the drafting team and verified by the editorial team.

2.5 Analysis

The data was analyzed using content analysis in two stages. The first phase consisted of dividing the studies into several categories based on their common characteristics. The second stage was to identify the effect of transformational leadership style on motivation, commitment, satisfaction performance and the decrease in burnout in the nurses.

3. Results

3.1 Selection of Studies

The initial search retrieved a total of 633 articles: 214 from ScienceDirect, 215 from Scopus and 204 from Proquest. From these, 288 duplicate articles were removed. Besides the inclusion and exclusion criteria, 68 articles were excluded. The review process for the selection of the articles progressed in stages, including the title review, abstract review, years and a full-text review. We extracted 214 studies according to the title, years published and abstract review and 63 studies from the full-text review. Finally, a total of 12 articles were selected for this study. The retrieval and screening process has been summarized in Figure 1.

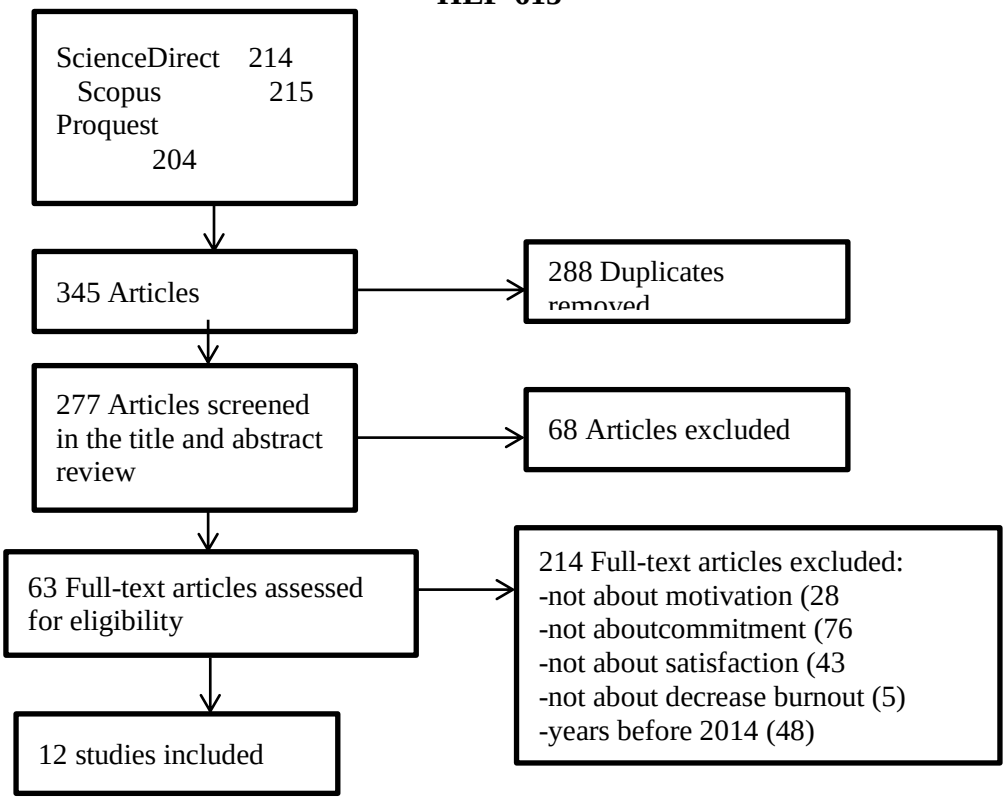

Figure 1. Literature search flow looking at the effect of transformational leadership style on motivation, commitment, satisfaction, performance and a decrease in burnout.

Based on the results, we obtained some 633 articles and then made one last screening as to whether any of the titles in the articles were the same or not. A total of 12 articles were selected. The studies included 7 focused on satisfaction, 2 on motivation, 2 on commitment, and 1 on a decrease in burnout. The role of transformational leadership style in improving nursing management and on reducing burnout among the nurses is because this style of leadership enhances the creativity and motivation among the nurses, thus it can decrease burnout[7]. For this outcome, there is a significant positive relationship between the nursing manager's leadership style and organizational commitment[8]

Table 1. Outcome and results

Author (Yr)/ Country	Method	Outcome
Asiri SA [9](2016)/ Arabia	*Cross-Sectional*	The style of leadership may increase the commitment of the nurses
Jodar G[3] (2016)/ Spain	*Cross-sectional*	Application of transformational style among the nurses improved nurse satisfaction and the desire to try to work better.
Jeon SH[1] (2018)/ Korea	*queasy Experiment*	Ethical leadership can affect trust, fairness, and respect among nursing, the members of the unit, and this can affect the staff nurse's job satisfaction
Lin P[10] (2018)/ Taiwan	*quantitative study Cross-sectional*	Transformational leadership style and organizational commitment can improve the job satisfaction of nurses
Ebrahimzade N [7] (2015)/Iran	*Cross-sectional*	Leadership style that is transformational could further reduce the risk of burnout
Xie Y[11] (2018)/ China	*An empirical study*	Transformational leadership style brings in a direct impact on innovation in a team atmosphere
Boamah SA[12] (2018)/ Canada	*Cross-sectional*	There is a relationship between transformational leadership and management by passive exception (MBEP)
Musinguzi C[6] (2018)/ Uganda	*Cross-sectional*	Transformational style had a positive impact to stimulate motivation and job satisfaction of nurses
Abdelhafiz IM [13](2018)/ Jordania	quantitative, cross-sectional, comparative and correlational	Transformational leadership increases the job satisfaction of the nurses
Paul MA [14](2017)/ Saudia Arabia	*survey*	Transformational leadership is the most dominant leadership style
Choi SL [5](2016)/ Malaysia	*survey*	Transformational leadership style can improve job satisfaction among the staff nurses
Morsiani G [15](2016)/ Italy	*Mixed Methods Study Cross-sectional*	Transformational style had a positive impact on stimulating the motivation and job satisfaction of the convinced nurses

After screening, there were 12 articles obtained in accordance with the inclusion criteria for further review. All 12 studies evaluated 'satisfaction' and most of the studies addressed the positive results. For example, transformational leadership (TRL) had a correlation with organizational commitment which was determined using the Pearson Product-Moment correlation[14]. Transformational leadership increases the nurse's job satisfaction and thus contributes to the increased retention of the nurses[16]. Leadership style and employee empowerment could play an instrument role in promoting organizational commitment.

4. Discussion

Of the twelve journals that have been a part of the systematic review, it can be concluded that an effective transformational leadership style can have a positive impact on job satisfaction,

motivation, nursing management and innovation and it can decrease burnout in the nurses. The nurse manager needs to be improved through behaviors based on greater respect, caring for others, professional development and appreciation [15]. Transformation leadership could serve as a guide for the nurse managers to help them improve their leadership style, and to improve the levels of job satisfaction in the staff nurses[15]. The managerial reliance on the transformational style in the society under study could reduce the degree of burnout in general in addition to emotional exhaustion and depersonalization [13].

Supervisor support plays an important role in that it is more likely to influence the health outcomes of the nurses in terms of job characteristics. Supervisor support was one of the job characteristics highly associated with transformational behavior. Supervisor support is a core transformational behavior and it increases the job satisfaction felt by the nurses [10]. If the above is increased, then the performance of the nurses will also be increased when they are providing nursing care. The relationship between leadership style and the staff perceptions of their empowerment is important for nursing managers and leaders in order to create a working environment that encourages and facilitates a high level of commitment among the nursing staff [4]. Staff motivation, job satisfaction and teamwork were positively correlated with transformational leadership whereas only staff job satisfaction and teamwork were positively correlated with transactional leadership [6]. Transformational leadership is more helpful for building an innovative atmosphere. Leaders with TLS focus on establishing a shared vision, which helps the team members to perceive the support from their leaders, to establish innovation values and to increase their innovation autonomy and degrees of cognitive innovation [10]. Transformational managers use new methods to inspire their employees to ponder over issues, encouraging them to take a part in the future of the organization, to consider their personal differences and to stimulate and foster self-confidence in the employees by entrusting responsibilities to them. Increasing organizational commitment and improving organizational culture can reduce burnout, emotional exhaustion, and depersonalization in the employees.

Transformational leadership can be used as a basic consideration in improving job satisfaction, motivation, nursing management, innovation and decreasing the burnout of nurses. Specifically, this refers to the relationship that TFL has on employee empowerment and organizational commitment, therefore the findings of this systematic review contribute to the exiting literature on the effect of leadership style on nursing practice and outcomes.

5. Conclusion

Leaders with the proper leadership style should be selected in enterprises. A leader should be aware of the impact of their leadership style on their team. Leaders should also pay attention to the incentive role of their charisma. Furthermore, leaders should actively improve their leadership style and make full use of the advantages of transformational leadership style to set examples for their subordinates with their own virtue, to motivate their subordinates with their individual personalities, to show their subordinates humanistic care, and to increase their subordinates' confidence and sense of belonging. Moreover, leaders should motivate their subordinates by combining the vision and goals of their enterprises with their subordinates' needs. The relationship between transformational leadership style and the staff perceptions of their empowerment is important for nursing managers and leaders, as nurse managers have direct impact on the staff nurse’s job satisfaction, which in turn

affects the nurse's intention to leave, the turnover rate, the quality of care and patient outcomes. However, involvement in the decision-making process on its own, although this is definitely an important step forward, is not sufficient. The nurse manager needs to be aware of the virtuous circle that their transformational leadership behaviors can trigger. Therefore, we suggest that this becomes the strategic priority of nursing directors shared by top managers and implemented in a top-down manner to ensure that the process is legitimate, clear and accepted by all.

THE ROLE OF PROFESSIONAL INDEMNITY INSURANCE IN THE NURSING PROFESSION

Z V Chumaida1, F S R Roro and H Y Sabrie

Faculty of Law, Universitas Airlangga, Surabaya, Indonesia
Corresponding author: hilda_sabrie@yahoo.co.id

ABSTRACT

Professional Indemnity Insurance for the nursing profession provides cover for any legal costs and expenses incurred in their defence, as well as any damages that may be awarded. This is if the nurses are alleged to have provided inadequate services that cause the patients injury. The authority of the nurse in carrying out their professional duties is regulated by the Minister of Health Regulation No. 148/2010. This is so then the nurse has legitimacy when carrying out the practices within their profession. Related to the authority and duty of the nurses, they also have liability that needs to be protected by professional indemnity insurance. This is certainly based on Law Number 40 of 2014 concerning Insurance. The responsibility of the nurse when making a mistake (negligence) in carrying out their duties at the hospital is possible to be transferred to the hospital through insurance coverage. In this case, the hospital acts as the insured and the insurance company acts as the guarantor. The hospital is obliged to pay a premium to the insurance company. The method of this article was normative, which allowed the authors to explore the topic in-depth through two approaches; the conceptual approach and the statute approach. The conclusions of this paper are that first, the nurses as professionals in the field of health are very important to protect throgh professional indemnity insurance. Second, in this case, the hospital acts as the insured. On the other hand, the insurance company is an entity which provides *insurance*. The hospital is obliged to pay an insurance premium to the insurance company as the insurer.

1. Introduction

The nursing profession is a profession that is an integral part of the health services, in hospitals alongside doctors. The nursing profession is currently regulated by Law No. 38 of 2014 concerning Nursing. In Article 3, it is clearly stated that the nursing regulation aims to (1) improve the nursing quality; (2) improve the quality of the nursing services; (3) provide legal protection and legal certainty to the nurses and clients and (4) improve the level of public health.

The position of a nurse in the hospital is as a health worker who serves every patient in the hospital. Nurses have a relationship with the hospital as a legal entity by having a binding legal relationship with the employement agreement agreed upon by the hospital as an employer with the nurses as workers / employees. This work agreement then gave birth to the rights and obligations of those who made it because Article 1330 BW (Burgerlijk Wetboek) states that: "All agreements made legally apply as laws for those who make them". This is where each party has rights and obligations that are agreed upon through a work agreement. It is an employee that possesses the skills, qualifications and abilities needed to contribute to and further the aims of the employer. Both the Employee and Employer accept the terms and conditions set forth within the agreement.

As a professional nurse, the nurses are responsible for the work that they do. The types of activities conducted by the nurses come with the possibility of risks that can harm the patients as the consumers of the health services provided by the hospitals through the medical personnel (doctors / nurses).[1] Nurses as health workers are susceptible to demands for compensation from the patient for medical actions that are independent or for the medical actions that are instructions from the doctor. The hospital as the employer has an interest in the health services provided to the patients. They must also provide protection to every health worker who carries out their work (health services) for his benefit. For this reason, there is a need to transfer the risk by insuring the nurses against the demands for compensation claims.

In this case, the hospital acts as the insured and the insurance company acts as the guarantor. The hospital is obliged to pay a premium to the insurance company as the insurer and the insurance company is obliged to cover the burden of responsibility or risk related to the work of the nurse as a nursing / health worker who works for the benefit of the hospital as the insured. For this reason, in this paper, the writing method used was normative juridical, thus emphasizing the problem of how the role of liability insurance is specific to the nursing profession.

2. Methods

This article conducted a normative analysis of the law as the method of analysis. Doctrinal analyses involve an effort to understand the best balance of rights and obligations under the framework of each party defined by the insurance law perspective. The method of this article was normative, which allows the authors to explore the topic in-depth using two approaches; conceptual and statute. The conclusions of this paper are that first, the nurses, as a professional in the field of health, are very important to protect throgh professional indemnity insurance. Second, in this case, the hospital acts as the insured. On the other hand, the insurance company is an entity which provides *insurance.* The hospital is obliged to pay an insurance premium to the insurance company as insurer. The normative method inspiration was drawn from the moral, legal and political philosophy and its analysis around the questions of what ought to be.[2]

2.1 Literature Review

2.1.1 Definition of Insurance. The definition of insurance is the transfer of the possibility of the risk of an uncertain event (evenement).[3] The risk transfer can be in part or in full to the insurance company with premium payments.

2.1.2 Definition of Indemnity Insurance Nurse Profession. Indemnity insurance claims related to the nurse profession is insurance that aims to protect professionals, in this case nurses, against the legal liability of third parties who suffer from thefinancial losses arising from professional negligence. In carrying out their duties, nurses have the right to:

2.1.2.1 Obtain legal protection as long as they are carrying out duties in accordance with service standards, professional standards, operational standard procedures and statutory provisions.

2.1.2.2 Obtain correct, clear and honest information from the clients or their families.

2.1.2.3 Receive payment for the nursing services that have been provided.

2.1.2.4 Refuse the client's wishes which are contrary to the code of ethics, service standards, professional standards, operational standards of procedures and the provisions of the legislation.[4]

In carrying out their duties, the nurse has the authority to take medical action in a limited manner. If these actions result in a loss for the patient, the nurse can be prosecuted for their actions [5]. The importance of professional insurance for the nurses is to protect them against unwanted events when demands occur related to a third party.

3. Discussion

The Risk Transfer in Professional Indemnity Insurance

Insurance is an effort that can be used to overcome the possibility of accumulating losses due to uncertain events. Through an insurance agreement, there is a possibility that there is a risk of events that can cause losses that threaten the interests of the insured (hospital). These can be transferred to the insurance company. In return, the insured pays an agreed premium. With the existence of insurance, the hospital, which is positioned as the insured, has an interest to feel safe from the threat of loss due to the claim on the part of the patient.

The hospital, as the insured, has certain interests in its business activities (providing health services) to the community as the users of the hospital health services. The intended interest is responsibility due to the actions of the health personnel (nurses) who make mistakes both medical and in nursing that can cause harm to the patients. Interest is one of the principles of the insurance agreement. In an insurance agreement, there must be an interest even though the interest does not have to appear at the beginning of the insurance agreement. The interest must exist at the time even when the event is uncertain.

The transfer of the nurses' responsibilities to the hospital through insurance can be interpreted as a form of legal protection to nurses in carrying out their profession to provide health services to patients. The legal protection of the nurses when carrying out their nursing duties has been regulated in Article 36 of Law No. 38 of 2014 concerning nursing. This explains that the nurses, in carrying out their nursing duties, have the right to:

a. Obtain legal protection as long as they are carrying out their duties in accordance with the service standards, professional standards, operational standard procedures and statutory provisions.
b. Obtain correct, clear and honest information from their clients and/or their families.
c. Receive payment for the nursing services that have been provided.
d. Refuse the client’s wishes if they are contrary to the code of ethics, service standards, professional standards, operational standard procedures and the provisions of the legislation.
e. Obtain work facilities according to certain standards.

Nurses, in carrying out their duties, have the right to obtain legal protection for all claims from the recipients of health services as long as the health services provided by nurses are carried out in accordance with the health service standards, professional standards, standard operating procedures and if they do not conflict with applicable laws and regulations.

If the nurse, at the time of carrying out the task, turns out to be negligent which causes the patient to suffer an injury or to suffer loss so then a lawsuit arises from the patient's family. The hospital is then responsible for their negligence. This can be accompanied by law. The responsibility of the hospital for the negligence of their health personnel, especially the nurses, is strengthened by the provisions of Article 46 of Law No. 44 of 2009 concerning Hospitals which confirms that "the hospital is legally responsible for all losses incurred due to negligence committed by health personnel in the hospital".

The term accountability is a newly developed term meaning to hold someone accountable because their negligence has caused harm to other parties. In the field of health services, the problem of accountability occurs as a result of the legal relationship between the medical personnel (doctors, midwives, nurses) and the service users (patients) as stipulated in the agreement. Liability can be interpreted as a form of nurse participation in making a decision and learning with the decision as a consequence. Nurses have accountability, meaning that if there are parties who sue, the nurse must be prepared and brave enough to face it, especially those related to the activities of their profession. The nurse must be able to explain the activities or actions that they are carrying out.

Professional indemnity insurance is an insurance that protects against claims arising from losses resulting from the actions related to one's profession. Therefore, from the obligations that they bear, it makes a person careful when carrying out actions related to their profession. Professional indemnity insurance is also an insurance product that provides a guarantee of loss due to a particular profession. For example, in this case, paramedics who are legally responsible for paying compensation for losses arising from bodily injury caused by the guaranteed environment during the validity period of the policy.

The purpose of professional indemnity insurance is to protect professionals against legal liabilities when it comes to paying damage to people who suffer financial losses arising from their own professional negligence or from their employees when conducting business. Therefore, in carrying out its noble duties, nurses certainly have a large responsibility for their duties in serving sick patients. Therefore nurses in carrying out their duties must be very careful, not to make mistakes or negligence in serving patients.

In the case of premium payments to the insurance companies in the hospital, this can be done by withdrawing a few percent of the salaries of the health workers working in the hospitals. The premium received by the insurance company will protect the nurses when they are carrying out their duties, so then the nurses as health workers have a sense of security because their interests have been transferred to the insurance companies (guarantor). The provisions regarding the amount of premium that must be paid by the hospital to the insurance company depends on the agreement of both parties and it also depends on the extent of the quality of responsibility that must be borne by the insurer. This is so then the premium delivered by the hospital is in accordance with the guarantor.

The Transfer of the Risk of Nurse Liablity to the Hospital Through Professional Indemnity Insurance

As explained in the article above, the transfer of the nurses's liablity to the hospitals through insurance is a form of legal protection for the nurses when they are carrying out their profession to provide health services to the patients who use the hospital services. If the nurse, in carrying out her duties, turns out to be negligent so as to cause harm to the patient being treated, then of course this will

prompt a lawsuit from the family. This is what can be transferred to the insurance company through professional indemnity insurance[6].

The responsibility and liability of the hospital related to the negligence of the health personnel, especially the nurses, is strengthened by the provision of Article 46 of Law No. 44 of 2009 concerning Hospitals, which confirms that:

"The hospital is legally responsible for all losses caused by the negligence carried out by the health workers in the hospital."

Hospitals can be held responsible for the liability of patients who suffer from losses because the nursing actions are carried out in order to carry out their working relationships. The transfer of the risk of the nurses' responsibilities to the hospital is done through professional accountability insurance.

According to Article 65 of Law Number 36 of 2014 concerning the Health Workers Juncto Article 35 Paragraph 6 of Law Number 38 Year 2014 concerning Juncto Nursing Article 46 of Law Number 44 of 2009 concerning Hospitals, the Hospital is legally responsible for all losses incurred by negligence carried out by health workers in the Hospital. The provisions referred to provide legal constructions that in relation to the aspect of health law, risk liability and the lex specialis of Article 1367 paragraph (3)

The existence of risk indemnity requires the supervision of any credentials, namely that of the doctors who employ nurses in hospitals as health workers as the recipients of mandates. Supervision is one of the reasons for liability for the unlawful acts committed by health workers when carrying out the work.

In the private (civil) law system, there are several principles of liablity, including:

3.2.1 Contractual Liability.

Liability of this type arises because of a broken promise. That is, not carrying out an obligation (achievement) or not fulfilling the rights of another party as a result of the contractual relationship. In relation to the therapeutic relationships, the obligations or achievements that must be carried out by health care providers are in the form of effort, not results. Therefore doctors or other health workers are only liable for the medical efforts that do not meet the standards, or in other words, the medical efforts that can be categorized as civil malpractice.

3.2.2 Liability in Tort

This type of liability is a liability that is not based on the existence of a contractual obligation, but rather, it is based on an act against the law. An understanding against the law is not only limited to acts that are contrary to the law, self-legal obligations or other legal obligations but it is also contrary to good morality and contrary to the accuracy that should be done against others.

3.2.3 Strict Liability

This type of liability is often called a liablity without error (liability whitout fault), considering that someone must be responsible even though they did not make any mistakes; intentional, recklessness or negligence. A liability like this usually applies to products sold or articles of commerce, where the producers must pay compensation for the catastrophe caused by the product that they produce unless the manufacturer has warned against the possibility of such a risk.

3.2.4 Vicarious Liability

There is the principle of transferred liablity and indemnity. Liablity of this type arises due to errors made by the subordinates. In relation to the medical services, the hospital (as an employer) can be liable for the errors made by health workers who work as a subordinate (employee).

In accountable insurance for professional nurses,the hospitals is responsible for losses incurred due to the negligence committed by the nurses as health workers in the hospital [8].There is a transfer of responsibility from the nurse to the hospital when and where the nurse is on duty. Insurance is therefore accountable for the nursing profession using the principle of vicarious liability. The principle of accountability transferred requires that someone be liable for the actions of others, also called imputed liability.

As explained above, the principle of vicarious liability can be used as a means to provide legal protection for the nurses who work in a hospital who make mistakes (negligence) so long as the nursing actions are carried out within the scope of their duties as health workers and that they are not intentional. In other words, this action is a mistake in the form of negligence (default).

The transfer of the nurses' responsibilities to the hospitals through insurance and professional nurse accountability is based on the principle of vicarious liability. This is possible on the basis of contractual freedom. In the case of the transfer of responsibility, the hospital acts as the insured and the insurance company acts as the guarantor. The insured has an obligation to pay a premium based on the agreement of the parties to the insurer to take care of all of the consequences and the burden of responsibility related to the risk of the work of the nurse as a health worker who works for the benefit of the hospital. The hospital as a corporation, based on the Vicarious Liability principle, is responsible for any negligence carried out by the Health Care Provider[9], which in this case is the nurses who work for and on behalf of the hospital. This is so long as these actions have been carried out to the standards that have been regulated by the profession, by the institutions and by the government.

4. Conclusion

Nurses as professionals in the field of health are very important to protect through professional accountability insurance. In this case, the hospital acts as the insured and the insurance company acts as the guarantor. The hospital is obliged to pay a premium to the insurance company. The Importance of Transferring Nurses' Responsibilities to Hospitals through Nurse Professional Accountability Insurance is based on the principle of vicarious liability in order to protect the nurses as the health workers who work in hospitals from the demands from the patients for the medical actions that they have performed.

Among the practice nurses in Indonesia, there are still many who are not protected with professional insurance. Therefore when a third party demands it, they often have to bear the cost on their own. For this reason, the need for the government to provide protection through professional insurance, especially to the nursing profession, is the spearhead when dealing with patients. The government should socialize insurance and professional accountability by requiring each hospital agency to insure both the doctors and nurses working in the hospital with professional indemnity insurance.

ORAL HYGIENE BY TOOTH BRUSH, SPONGE AND GAUSE WITH CHLORHEXIDINE 0.2% ON VAP

Ainur Rusdi, Nursalam, Andri Setiya Wahyudi

Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia

Email: ainur.rusdi-2017@fkp.unair.ac.id

ABSTRACT

Vetilator Associated Pneumonia (VAP) is a lung infection that occurs in patients attached to ventilators who are treated in the Intensive Care Unit (ICU). VAP is a cause of increased morbidity and even causes death in patients, thus requiring intervention. In the US the prevalence of VAP accounts for 20-70%, 10% causes death. VAP in the ICU RSUD dr. Soetomo in 2017. Because this infection occurs during intensive care, it causes longer ICU care, causes high disability and financial burden. The causes of VAP pathogens in the study were aerobic Eterobacteriaaceae (25%), staphylococcus aureus (20%).. According to the Central for Association Control (CDC) the incidence of VAP was 39% in 2011. The purpose of this paper illustrates the incidence of VAP in service settings in this case is RSUD dr. Soetomo. This design is a quasi experiment. The population in this study were all adult patients who used ventilators in intensive care. Research shows that VAP can be prevented by oral hygiene (brush, sponge and gause).

Keywords: respirator, VAP, prevention with oral hygiene

1. Introduction

Pneumonia is an inflammatory condition in the lungs caused by bacterial, viral or fungal infection[1]. The descriptor used when the patients have an artificial airway and receive mechanical ventilation is ventilator associated pneumonia (VAP) [1]. VAP is the most common type of nosocomial pneumonia and it is a major cause of morbidity and mortality especially among patients in intensive care units (ICUs)[2].

The rate of occurrence of VAP varies from 10 to 41.7 per 1000 ventilators per day and it is associated with mortality rates ranging from 24% to 76%[2]. Several other studies reported that the occurrence of death ranged from 24% to 50% with potentially higher numbers in the immunocompromised group of patients or when multi-resistant organisms are involved[3].

The most important mechanism in the development of VAP is the ongoing microaspiration of oropharyngeal colonization into the lower respiratory tract. Twenty-four hours after the patient enters the ICU, the normal oropharyngeal flora changes to gram-negative pathogens, which

increases the amount of dental plaque. Plaque is an environment that is suitable for the growth and accumulation of pathogens [4,5]. In addition, the tracheal tube can operate as a conduit for a pathogen from the oral cavity to the lungs. Some studies also show there to be a link between dental plaque colonization and respiratory pathogens[5].

The prevention of VAP requires both clinical and non-clinical interventions to provide implementation and support in the intervention. Several studies have shown that the maintenance of oral hygiene in Indonesian patients under the MV can reduce the level of VAP [6]. Chlorhexidine has become the most commonly used product for oral hygiene and studios have previously validated its efficacy in reducing VAP levels[1,6]. Chlorhexidine gluconate 0,2% mouthwash is an anti-plaque agent with strong antimicrobial activity that is effective at low concentrations while facilitating alignment in the digestive tract[3,7,8]. There are different variations within each studio in terms of the frequency of administration. There are once a day and twice a day most commonly. In addition to the frequency difference, the media or oral hygiene device also varies, such as using toothbrushes, sponges or gauze. The aim of this discussion was to find out the effectiveness of oral hygiene solutions using 0.2% chlorhexidine using toothbrushes, sponges and gauze media with a twice-daily administration on the patients with mechanical ventilation.

2. Methods

Study design

The design of this study was a systematic review with a mixed method study approach (qualitative and quantitative) formulated to review the relevant research studies and with comprehensive analysis. This systematic reporting structure used PRISMA *(Preferred Reporting Items for Systematic Reviews and Meta-Analysis)*

Eligibility criteria

This systematic review applied the inclusion and exclusion criteria that focus on several research study designs and some of them used RCTs (Randomized Control Trial). The journal articles were published in English between January 2010 and January 2019. The search strategy used the PICOS framework to identify the keywords.

Search strategy

The literature search of the professional journal publications was conducted in the following search engines: SCOPUS, SAGE, ScienceDirect, Proquest and Pubmed. The literature review are conducted using “oral hygiene”, “VAP”, “Respirator”, and “prevention” keywords.

Study Quality Assessment

A total of 12 studies were selected and reviewed that met all of the eligibility criteria. The standard protocol used as a guideline for this systematic review method was PRISMA as shown in Figure 1 below. The steps taken included: (1) the removal of duplications, (2) the independent examination of the titles, abstracts and keywords and then deleting irrelevant citations according

to the inclusion criteria, (3) for the titles and abstracts that appeared to meet the inclusion criteria and that were according to the objectives of the systematic review, the next step was to choose a journal with the full text available and (4) the final step was the selection of the articles that had been randomized to reduce the risk of bias. Meta-analytic techniques could not be done adequately because of the heterogeneity in terms of the definition of the research design and the characteristics of the results.

3. Result

- *Study selection*

The search strategy was carried out by generating a total of 1491 citations. These were then screened after removing the duplicates and 491 were found. Following this, 393 existing literature items were deleted because the title and / or abstract did not match the specified eligibility criteria. Finally, 38 complete articles were removed from the second stage of screening and 12 papers were included in the systematic review.

- *Study characteristics*

A total of 12 studies were finally selected for the review. They consisted of (1) a non-randomized pre-test / post-test design, (2) a cross-sectional randomized controlled trial study (3) and (4) an experimental study design.

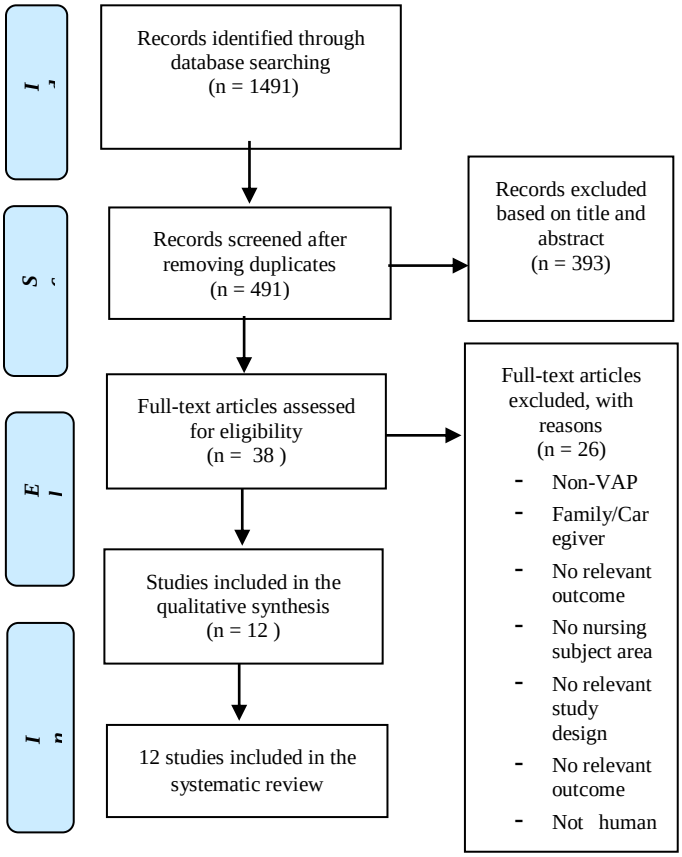

Figure 1. Flow Diagram

- *Result of synthesis*

The patients who underwent oral hygiene with a toothbrush experienced a significant decrease in the duration of mechanical ventilation and a tendency to reduce the incidence of VAP and their length of stay in the ICU, even without significant statistics. Period 2 protocols are easier to implement and they are more effective. The incidence of VAP decreased significantly in period 2. After 24 oral hygiene tests were carried out on 559 patients, VAP occurred, which meant 6.9 average VAP incidences per 1000 days / ventilator. The cost savings to prevent and treat VAP were as much as 6319 euros. In each group, 38.6% of patients developed VAP. The incidence of VAP in the intervention and control groups was 4.8% and 6% respectively. On the third day, there was 14.3% and 20.2% on the fourth day and 29.8% and 47.6% on the fifth day. Microorganisms were isolated from the aspiration of the endotracheal tubes. Enterobacter was found in 14 patients in the experimental group (56%) and in 20 patients in the control group (50%). Acinetobacter was found in 7 patients in the intervention group (28%) and 12 patients in the control group (30%). Klebsiella was found in 4 patients in the intervention group (16%) and 8 patients in the control group (20%).

Discussion

Chlorhexidine is an aromatic salt that has antimicrobial properties. In other words, it kills bacteria and other microorganisms. Chlorhexidin is bacteriostatic for gram-negative germs, yeast, fungi, protozoa, algae and viruses and it is very sensitive to several germ species such as pseudomonas spp. proteus spp, haemophilus spp, diptheroid spp and actinomyces spp.

Oral hygiene that is carried out well can kill bacteria in the mouth, thereby reducing the colonization of the gastrointestinal bacteria that can invade the respiratory tract which can cause VAP. The assessment of VAP events used 5 indicators, namely body temperature, leukocytes, tracheal secretions, oxygenation and a chest radiograph.

The systematic review showed good results with oral hygiene concerning decreasing the incidence of VAP with the optimal application of bandages.

Given that VAP is the most frequently occurring nosocomial infection in the ICU and it is associated with increased morbidity and mortality[9,10], any strategy that has the potential to reduce its incidence should be explored. According to the Centers for Disease Control (CDC), the prevention of VAP requires a multifaceted approach [11]. They further recommend that this approach should include the development and implementation of a comprehensive oral hygiene program. Standardized protocols that include the use of an antiseptic agent can potentially reduce the risk for patients in acute care settings of developing VAP. Thus the CDC supports interventions to improve oral health and the subsequent reduction in the colonization of dental plaque with respiratory pathogens which may result in the development of VAP

Conclusion

A prevention effort to reduce the incidence of VAP in various countries is sought to reduce the

incidence of VAP in hospitals. The intervention in VAP is currently done but there are some obstacles that make the implementation in VAP non-optimal.

1	Impact of oral hygiene involving toothbrushing versus chlorhexidine in the prevention of ventilator- associated pneumonia : a randomized study (Claudia Fernanda de Lacerda Vidal, et all, 2017) [12]	213	Randomized Controlled Trial	Patients who underwent oral hygiene including a toothbrush experienced a significant decrease in the duration of mechanical ventilation and a tendency to reduce the incidence of VAP and their length of stay in the ICU, even without significant statistics.
2	Comparative study of 2 oral care protocols in intensive care units Cohort Study **(**Jérôme Ory PharmD, et all, 2017) [8]	2030	Cohort Study	Period 2 protocols are easier to implement and they are more effective. The incidence of VAP decreased significantly in period 2.
3	Reducing ventilator-associated pneumonia in adult patients through high standards of oral care: A historical control Study. (Lee R. Cutler, Paula Sluman, 2016) [1]	1087	Historical Controlled Study	After 24 oral hygiene tests were carried out, out of the 559 patients, VAP occurred, which meant 6.9 average VAP per 1000 days / ventilator. The cost savings to prevent and treat VAP was as much as 6319 euros.
4	Oral Care and bacteremia risk in mechanically ventilated adults (Deborah J.Jones et all, 2010) [7]	30	Prospective pre-post test	Seventeen percent of patients were positive for pathogenic oral cultures before the first oral hygiene treatment. No patient had positive transient bacteremia in their quantitative blood culture before and after the oral hygiene interventions.
5	Oral health and ventilator-associated pneumonia among critically ill patients: a prospective study. (Saesom, et al, 2016) [2]	162	Prospective cohort study.	There is a strong relationship between poor oral health and an increase in the initial risk of VAP. Oral care can prevent the development of VAP in critically ill patients treated with a mechanical ventilator.
6	Effects of three approaches to standardized oral hygiene to reduce bacterial colonization and ventilator-associated pneumonia in mechanically ventilated patients (Berry et all, 2011) [3]	109	Randomized Controlled Trial	Group B showed a greater tendency to reduce bacterial colonization and there was no significant difference on day 4. The incidence of VAP was evenly distributed in groups B and C (5%) while in Group A it was only 1%. Many studies have advocated the use of oral cleansing to reduce dental plaque colonization as a standard oral hygiene protocol, including the use of toothbrushes as a reduction factor in dental plaque colonization with respiratory pathogens

No	Title, Authors, & Time	N	Design	Main Result
7	Does the presence of oral care guidelines affect oral care delivery by intensive care unit nurses? A survey of Saudi intensive care unit nurses (Ahmed K. Alotaibi et all, 2014) [13]	215	Cross sectional Survey	140 nurses provided mouthwash therapy every hour with chlorhexcidine 0.12%. Manual toothbrushing / 12 hours was reported to be carried out by more than 125 nurses. Only 80 people did subglotic suction. Most nurses (169 people) adhered to the oral care guidelines for patients with mechanical ventilation in the ICU. There were significant differences between the nurses who performed oral care guidelines compared to those who did not use the oral care guidelines
8	The effects of oral rinse with 0.2% and 2% chlorhexidine on oropharyngeal colonization and ventilator associated pneumonia in adults' intensive care units (Zand et al, 2017) [5]	114	Randomized Controlled Trial	There were significant group differences between the experimental group and the control group. In the experimental group, those suffering from VAP totaled 13 people (22.8%) and 44 (77.2%) people did not suffer from VAP. In the control group, those suffering from VAP totaled 3 (5.3%) people and 54 (94.7%) people did not suffer from VAP.
9	An evidence-based oral care protocol to decrease ventilator-associated pneumonia (Lisa Cuccio et al, 2012) [14]		Quasi-experimental pre and post	The incidence of pneumonia decreased from 4.3 to 1.86 per 1000 ventilator days during the assessment, with an estimated cost of 700,000 dollars and up to 798,000 dollars.
10	Oral decontamination techniques and ventilator- associated pneumonia mechanically ventilated patients. (Ranjitha Chacko, 2017) [15]	206	Randomized Controlled Trial	12 patients had VAP; 5 from the experimental group and 7 from the control group. VAP incidence in the participants was only 101 per 1000 ventilator days; it was 8.6 / 1000 ventilator days for the experimental group and 11.6 / 1000 ventilator days for the control group. There were no significant differences in the incidence of VAP between the 2 groups.
11	Prospective, randomized, controlled study evaluating the early modification of oral microbiota following admission to the intensive care unit and oral hygiene with chlorhexcidine (Felipe Francisco Tuon, 2017) [6]	16	Prospective Randomized Controlled Trial	Both groups had the same Charlson comorbidity score. On day 5, all patients had positive culture results for OM and DP. The OM and DP culture results showed a similar prevalence for the MDR bacteria. There was a lower percentage of MRSA infections for the CHX group compared to the placebo group.
12	The effect of brushing with a soft toothbrush and distilled water on the incidence of	168	Randomized Controlled Trial	In each group, 38.6% of patients developed VAP. The incidence of VAP in the intervention and control groups was 4.8% and 6%

EFFECTIVENESS OF BUNDLE CARE TO PREVENTION SURGICAL SITE INFECTION : SYSTEMATIC REVIEW

Edy Purwanto, Nursalam, Tintin Sukartini
Faculty of Nursing, Airlangga University, Surabaya, East Java, Indonesia
Email: edy.purwanto-2017@fkp.unair.ac.id

ABSTRACT

Care bundles are a strategy that can be used to reduce the risk of surgical site infection (SSI), but individual studies of care bundles report conflicting outcomes. This study assesses the effectiveness of care bundles to reduce SSI among patients undergoing colorectal surgery. The method used in this systematic review consists of 5 stages: (1) identification of instruments in the literature (database search); (2) identification of relevant literature based on title and abstract; (3) inclusion and exclusion criteria; (4) get fulltext literature; (5) grading based on the literature component and analysis of selected instruments. The database used in the search for literature were scopus, Proquest, Sciencedirect, BMC, Iranian Journal, PubMed by limiting the keywords "Surgical Site Infection" AND "Prevention" AND "Bundle care", published year between 2014-2019. Thirteen studies were included in the analysis. From the result of this study it was found that bundle care can reduce surgical site infection. Bundle care which is the most dominant intervention is given in to prevention surgical site infection on patients colorectal surgery.

Keywords: Surgical Site Infection, bundle care, prevention

1. Introduction

Surgical site infections (SSIs) are infections that occur at the incision site following an operation. The current risk of a SSI after any procedure is less than 2%. This rate pales in comparison to the risk of SSIs after colorectal surgery (CRS) which ranges from 15.1 to over 30%. In 2014, the Joint Commission Center for Transforming Health Care in collaboration with the American College of Surgeons (ACS) surveyed seven prominent hospitals centers in the USA including the Mayo Clinic and the Cleveland Clinic and identified a baseline SSI rate after CRS of 15.8%. Each SSI in turn contributes a 3% mortality risk, with 75% of these deaths directly attributable to the SSI. In 2013, our institution implemented a surgical site infection reduction bundle in efforts to reduce surgical site infections among our colon and rectal surgery cohort of patients.

The potential for the use of care bundles was first proposed by the Institute for Healthcare Improvement in 2001 to improve outcomes in critical care [1].With the bundle approach, a minimum of three robust, evidence-based interventions are implemented collectively and

consistently so that there is a possible summation of their effects to reduce complications or adverse events. Utilizing measures from the SCIP guidelines and institutional practices, a bundle of 11 elements were created.

The objective of this study is to evaluate the effects of a surgical site infection reduction bundle on surgical site infection rates. Additionally, we seek to evaluate compliance with the bundle elements and the ease at which a new process can be implemented and adopted within an institution [2]. This study assesses the effectiveness of care bundles to reduce SSI among patients undergoing surgery.

2. Methods

2.1. Protocol

A systematic review was performed in line with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) statement and checklist [3,4].

2.2. Eligibility criteria

Scope literature is the use of interventions in the prevention of surgical site infection in clients undergoing surgery. is the literature is in the English language in order to increase the amount of search results. The inclusion criteria determined in the literature sorting are full text, interventions with bundle care, adult patients undergoing surgery, and cohort and experimental studies.

2.3. Information sources

Five databases were systematically searched (Scopus, Proquest, ScienceDirect, PubMed) from January 2014 to February 2019.

2.4. Search

The search terms used were "surgical site infection" AND "prevention" AND "bundle care".

2.5. Study selection

The protocol standard for selecting research studies is suggested in the PRISMA method for systematic review followed by screening by removing duplicates, then reviewers selecting titles, abstracts, and keywords, then deleting irrelevant quotes according to the selection criteria.

2.6. Data collection process

Articles that meet later criteria are evaluated regarding quality and validity with a focus on sample size, client allocation and needs and bias factors. Data extraction was carried out by one reviewer and examined by the second reviewer.

2.7. Data items

Data extraction is designed using the main criteria of the Greenhalgh framework. The components taken were objectives, research design, population (number of samples, characteristics and

recruitment methods), intervention in the form of bundle care, outcome measures, data collection methods, and results analysis.

3. Result

2.1. Study selection

A total of 37 articles were found using predetermined keywords. After the removal of 2 duplicates, 35 records remained. Twenty-two did not meet the inclusion criteria, including 7 articles which were eliminated due to not being relevant topics, 7 articles were not in English, and 8 articles involved fewer than 20 participants. Thirteen articles were included for data in systematic review. See figure 1.

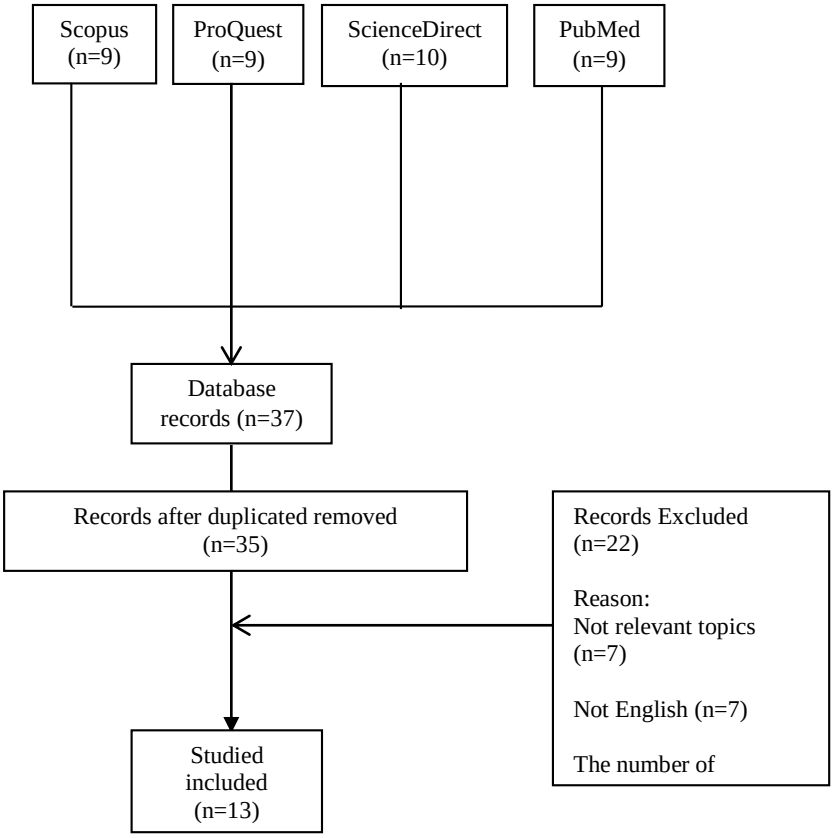

Figure 1. Flow diagram

2.2. Study characteristics

The research was conducted in various countries with various methods. The research method found in the articles are retrospective cohort (n=10), pragmatic study (n=1), and quasi-experimental study (n=1). The most widely used research design was retrospective cohort and the highest number of samples was 1351 respondent. See table 1.

Table 1. Summary of study characteristics

Author/Years	Study Design	Sample	Intervention	Outcomes measures	Result
Tufts *et al.*, (2018)	Cohort	N=424	Multidisciplinary bundle of 13 perioperative Components	Surgical Care Improvement Program (SCIP)	Implementation of a multidisciplinary care bundle was associated with a 61% reduction in SSIs ($p < 0.001$)
Weiser *et al.*, (2018)	Pragmatic study	N= 1828	Multidisciplinary bundle of 13 perioperative Components	Surgical Care Improvement Program (SCIP)	Meaningful reductions in SSI can be achieved by implementing a multidisciplinary care bundle at a hospital-wide level ($p < 0.001$)
Bruce *et al.*, (2018)	retrospective cohort study	N= 875	Multidisciplinary bundle of 13 perioperative Components	Surgical Care Improvement Program (SCIP)	Implementation of an abdominal closure bundle was not associated with a significant reduction in overall SSI rate ($p=0.002$)
Mok *et al.*, (2019)	Retrospective cohort study	N=718	SSI prevention integrative care bundle approach informed by best practice guidelines was implemented in the HFU	Surgical Care Improvement Program (SCIP)	Compared with patients with no SSI, patients with SSI were 4.27 times more likely to be readmitted within 30 days, had 2.47 times longer length of stay, and 2.15 times the inpatient bill size.
Yazici and Bulut, (2018)	quasi-experimental study	N= 128	Sub-parameters of the HAI prevention care bundle	Surgical Care Improvement Program (SCIP)	The infection rates decreased with increased compatibility of the care bundle prepared from evidence-based

Author/Years	Study Design	Sample	Intervention	Outcomes measures	Result
					guidelines (p > 0.05)
Lawrence *et al.*, (2019)	Initial cohort	N = 150	4-part perioperative bundle		4-part bundle decreased SSI rate from 22% to 11% (p=0.012)
Hoang *et al.*, (2019)	Quasi experimental	N= 1351	Multidisciplinary bundle of 13 perioperative Components	Surgical Care Improvement Program (SCIP)	Comparing the group A to group C there was a decrease in total SSI (9.4%e4.7%, p<0.05)
Tanner *et al.*, (2016)	prospective cohort design	N=127	Multidisciplinary bundle of 13 perioperative Components	Surgical Care Improvement Program (SCIP)	The single intervention that showed an associated reduction in SSI was preoperative warming (p=0.032)
Liu *et al.*, (2017)	retrospective review	N=86	Multidisciplinary bundle of 13 perioperative Components	Surgical Care Improvement Program (SCIP)	The difference was statistically significant (P=0.01)
Bert *et al.*, (2017)	retrospective cohort	N=1322	SNICh protocol combined with bundle	Surgical Care Improvement Program (SCIP)	The application of the bundle was not statistically associated to a decrease of the risk of infection
Johnson *et al.*, (2016)	retrospective cohort	N= 635	Multidisciplinary bundle of 13 perioperative Components	Surgical Care Improvement Program (SCIP)	Risk-adjusted odds ratio for surgical site infection decreased from 1.6 (95% confidence interval 1.0–2.6) to 0.6 (0.3–1.1)
Lutfiyya, Parsons and Breen (2012)	retrospective cohort	N=430	Development of the Colorectal Care Bundle	Surgical Care Improvement Program (SCIP)	The absolute decrease of 14.49% is significant (p < 0.0001). The rate of superficial SSI decreased from 15.12% to 3.59% (p < 0.0001).
Itani (2015)	Retrospective study	N=559	Multidisciplinary bundle of 13 perioperative	Surgical Care Improvement Program (SCIP)	Subgroup analysis of the post bundle period,

Author/Years	Study Design	Sample	Intervention	Outcomes measures	Result
			Components		superficial SSI occurrence was associated with a 35.5% increase in variable direct costs ($13 253 vs $9779, P=0.001) and a 71.7% increase in length of stay (7.9 vs 4.6 days, P< .001)

2.3. Summary of studies

3.3.1. Multidisciplinary bundle of 13 perioperative components. Seven A study using Multidisciplinary bundle of 13 perioperative components was 8 studies [6,15,17,18]. This action is carried out by observing 13 steps as listed in table 2.

Table 2. Components of the perioperative bundle

Preoperative	Appropriate oral antibiotic selection Appropriate oral antibiotic administration the night before surgery Mechanical bowel preparation Medical evaluation for elevated hemoglobin A1C Skin cleansing with chlorhexidine the night surgery Surgeon notification of SSI risk using MSK SSI prediction tool
Intraoperative	Antibiotic administration before initial incision Appropriate method of hair removal (electronic clippers or no hair removal) Maintenance of normothermia Intraoperative antibiotic re-dosing Separate surgical closing tray for open procedures
Postoperative	Discontinuation of antibiotics at 24 hours Patient shower on postoperative day 2

SSI prevention integrative care bundle approach informed. SSI prevention integrative care bundle approach informed contain 15 items in one study [8].

Table 3. SSI prevention integrative care bundle approach informed

Preoperative	Optimize modifiable patient risk factors (e.g., diabetes) and Nutrition Prevention of anemia Preoperative skin preparation with chlorhexidine body wash to reduce skin microflora Screening and isolation of surgical hip patients from patients with MRSA
Intraoperative	Antibiotic prophylaxis Maintaining body core temperature: Preventing intraoperative hypothermia Prevention of anemia Intraoperative antibiotic re-dosing Separate surgical closing tray for open procedures
Postoperative	Postoperative fever examination, which includes regular wound inspection Prevent wound contamination Optimize nutrition Prevention of anemia Early mobilization and discharge planning

Sub-parameters of the HAIs prevention care bundle. There is one study that uses Sub-parameters of the HAIs prevention care bundle consisting of several items [9]. Contain of VAP: Bedhead height suitable, no need for aspiration, no need for oral care, cuff pressure suitable, no liquid

accumulation in the ventilator circuits, ventilator circuits are not dirty, peptic ulcer prophylaxis received, deep vein thrombosis prophylaxis received. CLABSI: the need for catheter continues. Central venous catheter's dressing need has been met, dressing has been suitably applied, dressing date available, fluid sets have been replaced. CA-UTI: the need for catheter continues, the urinary bag and catheter are below the bladder level, no withdrawal from the urinary bag, the urinary bag does not touch the floor.

4-part of perioperative bundle. The 4-part perioperative bundle implemented consisted of the following 4 components: double-ring wound protector: 500 mL bacitracin/saline irrigation of incision before skin closure; gown/glove change and sterile instruments for fascial and skin closure; negative-pressure incisional dressing [10].

SNICh protocol combined with bundle. The surgical bundle assessed the appropriateness of 5 items: the infection risk index calculation (it depends on ASA score, the length of operation, and the class of wound contamination), the preoperative shower, the trichotomy, the antibiotic prophylaxis, and the body temperature control.

Development of the colorectal care bundle. There is one study that uses Development of the Colorectal Care Bundle [16]. The step are Preoperative: give patient the SSI patient education sheet, encourage smoking cessation 30 days before surgery, use preoperative antiseptic skin cleansing: with chlorhexidine wipes (night before and morning of surgery), mechanically prepare the colon the day before surgery, administer non-absorbable oral antimicrobial agents (neomycin and metronidazole) the night before surgery, screen diabetic and nondiabetic patients using HbA1C levels. Holding: check blood glucose levels; if >140 mg/dL, start insulin infusion, remove hair with clippers in holding area (SCIP 6), apply forced warm air gown to maintain normothermia. Intraoperative: prescribe appropriate antibiotic (SCIP 1), dose prophylactic antimicrobial agent based on weight, administer prophylactic antimicrobial agents IV on time (SCIP 1), redose prophylactic antibiotic based on duration of operation, use standardized antiseptic agent for skin preparation: chlorhexidine gluconate (chloraprep), use at least 80% fraction of inspired oxygen, ensure double gloving for all scrubbed surgical team members, maintain perioperative normothermia (SCIP 9), aggressively control glucose in all patients; start insulin infusions for any blood glucose level >140 mg/dL, perform pulse lavage of subcutaneous tissues for all open operations using 2 L of saline.

Surgical care improvement program (SCIP). Measurement of surgical site infection is done using SCIP. SCIP is a national quality partnership committed to improving patient safety by driving down postoperative complications. The goal is to reduce 4 types of surgical complications by 25% by 2010, surgical site infections, perioperative heart attack, deep vein thrombosis, postoperative ventilator-associated pneumonia.

4. Discussion

The aim of this systematic review was to review the effectiveness of care bundles to reduce SSI among patients undergoing colorectal surgery. The review revealed the limited available research in this field of study, identifying only thirteen relevant studies.

Based on the article reviewed, it was found that the effectiveness of bundle care was applied to prevent SSI. The overall SSI measurement uses SCIP designed to measure SSI prevention. In all studies focused on patients with adult colorectal surgery. The perioperative components multidisciplinary bundle of 13 model is the most widely used step in this review. There are 8 studies

that use the model. Overall, using multidisciplinary bundle of 13 perioperative components found a significant result, namely the influence of bundle care on prevent SSI. The bundle was associated with a 61% reduction in SSIs ($p < 0.001$) [5]. The development of the Colorectal Care Bundle that was applied found an absolute decrease of 14.49% is significant ($p < 0.0001$). The rate of superficial SSI decreased from 15.12% to 3.59% ($p < 0.0001$) [16]. The 4-part perioperative was found to decrease SSI rate from 22% to 11% ($p=0.012$) [10]. The infection rates decreased with increased compatibility of the Sub-parameters of the HAIs prevention care bundle prepared from evidence-based guidelines ($p > 0.05$) [9]. SSI prevention integrative care bundle approach informed compared with patients with no SSI, patients with SSI were 4.27 times more likely to be readmitted within 30 days, had 2.47 times longer length of stay, and 2.15 times the inpatient bill size [19].

However, in 2 studies it was found that there was no association between the use of bundle care in SSI. Implementation of an abdominal closure bundle was not associated with a significant reduction in overall SSI rate ($p=0.002$) [7]. The use of SNICh protocol is combined with bundle in the application of patients with surgery with the results of bundle was not statistically associated to a decrease of the risk of infection [14].

The use of bundle care can be applied to the surgical service order. This can be applied in the form of a standard operational procedure. In addition, counseling can be done to health workers who work in the operating room so that it can be applied properly.

The article's collected in the systematic review were only 13 pieces with different research locations. Searching for literature that is constrained by language is because there were articles that use languages other than English. Resource constraints in translating English into Indonesian. Detailed discussion is still in the whole range of bundle care used to prevent SSI from colorectal surgery and a meta-analysis has not been conducted so that effective methods for prevent SSI cannot be determined.

5. Conclusions

This systematic review aims to find evidence of the effect or effect of bundle care on prevent SSI. The search for literature is based on relevance and then evaluates the quality of the literature. The findings show that bundle care has an effect on the prevent SSI. Weaknesses of methodology, small sample size, short duration, and challenges related to blinding. So it can be concluded that bundle care is most widely used in colorectal surgery.

EARLY ASSESSMENT AND DETECTION WITH CINCINNATI PRE HOSPITAL STROKE SCALE (CPPS) IN PRE HOSPITAL MANAGEMENT IN ACUTE ISCHEMIC STROKE PATIENTS TO INCREASE SURVIVAL RATE

Made Martini[1], I Dewa Ayu Rismayanti[2], Gede Budi Widiarta[3], G. Nur Widya Putra[4], Kadek Yudi Aryawan[5], Putu Agus Ariana[6], Mochamad Heri[7], Ni Nyoman Ari Ratnadi[8]
Sekolah Tinggi Ilmu Kesehatan Buleleng

BACKGROUND Stroke is known as the third leading cause of death in America after heart disease and cancer with an estimated 5 million people per year. In Indonesia stroke is the first cause of death. This happened because of the increase in the prevalence of stroke from 8.3 / 1000 in Riskesdas 2007 to 12.1 / 1000 with respondents> 15 years. One of the causes of increased mortality and disability from ischemic stroke patients include: first aid person or community does not know the initial signs and symptoms of acute stroke and risk factors. This has an impact on the delay, so that patients experience complications such as disability/even disability of death. The speed and accuracy of recognizing the signs and symptoms of acute attacks of ischemic stroke greatly influences the success of treatment.

PURPOSE to analyze and find out as a simple tool in early detection of acute ischemic stroke patients, namely CINCINNATI PRE HOSPITAL STROKE SCALE (CPPS), so that it can be used and used for patients, communities, nurses and EMS teams in providing early relief from acute ischemic stroke patients

METHODS This scientific writing paper used a systematic review design. This papers was taken from a collection of electronic databases several studies published from 2005 to 2018, using key word CCPS, stroke, emergency and pre hospital, articles were collected using Google Scholar, PubMed, Proquest, Ebscho. In the research article there are quantitative and qualitative studies. There were 10 articles in the research collection and selected using the inclusion criteria, namely full text, English, and discussed CPPS in managing stroke at pre hospital.

FINDING CPPS is one of the pre-hospital assessment tools that have high sensitivity that can be used as a simple screening tool for ambulance nurses, the public, stroke patients and EMS teams quickly and early prediction for stroke patients as a consideration for the patient's transport to the hospital immediately, so as to improve the survival rate and quality of life of stroke patients, especially in reducing mortality and morbidity.

CONCLUSIONS AND RECOMMENDATIONS The earlier and faster management of ischemic acute stroke patients will increase the survival rate of stroke patients, patients with acute ischemic stroke have a critical time of less than the first 3 hours of a stroke. Good cooperation between family, patients, community and professional health team, especially in understanding and implementing CPSS, which is recommended as a tool for assessing stroke prediction can reduce stroke mortality and disability patients.

Key Words : **CPPS, pre hospital, stroke, scale**

BACKGROUND

Stroke is the third leading cause of death in the United States, which is after heart disease and cancer with an estimated 5 million people per year. The first and recurring acute stroke events are 700,000 people each year. In Indonesia stroke is the first cause of death. This happened because of the increase in the prevalence of stroke from 8.3 / 1000 in *Riskesdas* 2007 to 12.1 / 1000 with respondents over 15 years. (*Riskesdas*, 2013). There are various risk factors and the causes of the increase in the number of stroke cases among them are the communities or helpers, especially the first helper, who do not know the initial signs and symptoms of acute stroke and risk factors. This has an impact on delay so that patients experience complications such as disability or death. The speed and accuracy of recognizing the signs and symptoms of acute attacks of ischemic stroke greatly influences the success of treatment (Savitz, 2007; Zohrevandi, 2014). In reality the patient's family is often late to bring the patien to the hospital, even more than 12 hours the patient is delivered by the family to get help (Agoes, 2012). According to Goldstein and France (2008), one of the factors that caused delay in ischemic stroke patients entering the emergency room at the pre hospital level included insufficient knowledge about stroke signs and symptoms which was 62.3%. A similar study by Kim et al. (2011) stated that quick or delay of stroke patient enter to hospital depends on patient and family knowledge, distance and transportation. Delaying judgment and diagnosis means delaying the salvage of the brain injury. Remember the principle of time is brain with golden hour means time is the same as saving the brain because every one minute delaying therapy, the patient must pay for it with damage to 1.9 million brain cells (Maggiore, 2012). This situation has not been fully realized by the societies and partly from the health care provider. This statement is seen in several studies conducted by Nicole and Thrift (2005) explaining that only 20-30% of respondents (total respondents: 822) knew about signs and symptoms and risk factors for stroke. Similar research is also explained by Ferris et all (2005); Ravenell, et all, (2015) who states that communities knowledge and awareness about stroke are still very lacking. See table 1. So efforts to increase communities knowledge and awareness about the importance of early detection of acute stroke and risk factors are stated in the recommended pre hospital management by AHA / ASA (2011) which consists of 4 links namely reaction speed and recognizing signs and symptoms stroke, the speed of activating the EMS system, the speed of transporting immediately and early diagnosis and treatment at the hospital. But the fact is there are still many stroke patients who are late to the hospital and only a small percentage use the EMS system (AHA, 2011: 136).

In Indonesia the EMS system has not been implemented as a whole so that health care providers have not been able to quickly assess stroke patients in the pre hospital area, so health education in the community (patients and families) is important especially in recognizing acute stroke signs and symptoms and risk factors for stroke, then immediately activate the emergency ambulance or ask for the closest family help to facilitate patients being admitted to the hospital. Health care providers can direct families as first responders through the Cincinnati Prehospital Stroke Scale (CPSS) assessment method.

This method is very simple, accurate and easy to apply. One study of the ability of nurses to assess the signs and symptoms of acute ischemic stroke by using CPSS states that the ability of nurses to quickly assess the clinical condition of patients before attending education and training shows that the sensitivity level of CPSS is only 61% - 66%. However, after

attending the training, nurses were very easy to identify the condition of neurological disorders in stroke patients, the level of sensitivity of CPSS was 86% -97% (AHA, 2011).

Thus the community and health care providers, family members and EMS staff from the Emergency Department / stroke unit can implement it easily because it only takes less than 1 minute to assess and diagnose the possibility of acute ischemic stroke (AHA, 2011: 136). Saving the penumbra, avoiding secondary insult and controlling risk factors are the objectives of emergency management in acute ischemic stroke patients (Setyopranoto, 2011).

The benefits expected from this paper, theoretically can contribute in efforts to increase success by early detection of signs and symptoms of acute ischemic stroke by using the Lingkati Prehospital Stroke Scale (CPSS) at the pre hospital and intra-hospital levels, The benefits expected from this paper, can theoretically contribute to efforts to increase success by early detection of signs and symptoms of acute ischemic stroke using the Lingkati Prehospital Stroke Scale (CPSS) at the pre hospital and intra-hospital levels, while the practical benefits: increasing early knowledge and alertness patients and the community in general as well as emergency care staff about stroke and management and can be considered as input for improving nursing services for patients with ED in the emergency room (Emergency Installation), ICU (Intensive Care Unit), general care rooms and stroke care units.

RESEARCH METHOD

The method used in this systematic review is internet writing from databases, Google Scholar, Direct Science, PubMed, Proquest and Ebsco, searches are limited to 2005 - 2018 publications, using keywords (keywords), namely CPSS, pre hospital, stroke, scale, can be accessed full text in pdf format. Inclusion criteria are articles that discuss stroke assessment systems by using CPSS tools in the management of stroke patients with non-hemorrhagic stroke, while exclusion criteria are articles that discuss the assessment of pre-hospital hemorrhagic stroke patients who do not use CPSS measuring instruments and journal articles that do not use English. From the search results obtained 1,200 articles discussing stroke in general, after eliminating there are 500 articles in the same, from 500 articles sketched through full text criteria with pdf article format limited to 2005 - 2018 then eliminated 299 articles and obtained 46 articles according to inclusion criteria and exclusion, from 46 articles, 10 articles were able to meet the author's criteria (26 articles discussed hemorrhagic stroke and TIA (trans ischemic attack) and 10 articles found no results related to CPSS. Data from articles that were obtained were then extracted data. This extraction was carried out by analyzing data based on year, title, research method and research results.

Table 1. Summary of article (N = 10)

No	Authors and Year	Title	Research Method	Research Result
1	Jonathan R. Studnek, Andrew Asimes, Jodi Dodds, Doug Swanson, 348-353, 2013	Asseissing The Validity of The Cincinnati Pre Hospital Stroke Scale and The Medic Pre Hospital Assesment	The study used Cohort Retrospective study method, which took data from March 1, 2011 to September 30, 2011, from 416 patients	From the results of this study it was found that the value of study sensitivity by using Med PACS after demonstration

No	Authors and Year	Title	Research Method	Research Result
		for Code Stroke in An Urban Emergency Medical Services	suspected of stroke then 186 data of patients who met the inclusion and exclusion criteria were diagnosed with non-hemorrhagic stroke. This study compared the value of the sensitivity of the assessment of non-hemorrhagic stroke patients in pre-hospital using the Med PACS and CPSS assessment scale.	was 0.742 (95%) with a CI value of 0.672-0.802 while the sensitivity level of the CPSS assessment was 0.790 (95%) CI value was 0.723 - 0.845, so it can be concluded the initial assessment (pre hospital) using CPSS is more significant rather than using Med PACS.
2.	De Luca et all, 2013, 13:53	*The use of Cincinnati prehospital stroke scale during telephone dispatch interview increases the accuracy in identifying stroke and transient ischemic attack symptoms*	To measure sensitivity and positive prediction value (PPV) EMS dispatchers are diagnosed with stroke compared to CPSS Design: cross sectional Multy study Instrument: 21760 cases in which 18231 strokes by dispatchers and 9791 symptoms were confirmed by the results of the scene survey Treatment: nurses identify non-hemorrhagic stroke cases at the time the dispatcher receives a telephone and survey scene. Measuring sensitivity and Positive Prediction value (PPV) EMS dispatchers diagnosed with stroke compared with CPSS With a sample of 38 nurses from Italy who served in the emergency center	Identification using PPV: 34.3% (95% CI 33,7-35,0; 6262/18231). Sensitivity: 64% while CPSS: 56% more often used with a sensitivity of 71%, CPSS sensitivity is better for diagnosis of pre-hospital in cases of non-hemorrhagic stoke so that ambulance nurses must know and conduct stroke patients with CPSS devices
3.	Bray, JE; Martin, J;M; et all. 2005; 20:28-33	*Paramedic Identifi cation of Stroke: Community Validation of the Melbourne Ambulance Stroke Screen*	Objective: Speed up therapeutic access with stroke tools validation between, LAPSS & CPSS with MASS Design: Prospective study	Pre hospital tool analysis: Sensitivity of MASS: CPSS (p = 0.004) = 90%: 95%. MASS: LAPSS (p = 0.003) = 74%: 85% So CPSS is more sensitive in assessing

		Identification and On-Scene Time/ Frendll,D.M;Strauss, D.G; Vudenhill, B.K; Goldstein, L.B. 2009, 40:754-756	survey / final diagnosis in hospitals Performed on 154 patients suspected of stroke, the average age of 16-69 years. Design: retrospective study. Instrument: EMS documentation Treatment: the assessment was carried out before and after training by using CPSS compared to the final diagnosis when the patient is in the hospital. Patients were given 1 hour of education about CPSS. Performed during the transport process to the center of the patient then identified with RS diagnostic data, note the suspected stroke before and after training.	improve skills for the accuracy of stroke / TIA diagnosis
7.	Jieun Jang, Sung Phil Chung, Incheok Park, Je Sung You, Hye Sun Lee, Jong Woo Park, Tae Nyoung Chung, Hyun Soo Chung, Hahn Shick Lee. 2014	The Usefulness of The Kurashiki Pre Hospital Stroke Scale in IdentifyingThrombolytic Candidates In Acute Ischemic Stroke	The study used the Retrospective method by comparing the initial stroke assessment methods of CPSS and NIHSS at the time of the initial stroke until the patient arrived at the hospital and received IV-rtpA and IA-UK therapy, when patients arrived at the RSD assessed by using the data base taken from The Brain Salvage Through Emergency Stroke Therapy (BEST) using the Computerized Physician Order Entry (CPOE) system. Data is taken from September 1, 2010 to September 30, 2010.	The results found that both the CPSS and NIHSS studies were good studies given to hemorrhagic stroke patients before patients received IV-rtpA therapy and IA-UK therapy, where CPSS had a sensitivity value of 69% and a specific value of 63%.
8.	Stephen W. English, MD, Alejandro A. Rabinstein, MD, Jay Mandrekar, PhD dan James P. Klaas, MD, 2018	Rethinking Prehospital Stroke Notification: Assessing Utility of Emergency Medical Services Impression and Cincinnati Prehospital Stroke Scale	Used a retrospective single-center cohort study method in patients suspected of stroke from 2014 to 2015. Data obtained from patients were demographic data and stroke onset, Cincinnati Prehospital Stroke Scale (CPSS) score and using NIHSS, ie tools which is	Of the total patients suspected of stroke 130 people, 96 patients were diagnosed with non-hemorrhagic stroke, the use of preliminary assessment with NIHSS and assessment through face (face)

No	Authors and Year	Title	Research Method	Research Result
			used at the beginning of the assessment in diagnosing a stroke so that treatment can be given early.	assessment, arm (speech) and speech abnormalities (speech abnormalities) in the assessment with CPSS seemed more significant in non-hemorrhagic stroke patients (P <.05). CPSS identified 75% of acute stroke cases, and the NIHSS identified 60% of stroke cases. In the application, the value of CPSS is more accurate and more specific in assessing acute stroke.
9.	Amy S. Hurwitz , MD, Jane H. Brice , MD,, Barbara A. Overby , MSN, & Kelly R. Evenson , PhD, 2009	Directed Use of the Cincinnati Prehospital Stroke Scale by Laypersons	The method used by analyzing 100 patients who called EMS 911 with stroke symptoms by using CPSS review tool, then analyzed whether CPSS was performed correctly in assessing the symptoms of the initial acute stroke event.	Nearly 98% of patients who call EMS know CPSS and when reporting for the assessment of facial weakness sensitivity levels are 74%, and specificity is 94%. For the study of the arm, the sensitivity level is 96% and the specificity is 96% so that CPSS can be accurately identified in the symptoms of acute ischemic stroke.
10.	Jan C. Purru Cke, Christian Hametner, Andreas Engelbrecht, Thomas Bruckner, Erik Popp, Sven Poli 2014	Comparison of Stroke Recognition Stroke Severity Scores For Stroke Detection In A Single Cohort	This study used Prospective Cohort study method, the date of data collection which was November 1, 2007 until August 31, 2010, by using a sample of patients who entered the Emergency Department room with Suspected CNS dissorder, amounting to 689 patient data. This study compared the number of scores and the level of accuracy in the early detection of acute ischemic stroke patients with CPSS measuring devices, FAST (Face Arm Speech Test),	The results showed differences in sensitivity and specificity of data, among others: Sensitivity and CPSS specificity values were 83% (95% CI 76 to 88) and specificity was 69% (64% -73%), FAST sensitivity value was 85% (78% - 90%) and its specificity is 68% (63% - 72%) while LAPSS has a high specificity of 92% but a low sensitivity value of

No	Authors and Year	Title	Research Method	Research Result
			LAPSS (Long Angeles Pre Hospital Stroke Scale).	44%, so CPSS has the highest sensitivity value, CPSS is one accurate detection tool in assessing the initial disorders of acute ischemic stroke patients.

RESULT AND DISSCUSSION

Analysis of 10 articles taken from the inclusion and exclusion criteria was publications from several International Journals from 2005 to 2018, the entire journal discussed the effectiveness of using the initial assessment tool, CPSS (Cicinati Prehospital Stroke Scale). CPSS is an assessment tool at the beginning of an attack that can predict that the patient has a stroke, especially the type of ischemic stroke, these tools emphasize the study of three basic components, namely facial droop, arm drip and abnormal speech. Trained health workers such as EMS will easily assess the condition of stroke patients. Trained communities or health workers can assess the presence of paralysis in the face by asking patients to smile and show their teeth, noting the presence or absence of similarity / symmetry of facial movements. If it is asymmetric the results are abnormal. Next to assess weakness in the upper extremity or hemiparesis ask the patient to lift both arms up with closed eyes for 10 seconds. Note if one hand will appear weak / unable to move then it is categorized as abnormal. The last to assess the ability to speak ask the patient to repeat one word phrase such as: "I cannot teach my old dog with new tricks." If the spoken sentence is unclear and difficult to understand, there is a high probability of abnormal speech ability. The interpretation is that if one of the three abnormal signs is found then the probability of a stroke is 72%. But if all three are found it is likely the patient has a stroke of> 85% (ACLS, 2011).

Stroke is a disease that can cause death and disability, especially if the treatment is late and inappropriate. In acute stroke, especially frequent non-hemorrhagic strokes, people, helpers and health workers have difficulty in recognizing and taking action at the beginning of attacks often late, so an assessment tool is needed that is effective and efficient in recognizing stroke signs and symptoms, especially in ischemic stroke.

The goal of stroke treatment is to minimize injury to the brain and improve patient recovery. AHA (2011) describes a strong and established link between links in an effort to achieve successful treatment of stroke patients, namely the stroke chain of survival. This link explains the strength of the relationship between patients, families, health care providers to recover or save acute ischemic stroke patients through: introduction and reaction to early signs and symptoms of ischemic stroke, activate EMS quickly, transport immediately and inform the patient's condition to the hospital before arriving , rapid diagnosis and therapy at the hospital. But in Indonesia, not all hospitals apply it for various reasons.

There are several studies that say that the use of CPSS is effective and can increase

success, especially in accelerating the initial treatment of stroke patients who experience acute attacks, a study using the Cohort Study is taking EMS and RS records, carried out for 12 months in 441 patients suspected of stroke non hemorrhagic, an initial assessment (pre hospital using CPSS) was carried out by using an EMS hospital (ambulance), the results showed that of 441 patients, 371 (84.5%) patients did experience non-hemorrhagic strokes after examination further in the hospital and 70 people (15.9%) patients not non-hemorrhagic strokes the initial treatment was done quickly and precisely because it was earlier detected using CPSS (Oostema, 2015).

The important thing to do is to make a diagnosis and immediate treatment for patients with acute stroke symptoms and the key to preventing delay is to implement 8 stroke care including: Detection: early detection of signs and symptoms of acute ischemic stroke, Dispatch: Activate more early EMS dispatcher 119, Delivery: fast EMS identification, management and transportation, Door: accuracy of triage to stroke flashlight, Data: rapid triage, evaluation and management in emergency deployment, Decision: confirm stroke diagnosis and treatment immediately, Drug: fibrinolytic therapy through intra-arterial strategy and Dispotition: rapid setting of patients to ICU or stroke units to intensify patient condition monitoring (ACLS, 2011 revised edition of Manual Provider). NINDS explained that the time for the stability of patient care at the hospital depends on the assessment and management of patients at the pre hospital through the algorithm The suspect stroke algorithm (attached).

Perdossi (2011) describes the target time for management of acute ischemic stroke as follows: At the Triage stage: 10 minutes. The actions include: determine the criteria for rtPA therapy, report the stroke team, check the landfill lab (routine blood, PT / INR, PTT, blood chemistry and heart function, then medical care: 25 minutes. Actions include: Give Oxygen, IVFD NaCl, 0.9 %, Check TD, BB, NIHSS, check 12 lead ECG and head CT Scan. CT scan examination of head and lab: 45 minutes. Actions read lab results, CT scan and send results immediately to the stroke unit, and therapy: 60 minutes. The actions are starting from rtPA IV therapy, monitoring for ICH signs such as hypertension, severe headache, vital signs and decreased neurological status, so the time needed is no more than 3 hours (Setyopranoto, 2011).

Early detection in patients with acute attacks greatly affects the success rate of acute stroke patients, early detection is often carried out by ambulance officers or the community / family who find non-hemorrhagic stroke patients in acute attacks, so that a sensitive and effective tool is needed to assess early stroke patients. CPSS is a tool that has a high sensitivity value, in a study with Cross Sectional design using a sample of 38 ambulance officers working in an emergency center, who identified stroke cases with CPSS, then analyzed that CPSS was found to have a higher sensitivity in diagnosing stroke cases. acute ischemic at the onset of the attack, so ambulance nurses need to understand and apply acute stroke assessment with the CPSS assessment tool (De Luca et all, 2013).

There are a number of Prehospital Tools Assessment tools to assess early stroke, including: recommended ones such as CPSS, FAST, MAST, LAPSS to properly screen patients. In a study conducted, the study used the Cohort Retrospective study method, which took data from March 1, 2011 to September 30, 2011, out of 416 patients suspected of stroke then 186 data of patients who met the inclusion and exclusion criteria were diagnosed with non-hemorrhagic stroke. The study compared the sensitivity value of the assessment of non-hemorrhagic stroke patients in pre-hospital using the Med PACS and CPSS assessment scale.

From the results of the study it was found that the value of study sensitivity using Med PACS after demonstration was 0.742 (95%) with a CI value of 0.672-0.802 while the sensitivity level of the CPSS assessment was 0.790 (95%) CI value was 0.723 -0.845, so it can be concluded the initial assessment (pre hospital) using CPSS is more significant than using Med PACS (Studnek, et all, 2013: 348).

In a study by using Prospective Cohort study method, the date of data collection was November 1, 2007 to August 31, 2010, by using a sample of patients who entered the Emergency Department room with Suspected CNS dissorder, amounting to 689 patient data. This study compared the number of scores and the level of accuracy in the early detection of acute ischemic stroke patients with a CPSS measuring device (Prehospital Stroke Scale), FAST (Face Arm Speech Test), LAPSS (Long Angeles Pre Hospital Stroke Scale), the results showed that differences in levels sensitivity and specificity of data include: Sensitivity and CPSS specificity values of 83% (95% CI 76 to 88) and specificity of 69% (64% -73%), FAST sensitivity value is 85% (78% - 90%) and its specificity is 68% (63% - 72%) while LAPSS has a high specificity of 92% but a low sensitivity value of 44%, so that CPSS has the highest sensitivity value, CPSS is an accurate detection tool in assessing early disorders of acute ischemic stroke patients (Purru Cke, et all, 2014).

No less important actions in the management of ischemic stroke are minimizing waiting time, especially in the act of starting rtPA IV therapy, monitoring for ICH signs such as hypertension, severe headaches, vital signs and decreasing neurological status no more than 3 hours, so a stroke assessment tool is needed the initial sensitive and accurate assessment of ischemic stroke, said in a study using the Retrospective method by comparing the initial stroke assessment methods of CPSS and NIHSS at the time of the initial stroke until the patient arrived at the hospital and received IV-rtpA and IA-UK therapy, at when the patient arrived at the emergency room the hospital was assessed using a data base taken from The Brain Salvage Through Emergency Stroke Therapy (BEST) using the Computerized Physician Order Entry (CPOE) system. Data were taken from September 1, 2010 to September 30, 2010, from the results found that both the CPSS and NIHSS studies were good studies given to hemorrhagic stroke patients before patients received IV-rtpA therapy and IA-UK therapy, where CPSS had sensitivity values 69 % and 63% specificity, so it can be said that CPSS has a greater sensitivity value especially in assessing stroke patients with acute attacks before getting fibrinolytic therapy (IV-rtpA and IA-UK) (Jang, et all, 2014).

CONCLUSION AND SUGGESTION

The speed and accuracy of the diagnosis support the speed of fibrinolytic therapy as a special treatment option in patients with acute ischemic stroke who have a critical time in less than the first 3 hours of a stroke. Good cooperation between patients, families and professional health personnel in implementing CPSS as a stroke prediction assessment tool can minimize the injury of widespread brain cells (penumbra) and recovery of stroke patients and improve the quality of life of patients while reducing the incidence and death from stroke.

ABSTRACT

The increase of respiratory rate and decrease of peak expiratory flow rate in COPD are a major problem. These things need intervention that aims to as complish these problems. This research had purpose to know the effect of diaphragm breathing exercise combined with hand held fan against respiratory rate (RR) and peak expiratory flow rate (PEFR) in clients with COPD. This research type was quasi experiment with pre-test and post-test with control group design. 46 respondents of sample selected by consecutive sampling, 23 respondents as treatment group and 23 respondents as control group. The independent variable in this study was the diaphragm breathing exercise combined with hand held fan. The dependent variable were RR, and PEFR. Variable data collected by using a RR using observation sheets, and PEFR using measuring a peak flow meter instrument. The statistical test was used t-Test (Independent t-test and paired t-Test with significance α=0.05. The results showed that diaphragm breathing exercise combined with hand held fan was to improved RR with ρ=0.000, and PEFR with ρ=0.000. Diaphragm breathing exercise combined with hand held fan improve of RR and PEFR in COPD clients, because combined two intervention was increased of diaphragm muscle is muscle of breathing and could stimulates sympathetic and trigeminal nerve in COPD clients.

Keywords: diaphragm breathing exercise, hand held fan, respiratory rate, peak expiratory flow rate, chronic obstruction pulmonary disease

1. INTRODUCTION

Increased respiratory rate and decrease peak expiratory rates are major problem in COPD (Yatun et al., 2016). Chronic obstructive pulmonary disease (COPD) is respiratory disorder characterized by progressive airflow limitations due to blockage of the airways, since the blockage is peripheral, so the volume of air can be trapped in the lungs called hyperinflation (Borge et al 2014). The sign of airflow limitation is a decrease in FEV_1/ FVC ratio. The decrease in FEV_1 is a typical sign of COPD clients. PEFR was used peak flow meter and equal to expired volumes for 1 second (FEV_1) (Yatun et al., 2016).

The Global Initiative for Chronic Obstructive Lung Disease (GOLD) describes COPD as the 3rd cause of death by 2020, about 3 million deaths caused by COPD in 2012, an estimated 6% of all deaths worldwide that year. COPD as the fifth leading cause of death in Indonesia, an estimated 4.8 million clients are exposed to COPD. The prevalence of COPD from RISKESDAS 2013 is 3.7%

(Ministry et al., 2013). In East Java the problem of COPD was 3.6%. Data of COPD in Jombang Hospital in 2014 is 876 clients, in 2015 as many as 1567 clients and in 2016 as many as 2046 clients. Data from January to September of 2017 were 1478 and COPD became the second most common lung disease after TB disease (Medical Record of Jombang Hospital 2017).

Data of examination of peak expiratory flow of Paru Jember Hospital conducted on 21 people in February 2014 (Novarin et al 2015), found that 90,47% of them had severe obstruction with peak expiratory flow value 50-300 L/m, while 9, The remaining 53% had moderate obstruction with an exposure peak flow range of 300-600 L/m. During this time the client only consume pharmacological therapy prescribed by the doctor.

COPD that is not immediately treated will experience respiratory failure and further deaths occur. This is due to a decrease in respiratory muscle strength so that recoil and compliance pulmonary decreases. This decrease can cause progressive airflow disruption, resulting in perfusion disorders that may develop into arterial hypoxemia. The spirometry examination results will result in a decrease in force expiration volume (FEV) and an abnormal FEV/ FVC ratio, and a decrease in peak expiratory flow (APE) or also called Peak Expiratory Flow Rate (PEFR) (Lemonere & Burke, 2000 in Ritianingsing, 2008).

RR and peak expiratory rate the loware a clinical manifestation of COPD (Yatun et al., 2016). If an infection develops, shortness of breath will increase, sometimes accompanied by signs of right heart failure, gradually a rise the persistent pulmonary corpus. COPD clients will experience a decrease in pulmonary functional capacity, the main problem being complained of is shortness of breath during activity. Decreased pulmonary functional capacity in COPD clients is not only a result of airway obstruction but also a result of peripheral muscle weakness caused by hypoxia, hypercapnia, inflammation and chronic malnutrition. The condition of decreased PEFR in COPD clients shows a decline in the function of basic human needs. An intervention is needed that aims to alleviate the needs that the client needs and help deal with the difficulties.

One of the nursing theory's references in nursing intervention is Roy's adaptation theory. Roy explained that an adaptation process includes input (in the form of stimulus), process, effector, and outcome (Alligood, 2014). Diaphragm breathing exercise combined with hand held fan can be recommended as a nursing intervention and used as an input (stimulus) in the adaptation process to decrease the perception of dyspnea. This breathing exercise diaphragm is one of the breathing techniques, which aims to increased diaphragm excursion and could increased muscle strength of the diaphragm which is the major muscle of breathing (Cahalin et al 2002 in Morrow et al., 2012). Combined with hand held fan can stimulate the trigeminal nerve that can be maximized then the client can take a deeper and more effective breath so as to maintain lung expansion (Luh et al., 2017). The combined of interventions is expected to shape adaptive behavior in COPD clients to improve RR and increased PEFR score.

Based on evidence-based practice research conducted by Yamaguti et al. (2012), diaphragm breathing exercise can increase abdominal movement during natural respiration, thereby increasing the functional capacity. diaphragm breathing exercise can increase the strength of the diaphragm muscles which are the major muscles of the breathing and act as the bottom edge of the thorac. Diaphragmatic contractions pull the muscles downward, increasing the chest space and actively developing the lung (Black & Hawks 2014). Another study by Wong et al. (2016) on the effect of Electric Fan on dyspnea in Chinese on clients of end-stage cancer shows that cold air from the fan

can reduce dyspnea and can be used as a non-pharmacological treatment. But it is not enough to conclude that the effect of diaphragm breathing exercise in combined with hand held fan can increase RR and PEFR in COPD clients.

The purpose of this study was to prove the effect of diaphragm breathing exercise combined with hand held fan to improve of RR and PEFR in COPD clients. It is expected to facilitate the provision of nursing interventions in improve of RR and increasing PEFR in COPD clients as well as other possible cases of this therapy.

2. METHODs

2.1 Study Design

This research is quasi-experimental with pre-test and post-test with control group design.

2.2 Sampling

The population is the client COPD outpatients in hospitals Jombang. 46 respondents of sample selected by consecutive sampling, 23 respondents as treatment group and 23 respondents as control group.

Consecutive sampling is the selection of samples by determining the subjects that meet the criteria of research entered into the study until a certain time, so that the number of clients required is met (Nursalam, 2016).

(1) Aged 40-75 years, (2) Client COPD diagnosed by Lung Specialist, (3) Client with COPD criteria GOLD II ($50\% \leq FEV_1<80\%$) and GOLD III (value $30\% \leq FEV_1<50\%$), (4) Client has literacy, (5) Client has good hearing, (6) Client understands command. While the exclusion criteria of this study were: (1) Unstable and exacerbated COPD clients, (2) Clients suffering from other diseases, such as cardiopulmonary, musculoskeletal and mental disorders, (3) Clients who are not cooperative, (4) Respondents experiencing acute exacerbations with productive cough or purulent cough may aggravate shortness of breath, (5) Respondent refuses to visit next, (6) Respondent dies before *post test.*

2.3 Procedure

The study protocol was approved by the research ethics commission of the University of Airlangga Surabaya Indonesia.

The study implementation was started by determining the affordable population according to the inclusion criteria then calculated using the formula of large continuous data samples to obtain the sample size according to the needs of the researcher. Respondents were given first explanation of the purpose of the research and signed the informed consent as willingness to be the respondent. Divide the respondents into groups of treatment/ intervention and control groups by lottery. Respondents in the intervention group and control group performed perceptual measurements of RR and Peak Expiratory Flow Rate (PEFR) first. In the control group treated according to therapy or treatment in Poli Paru Jombang Hospital. The intervention group conducted a meeting at the client's home by showing the video and giving the therapy training diaphragm breathing exercise combined of hand held fan for 3 times a week: breathing exercises by asking respondents to take a half-sitting position and left hand position above the rectus abdominal muscle (bone anterior ribs), then the right hand holds a portable face fan with a distance of 10-15 cm from the face, then breathes air through

the nose with the shoulder position maintained/ not lifted up and removes the air through the mouth in a way with a longer extension of exhale done with duration of time 25 minutes 3 times a week (done once in 2 days) for 4 weeks. In the fourth week the researchers conducted post-test measurements of RR and PEFR in the intervention and control group. Data obtained, analyzed using statistic.

Research Instrument

Peak Expiratory Flow Meter was to measure peak expiratory flow rate and baseline vital sign (respiratory rate) were recorded. While participant characteristic is the basic data obtained directly from the patient through the demographic data questionnaire.

2.4 Data Analysis

Descriptive analysis is done to get description of respondent's characteristic. The results of the analysis of the frequency distribution, percentage in each variable.

The inferential analysis used in this study was for ratio data if the data were normally distributed and homogeneous, using Independent t-Test and Paired t-Test.

3. RESULT

3.1 Participant Characteristics

Total		23	100	23	100	46	100

Table 1 shows that most of the respondents of the treatment group and control group were male (18 persons (78.3%). In the treatment group half of respondents aged 40-60 years, ie as many as 12 people (52.2%), while the control group most of the respondents aged over 60 as many as 15 people (65.2%).

The education level of most of the treatment group respondents were 21 people (91.3%) and control group as many as 22 people (95.7%) with elementary school education. At work most of the respondents of the treatment group as much as 15 people (65.2%) and the control group as many as 14 people (60.9%) have a farmer job.

In smoking history most of the respondents both in the treatment group and the control group had smoking history, that is as many as 18 people (78.3%). In the long sick, most of the treatment group respondents were 11 people (47.8%) and the control group as many as 14 people (60.9%) suffered from COPD pain for 1-3 years. Body mass index (BMI) data were mostly 14 respondents (60,9%) and control group 16 people (69,6%) had normal body mass index

3.2 Data Distribution of research variable before the intervention

Tables 2 Data distribution of variable such as Respiratory Rate and Peak Expiratory Flow Rate control and intervention group before the intervention

Variable	Control (n=23)	Intervention (n=23)
Respiratory Rate	24,17±1,486 Mean±SD	24,17±1,669 Mean±SD
PEFR	210,43±38,551 Mean±SD	203,91±34,077 Mean±SD

Table 2 shows the control group before the intervention had the mean respiratory rate was 24.17 (SD 1.486) and peak expiratory flow rate, ie, 210.43 (SD 38.551).

Treatment groups prior to intervention had the mean respiratory rate was 24.17 (SD 1.486) and peak expiratory flow rate, ie, 210.43 (SD 38.551).

In conclusion there was no difference in perception value of respiratory rate, and peak expiratory flow rate before intervention diaphragm breathing exercise combined with hand held fan between control group and treatment group.

3.3 Data Distribution of research variable after the intervention

Tables 3 Data distribution of variable such as Respiratory Rate and Peak Expiratory Flow Rate control and intervention group after the intervention

PAT-535		
Variable	**Control (n=23)**	**Intervention (n=23)**
Respiratory Rate	23,65±1,229 Mean±SD	20,91±1,229 Mean±SD
PEFR	218,70±36,470 Mean±SD	260,87±33,563 Mean±SD

Table 3 shows the control group after the intervention had the mean of respiratory rate is 23,65 (SD 1,229) and peak expiratory flow rate is 218,70 (SD 36,470).

Treatment group before intervention had the mean value of respiratory rate was 20.91 (SD 1.229) and peak expiratory flow rate is 260.87 (SD 33.563).

In conclusion there are differences in respiratory rate, and peak expiratory flow rate after intervention diaphragm breathing exercise combined with hand held fan between control group and treatment group.

3.4 Analisys Respiratory Rate of COPD Clients

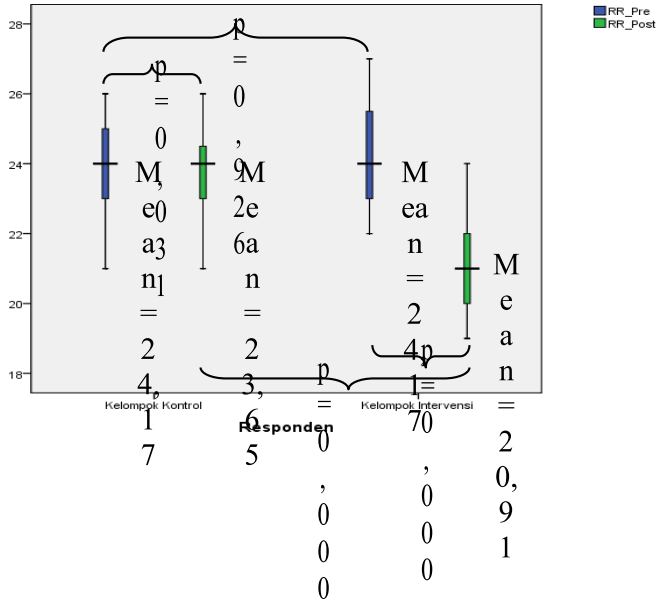

Figure 1 Test Results Independent t-Test and Paired t-Test Respiratory Rate

Based on figure 1 it is known that the Independent t-Test post-test statistic shows that p = 0,000 means that there is a difference of respiratory rate between the treatment group and the control group after the intervention is given.

The results of paired t test in the treatment group p value = 0.000, and the control group value p = 0.031 which means there is a significant difference respiratory rate before and after intervention.

3.5 Analisys Peak Expiratory Flow Rate of COPD Clients

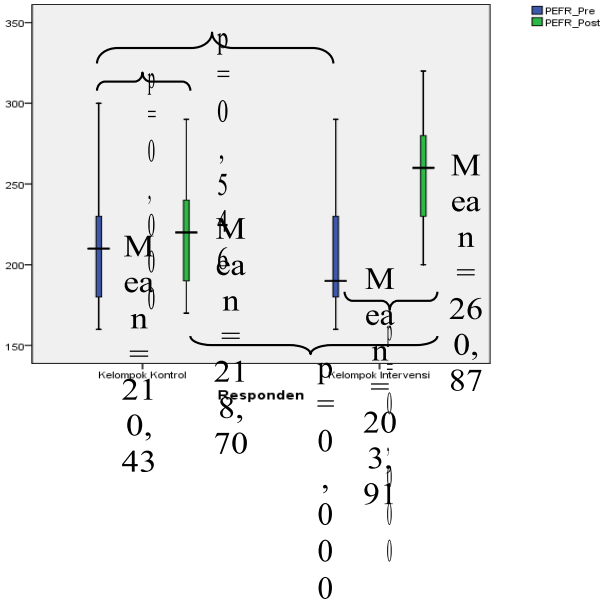

Figure 2 Test Results Independent t-Test and Paired t-Test Peak Expiratory Flow Rate

Based on figure 2 it is known that the test result of the Independent t-Test post-test indicates that p = 0,000 means that there is a difference of peak expiratory flow rate between the treatment group and the control group after the intervention is given.

The result of paired t test in the control group and the group of p value = 0,000 which means there is significant difference to the peak expiratory flow rate before and after the intervention.

4. DISCUSSION

4.1 Diaphragm Breathing Exercise Combined with Hand held fan to Respiratory Rate

The results showed that there was an influence ofintervention diaphragm breathing exercise combined with hand held fan on the improvement of respiratory rate. The results of this study are in line with research conducted by Pangestuti, et al in 2015 under the title The Effect of Diaphragmatic Breathing Exercise on Respiration Function (RR and PEFR) in Elderly at UPT PSLU Jember Regency. The study shows that there is significant diaphragmatic breathing exercise effect on Respiration Function (RR and PEFR). This breathing exercise diaphragm is one breathing technique, which aims to reduce dypsnea by increasing the diaphragm excursion and can increase the muscle strength of the diaphragm which is the major muscle of the breathing (Cahalin et al 2002 in Morrow et al., 2012). If the diaphragm muscle work can be maximized then the client can take a deeper and more effective breath so as to maintain lung expansion (Luh et al., 2017). It may increase tidal volume and reduce the symptoms of Air Trapping or air trapped in the alveoli, reduce hyperinflation, thus increasing ventilation and perfusion, and improving the respiratory rate.

In addition, the flow of cold air that affects the cold temperature receptors in the face, especially the trigeminal nerve that runs under the skin in the nose and mouth. This trigeminal nerve

can activate the muscles, one of which is anterior abdominal muscle digastrics (Booth et al., 2016). The anterior abdominal muscles of digastrics are related to the diaphragm muscles, which are the major muscles of the breathing and act as the lower edge of the thorac. Diaphragmatic contractions pull the muscles downward, increasing the chest space and actively developing the lung (Black & Hawks 2014).

4.2 Diaphragm Breathing Exercise Combined with Hand held fan to Peak Expiratory Flow Rate

Diaphragm breathing exercise combined with hand held fan that is done 3 times a week within 4 weeks with duration of 25 minutes each workout can have an impact on the increase in peak expiratory flow rate or referred to as peak expiratory flow. Light activity performed routinely in longer duration, more than 15 minutes will be able to stimulate the sympathetic nerves in the adrenal medulla that stimulates the endocrine glands to release epinephrine and norepinephrine. Norepinefrin will bind to the receptor α and $ß_2$. Sympathetic activity, epinephrine binds to $ß_2$ in heart and skeletal muscle strengthening mechanism of vasodilator locally in the tissues of the lung, so it will happen bronchodilation so that the air and out will go more smoothly and the value of the peak flow expiratory (APE) will increase (Novarin et al., 2015).

5. CONCLUSION

Intervention diaphragm breathing exercise combined with hand held fan affects the decrease of dyspnea perception, improvement respiratory rate and increase peak expiratory flow rate of respondents with COPD in Poli Paru RSUD Jombang. Further research required a study of diaphragm breathing exercise combined with hand held fan of COPD clients by using standardized handheld fans and lungspirometry testas one of the research variables.

ABSTRACT

Fever is one of the most dominant clinical manifestations of inflammation that requires immediate treatment. Fever causes dehydration, seizures to impaired consciousness, so the need for traditional medicine is greatly increased among the community. Psidium guajava leaf is a medicinal plant that can be used as a complementary therapy. The purpose of this systematic review is to collect evidence based on previous research on Psidium guajava leaves used to reduce fever. Literature search uses keywords such as "Psidium guajava leaf" AND "medicinal" AND "plant" AND "fever" through several electronic databases such as Scopus, ProQuest, and Science Direct. The initial search took 264 potentially relevant studies, and 6 studies were selected to be reviewed according to inclusion criteria such as guava leaves from Mytaceae family, guava leaves to reduce fever and articles taken from 2014 to 2019. The results showed that Psidium guajava leaves has been used to treat fever. It is known that the phytochemical test results on guava leaf extract contain ingredients that can help to reduce fever. Further research is needed on the compunds, dosages and effects of Psidium guajava leaves. Health workers need to consider Psidium guajava leaves as medicinal plants to reduce fever.

Keywords: Psidium Guajava, fever, systematic review

1. INTRODUCTION

The use of traditional medicine has been around for a long time and the sources of traditional medicine are easily accessible and reachable throughout the world[2]. Traditional medicine is of high value and globally around 85% of plants contribute to traditional medicine in primary health care[8].Traditional treatments using guava leaves show interesting results in the health filed. The use of medicinal plants plays an important role in disease and it is highly developed. Trends in the knowledge of traditional medicine have become of interest in ethnomedical knowledge research and development[7].

The Psidiumguajava Linn (*Myrtaceae* family) is a tropical plant that is characterized as an antimicrobial drug with anticancer activities, adding value to the guava plants. Additional benefits are that it is relatively inexpensive, accessible and that it can adapt to a variety of different soil and climatic conditions. One clinical manifestation that can be cured with this plant is fever. It is known that guava plants, especially the leaves, have anti-inflammatory and antipyretic activity[2]. Although modern health care is available, traditional medicine can be indicated[8].

Psidiumguajava leaves from the *Myrtaceae* family have a medicinal effect and they are included in the complementary therapies that are needed by society. It is very important for nurses

and health workers to know that complementary treatments involving plants have been developed. Based on this thought, it is important to study the use of guava leaves as used by the community as a traditional medicine to reduce fever through a systematic review of the literature.

2. RESEARCH METHODS

The systematic search of the literature collected articles about traditional medicine involving guava leaves related to fever. The species focused on in the search was *Psidiumguajava* of the *Myrtaceae* family. Articles were quoted from 2014 to 2019. The keywords used were "*Psidiumguajava leaf*" AND "*medicinal*" AND "*plant*" AND "*fever*". The combination word was with the species "P", and then we filtered the articles according to the topic of the use of guava leaves containing the *Myrtaceae* family. This was further evaluated using the PRISMA flow model.

The eligibility criteria for this systematic review included all instruments in the form of interviews that investigated the use of guava leaves as a traditional treatment to reduce fever. In a previous review, guava leaves were complementary therapies and thus have been included in this study. This systematic review does not have any gender restriction. The procedure of the use and components of the guava leaves have been included in this systematic review.

3. RESULTS

As many as 264 articles were found from within 4 databases: 34 articles from Scopus, 14 articles from PubMed, 87 articles from ProQuest, and 129 articles from ScienceDirect (Figure 1). Some of the articles were filtered by the abstract according to the inclusion criteria. Articles were then eliminated to get 6 articles which included the topic of focus. Although its use is still small, other types of plant species are used but guava leaves have been used to reduce fever commonly. The methodological aspects of the 6 articles have been arranged in Table 1 and we have documented the use of guava leaves in Table 2.

Figure 1. The selection process of the articles included in the review using a PRISMA 2009 Flow Diagram

Title (Authors)	Population Design	Intervention	Outcomes
Indigenous uses of ethnomedicinal plants among forest-dependent communities of Northern Bengal, India (Raj *et al*., 2018)	Population: - 400 respondents - Respondents over 30 years - Who have knowledge of traditional medicine Design: Ethnomedicinal survey	- Pre-and post-test interviews - Respondents identified plants on the herbarium sheet installed	- 140 species of medicinal plants used - *Psidiumguajava*, L (*myrtaceae family*) - Used to treat dysentery and abdominal pain but in previous studies, guava leaves were used to treat cold and cough, fever (humans and animals), indigestion, toothache and joint pain
An ethnobotanical survey of indigenous medicinal in Hafizabad district, Punjab-Pakistan (Umair *et al*., 2017)	Population: - 201 informants - Traditional physician - Male (n= 175), female (n= 26) Design: Ethnomedicinal study	Semi-structured interviews conservations	- 85 species of medicinal plants used - *Psidiumguajava*, L (*myrtaceae family*) - Decoction of guava leaves is used to treat diarrhea, diabetes, diuretics, karminative vermigue, toothache, fever, flu and cough
Medicinal plants used by the people of Nsukka Local Government Area, south-eastern Nigeria for the treatment of malaria: An ethnobotanical survey (Odoh *et al*., 2018)	Population: - 213 respondents - Age 21-60 tahun - Female (n= 126), male (n= 87) Design: Ethnobotannical survey	Interviews using a semi-structured questionnaire	- 50 species of medicinal plants used - *Psidiumguajava*, L (*myrtaceae family*) (8,5%) - Used to treat symptoms of malaria such as fever, chills, headache, vomiting or discomfort
*Psidiumguajava*L., *from ethnobiology to scientific evaluation:*	Population: *Psidiumguajava leaf* Design:	Searches were done in scientific disclosure databases such as Pubmed, Web of	- *Psidiumguajava*, L (*myrtaceae family*) - Used to treat symptoms of stomach pain, flatulence, fever, and

Elucidating bioactivity against pathogenic microorganisms survey (Morais*et al*., 2016)	Systematic literature	Science and Scopus.	diarrhea in causative agents such as protozoa - Guava leaves are used by means of infusion or decoction
An ethnobotanical study of plants used for the treatment of livestock diseases in the Tikamgarh District of Bundelkhand, Central India (Verma, 2014)	Population: - Old farmers who are experienced traditional shamans - Farmers who know about medicinal plants Design: Ethnobotanical study	- Survey questionnaire - Participatory observation - Field trip	- 41 species of medicinal plants used - *Psidiumguajava*, L (family: *Myrtaceae*) - Used to cure fever (1 liter of decoction of fresh guava leaves for 2 times a day)
Psidiumguajava: A Single Plant for Multiple Health Problems of Rural Indian Population (Daswani *et al*., 2017)	Population: Investigating the medicinal properties of guava products in the 1940s Design: Literature survey	Electronic databases such as Pubmed, Science Direct and Google Scholar.	- *Psidiumguajava*, L (family: *Myrtaceae*) - Laboratory test: Flavonoid (Quercetin) - Used to cure gastrointestinal infections, oral/dental infections, diabetes, cardio disease, cancer, malnutrition, pain, fever, liver and kidney problems

4. DISCUSSION

A total of 6 articles used a survey design and the existing literature. The samples and variables from the articles varied, while the interventions used more interviews. From the entirety of the articles, it shows that besides helping to cure some of the symptoms of the disease, guava leaves can help to reduce fever. Regarding the use of guava leaves, the dosage has not been explained according to age or weight. Two articles did not mention how to use guava leaves, but some articles mentioned that the guava leaves are boiled or infused.

The data shows that the community uses guava leaves to reduce fever and other health problems. People in Nsukka, Nigeria, use a decoction of guava leaves for malaria complaints such as fever, chills, headache, vomiting or discomfort. Guava leaves are also combined with other leaves[6]. The interviews were conducted pre- and post-test on 400 respondents who were knowledgeable about traditional medicine. The respondents identified the plants in the herbarium sheet installed as guava leaves (*Myrtaceae*) out of 140 species of medicinal plants used to treat

dysentery and abdominal pain. In previous studies, guava leaves were used to treat cough, fever, indigestion, toothache, and joint pain[7]. Two hundred and one traditional physician informants in the Hafizabad District of Pakistan were interviewed and group discussions were focused on guava leaves (*Myrtaceae* of 85 species of medicinal plants), which the group said were used to treat diarrhea, diabetes, diuretics, carminative vermigue, toothache, fever, common cold and cough[8]. Guava leaves are used to cure a fever by drinking 1 liter of decoction of fresh leaves every day until recovery[9].

In general, guava plants have compounds such as tannins, phenols, flavonoids, saponins, carbohydrates, alkaloids, sterols, terpenoids, and phenolic compounds. In particular, guava leaves have antimicrobial compounds such as 1,2-Benzenedicarboxylic acid, dibut, Alpha-bisabolol, 1,2-Benzenedicarboxylic acid, buty, hexadeca-2,6,10,14-tetraen, caryophyllene, germacrene, quercetin , quercetin 3-O-α-L-arabinofuranoside, quercetin-3-O-β-D-arabinopyraside, quercetin and quercetin-3-O-arabinoside, 11-hydroxy-35- tricont-pentatriacontanoate, hexaeicosan-16-ol, tricosan-17-ene-5-ol, nonacosan-23-ene-3-ol, lupeol, betulinic acid and antileishman activity (Nerolidol)[5]. Flavonoid compounds in the guava leaves have been found through phytochemical tests. Guava leaves are used to cure gastrointestinal infections, oral/dental infections, diabetes, cardio disease, cancer, malnutrition, pain, fever, liver and kidney problems[2].

Traditional medicine is becoming increasingly advanced because it is very economical, easy to obtain, has minimal side effects and has a good effect through decoction, infusion or extraction. *Psidiumguajava* leaves can be regarded as alternative traditional medicinal plants. *Psidiumguajava* leaves have a component that has turned out to have good benefits for health problems. For some of the compounds and according to one article, there is no confirmed appropriate dose. Some parts, effects and guava extracts have been tested as toxic, so guava leaves are safe to use as a part of traditional medicine.

5. Conclusion

Six articles revealed that out of various species, *Psidiumguajava* is a medicinal plant used by the community to reduce fever despite the availability of modern health care services. This finding provides basic data for further research on the compounds, dosage and effect of guava leaves. Health workers need to consider the guava leaf as a medicinal plant to reduce fever.

ABSTRACT

Chemotapeutic Induced Nausea and Vomiting (CINV) is a term used to describe the incidence of nausea vomiting in post chemotherapy patient. Nausea Vomiting is the most common side effect felt by cancer patients after chemotherapy. Nausea vomiting is a strong contraction of the abdominal muscles which causes the stomach contents to be pushed out through the mouth. Nausea vomiting causes disturbances in the immune system, quality of life of patients. Aromatherapy ginger is a natural herb that has been used for years as an antiemetic, appetite, and quality of life for patients. But the most effective methods among these are still questionable. This study aims to identify interventions that effectively reduce nausea and vomiting using complementary ginger therapy. This study aimed to determine the effectiveness of ginger in chemotherapy-induced nausea and vomiting with systematic reviews and following the guidelines of the PRISMA statement. Scopus, PubMed, and Science Direct databases from 2014-2018. Articles identified using search terms or keywords for ginger, vomiting nausea, appetite, quality of life, cancer, chemotherapy. All studies included access-based, randomized controlled trials, case-control studies and Randomized. 15 of the 1531 papers were included. Additional randomized control trial design studies are needed to strengthen the findings.

Keywords: Ginger, nausea vomiting, anorexia, quality of life, cancer, chemotherapy

1. Introduction

One therapy for cancer patients is chemotherapy. Chemotherapy Induction of Nausea and Vomiting (CINV) is a term used to evaluate the incidence of nausea in patients after chemotherapy [1]. Nausea and vomiting is due to strong abdominal muscle contractions that causes the stomach contents to be pushed out through the mouth [2]. Nausea can also cause interference with the immune system, impair cognitive function, cause social problems, result in someone being unable to fulfill their social responsibilities and cause physical disorders[3].

According to Globocan's data, the International Cancer Research Agency (IARC) in 2012 stated that cancer was the cause of death of around 8.2 million people. There were 14.067.894 new cancer cases and 8.201.575 cancer deaths worldwide. The biggest cause of cancer deaths every year is by lung, liver, stomach, colorectal and breast cancer. The number of cancer patients is expected to increase every year, and it is estimated to reach 23.6 million new cases per year in 2030 [3]. It is a

disease that has become a public health problem in the world and in Indonesia. Every year, 12 million people worldwide suffer from cancer and 7.6 million of them die [4].

Several studies have shown non-pharmacological and pharmacological interventions to reduce nausea and vomiting in chemotherapy patients. Pharmacological therapy consisting of 5-HT3 receptor antagonists has been widely used and it is the first choice for the treatment of nausea and vomiting. Regardless of its effectiveness, the patients still feel nausea [4]. The side effects of the drugs used in chemotherapy can stimulate the center of the Cemoreceptor Trigger Zone (CTZ) [3]. The intensity of the negative effects can prolong the chemotherapy schedule and non-pharmacological therapy can be a form of self-care. Providing comfort to the clients by reducing or eliminating nausea is important in care to control nausea and to increase the appetite and quality of life of chemotherapy clients [3]. The systematic review of doxorubicin-based chemotherapy reviewed the therapies that can be done after chemotherapy, but there is no literature review that discusses the effectiveness and therapy as a whole when undertaken to reduce the nausea from chemotherapy, so then the medical personnel can compare their respective therapies [5]. The aim of a systematic review of ginger is that it is a complementary therapy that is safely used in the treatment of nausea and vomiting, anorexia, appetite and fatigue to improve the quality of life of chemotherapy patients [6].

2. Material and Methods

Using electronic databases, namely Scopus, PubMed and ScienceDirect, the searches were done with ginger and “nausea and vomiting”, “appetite”, “quality of life”, “cancer” and chemotherapy as the main keywords. From this search, only papers including human models published in English were considered. In the second step, "Chemotherapy", "nausea", "vomiting", "ginger" were added to the same keywords as before. Randomized controlled trials (RCT), case-controls and randomized studies were included. This systematic review used PRISMA, which consists of a literature search strategy, inclusion and exclusion criteria, research design (RCT consists of 11 articles, CC consists of 2 articles, C consists of 2 articles), population (Gender, age, frequency of chemotherapy), clinical outcome interventions and the study selection.

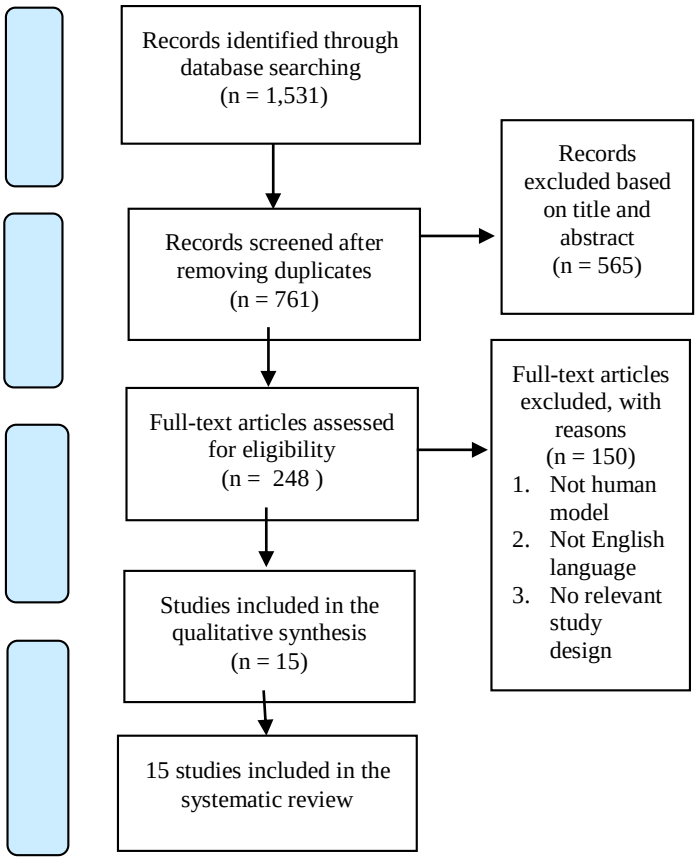

Figure 1 Flow Diagram

3. Results

3.1 Literature search and study selection

A total of 1,531 articles were found using the selected keywords.

3.2 Study characteristics

The total number of respondents in the literature was 892 respondents, in the range of 34 - 150 respondents per study. The respondents were aged between 18-80 years old. The PICOT table shows the characteristics and interventions carried out in 15 research articles about the effects of ginger treatment, according to [6], [7][8], [9].[10], [11], [12], [13], [14]. In total, 13 out of 15 articles discussed the effect of ginger extract treatment on nausea and vomiting, quality of life and appetite in cancer patients after chemotherapy. This consisted of encapsulated ginger, which contains powdered ginger root (167 mg or 400 mg), powdered and dry ginger powder (300 mg or 500 mg), 6-gingerol capsules containing ginger extract, referred to as 6- gingerol 5 mg (1.4 % b / b ginger extract) and ginger tablets (800 mg). The liquid extract from ginger (0.25 g) contained gingerol, zingerone and shogaol. The participants receive 500 mg of powdered ginger, mixed with a spoonful of yogurt to facilitate swallowing. Two articles discussed the effect of ginger essential oil on nausea and vomiting, quality of life and appetite in cancer patients after chemotherapy, as according to [2], [15].

The patients receive 5 days of aromatherapy treatment using ginger essential oil. All of the participants received standard nausea and vomiting prevention drugs (5-HT3).

3.2 Results of the individual studies

Eleven articles mentioned that the effects of ginger are significant on nausea and vomiting, anorexia, appetite, fatigue and quality of life [15], [2], [11], [6][14], [13],[12], [9]. These eight articles state that using ginger twice a day can reduce the severity of nausea and vomiting. Dome also argue that giving the aroma of ginger can reduce the frequency of acute vomiting and some further argue that using oral ginger can also reduce the severity of nausea and vomiting in chemotherapy patients. In addition, it can eliminate anorexia and increase the appetite of patients after chemotherapy. [7][10], [8]. Four articles stated that ginger is safe so it is recommended for patients after chemotherapy. Ginger extract can be consumed by patients to increase their appetite and reduce patient fatigue. Ginger is also high in antioxidants so extra ginger is very useful for improving overall quality of life.

4. Discussion

Some of the existing research has examined the effect of ginger on control CINV gives different results, but the vast majority of researchers have stated that ginger can decrease the frequency, intensity and severity of nausea and vomiting that is due to chemotherapy [15], [2], [11], [6][14], [13]. The studies state that there is no significant difference between the groups given ginger and a placebo in lowering nausea vomiting of chemotherapy [12], [9]. There are several things that can affect the results of the research-related effectiveness of ginger against nausea and vomiting including the characteristics of the respondents, the regimen of chemotherapy, the use of antiemetics, the preparation of capsules of ginger, the ginger dose given, and the length of the granting of ginger [7],[8].

This systematic review investigated the effectiveness of the use of ginger against complex nausea, vomiting, appetite and quality of life in cancer patients after chemotherapy. The study used a heterogeneous research design. Health professionals need to have the ability and knowledge to provide a professional intervention. Nausea and vomiting is the final stage of action by the health workers on clients that can increase discomfort during chemotherapy. Comfort is a necessity in various diseases for the sake of health (Siefert, 2002). Nausea and vomiting in patients after chemotherapy is a common symptom that can weaken them and it can also cause delayed dehydration, an electrolyte imbalance, weight loss and anorexia. Anorexia is the frequent loss of appetite that is experienced by patients with cancer but often ignored. In advanced cancer, anorexia is the fourth most common symptom after nausea, vomiting, pain, and fatigue [11].

Complementary therapy can be used as support therapy for cancer patients who undergo chemotherapy. One of the herbs that can be used is ginger (Zingiberofficinale) [14]. Ginger is one herb that has been used for years, especially as an antiemetic [10]. It is one of the cornerstones of modern antiemetic therapies such as ondansetron and granisetron. Several studies have shown that ginger is effective at increasing comfort, controlling emotions and reducing nausea, vomiting, anorexia, motion sickness and seasickness post-surgery and during pregnancy [7].

Ginger Aroma Essential oil (EO) is a non-pharmacological supplementary therapeutic method with no adverse side effects. It is used to prevent and reduce nausea and vomiting. Ginger aromatherapy can also block serotonin in the neurotransmitters synthesized in the central system in

the emlerochromophin cells that can give off the feeling of being comfortable. This can be used to overcome nausea and reduce anorexia [2].

Interventions related to complementary therapy are appropriate and efficient at suppressing nausea and vomiting, and increasing appetite while overall improving the quality of life of the patients. Ginger is one of the plants that is effective as an antiemetic which can shorten the chemotherapy period in cancer patients. Based on the article above, the researchers recommend complementary treatment using ginger to suppress nausea and vomiting, to increase appetite, and to increase the quality of life of cancer patients after chemotherapy. Studies with RCT designs are needed to strengthen the results of this systematic review.

The side effects of chemotherapy in the form of nausea and vomiting can lead to heavy stress on the patient. This stimulates the enterochromaffin cells and chemotherapy agents in the digestive tract, causing them to release serotonin receptor triggers. The receptor activation triggers a vagal afferent pathway which activates the vomiting center and causes the response of throwing up. The potential of the emetic chemotherapy agent itself is the main stimulus against the nausea and vomiting caused by chemotherapy (Chemotherapy Induced Nausea and Vomitting/CINV)[9].

5. Conclusion

This systematic review indicates that ginger supplements have the potential to effectively suppress vomiting and nausea, and that it can also increase appetite, reduce fatigue, reduce anorexia and improve the quality of life of cancer patients post-chemotherapy. This review explains that a systematic ginger intervention has the potential to be used as an effective therapy for nausea and vomiting. The urgency of using ginger as a therapy requires further investigation, but it is safe and can be well tolerated by participants as a modality for non-pharmacological therapy.

Table 1. Studies that formed the basis of making the systematic review

No.	Title, References	Variable, Sample, Treatment	Study Design	Results
1	Comparison of the Complications of Platinum-Based Adjuvant Chemotherapy With and Without Ginger in a Pilot Study on Ovarian Cancer Patients (Shokri et al., 2017) Received 5 February 2016. Accepted 24 September 2016. Available online 25 October 2016 Women's Reproductive Health Research Center, Tabriz University of Medical Sciences, Tabriz, Iran	Variables: Cancer Chemotherapy Ginger Sample: N = 49 Treatment: Platinum Based Adjuvant	Case control	Poor outcome including serum CA125>35, metastasis, recurrence or death was documented more commonly in the control group (69% versus 40%). Metastasis frequency was confirmed by a computerized tomography (CT) scan 6 months after treatment and this was significantly lower in the case group (P = 0.04). There was no significant difference regarding mortality and disease free survival during the one year follow-up after treatment between the 2 groups (P = 0.55). Chemotherapy complications such as nausea, vomiting, weight loss, and peripheral neuropathy were detected in the case group less often than in the control group but the difference was not significant.
2.	The effect of a standardized ginger extract on chemotherapy-induced nausea-related quality of life in patients undergoing moderately or highly emetogenic chemotherapy: A double blind, randomized, placebo controlled trial (McCarthy et al., 2017) Received: 30 June 2017. Accepted: 8 August 2017. Published: 12 August 2017	Variables: Cancer Chemotherapy Ginger Induced Nausea Qualiti of life Sample: N = 40 Treatment: Ginger extract	Randomized Control Trial	Adjuvant ginger supplement placebo in chemotherapy induced better in terms of nausea and quality of life than additions.
3	A phase II randomized double-blind placebo-controlled study of 6-gingerol as an anti-emetic in solid tumor patients receiving moderately to highly emetogenic chemotherapy. (Konmun et al., 2017) Received: 7 March 2017. Accepted: 22 March 2017. Published online: 27 March 2017 Springer Science + Business Media New York, 2017	Variables: cancer Chemotherapy ginger CINV Quality of life appetite Sample: N = 80 Treatment: Ginger placebo	Randomized Control Trial	The difference for the mean of the appetite score was significant (P = 0.001) and more noticeable over time. The mean FACT-G score indicating quality of life was significantly higher (86.21) in the 6-gingerol group at 64 days compared with that of the placebo group (72.36) (P\0.001). No toxicity related to 6-gingerol was observed. Patients treated with 6-gingerol reported significantly less grade 3 fatigue (2 vs. 20%; P = 0.020). 6 - Gingerol significantly improved overall CR rate in CINV, appetite and quality of life in

Table 1. Studies that formed the basis of making the systematic review

No.	Title, References	Variable, Sample, Treatment	Study Design	Results
				cancer patientsreceiving adjuvant chemotherapy. A phase III randomized study of 6-gingerol is warranted to confirm these results.
4	Efficacy of ginger for the prophylaxis of chemotherapy-induced nausea and vomiting in breast cancer patients receiving adriamycin–cyclophosphamide regimen: a randomized, double-blind, placebo-controlled, crossover study (Thamlikitkul et al., 2017) Received: 19 April 2016. Accepted: 19 September 2016. Published online: 6 October 2016	Variables: Ginger cancer Chemotherapy Nausea Vomiting Sample: N = 34 Treatment: Ginger placebo	Randomized Control Trial	There were significant differences between ginger and the placebo in terms of vomiting incidence and severity, rescue medication use, chemotherapy compliance, and adverse events.
5	Determination of the concentration of major active anti-emetic constituents within commercial ginger food products and dietary supplements (Isenring et al., 2017) Received 6 December 2016. Received in revised form 31 January 2017. Accepted 1 February 2017	Variables: Antiemetic Ginger Treatment: Zingiber officinale		Of the twenty commercially available ginger products, those with the highest content were most effective. The ingredients of both the active and antiemetic substances are standard ginger extract and supplements.
6	Antioxidant activity of ginger extract as a daily supplement in cancer patients receiving adjuvant chemotherapy: A pilot study (Danwilai, Konmun, Sripanidkulchai, & Subongkot, 2017)	Variables: Chemotherapy Cancer Ginger Sample: N = 43 respondents Treatment: Ginger extract	Randomized Control Trial	Daily ginger supplements starting three days before chemotherapy have been shown to significantly increase antioxidant activity and reduce the levels of oxidative markers in patients who receive moderate to high emetogenic potential chemotherapy compared with the placebo.
7	A randomized, double-blind, placebo-controlled, multicenter study of a ginger extract in the management of chemotherapy-induced nausea and vomiting (CINV) in patients receiving high-dose cisplatin (Bossi et al., 2017)	Variables: CINV Ginger Sample: N = 121 respondents Treatment : Ginger extract	Randomized Control Trial	The benefit of ginger over the placebo in the Functional Living Index Emesis nausea score showed that there were differences identified for both females (P¼0.048) and HNC patients (P¼0.038).
8	The effectiveness of inhaled ginger essential oil in improving the dietary intake in breast-cancer patients experiencing chemotherapy-induced nausea and vomiting (Salihah et al., 2016)	Variables: CINV Cancer Ginger Sample: N = 60 Treatment:	Randomized Control Trial	A significant increase in energy intake was also observed over time [F (2.57) = 54.21, P <0.001], reaching almost 90% of the energy needs 5 days after chemotherapy. Inhaled aromatherapy using EO ginger was considered to be a little more beneficial than ginger FO (63.3% vs. 61.6%). Delivered

Table 1. Studies that formed the basis of making the systematic review

No.	Title, References	Variable, Sample, Treatment	Study Design	Results
		Inhaled ginger essential oil		through necklaces, which is a treatment method considered appropriate for the women who participated.
9	Efficacy of ginger in the control of chemotherapy induced nausea and vomiting in breast cancer patients receiving doxorubicin-based chemotherapy (Ansari et al., 2016)	Variables Chemotherapy CINV Cancer Ginger Sample: N = 150	Randomly selected in to 2 groups	In those patients who received the AC regimen, vomiting was less severe (0.64 ± 0.87) comparing to those who received the placebo (1.13±1.12), which was statistically significant (p-Value <0.05). Further and larger studies are needed to draw conclusions.
10	Effect of Ginger and Chamomile on Nausea and Vomiting Caused by Chemotherapy in Iranian Women with Breast Cancer (Sanaati, Najafi, Kashaninia, & Sadeghi, 2016)	Variables: Chemotherapy CINV Cancer Sample: N= 65 Treatment : Ginger and chamomile	Randomized, double-blind and clinical trial study	Ginger and chamomile were both significantly effective at reducing the frequency of vomiting, with there being no significant difference between the ginger and chamomile groups. Moreover, unlike the chamomile, ginger significantly impacted on the frequency of nausea.
11	Effects of inhaled ginger aromatherapy on chemotherapy-induced nausea and vomiting and health-related quality of life in women with breast cancer (Lua et al., 2015) Malaysia Received 18 September 2014; received in revised form 31 December 2014; accepted 27 March 2015. Available online 21 April 2015. Saromatherapy	Variables: CINV HRQoL Cancer Treatment: Inhaled ginger aromatherapy Sample: N = 60	Randomized cross-over study	A statistically significant change from the baseline for global health status (P < 0.001) was detected after ginger essential oil inhalation. A clinically relevant 10 point improvement was found in role functioning (P = 0.002) and appetite loss (P < 0.001), which were also documented while the patients were on ginger essential oil.
12	Oral intake of ginger for chemotherapy-induced nausea and vomiting among women with breast cancer (Arslan & Ozdemir, 2015) Submitted August 2014. Revision submitted November 2014. Accepted for publication December 14, 2014	Variables: CINV Cancer Sample: N = 60 Treatment: Oral intake ginger	Randomized, controlled trial	The researchers analyzed the five-day mean score of nausea severity and the number of vomiting and retching episodes. Based on this comparison, the nausea severity and the number of vomiting episodes were significantly lower in the intervention group than in the control group (p > 0.05).
13	The Effect of a Standardized Ginger Extract on Chemotherapy-Induced Nausea-Related Quality of Life in Patients Undergoing Moderately or Highly Emetogenic Chemotherapy: A Double Blind, Randomized, Placebo Controlled Trial. (Marx et al., 2017)	Variables: Nausea and vomiting Quality of life Cancer Chemotherapy Sample: N =51 Treatment Ginger extract	Double-blind, randomized placebo-controlled trial	Ginger is effective for reducing nausea and vomiting due to chemotherapy. There were no significant result in Cycle 2. In Cycle 3, global QoL (p = 0.040) and fatigue (p = 0.013) were significantly better in the intervention group compared with placebo

Table 1. Studies that formed the basis of making the systematic review

No.	Title, References	Variable, Sample, Treatment	Study Design	Results
14	Can ginger ameliorate chemotherapy-induced nausea? Protocol of a randomized double-blind, placebo-controlled trial. (Marx et al., 2014)	Variables: Ginger CINV Sample: N = 146 Treatment: The placebo capsule contains 300 mg of inactive / reacting material.	Double-blinded randomized-controlled trial	Ginger effectively reduced the nausea and vomiting that was due to chemotherapy.
15	Additive effect of rikkunshito, an herbal medicine, on chemotherapy-induced nausea, vomiting, and anorexia in uterine cervical or corpus cancer patients treated with cisplatin and paclitaxel: results of a randomized phase II study (JORTC KMP-02) (Ohnishi & Takeda, 2015) Received: Dec 21, 2016 Revised: Mar 6, 2017 Accepted: Mar 6, 2017	Variables: CINV anorexia cancer Sample: N = 54 Treatment: Rikkunshito Herbal medicine	Randomized Control Trial	Rikkunshito provided additive effects for the prevention of CINV and anorexia.

Emailakbar.nur-2017@fkp.unair.ac.id

ABSTRACT

Asthma prevalence increases sharply and currently asthma is known as the most frequent cause of disability, it requires a lot of costs and preventable diseases with death and One non-pharmacological therapy that can increase the forced expiratory volume in 1 second (FEV1) and asthma control is practice yoga pranayama. Yoga is called a "low impact" sport that can be adapted to the abilities of its practitioners so that it is suitable for anyone. This systematic review is to find out the effectiveness of yoga pranayama on the treatment of non- pharmacological asthma in increasing the forced FEV1 and asthma control. Electronic search comes from the Scopus, Medline, Ebsco, and Pubmed databases. The keyword used are "yoga pranayama", FEV1". And "asthma control" with the limitation of article search starting in 2012 until 2018. Literature search found 124 citations, then after review there were only 15 quotes that met the inclucion criteria. Yoga pranayama exercises given to asthmatic patients to see changes in levels FEV1, and PEFR levels for 12 weeks the results obtained were a significant change ($P<0.001$) in pulmonary ventilation. A brief study of yoga practice improves parameters for pulmonary function, increases FEV1 and controlled asthma.

Keywords: asthma, yoga pranayama, FEV1, control asthma

1. Introduction

Asthma is a chronic inflammatory disease characterized by episodic wheezing, coughing and tightness in the chest due to blockage of the large airways. In general, patients can be treated effectively using the drugs that are currently available. However, most people with asthma often relapse or, where it is uncontrolled, this makes it a treatment challenge for the health services. Decreased FEV_1 is a typical characteristic of asthma patients. Nowadays, asthma has become a public health problem in various countries. Asthma can be mild as well as severe [1],[2]

According to the World Health Organization [2], asthma sufferers total 235 million people. The death rate due to asthma in Indonesia reached 24,773 people or around 1.77% of the total population. This data also put Indonesia in the 19th position in the world regarding deaths from asthma according to the Global Initiative For Asthma [3]. Every year there are around 180,000 deaths worldwide and asthma has become a serious disease in recent years [4]. Research has revealed that there is a decrease in lung function in individuals with permanent asthma or in those with a history

of asthma in children and young adults. Chronic airway inflammation can cause a decline in the long-term pulmonary function in asthma patients [5].

The management of asthma is focused on reducing the symptoms, preventing recurrence and decreasing the corticosteroid consumption [3],[6]. Asthma control can be monitored using a specific measuring instrument, namely the Asthma Control Test. The Asthma Control Test is a method of evaluation done by assessing the final score obtained from the answers to the questions raised by the asthma patients. The results of the score are classified into 3 categories, which are fully controlled, partially controlled and uncontrolled. These results are expected to help asthmatics to determine the need to consult a health worker or be able to do self-care at home [7],[8].

The assessment of the severity of the disorder can be assessed by a pulmonary physiology test, namely by examining the peak flow of forced expiration. The APE value can be obtained through a simpler examination using a Peak Expiratory Flow Meter (PEF meter). The first second forced expiratory volume (VEV_1) and forced vital capacity (FVC) measurements are performed with forced expiratory maneuvers through standard procedures. The examination is very dependent on the patient's ability to understand the clear and cooperative instructions. To get an accurate value, the highest value is taken from 2 - 3 values that are reproducible and acceptable. The pulmonary function test results in asthma patients mean that their airway obstruction can be known if the ratio of FEV_1 (forced expiratory volume in 1 second) or forced vital capacity (FVC) <75% or $_{VEV}1$ <80% predictive value [9],[10].

The management of asthma aims to improve the quality of life of the patient better by making their asthma status that of controlled asthma. Uncontrolled asthma is caused by several components, including smoking habits, the incorrect use of corticosteroid drugs, genetics, inappropriate treatment and a lack of knowledge about asthma. The forms of management that can be done to avoid a worsening condition in asthma patients is to improve ventilation, to strengthen their breathing muscles and to prevent complications from occurring so then it can increase the forced expiratory volume in 1 second (FEV_1). Pulmonary rehabilitation will get very optimal results if it is done early. One possible form of pulmonary rehabilitation in asthma patients is through yoga pranayama breathing exercises. Exercise Pranayama is a breathing exercise with the technique of breathing slowly and deeply using the diaphragm muscles, allowing the abdomen to rise slowly and the chest to fully expand. Yoga is a method of physical and mental training for all ages. Yoga provides relaxation to the body, improves blood circulation and controls breathing. Yoga is very good for people with asthma [11],[12]. Yoga has beneficial effects for chronic asthma sufferers such as reducing the need for asthma medication, increasing the exercise capacity, increasing the FEV_1 asthma functionality and controlling their capacity [13],[15].

2. Methods

The method used for writing this article was a systematic review, beginning with the selection of the topic and then determining the keywords using English. They were put through the Scopus, Medline, Ebsco, and Pubmed databases. The keywords used for searching for articles were "Yoga pranayama", "FEV_1" and "control asthma". In the literature search, 124 articles were obtained. The articles were published starting in 2010 and going up to 2018. The search was narrowed again from 2011 to 2018. As many as 15 articles that were considered to be relevant were evaluated using the Problem, Intervention, Comparison and Outcome (PICO) method. The inclusion criteria in this

systematic review included the age of the respondents being between 6-65 years and those who have been diagnosed with asthma. The total number of subjects used in this systematic review was 2,583 respondents.

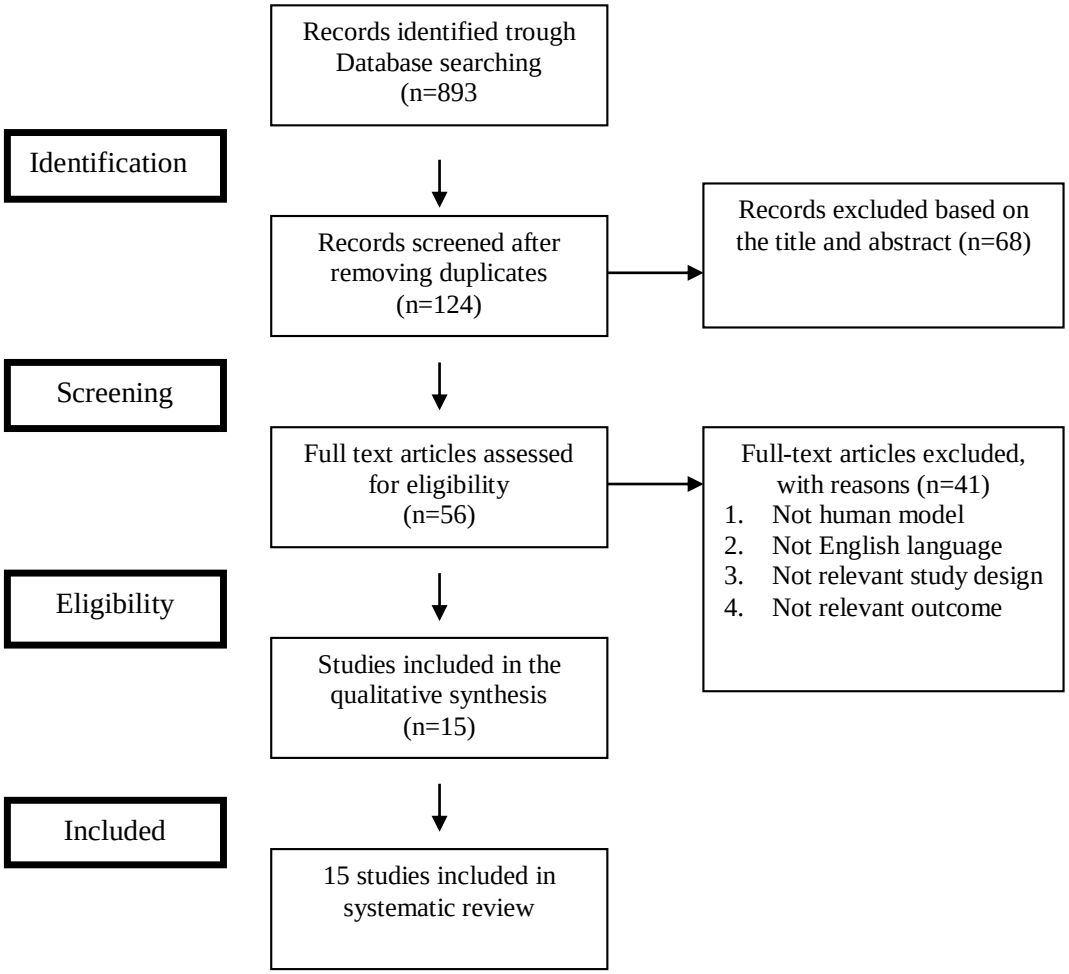

Figure 1. Flow Diagram

3. Results

3.1 Literature search and study selection

From the search results and by using the specified keywords, the researcher found 893 articles and then conducted screening by looking at the title and abstract. The search first obtained 56 journals. Lastly, there were 15 journals that meet the inclusion criteria study characteristics.

*3.1.1 Population.*The total respondents in the selected literature were 2,583 with an age range of 6 - 65 years old.

3.1.2 Intervention characteristic. In this systematic review, 15 journals were reviewed. The journal shows the characteristics of subjects who can take yoga practice are subjects with stable asthma, do not suffer from respiratory complications other than asthma, are able to communicate well, do not have upper extremity disorders and interventions carried out in the study are complementary therapy to support pharmacological therapy which is doing yoga

pranayama exercises in asthma patients. By doing yoga exercises, regular pranayama has been shown to be significant in terms of improving lung function, increasing diffusion capacity, decreasing the amount of stress due to tightness and increasing the Forced Vital Capacity (FVC). Forced Expiratory Volume in 1 second (FEV_1), the Peak expiratory Forced Rate (PEFR), and asthma control so can improve the quality of life of asthma patients. Cardiorespiratory performance after practicing yoga can increase lung capacity and improve lung ventilation function so then there is a good exchange between O2 and CO2 after breathing exercises.

3.2 Result of Individual Studies

The research conducted on asthma patients showed significant results statistically for all pulmonary function parameters. Yoga pranayama given to yoga groups for 6 weeks of practice showed a significant increase in Forced Expiratory Volume in one second (FEV_1) and PEFR was looked at in relation to the lung function tests of asthmatics who had performed yoga pranayama [4],[16]. The effect of yoga pranayama showed a significant increase in FEV_1 ($t = 4.38$ so $P < 0.05$). In the PEFR ($t = 4.03$ to $P < 0.05$) of the pulmonary function tests, all of the patients showed an improvement in their quality of life as analyzed by the Wilcoxon test. There was no significant increase in FEV_1 and PEFR between men and women, nor were there significant differences in FEV_1 and PEFR in terms of increasing in age from 50 and less than 50 years [4].

Yoga pranayama exercises, which consist of slow pranayama techniques and fast pranayama for 12 weeks, can be used to evaluate lung function. The results obtained in the group that carried out slow pranayama for 30 minutes every day had a significant increase in FVC, FEV_1, PEFR, PEF, and MVV [$P < 0.05$] while in the group that conducted fast pranayama for 30 minutes every day, there was a significant increase in the value of FEV_1/FVC, PEFR and PEF 9 ($P < 0.05$). Yoga pranayama is also effective at reducing the fatigue that is the result of undergoing radiation therapy. In this study, yoga pranayama was carried out for 8 minutes in both the morning and evening for 6 weeks [17],[18]

Yoga pranayama breathing exercises are given to bronchial asthma patients to see if there are changes in their respiratory rate (RR), breath holding time [BHT] and PFT (FVC, FEV_1, FEV_1%, and PEFR) for 12 weeks. The results obtained showed that there were significant changes ($P < 0.001$) in pulmonary ventilation after the practicing of yoga pranayama by the asthma patients. Yoga pranayama exercises carried out for 12 weeks with a duration of 20 minutes 2 times a day also showed a significant reduction in symptoms and an increase in FEV_1 and PEFR in the intervention group ($P < 0.001$) compared to the control group [19],[20]

The goal of asthma control is to reduce the frequency of asthma attacks, to improve the inflammation of the respiratory tract, to increase physical activity and lung function and also to improve quality of life, which is an important component in the management of asthma [21],[27]. Yoga exercises given for 2 months to asthma patients have shown a statistically significant increase ($P < 0.001$) in forced vital capacity (FVC), forced expiratory volume in 1 second (FEV_1) and peak expiratory flow rate (PEFR) [14],[21].

4. Discussion

In general, all of the journals that have been reviewed provided results indicating that yoga pranayama is very effective for increasing forced expiratory volume in 1 second (FEV_1) and asthma control. This systematic review included 15 cases of yoga pranayama given to asthma patients. Cardiorespiratory performance after practicing yoga can increase the lung capacity and improve the lung ventilation function so that there is a good exchange between O2 and CO2 after the breathing exercises. The delivery of oxygen to the muscles and increased oxygen delivery to the tissues can reduce the reflex response to hypoxia [22]. Pranayama breathing and yoga posture stretching are used to increase breathing stamina, increase the strength of the chest muscles, relax the lungs, increase energy and calm the body [10].

Research shows that various exercises such as upper limb exercises, Tai Chi and yoga can improve FEV_1, PEFR, and asthma control. Yoga has been included as a recommended component of training for pulmonary rehabilitation programs and in addition to physical therapy treatment in rehabilitation programs. It has been shown to improve mind and body coordination. Yoga is called a low impact sport because it can be adjusted to the needs and abilities of its practitioners, so it is suitable for anyone including asthmatics through asanas (yoga postures) and pranayama (breathing techniques) [23],[25].

Appropriate asthma management includes making the lung function close to normal, preventing recurrence, controlling it regularly and improving fitness by doing the physical exercises that have been recommended. Yoga pranayama exercises are exercises that concentrate more on breathing so then they can be applied to asthmatic patients. Yoga pranayama is useful for maximizing the oxygen intake and improving blood circulation [18], [26].

Regular yoga practice can improve the quality of life of patients and it can improve their lung function. Yoga is also effective in the management of asthma and many scientific studies are needed in this field to utilize yoga [15],[27]. Yoga pranayama performed twice a week for 12 weeks can increase forced vital capacity and FEV_1 and it can also stimulate oxygen in the blood and increase the glycolytic capacity in adults [28–30].

Yoga can also be practiced as adjuvant therapy by performing standard asthma medical treatment to get better results. Yoga is one of the interventions that can support pharmacological therapy because it is effective at improving pulmonary function, increasing the volume of expiration and controlling asthma [14],[16],[29]. Yoga pranayama breathing exercises can also be useful in children with chronic asthma that is mild, moderate and uncontrolled but not severe and acute asthma sufferers [8],[31].

5. Conclusion

Based on the results of the analysis of all of the journals in this systematic review, it shows that there are significant results and that yoga pranayama exercises can affect FEV_1, PEFR, the FVC values, and decrease the frequency of asthma recurrence. This means that the asthma control gets better. Short-term studies on yoga practice have found significant results related to increased lung function parameters, increased diffusion capacity, reduced stress levels due to asthma and improved quality of life. Yoga training in asthma patients has been reported to improve lung function compared to

conventional therapy.

NURSE ROLE TO GET SATISFACTION ENDOSCOPY: A SYSTEMATIC REVIEW

Ratri Ismiwiranti[1], Nursalam[1], Erna Dwi Wahyuni[1]
[1]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
Email: ratri.ismiwiranti-2017@fkp.unair.ac.id

ABSTRACT

Endoscopy is a procedure for a known gastrointestinal problem. It could stimulate a negative effect on patients. Nurse endoscopist had roles to increase readiness and patient tolerant in order to grow up patient's satisfaction. Patient's ability to adapt is importantly required to support the procedure. This review to identify the role of nurse that can improve patients' satisfaction. The authors found 1800 article in accordance with the relevant literature in various data using the keywords "endoscopy, satisfaction, nurse, role". Data based on SCOPUS, Springer, Science Direct, Proquest. The criteria consisted of articles found, five years limit journal (2013-2018) and selected 17 articles that suitable with criteria. Nurse endoscopist role to get satisfaction were: 1) giving information with effective communication that planned, structured, and always improved by media or face to face; 2) easing negative feedback as hypnosis, yoga aromatherapy, etc ; 3)improve nurse attitude (respect, empathy, assertive and trusted); 4) comprehensive discharge planning. All of the purposes could be implemented for improving patients satisfaction with individually tailored to the patient's needs. When nurse doing there is a role, it can make satisfaction for all, could properly diagnosis and treatment, exactly and successful, and also decrease anxiety, pain and stabilize hemodynamically.

Keywords: endoscopy, satisfaction, nurse, role

1. Introduction

The endoscopy procedure often has a negative impact on the patient. Endoscopy can cause anxiety, nervousness and pain related to the procedure [1] [2]. More often, the patients are afraid of the preparations, procedure, environment and outcome [1]. The fear of a negative experience felt by the patient is a serious problem as the high negative feeling of the patient can cause the diagnostic process or therapy to be incomplete, with severe pain related to the difficulty of following through with the endoscopy procedure [3].

The patients need detailed information regarding the benefits, any unpleasant conditions and other things related to the endoscopic procedure [4]. When the patient understands clearly everything about the procedure and how the procedure is done, then the patient will be better prepared to face it. When the patient is ready to face the procedure, the patient will follow all of the instructions given by the nurse and doctor during the procedure. The procedure can therefore go well and the patient's satisfaction will increase [5] [6].

Nurses who have the appropriate competence will support the patient in adapting to the procedure [7]. The patient's adaptation capability will lead to satisfaction, especially for the patients and all of the healthcare personnel associated with the endoscopic procedure [8] [9].

The purpose of this systematic review is to summarize the nurse's competence and how it can improve patient satisfaction by synthesizing the previous studies. We hope that this systematic review can be used as information for the nurses and especially endoscopy nurse, the endoscopist and clinical research as a whole.

2. Methods

The systematic goal was developed based on the PICO (Patient, Intervention, Comparison, and Outcome) framework model [10]. This systematic review was performed in line with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) statement and checklist [11]. The research methods used include qualitative and quantitative fieldwork, a prospective randomized control design, a double blind clinical trial, a questionnaire-based survey, a randomized control trial, an investigative survey, an initial study, a cross-sectional study, a quasi-experiment, a prospective survey and an anonymous survey

2.1 Search strategy and data sources

The systematic search of the PICO baseline electronic data framework was carried out according to the PICO framework. The first step was to search the SCOPUS, PROQUEST, Springer Link, and Science Direct databases to identify the key articles and to identify the keywords by adjusting the key concepts of 1. Procedure endoscopy, 2. Nurse competence and 3. Patient Satisfaction. Our keywords were used to search for quotes and full articles including the title, abstract, full text and reference information. The second step was translating the keywords into English to find the relevant articles in the selected electronic databases. The third step was to filter using the PICO framework to determine which articles passed for further review according to the topic. The search strategies were limited to the last 10 years between 2008 and –2018.

2.2 Inclusion criteria

This systematic review established inclusion criteria that focused on quantitative studies, qualitative studies and mixed method studies. A feasibility study was used to describe the various types of nurse competence that can be used to improve the satisfaction of the endoscopy patients with the language eligibility criteria focused on minimal abstracts using English. The year of publication was limited to the last 10 years from 2008 - 2018. Further criteria for the inclusion group were studies with adult endoscopy patients (>12 years) and all types of endoscopy procedure (EGD or colonoscopy).

2.3 Exclusion criteria

Non-English, reviews and non-research articles.

2.4 Screening

The protocol standard for selecting the research studies is suggested in the PRISMA method for systematic review. This is followed by screening by removing the duplicates before three reviewers select the titles, abstracts, and keywords before deleting irrelevant quotes according to the selection criteria. The reviewers noted the reasons for choosing such research studies including the selection of the inclusion data. The selection of the research studies was recorded by two reviewers and then they were compared to one another to be adjusted for feasibility according to the criteria set. Secondly, to minimize the risk of there being an incorrect study entry in the stage of selection, there were several research studies that can be applied after a review by one or two reviewers. This is to allow them to be included in the next review stage. The full text of the articles was obtained if the title and abstract meet the inclusion criteria or if the feasibility study was clearly resolved by a joint discussion between the reviewers.

2.5 Data extraction

The following data was extracted: author, year, journal, country, setting of the study, aim of study, research questions, type of study, sampling methods, key findings or if there were relevant secondary outcomes. Two authors (RI and ADA) were involved in the data extraction and after organizing the results into a table, the findings were discussed and reviewed again.

2.6 Quality assessment

The assessment of the quality of the articles to be reviewed used the quantitative study tool the Critical Appraisal Skills Program (CASP). There were 10 different questions that considered the results of the quantitative studies, the validity of their studies and the use of the results [12]. CASP is a tool for evaluating the quality and utility of research reports [13]. The 10 questions in CASP are answered by selecting "yes", "no" or "not now" for each question. The allocation of the scores on a scale of 10 for each article reviewed was based on how many "yes" answers there were. A score for yes above 7 or more refers to the quality of the article being very good. The purpose of the quality assessment was not to distinguish between the different levels of quality but to work as a part of a systematic process to provide a high-quality review based on the existing topics.

2.7 Analysis

Due to the methodological diversity of the studies included and the limited number of studies specifically addressing the objectives set for this review, descriptive synthesis was considered to be the most appropriate analytical method.

3. Results

3.1 Study result

The search strategy was carried out by generating a total of 1800 citations, of which the authors deleted 1679 during the first screening because the title and / or abstract did not match the specified eligibility criteria, the year published journal, where it was not original research, where the endoscopy was conducted on children and other gastrointestinal endoscopy methods. In total, 103 full articles came from the second stage of screening and 24 of the articles obtained were

retained for review. Following this, 8 additional articles were obtained from the reference screening stage and thus the last session included 16 articles on the interventions used to improve the endoscopy patients' satisfaction (see Figure 1)

3.2 Study Characteristics

3.2.1 Types of study. Two studies employed a fieldwork study, which is a method using inductive reasoning that emphasizes the generation of theory based on the observations of patterns in terms of the qualitative data. Three studies used RCT, two studies used prospective and RCT, two study were cross-sectional, an initial study, prospective, prospective and RCT, one survey was an investigation and two studies were quasi-experimental involving a clinical trial and an anonymous survey.

3.2.2 Types of participant. The number of samples in this study varied. For quantitative research, the number of patients ranged from 52 – 1800. For qualitative research, the number of patients was 8. This study showed that the patients were undergoing either an upper or lower endoscopy. Most of the studies showed that the patient's required information from the nurse and that it had to be clear. They also needed the nursing intervention to decrease their negative feelings. Most of the studies, up to 87,5% (14 from 16 studies), explained that the patient needed the nurse to have competence in terms of their communication.

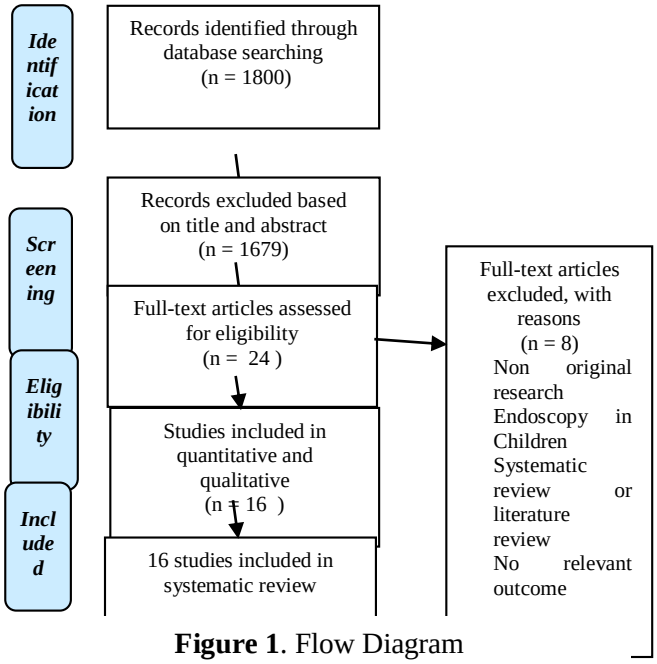

Figure 1. Flow Diagram

3.3 Summary of studies

The literature search identified 16 journals that described the competence of the endoscopy nurses required to improve the patients' endoscopy satisfaction. From the articles, four retrieved five categories concerning nurse competence that should be applied to improve patient endoscopy satisfaction, namely: 1) providing education; 2) comforting their negative reactions; 3) accompanying the patients with a caring attitude and 4) their skills.

3.3.1 Providing Education. Eight out of the 16 articles were reviewed in this context Patients who undergo endoscopy actions often don't have much knowledge about the endoscopy or the procedure itself. The nurse must have competence to provide education to the patient. Effective communication becomes an important prerequisite for improving the patient service in a manner that is safe and satisfactory [5].

Nurses as health workers who have the time to interact with the patient the longest have the opportunity to use their time to provide a thorough education to the patient of their condition [14] [15]. Endoscopy nurses need to have an effective amount of time with the patients in order to discuss about the purpose and benefits, in addition to any unpleasant things and how to handle them, tailored to the needs of the individual patients [8].

The information provided and any related actions can be done directly or with the use of different forms of media. Structured information can be organized in a form which facilitates the nurses and which improves their ability to communicate, to decrease anxiety and to improve patient satisfaction [6] [16]. In addition to this, the information can also be arranged in the form of CD-ROMs, videos and other media information compiled programmatically and structured to decrease anxiety as well as increasing customer satisfaction. This includes the readiness to perform other procedures [17–19].

The information provided is not only related to the preparation of the procedures, but it also include things that may occur during the endoscopy such as possible delays, an extension of the waiting time, the possibility of sedation to be provided, as well as the possible results and other related actions by adjusting to the conditions and needs of the patient.

3.3.2 Comforting their Negative Reactions

For 10 out of the 16 articles reviewed, the endoscopy procedure stimulated the occurrence of nervousness and anxiety. A high level of anxiety experienced by the patients before an endoscopy will lower the patient's tolerance [2]. Endoscopy nurses need to have competence to help the patients to manage their anxiety, pain and negative reactions. An endoscopy is often done without the use of sedation, Also in Indonesia, there is the concern that the actions that are carried out should be done relatively quickly, safely and in a cost-efficient manner, lowering the side effects due to the use of sedation [20] [21]. From the few studies mentioned, some states do not offer sedation for the patients who are to undergo an endoscopy action due to the increased costs. In addition to the reason of cost, the use of sedation involves risks: the suppression of the circulation, respiratory depression, recovery time and amnesia of the anterograde type [22].

Nurses can conduct interventions to help the patients to comfort their negative reactions caused by the procedure such as behavioral relaxation techniques, breathing deeply, hypnosis and they can also provide distractions through audiovisual media [18,21,23,24]. An alternative nursing intervention is to provide aromatherapy or yoga.

Comforting the negative reactions that are felt by the patient also can be done by facilitating psychological preparation, in the form of an intervention to control the information, cognition and behavior of the patients given before the action since doing so before the procedure means that the patient will be able to adapt and ready to face the action. This may be combined with the

above mentioned alternative therapies [1] [25]. Previous studies showed that the intervention can reduce anxiety, increase the patient's tolerance and readiness as well as improve the satisfaction of the patients which will have an impact on the success of the diagnosis and treatment.

3.3.3 Accompany patient with caring attitude

In 8 of the 16 articles reviewed, how the endoscopy patients feel satisfaction is heavily influenced by the attitude and intervention given by the nurses. The patients will be satisfied when the nurse has time to share their stories and to provide the information needed by the patient, which is meant here to refer not to how much time is spent together with the patient but instead how the time is spent [8].

The attitude of the nurses and their sensitivity related to empathizing with the patient's condition will result in positive feedback, such as when describing the information required by the preparatory actions related to the patients. Their responsiveness will help the patients to cope with their perceived anxiety. These conditions will enhance the readiness of the patient in terms of receiving the procedure, including the instructions as preparation against any wayward actions, facilitating less discomfort with the procedure [4]. There is also how the nurse accompanied the patient during the procedure.

3.3.4 Skills. Twelve articles were reviewed. Most of the patients felt anxiety related to the procedure and the results found likewise [4]. The results of a survey on increased patient satisfaction demonstrated that there are five areas that cause negative feedback. One is the ability of the department to deliver post-procedure advice consistently to all patients. The endoscopy nurse must have the skills needed to make sure that the patient be able to do the procedure properly. Therefore, the nurse’s presentation of the endoscopy should comprehensively provide an explanation about everything related to the outcome of the procedure [7].

4. Discussion

The results of the review demonstrate that the nurse’s competence related to improving patient satisfaction is through communication. Effective communication built between the nurses and patients will give rise to trust in the other. The confidence of the patient will improve their readiness and skill of adaptation related to receiving the endoscopy.

Communication can be done, when nurse have a good skills, caring attitude, knowledge to accompanying patient during procedure. If nurse can do that properly, patient also can receive all of procedure. The patient can sure that the procedure is more useful than having negative feelings.

The satisfaction felt by the patient means that the patients are sure and believe in the endoscopy. The endoscopy nurse must provide proper advocacy with the attitude of the nurses being one of someone who can demonstrate empathy, assertiveness and a therapeutic manner. Endoscopy nurses have a role which is important from the point of first meeting with the patient. For the first time, the patient sensed that he was cared for by the nurses and since that time, the patient felt satisfaction. The endoscopy nurse's attitude and ability to be a good listener is also needed [2] [6].

The nurse's competence is not only limited to the aspect of information and attitude, but it

also includes an increase in the ability of the nurses to provide interventions that can help the patients to lower the negative effects (anxiety, nervousness, pain etc) that are perceived by the patients. The interventions may include health education, videos, audiovisual information, psychological preparation, hypnosis, aromatherapy, yoga and more. It is expected that when giving the intervention, it will help the patient to adapt to the process of preparation and it will help the endoscopy patients to receive the results of the procedure, as well as to be obedient when executing the therapy [1,17,25–27]. It is also important to note that the nurses should always pay attention and adjust the interventions conducted with the patients according to their needs on an individual basis [16].

This review is limited. Considering the studies related to the initial search, an extensive search strategy can be implemented. All of the results of this systematic review are based on the findings of a study of the secondary data that has been included. The studies explored were not taken in detail so there is a possibility that this aspect that has not been touched upon. This study focuses on the context of the nurses' competence to achieve and improve on the satisfaction of the patients undergoing endoscopic actions that may limit the data retrieved. However, the systematic review was designed to obtain data in the context of the nurse's competence in terms of achieving and improving on patient satisfaction related to the endoscopy procedure. There are limitations associated with this systematic review. The journals taken in this systematic review are only related to the nurse's competence related to improving patient satisfaction. The sample in this study consisting of patients aged > 12 years or adult TB patients. The interventions discussed are for endoscopy patients in general (upper and lower) and not based on procedure (gastroscopy or colonoscopy). Therefore, specific interventions for each category and the discussion of the nurse's competence that increases readiness and satisfaction that is directly related to procedure success are important areas for further study.

5. Conclusion

The results showed that the nurse's competence in relation to the endoscopy procedure can improve patient satisfaction, which is in terms of providing education, comforting their negative reactions, accompanying the patient with a caring attitude and having good skills. The main thing is communication. The results of this systematic review showed that nursing competence for the patients receiving an endoscopy is needed to improve patient satisfaction. The procedure will be more effective and provide benefits for all if the nurses fulfill their role properly as part of a good team and not as a single worker.

Appendix

Table 1. Journal Analysis Table

No	Title, Authors, & Time	N	Design	Main Result
1	Impact of video information before unsedated upper gastrointestinal endoscopy patient satisfaction and anxiety : a Propective Randomized Trial [17]	440	*Prospective Randomized trial*	Information that is given by video could help the patient to reduce their anxiety, improve their satisfaction and make the patient ready to undergo other procedures.
2	The best way possible ! A fieldwork study outlining expectations and needs for nursing of patients in endoscopy facilities for short-term stay (Rn, Brian, Msce, Sørensen, & Rn, 2014)	8 patients 4 nurse	*A fieldwork study*	Part of nursing related to endoscopy patients is easing the patients' feeling of nervousness and anxiety (there are three individual strategies in this study: getting it over with, the meaning of the words and taking precautions) and also to maintain an element of control. So to be successful, the nurses need to get to know the patient's individual way of managing their needs.
3	Enhanced Communication Performance Improvement and Patient Satisfaction in an Endoscopy/Ambulatory Surgery Unit (Griffiths, 2015)	1800	Initial study	Delivering safe patient care can be enhanced only by improving the effectiveness of the communication among care givers. Nurses that have more time to interact must use this to communicate and educate patients in whatever time frame is available
4	Endoscopy patient satisfaction survey : improving the patient experience [7]	52	Questionnaire-based survey	Areas of strength with predominantly positive feedback included the pre-procedure information given, the consent process, the help of the receptionists and the environment of the unit itself. There were five main areas that received negative feedback: 1) the ease with which appointments can be made; 2) the process of following directions to the department on the day of the procedure; 3) the unexpected waiting times; 4) the amount of sedation given; 5) the ability of the department to deliver post-procedure advice consistently to all patients. This study proposed the following: 1) interpreters should be available to help the patients from ethnic minorities to make and keep their appointments; 2) patients should be given maps before their appointment detailing directions to the department clearly; 3) details should be imparted to all patients with

				respect to likely waiting times and possible delays (including median waiting time based on previous month's data); 4) endoscopists should attend a formal training course in sedation with protocols readily available in the department; and 5) it should be ensured that the patients do not leave the department without the appropriate advice being given.
5	Effective communication enhances the patients endoscopy experience (Toomey, Corrigan, Singh, Nessim, & Balfe, 2015)	71 when survey and 60 after survey	A Prospective Survey	Structured information leaflets and improved staff communication skills reduce anxiety and enhanced the patients' experiences.
6	Efficacy of Conversational Hypnosis and Propofol in Reducing Adverse Effects of Endoscopy (Izanloo et al., 2015)	140	Randomize Control Trial	The results suggested that a conversational hypnosis technique could reduce anxiety as well as the sedation process in a procedure such as an endoscopy
7	Effects of Visual and Audiovisual Distraction on Pain and Anxiety Among Patients Undergoing Colonoscopy [3]	180	A prospective, randomized, controlled design	The reduction of the anxiety level was greater in the two intervention groups, although significant differences were not found. Several reasons may explain why the visual and audio-visual distractions did not significantly reduce the levels of anxiety. First, greater anxiety may be produced by the concern about the pathological findings of the examination than by the endoscopy procedure itself. Second, watching a DVD play is interesting and engaging.
8	Does Anxiety or Waiting Time Influence Patients' Tolerance of Upper Endoscopy ? (Pontone et al., 2015)	105	Cross-sectional study	According this study, waiting time does not have a significant impact on the perception of pain and discomfort related to the endoscopic procedure. On the other hand, high pre-procedural levels of anxiety were associated with a low tolerance.
9	TIME - MAKING THE BEST OF IT ! A Fieldwork Study Outlining Time in Endoscopy Facilities for Short- Term Stay (Bundgaard et al., 2016)	9	Fieldwork study	The study underlines the possibility of combining the health care systems, patients and the nurses' perspectives on and their expectations of how to spend the nursing time in endoscopy settings. In successful patient pathways, the nurses maximize the patient outcome, support the goals of the healthcare organizations, are reliable, assure, tangible, empathic and responsive and are individually tailored to the patient's needs. The study contributes by underlining the importance of discussing not how to

				get more time in the context of clinical practice but instead how to spend the time in the best way possible.
10	Day surgery nurses ' selection of patient preoperative information (Mitchell, 2016)	137	A survey investigation	Nurses working with competing demands and frequent interruptions prioritized patient safety information. Although they were providing technical details during the time-limited encounters, efforts were made to individualize the provisions. A more formal plan of verbal information provision could help to ease the nurses' cognitive workload and enhance patient satisfaction
11	A Study on the Effects of a Health Education Intervention on Anxiety and Pain During Colonoscopy Procedures (Hsueh et al., 2016)	213	A quasi-experimental design	This study found that using a multimedia health informatics CD-ROM to provide information on the colonoscopy procedure effectively reduced the examination-related anxiety and pain of patients.
12	The Effect of Psychological Preparation on the Level of Anxiety before Upper Gastrointestinal Endoscopy[25]	98	A clinical trial	Psychological preparation was effective at reducing the pain of the endoscopy patients and it can be considered as an efficient method for decreasing anxiety.
13	Effect of psychological preparation on anxiety level before colonoscopy in outpatients referred to Golestan Hospital in Ahvaz (Boustani, Pakseresht, Haghdoust, Qanbari, & Mehregan-nasab, 2017)	80	A double blind clinical trial	In this study, traits and the state of the patient's anxiety levels after a psychological preparation showed a statistically significant reduction. This indicates the effectiveness of the intervention programs used to reduce anxiety before a colonoscopy.
14	Complementary Therapies in Medicine Aromatherapies using Osmanthus fragrans oil and grapefruit oil are effective complementary treatments for anxious patients undergoing colonoscopy : A randomized controlled study [26]	362	A randomized controlled study	Aromatherapy using Osmanthus fragrans oil and grapefruit oil are effective complementary treatments for anxious patients undergoing a colonoscopy.
15	Factors Associated with Anxiety About Colonoscopy : The Preparation , the Procedure , and the Anticipated Findings [4]	1316	An anonymous survey	Fewer people had high anxiety about preparation than about the procedure and findings of the procedure. There are unique predictors of anxiety about each colonoscopy aspect. Understanding the nuanced differences in aspects of anxiety may help to design strategies to reduce anxiety, leading to improved acceptance of the procedure, compliance with preparation instructions, and less discomfort with

				the procedure.
16	Pain Management Nursing Using Yoga Nidra Recordings for Pain Management in Patients Undergoing Colonoscopy (Li, Shu, Li, & Liu, 2019)	144	Quasi-experimental	Both the yoga nidra recording and the relaxation music helped to reduce the pain that the participants undergoing a colonoscopy experienced. The yoga nidra recording was the most successful intervention among the three groups.

THE EFFECT BRAIN GYM TO FINE MOTOR DEVELOPMENT ON PRE SCHOOL CHILDREN

Desy Siswi Anjar Sari, Anja Hesnia Kholis, Anis Satus Syarifah, Fitri Firranda Nurmalisyah
Stikes Pemkab Jombang, Jombang, East Java, Indonesia
Email: anjar_sari88@yahoo.co.id

ABSTRACT

Pre-school is a golden period in the development process. It consist of cognitive, physical, motoric, and psychosocial aspects of a child developing optimally. One of the developmental parameters is fine motor, its related to physical skills that involve the muscles of the fingertips and eye-hand coordination. The aim was to analyse the effect of brain gymn to improve fine motoric design. The design was a one-group pre-experimental with pre-posttest. The population was all students pre school in Sentul Jombang, East Java. Total sample were 33 respondents which matched the inclusion and exclusion criteria. The data collected by questionnaire sheets were adopted from instrument for assessing child development, namely KPSP. Intervention was given by brain exercise were carried out 3 times a week for 2 months then analyzed using Wilcoxon with a significance value of $\alpha = 0.05$. The results showed that brain exercise in pre-school children was able to improve fine motor skills ($p = 0.000$). Brain gym is one of the effective ways to improve fine motor skills in children because being able to facilitate blood flow and oxygen to the brain also helps overall brain development. Therefore, brain gym is highly recommended for pre-school children.

Keywords: brain gym, motor development, pre-school

1. Introduction

Early Childhood Education (PAUD) is a coaching effort aimed at children from birth up to the age of six years which is carried out through the provision of educational stimuli to help their growth and physical and spiritual development so then the children have a sense of readiness upon entering further education[1]. One form of development that must be achieved by the children is fine motor skills, because fine motorics is an important aspect of development, especially for those 4-6 years of age[2].

The WHO (World Health Organization) reported that 5-25% of pre-school children suffer from minor brain dysfunction, including fine motor development disorders[3]. According to the Indonesian Ministry of Health, 0.4 million (16%) toddlers in Indonesia experience fine and rough motor development disorders, hearing loss, poor intelligence and late speech[4]. Based on the data from the Level I Health Service of East Java Province 2008 for the detection of under-five growth in East Java, it was set at 80% but coverage was examined from 40 to 59%. Those who experienced non-optimal development was 0.14% [5]. Children need to be given new stimulation that is fun; with stimulation, the child will be more enthusiastic when practicing to improve their fine motor skills. According to brain gymnastics experts such as Dennison[6], brain exercises are a series of simple movements that are fun and that can help the development of the brain as a whole. It includes the coordination of eyes, ears, hands and all of the body. Thus, providing a stimulus that improves

the fine motor skills helps to develop eye-hand coordination. This study aims to determine the effect of applying the brain gym method on fine motor skills in pre-school children. The benefit of this research is to contribute to the development of the science and services of early childhood education, especially the knowledge related to gross motor skills. This study provides a recommendation of the brain gym method to optimize the fine motor skills in pre-school children.

2. Methods

This study aimed to determine the effect of brain gymnastics on fine motor development in pre-school age children. The research method used a pre-experimental design with a one group pretest and post-test design. Through the use of the design of this study, there were only experimental groups involved. The population in this study consisted of all pre-school children in PAUD village, Tembelang Jombang, East Java. The sample in this study consisted of 33 respondents, all of who were pre-school age children. The sampling technique used in this study was Total Sampling, which is in accordance with the criteria of inclusion that the children were in good health, cooperative and both men and women.

The time of the study was from the beginning of September to the end of October 2017. The time taken for the research was 2 months with the frequency of exercise being 3 times a week. The data was collected through a questionnaire sheets adopted from KPSP[7]. The statistic tests used in this study were non-parametric statistical test and the Wilcoxon Rank Test. Stikes Pemkab Jombang published the ethics recommendation for this research. The training activities consisted of 3 main parts. First, there was a 5 minute warm up session to familiarize the body organs with the movements of the exercise as well as to see if there was an increased body temperature. Second was the core established training program, namely brain gymnastics. Before doing the core training, the trainer gave directions. Beyond therapy and practice, the subject was recommended to carry out their daily activities as usual for 10 minutes. Third was cooling down, which was done during the function to restore the body's condition to its original state when doing the exercise and at the end of the exercise, an evaluation of the results of the exercise was held. The post-test as done after getting the treatment from the researchers in order to find out the results of the training achieved by the sample after receiving treatment with brain gym.

3. Result

Table 1. Frequency and percentage distribution of the respondent's demographic details

Demographic data	Categories	f	%
Age	2,5 – 3,4 year	18	55
	3,5 – 4,4 year	15	45
BAB 1	Total	33	100
Sex	Women	17	52
BAB 2	Man	16	48
BAB 3	Total	33	100

Based on Table 1, it is known that most of the respondents were aged between 2.5 - 3.4 years, totaling 20 respondents (60%). Based on Table 2, it is known that more than half of the 17 (52%) respondents were female.

Table 2. Brain gym before and after treatment

Fine motor development	Before		After	
	f	%	f	%
Well	2	6	29	88
Enough	24	73	4	12
Less	7	21	0	0
Total	33	100	33	100

Based on Table 3, it was found that more than half of the 24 respondents (73%) had sufficient fine motor skills before the brain exercises were conducted. More than half of the 29 respondents (88%) had good fine motor skills after the brain exercise at PAUD Tembelang Jombang, East Java.

This study used the Wilcoxon Rank Test to determine the effect of brain gymnastics on the improvement of fine motor skills in the pre-school age children. The significance level (α) was less than 0.05. The Wilcoxon Rank Test results obtained a p value = (0,000) <(0,050), so H1 was accepted. This means that there was an effect of brain gymnastics on increasing the fine motorics in pre-school age children.

4. Discussion

The results of the previous studies on brain gym most have shown it to have an effect on the sufficient fine motor skills of pre-school age children. Pre-school age children who have fine motorics know that the average child is still not able to move well. This is because the brain exercise has never been applied to support and hone the children's fine motor skills. According to Dennison [6], the factors that accelerate or slow down fine motor development include genetics and health. The complicating factors are the birth process, nutrition and stimulation.

The sex factor showed that 53.3% of the children were female. Because girls tend to be ashamed and afraid of strangers, the children did not do the fine motor movements as directed by the researchers. According to El-idhami[8], they explained that girls have a subtle motor development that is slower than boys. This is because girls have a more shy and fearful nature so they do not easily become close to someone new to them.

The results of the study after being given brain gymnastics were that there were fine motor skills across the sample of pre-school age children. The children who had good fine motor skills were those who had been given the intervention or stimulation via the brain gymnastics method for 15 minutes 3 times a week for 2 months while at school. The benefits of brain gymnastics for pre-school children is that they increase children's concentration while learning, improve their memory, increase the children's confidence when playing with their friends and this makes the children think faster. This is so then they can do the fine motor movements properly using their fingers[9]. Brain movements using the hands and feet accompanied by music can increase the children's enthusiasm to start lessons and to practice their physical abilities such as writing and drawing. This can improve their hand movements perfectly [10].

From the results of the analysis obtained by Hasih, there is an influence from brain gymnastics on the improvement of fine motor skills of the pre-school age children in Sentul Village PAUD Tembelang Jombang. The results of the study show that doing brain exercises can improve the children's fine motor skills better. Brain gym is a series of exercises based on simple body movements. Motion exercises stimulate the left and right brain (lateral dimensions), relaxing the

front and back of the brain (dimensions, focus), and stimulating the midbrain (limbic) and part of the cerebrum (concentration) which increases the child's ability to perform fine motor skills such as writing and drawing [10].

5. Conclusion

Brain exercises given to pre-school children are effective as an intervention to improve fine motor skills in PAUD, Tembelang, Jombang, East Java, Indonesia. Brain gym interventions can be a reference for improving the fine motor skills in pre-school age children.

HOT HERBAL COMPRESS TO RELIEVING ENGORGED BREAST IN LACTATION PERIOD

K D Purnamasari[1], S Fatimah[1]
[1]Department of Midwifery, Faculty of Health Sciences, Galuh University, Indonesia
Email: kurniatidevip@gmail.com

ABSTRACT

Breast engorgement affects during lactation discomfort. These problems are experienced by more than two-thirds of the lactation period. Unfortunately, there are limit methods of care for the engorged breastfeeding woman. This paper proposes a method for breast engorgement management to mitigate or preclude breast infection in the mother during the lactation period. The present study was conducted to determine the effect of hot herbal compress on relieving breast engorgement in lactating women. Participants included 20 women with breast engorgement divided into intervention and control groups, with participants in both groups being applied routine interventions and the intervention group was also applied a hot herbal compress. Both groups received these treatments 6 times for 2 days. According to the results, a significant difference was observed in the overall breast engorgement severity in the intervention group. The results of the hot herbal compress were compared with the results of routine interventions. From the results of this study indicate that the trend of the engorged breast using hot herbal compress treatment shows different results when respondents experience at the same time of treatment. The value generated in the engorged breast using hot herbal compress and routine interventions generally provided comparable clinical efficacy and could be considered as complementary and alternative treatments for the engorged breast.

Keywords: hot herbal compress, engorged breast, lactation

1. Introduction

Breast engorgement is a painful condition affecting large numbers of women in the early postpartum period[1]. It is often experienced by women on the third day until the fifth postpartum[2]. Engorgement leads to pain and if it is untreated, it can lead to mastitis and thus it can impact on the scope of exclusive breastfeeding. Globally, the suboptimal nature of the exclusive breastfeeding of children between 0-23 months of age causes a decrease of 804,000 child deaths each 9 years or 11.6% of all child mortality[3]. According to the Indonesia Demographic and Health Survey in 2012, the median duration of exclusive breastfeeding was 21.4 months. Based on the previous studies conducted in various countries, breastfeeding problems are common and associated with early cessation[4]. The early postpartum period is a critical time to set a foundation for the successful initiation of breastfeeding and to promote continued breastfeeding[3][5]. However, 17% of mothers sought emergency unit help due to problems with infant health, post-delivery complications or breastfeeding in the first two weeks after childbirth[6]. Breast engorgement may make it difficult for women to breastfeed. It may lead to complications such as an inflammation of the breast, infection and sore/cracked nipples[7].

Another source of instability in this period is the fragmented engorged breast care[8]. So far, the consistent evidence for effective forms of treatment is lacking[9]. Midwives need a quick reference guide for the implementation of evidence-based strategies to promote breastfeeding for all mother-newborn dyads. This can lead to muscular pain which can be relieved through massaging the affected areas. It also includes the use of heat applied to the muscles which expands the blood vessels and reduces the blood viscosity. As a result, the blood flow in the body improves. The applied heat also reduces muscular tension and increases flexibility[10]. The appropriate amount of heat and timing has not yet been studied before, nor has the relaxing effect that it delivers been examined[11].

This treatment was easy to implement and it was non-invasive for the client. The results of this study are expected to make up the basic data as a cut of point reference in a complementary treatment, so using a hot herbal compress in the context of midwifery services can run effectively according to the engorged breasts experienced by the client. The purpose of this study was to investigate the effect of a hot herbal compress on relieving engorged breasts in the lactation period.

2. Method

This research begins by selection of ingredients in making a hot herbal compress. Before retrieving the data, the first thing to do was to identify the respondent in accordance with the criteria set by the researcher. Then the respondents gave their informed consent if the respondent agreed to the data collection being done by a questionnaire. The inclusion criteria of this study were postpartum women who had moderate to severe swelling pain in the breast using a VAS scale. The exclusion criterion was the postpartum women who experienced only mild swelling in the breast. After the data collection was complete, the respondents were fitted with a hot herbal compress which served to reduce the engorged breasts of the mothers.

The research design used was quasi-experimental with a control group. The results of the hot herbal compress treatment were analyzed to see the changes in the pain and the nature of the engorged breast. The results were expected to be a means of measuring the engorged breasts experienced by the postpartum mother. The design in this study was a pre-test and post-test with a control group design. This research was conducted using the quota sampling technique. The sample was then divided into two groups; the experimental and the control. The data was collected using a Visual Analog Scale (VAS) 30 minutes after the treatment. The sample consisted of 20 respondents who were postpartum mothers with engorged breasts. Their representation was determined based on the inclusion criteria. The data retrieval was done after the respondent agreed for the hot herbal compress to be placed in corpus mammae. Each operational standard was conducted as shown in Figure 1.

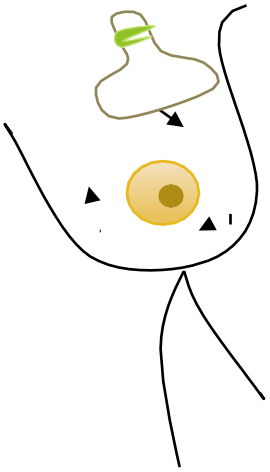

Figure 1. The reference position of the hot herbal compress[12]

The data retrieval began when the respondents experienced engorged breasts with a 5- 10 on the VAS pain scale. The hot herbal placed in corpus mammae. The ingredients are phlai, turmeric, zedoary, lemongrass and leech lime. The herbal ingredients were washed, pounded and mixed together with a little bit of borneo camphor and salt. The ingredients were wrapped tightly in a white piece of cloth. The process of making the hot herbal compress is as shown in Figure 2.

Figure 1. Reference photos of the herbs and herbal ball[12]

The data retrieval began when the respondents experienced engorged breast pain with a 5-10 VAS pain scale. The intervention was then carried out for 15 minutes. The baseline assessment before the intervention was conducted using a questionnaire to collect data on the demographics of the participants and their pain levels. The questionnaire included questions on pain measured using a tenth-point of the Visual Analog Scale. The instructions were provided by a certified trainer.
The results of the respondent's pain scale questionnaire were collected and then analyzed by the researchers assisted by enumerators. Furthermore, the data was presented in the form of an average value distribution. The statistical test used was the Wilcoxon test. The ethical review at the time of the study began by asking for permission to research in the health department and the place where the research data was collected. The research flow chart is as shown in Figure 3.

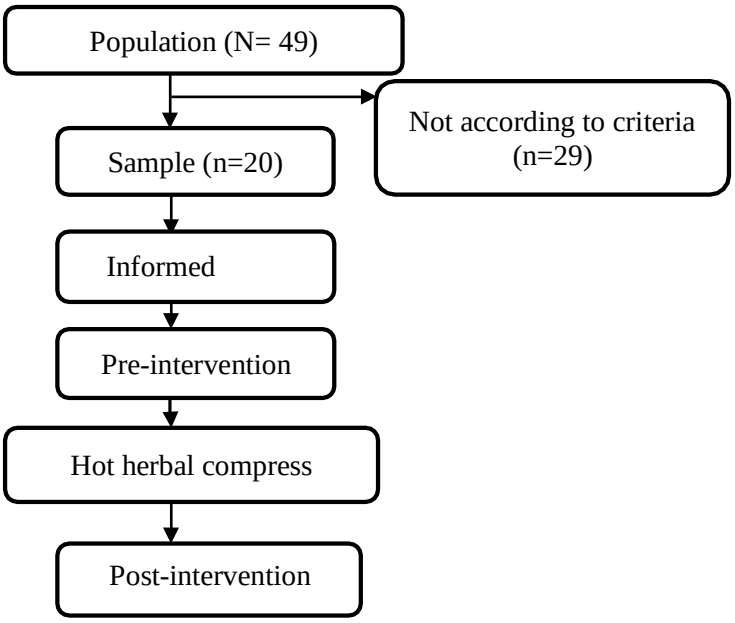

Figure 2. Flowchart

3. Results

This study shows that the average age of the respondents was (24.73 ± 2.71) years with the age range of the respondents being 21-30 years. The average parity of the respondents was (1.53 ± 0.52) with 1-2 pregnancies as a range. The average respondent's height was (156.46 ± 4.25) cm with a range of 152-167cm. The average pain scale using the visual analog scale (vas) was (6.33 ± 1.63) with a range of 5- 10. The characteristics of the respondents are as shown in table 1.

Table 1. Characteristics of the respondents

Characteristics	Min	Max	Mean ± SD
Age (years old)	21	30	24.73 ± 2.71
Parity	1	2	1.53 ± 0.52
VAS scale	5	10	6.331.63

Table 2. Distribution and average of engorged breasts in the lactation period

Variable	Pre		Post		*p-value*
	Median	Max-min	Median	Max-min	
Engorged breast pain	6.39	10-5	1.48	6-2	.000

The results of the intervention were analyzed using the Wilcoxon rank test. It indicated that the median post-test ranks, *Mdn* = 1.48, were statistically significantly higher than the median pre-test ranks, $p < .000$. Based on the distribution of the data from the analysis, the results obtained a significance level *(p-value*) of 0.000. This means that the engorged breast pain level in the respondents was significantly different. Based on Table 2 above, it can be seen that the average results of the engorged breasts in the 20 respondents enrolled in this study showed a decrease in

pain equal to 6 to 2 after being given the hot herbal compress.

2.1. Pretest

The results of this study indicate that the frequency of engorged breasts in the lactation period has a tendency to vary. The average maximum frequency that occurred in terms of engorged breast pain was on the tenth and the average minimum pain was in the fifth score.

2.2. Posttest

The average maximum frequency that occurred in the engorged breast after the intervention was measured on a scale of six and the minimum pain average was measured on a scale of two. The VAS scale for engorged breasts had a tendency to be directly proportional to the pretest of hot herbal compress on a moderate to heavy scale with a scale of moderate for as many as 15 people (75%) and heavy for as many as 5 people (25%), with an average pain scale 6.85. The VAS scale for the post-test proportional to the hot herbal compress was on a moderate to mild scale with a scale of moderate for as many as 5 people (25%) and mild for as many as 15 people (75%) with an average pain scale 2.95. The trend of the comparison of the VAS scales for the pretest and post-test hot herbal compress has been shown in Figure 3.

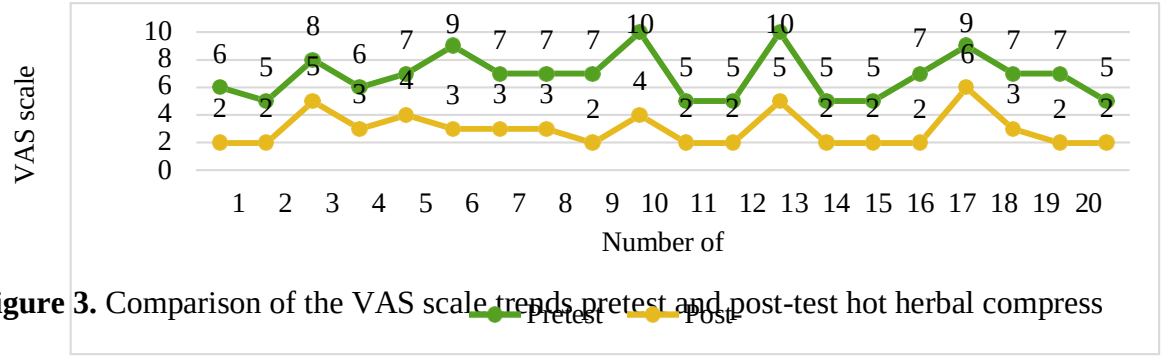

Figure 3. Comparison of the VAS scale trends pretest and post-test hot herbal compress

4. Discussion

The decrease in the intensity of engorged breasts occurred because the mother was given a hot herbal compress treatment for 30 minutes. This intervention was carried out when the mother had engorged breasts. Other potential confounding factors in this research could be the time of treatment. This result was accompanied by breast milk removal but the researchers did not examine the variable amount of breast milk expenditure in this study. The previous study shows that a hot herbal compress is a form of complementary care as an analgesic and anti-inflammatory treatment[13]. Heat from the hot herbal compression results in a dilation of the blood vessels and relaxation in the muscles[14]. Hot herbal compress therapy is a common alternative treatment to improve circulation and blood flow to a particular area[15]. Furthermore, the diverse components of the herbal ball offer various analgesic and anti-inflammatory properties[13]. The flavonoids in the turmeric herbs were substantiated in their analgesic and anti-inflammatory activities by a potential interaction with the prostaglandin cofactor substitution, while in the herbal ball these are acknowledged by traditional medicine practitioners as anti-inflammatory medicinal plants[16]. Phytochemical screening revealed the presence of certain secondary metabolites such as tannins, alkaloids, saponins, flavonoids and phenol. Flavonoids also inhibit either arachidonic acid lipoxygenation or related enzymes which are active in prostaglandin formation[17].

5. Conclusion

A hot herbal compress can be used as an alternative and efficient symptomatic treatment of engorged breasts. The results indicated that there was a significant improvement in VAS and it has been scientifically documented that a hot herbal compress can be effectively used as an alternative treatment for engorged breasts in primary health care. The future use of herbs for therapeutic purposes should be encouraged.

ASTHMA MANAGEMENT EDUCATION IN PARENT TO ASTHMA CONTROL BEHAVIOR IN CHILDREN;A SYSTEMATIC REVIEW

A R Virgin[1], M Amin[2], Makhfudli[3]
[1] Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
Email: arum.rahmawati.virgin-2017@fkp.unair.ac.id

ABSTRACT

Asthma control in children is very difficult to achieve because children are still dependent on parents or caregivers to make decisions about their health. Management of asthma by parents is needed in the control of child with asthma so there is no recurrence. The purpose of this systematic rewiew is to find out the effects of health education by parent to control asthma in child. The method used in this systematic review consists of 5 stages: (1) identification of instruments in the literature (database search); (2) identification of relevant literature based on title and abstract; (3) inclusion and exclusion criteria; (4) get fulltext literature; (5) grading based on the literature component and analysis of selected instruments. The database used in the search for literature were scopus, Proquest, Sciencedirect, BMC, Iranian Journal, PubMed 2010 and 2019 with relevant keywords. A total of 15 articles were identified through systematic searches and inclusion criteria from 2144 articles found. From the results of the study it was found that health education can change control behavior of child with asthma. Health education with counseling method is dominant intervention to give education for parents.

Keywords: education; asthma management; asthma control; children; parent

1. Introduction

Asthma control is the focus of modern asthma management. Asthma control in children is very difficult to achieve because children are still dependent on their parents or caregivers to make decisions about their health [1]. The management of asthma by the parents is needed so then there is no recurrence and asthma control can be achieved [2]. The fact is that the management conducted by the parents is still not optimal with the number of cases of recurrence. This is related to the poor knowledge of the parents about asthma management and this affects the child's health status.

Parents are an important key to controlling asthma in children [3]. The parents' knowledge about asthma severity and asthma management determines their help-seeking behaviors when it comes to managing their child's asthma [4]. The management of asthma can be improved by understanding asthma and finding solutions related to the obstacles in the management of asthma [5]. Accurate assessment and interventions by the parents and their children and timely good communication with health workers are both very important in the care and treatment of asthmatic children [6]. The experience of the parents with asthmatic children, particularly related to their beliefs, knowledge and attitudes about managing asthma, is important to asthma control [7]. Listening to the parents' experiences and understanding of asthma can lead to increased cooperation between the parents and nurses, which can enhance asthma management [8]. The parents may adopt a more positive approach when the nurses value the parents' knowledge and involve them in establishing asthma management strategies for their children [9].

The parents beliefs about asthma management, medication routines and adverse side effects impacts on asthma-related decisions and this results in consequences for the individual, the family and in turn, this are likely to affect the patient's quality of life and academic performance [10]. Therefore, it is crucial that most child health asthma education programs include the parents and focus on both the parents' and children's skillset and learning levels with the aim of developing successful asthma management strategies [11].

There are several methods used to improve asthma control in children by providing an asthma management education for the parent. Asthma management counseling is a face-to-face educational intervention. The content of the education program is stated according to the guidelines which were revised for children. It includes information on the pathogenesis of asthma, enviromental triggers for asthma exacerbations, asthma medications and how they act on disease and how the inhaled medications are used [12]. An asthma management intervention that is audiovisual is an educational intervention using audiovisual stimuli. This intervention emphasizes more how they act on disease and how they use inhalers as medication. [13]. This is because inhaler technique has an important clinical impact that is associated with asthma control [14]. The improper use of inhalers is one of the most common inhibitors of asthma control because it affects the acceptance of the patients' doses that are not optimal and the improvement of the patient's condition [15]. Intervention education through medication reminders shows that interactive voice response telephone calls that enquire about the symptoms, deliver education and encourage prescriptions refills resulted in a 32% improvement in controller adherence.

Intervention studies with asthma management education for the parents is carried through as asthma control in the children. Limited reviews have evaluated the effectiveness of the interventions and methods involved in providing asthma control. The importance of educational methods for children and their parents about appropriate asthma management has been highlighted in many studies, but little is known about the effectiveness of the education methods themselves [16].

The aim of this systematic review is to find out the effectiveness of asthma management educational interventions in parents as a form of treatment related to asthma control in the children with the aim of no recurrence. This review will enable practitioners to understand the scope of the problem and to potentially identify patients for screening. This will allow them to then provide the appropriate interventions to achieve asthma control in children.

2. Research methods

This research is a systematic review used to find out the asthma management education of the parents related to asthma control in the children from several related studies. There were 3 main steps to getting the data, which began with identifying and choosing the research related to the topic. Second, we assessed the research taken to see if it met all of the eligibility criteria. A review of the data within each study was then conducted. This review adopted the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines.

Study identification

The design of this study was a systematic review and the quantitative study was formulated to review relevant research studies and to conduct comprehensive analysis. This systematic reporting structure used PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) [17].

Eligibility criteria

This systematic review appliesd the inclusion and exclusion criteria that focused on several research study designs. Some of them used an RCT (Randomized Control Trial) or NRCT (Randomized Control Trial).

Search strategy

This review focused on studies investigating the role of asthma management education given to the parent to promote asthma control in the children. Several published reports with various study designs were considered and no restrictions were placed on the outcome measures. The eligible articles were retrieved from electronic databases, namely Scopus, PubMed and Cochrane. The systematic review was conducted by searching for relevant studies published between 2008 and 2019. The search strategies or key terms used for the search were four components combined, including: (1) health education OR (2) asthma children OR (3) control asthma OR (4) management asthma.

Study Quality Assessment

A total of 15 studies were taken and reviewed once the duplicate articles had been removed. The PRISMA diagram was used as a study guide in this systematic review followed by screening done adequately. This is because heterogeneity in the definition of the study design and in the main results is not always the same as in the initial study. The steps taken included (1) the removal of duplicated articles, (2) an independent examination of the titles, abstracts, and keywords, then deleting any irrelevant citations according to the inclusion criteria, (3) titles and abstracts that appear to meet the inclusion criteria according to the objectives of the systematic review were used to decide whether to look at the full text. (4) The final step was the selection of articles using a randomized method to reduce the risk of bias. Meta-analytic techniques cannot be done adequately because of the heterogeneity in the definition of the research design and due to the results' characteristics. The inclusion criteria were developed a priori and studies were included if they primarily explored the relationship between asthma management education given to the parent and asthma control. The exclusion criteria were as follows: (1) case reports, meta-analyses, systemic review, conference reports and articles without a research design; (2) the unavailability of the full text and (3) qualitative research studies. The main outcome is expected to improve asthma control in children.

3. Result

Study selection

The search using the Scopus and PubMed Cochrane Database of Systematic Reviews offered 2,144 documents. After screening and removing the duplicates, up to 1,210 citations were found. From that number, as many as 934 studies were discarded after reviewing the abstract where some who did not meet the criteria. The full texts of the 284 remaining citations were then reviewed in detail; 275 studies did not meet the inclusion criteria. Therefore this study finally reviewed 15 articles.

Result of the synthesis

3.2.1 Education conseuling. Effective communication between parent, children and health care provides is imperative for promoting adherence treatment asthma and control asthma. Improved

asthma outcomes with education have been reported in other socially deprived populations like. Counseling related to asthma management education for the parents showed a significant increase in asthma control in the children but it was not significantly effective when compared with the usual care [12]. The results suggested that the parents and children who received the face-to-face education programme were significantly less likely to require emergency care. [16]

3.2.2 Medication reminder. Medication reminder education is a form of personalized asthma education as well as generic written information. The medication regimen and asthma management plan was devised collaboratively with both the parent and child. The use of an electronic monitoring device reminder led to significant improvements in terms of the adherence to inhaled corticosteroids in school-aged children with asthma [18]. Medication reminder education in the 110 in the intervention group and when looking at the 110 in the control group made up of parents showed that the t Median percentage adherence was 84% in the intervention group compared with 30% in the control group ($p<0.0001$) [19]. Medication adherence in the parents related to asthma control was significantly higher in the intervention group who received feedback regarding their adherence. The mean adherence over the whole study was 79% in the intervention group versus 57.9% in the control group ($p <.01$). Adherence in the control group declined slightly over the study, whereas in the intervention group, the mean adherence was maintained and actually rose from 76.8% during the third month to 84.2% over the final month ($p<.01$).

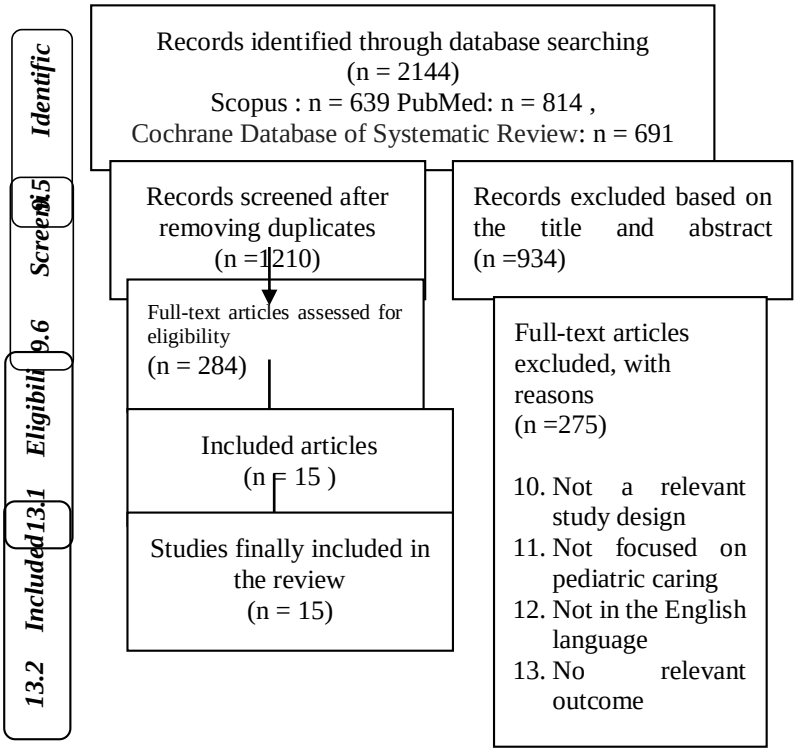

Figure 1. Flow diagram

3.2.3 Video education. The use of an audiovisual reminder significantly improved the adherence in school-aged children with asthma with corresponding improvements in several of the indicators of asthma control. [15]. The use of audiovisual reminders in education has significantly improved the adherence in school-aged children with asthma with corresponding improvements in the asthma

control indicators. There was an increase in knowledge in the groups with parents who had poor health knowledge by (p 0<01). However, there was an adequate or significant improvement in parents with a degree of health awareness after watching the video and practicing the correct use of inhalation at (p <0.001).

3.2.4 Asthma control test (ACT). The pre- and post-asthma control test scores (ACT) showed significant differences in the intervention group where the parents had asthma management education. With educational interventions during clinic visits, the majority of patients had higher ACT scores compared to usual clinical care. These findings are in agreement with the literature [20] indicating that an asthma control test after education showed that the intervention group and educational session resulted in a significantly higher proportion of well-controlled asthma patients with an ACT>19 (43% versus 77%) ($p < 0.001$) after three months. In the control group, this proportion remained similar (57% versus 67%) ($p > 0.1$).

4. Discussion

This systematic review was to find out about the effectiveness of asthma management education for the parent to control the asthma control of the children. The study used a heterogeneous research design. There are several findings related to various interventions regarding excellence. In accordance with the results of the review of the research studies conducted by [7], it was explained that asthma management education in families has changed the biology profile of childhood asthma to do with increasing control. The degree of uncontrolled or the most controlled form of asthma control can be seen by looking at the frequency of the recurrence of childhood asthma. [21] shows that that there is a relationship between knowledge and the attitudes of the mothers about asthma with the frequency of the recurrence of asthma in children. It can be concluded that increasing the knowledge of the families about asthma management can affect the degree of control of childhood asthma [22]. Counseling focused on asthma management education for the parents results in a significant increase in asthma control in the children but it is not significantly effective when compared with usual care [12]. In the counseling, the parents, doctors, nurses and children createe good relationships and beliefs together about the treatment [23]. The education counseling interventions in parents is performed by a respiratory nurse specialist. This is assessed by ACT over a three month follow-up period [24]. It has previously been shown that an educational session by an experienced respiratory nurse teaching the patients how to use their inhaler correctly improves their knowledge about their disease and other outcomes. The systematic review showed a good result from asthma management education through couseling with the parents to increase the adherence and control of asthma in children with no recurrence.

5. Conclusions

This review explains that asthma management education by the parents is effective at improving te asthma control in children. The evidence from th systematic review of clinical trials supports the conclusion that face-to-face education or conseuling is a more frequently deployed for educating asthmatic children. This approach helps in early recognition of poor asthma control. Thus nurses, who participate in educating asthmatic patients and their families due to their front-line role,

should instate appropriate formal methods of asthma education in asthma care and be able to identify effective approaches to improve the health outcomes. Despite the paucity of studies on asthma education with particular regard to hospital settings, the findings are impressive. Instituting face-to-face education in asthma care reduced health care utilisation (exhibited in substantial savings for hospitals in terms of the provision of direct care and financially improved healthcare outcomes for asthmatic children and their parents). This implies that face-to-face education in acute asthma care is the best deployment of education for asthmatic children and as well as being the most cost-effective method for health organisations. However, the optimum intensity of individual education was not ascertained.

Email: titis.eka.apriliyanti-2017@fkp.unair.ac.id

ABSTRACT

Psychoneuroimmunology is a psychological factor that affects the immune system and physical health through nerve and endocrinological pathways. Mindfulness as an exercise is aware of the conditions experienced by the body, mind, feeling, current situation and conscious thought to create a calm feeling or situation. This review aims to find the effectiveness of mindfulness management therapy for psychoneuroimmunology in supporting constructive coping mechanisms and good resilience by using systematic reviews based on PRISMA guidelines. Scopus, ScienceDirect, and Pubmed, that have been published within the limits of January 2013-November 2018 with relevant keywords. A total of 15 studies were selected and reviewed that met all eligibility criteria through a systematic search and inclusion criteria from 307 studies found. The study reviewed consisted of fourteen analyzes of randomized controlled trial studies and one quasi-experimental study. The study findings consist of various mindfulness management therapies that have an influence on psychoneuroimmunology, indicating that the more mindful someone will choose the strategy of coping stress approach and good resilience, evidenced by an increase in posterior cingulate cortex rsFC with dlPFC ($p = 0.05$). Our review study shows that mindfulness management related to psychoneuroimmunology has a good impact on supporting coping mechanisms and resilience.

Keywords: mindfulness, psychoneuroimmunology, cancer, coping mechanisms, resilience.

1. Introduction

The field of psychoneuroimmunology (PNI) discusses how psychological factors affect the immune system and physical health through the neural and endocrinological pathways. This relationship is very relevant for immunological health problems carried out through mediation, including infectious diseases, cancer, autoimmunity, allergies and wound healing. Psychosocial characteristics are related to changes in the immune function that indicate that psychological interventions such as relaxation, hypnotherapy and mindfulness are aimed at improving mood, coping abilities and social support in an effort to modulate immune function [1].

Mindfulness also refers to practices or techniques such as meditation practice based on the contemplative Buddhist tradition [2]. Over the past few decades, the significance of cancer-related research with mindfulness management on psychoimmunology has been carried out. Some methods for the management of mindfulness therapy include Mindfulness-Based Cognitive Therapy (MBCT), Mindfulness-Based Cancer Recovery (MBCR) and Mindfulness-Based Stress Reduction (MBSR). Mindfulness-Based Stress Reduction (MBSR) is a treatment program used to relieve stress and to overcome chronic diseases as an inflammatory biomarker (Arefnasab *et al.*, 2016; Reich *et*

al., 2014; Kenne Sarenmalm *et al.*, 2017). Mindfulness-Based Cognitive Therapy (MBCT) consists of certified 8-weekly-based skill training group programs originally designed to prevent the recurrence of depression formed as a basis for empirical research to test the predictors of relapsing in terms of depression (Schoenberg and Speckens, 2014; Omidi *et al.*, 2013; Chiesa *et al.*, 2015; Kingston *et al.*, 2015; Wong *et al.*, 2017). Mindfulness-Based Cancer Recovery (MBCR) is used to combat the greater decline in mood disorders (especially fatigue, anxiety and confusion) and stress symptoms including tension, sympathetic stimulation and cognitive symptoms in cancer patients [11].

The impact of cancer is not only physical, but it is also psychological such as interference with the patient's coping and resilience mechanisms. Disorders of coping and resilience mechanisms in cancer patients caused by stress are due to long treatment, the treatment processes themselves and side effects of treatment such as from chemotherapy in addition to the threat of death itself *[12]*. The (International Agency for Research on Cancer (2012) found that cancer accounted for 7.6 million deaths worldwide. The WHO estimates that the death rate from cancer will increase significantly by around 13.1 million deaths per year worldwide by 2030. That number is 70% in low and middle income countries such as in Indonesia [14]. The data from (Badan Penelitian dan Pengembangan Kesehatan (2013) reported that the cancer prevalence in Indonesia has reached 1.4% - 4,9%, or an estimated 347,792 people.

Efforts to improve coping and resilience mechanisms in cancer patients are necessary because the influence caused by the disruption of coping and resilience mechanisms can worsen the situation and lessen the effectiveness of the treatment process, which can potentially lead to increased mortality in cancer cases. Poor coping mechanisms will interfere with the recovery process and cause feelings of uselessness. Poor resilience can also reduce self efficacy and decrease the ability of individuals to find sources of support so then the patients cannot maintain their physical functioning in order to continue the treatment that they undergo [16]. This is evidenced by the results of the research conducted by Bruggeman-Everts (2017), which states that cancer sufferers need a positive coping strategy and to strengthen their resilience to adapt to their changing health.

The aim of this systematic review is to find the effectiveness of mindfulness management therapy for the psychoneuroimmunology of cancer patients in supporting constructive coping mechanisms and good resilience.

2. Research Methods

This study is a systematic review conducted to find out the effectiveness of mindfulness management therapy for psychoneuroimmunology as drawn from several related studies in supporting constructive coping mechanisms and good resilience. There are 3 main steps to getting the data, beginning with identifying and selecting the research related to the topic Second, we assessed the research taken that meets all of the eligibility criteria. Then third, we write the review and extract the data for each study.

2.1. Study identification

The identification method of this study was carried out in the form of a retail search strategy using three electronic databases (Scopus, ScienceDirect, and Pubmed) which focused on articles published within the limits of January 2013 to November 2018. We conducted a literature search for articles

published in English and the searches were conducted by developing search method strategies based on the PICO framework model (Patient Problems or Population, Intervention, Comparison, and Outcome) (Schardt *et al.*, 2007; Fineout-overholt and Johnston, 2005). The keywords used were "Mindfulness" AND "Psychoneuroimmunology" OR "Psycho" OR "Neuro" OR "Immunology" OR "Cancer", OR "Coping Mechanisms" OR "Resilience". Furthermore, the method chosen was studies that used a randomized clinical trial (RCT) approach that reviewed the effect of mindfulness on psychology, neurology and immunology (PNI). Only studies that had an exposure related to the mindfulness management of psychoneuroimmunology of cancer sufferers in supporting the coping mechanisms and resilience were included.

2.2. Eligibility criteria

The study design being the inclusion criterion in the Systematic Review is a Random Controlled Trial (RCT) design and a quasi-experimental study. The populations in this systematic review were: (1) all studies that described cancer patients getting Mindfulness Management interventions with or without a control group. (2) Men and women> 17 years old. (3) Looking at the effect of mindfulness management on psychoneuroimmunology in supporting coping mechanisms and resilience. Various types of mindfulness interventions that affect the psychological, neurological and immunological effects of cancer that provide support in terms of coping mechanisms and resilience. The main result of this systematic review is to look at the influence of mindfulness interventions on psychology, neurology and immunology and their support as relates to forming coping mechanisms and resilience. The research used was without any time limit for the duration of the intervention.

2.3. Study quality assessment

A total of 15 studies were selected and reviewed that met all of the eligibility criteria. The standard protocol used as a guideline for this systematic review method was PRISMA as shown in Figure 1 below [20]. The steps taken include (1) the removal of duplications; (2) the independent examination of titles, abstracts and keywords, then removing excerpts that are not relevant in accordance with the inclusion criteria; (3) title and abstracts that appear to meet the inclusion criteria and according to the purpose of a systematic review are kept, where the next step is to select journals with the full text available and (4) the final step is the selection of articles using a Randomized Controlled Trial and quasi-experimental studies to reduce the risk of bias. Meta-analytic techniques cannot be done adequately because of the heterogeneity in terms of the definition of disease type and the study design. However, to facilitate our analysis and discussion, we grouped the results of the review to examine the influence on the mindfulness management on psychology, neurology and immunology in relation to supporting coping mechanisms and resilience.

2.3.1 Quality of appraisal. The quality assessment of the articles to be reviewed was done using the JBI Critical Appraisal Tools. A systematic review combines the process of criticism and assessment of the research evidence with the aim of assessing the methodological quality of a study to determine the extent to which a study has discussed the possibility of bias in its design, implementation and analysis. There are 13 questions on the JBI Critical Checklist for Randomized Controlled Trials and 9 questions on the JBI Critical Appraisal Checklist for quasi-experimental studies (The Joanna Briggs Institute, 2017). The choice of answers consists of "yes", "no", "unclear" and "not applicable". Each article was assessed independently by 3 reviewers (TEA, K, JS). The assessment iwas combined with other

reviewers. If there were differences of opinion among the reviewers, then this was completed in the next discussion phase. The allocation of scores for each article reviewed was based on how many "yes" answers refer to the quality of the article. The purpose of this quality assessment was not to distinguish between the quality of the articles but to refer to systematic processes and standard processes that can help to provide high-quality reviews based on the existing topics.

2.4 Data extraction

The data was extracted independently by 3 reviewers from each study that met the requirements. The forms of data extraction included the details of the study, the research samples, the characteristics of mindfulness, the disease characteristics and the results of each study. Disagreements on the extracted data were resolved through a discussion among the reviewers.

2.5 Data analysis

The studies were grouped according to the effects of mindfulness on psychology, neurology and immunology and the role of psychoneuroimunology in supporting the patient's coping and resilience mechanisms.

2.5.1 Study selection. Figure 1 summarizes the search results and the selection of studies following the PRISMA guidelines [20]. The selection of journals based on the keywords used produced 248 articles, with the total going down to 156 articles after duplication screening. Following this, 119 were eliminated because of being irrelevant studies based on their titles and abstracts. A total of 37 articles with a complete full text were taken with 22 studies excluded because they did not meet the inclusion criteria as follows: not an intervention study (n = 11), not using English (n = 6) and having subjects that were <17 years old (n = 3). The results of the final 15 studies were used to carry out the systematic review.

2.5.2 Study characteristics. A total of 15 studies were finally selected for review consisting of 14 analyzes of randomized controlled trials and 1 quasi-experimental study.

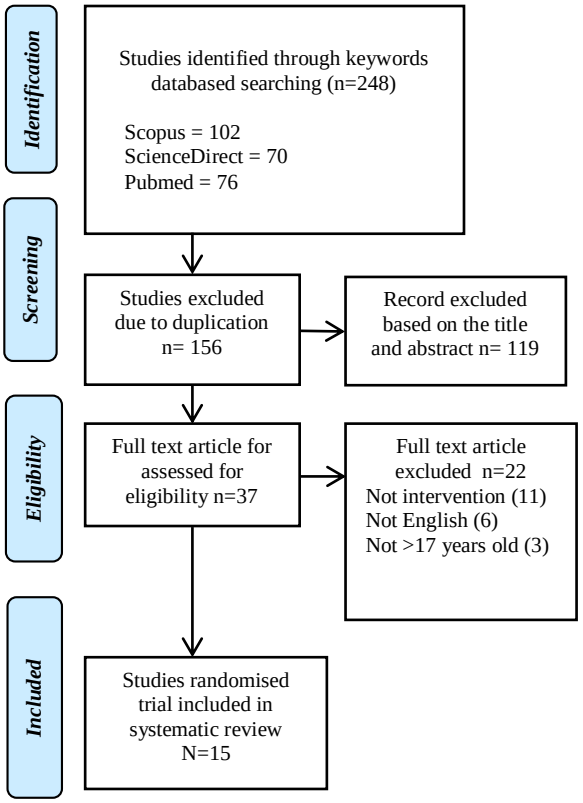

Figure 1 . *Flow diagram*

2.5.3 Population. The sample size of the 15 studies used in this systematic review totaled at least 23 people divided into two groups, namely the control and intervention groups, with the age range being 18 - 51 years. The characteristics of the female patients with stage I, II and III Breast Cancer aged > 18 years were the highest percentage of the samples, totaling as many as 271 people divided into 3 treatment groups.

2.5.4 Characteristics of the interventions. There were several types of mindfulness interventions used including Mindfulness-Based Cognitive Therapy (MBCT), Mindfulness-Based Cancer Recovery (MBCR), Mindfulness-based intervention (MBI) and Mindfulness Meditation (MM). The interventions were carried out with a different duration and frequency with the shortest time being 3 days at a duration of 25 minutes per day and the longest time being 8 weeks with a duration of 45 minutes per day.

2.5.5 Size of the clinical outcomes. The gathered research reported on the outcome measures used to measure psychology, neurology and immunology. Those used to measure psychology included the Symptoms of Stress Inventory (SOSI), the Profile of Mood States (POMS), the Beck Depression Inventory-2 (BDI-II) and the Hamilton Rating Scale for Depression (HAM-D). The measurement of the neurological results was done using salivary cortisol and neurological inflammation. To measure the immunology, the Lymphocyte Proliferation Test (LTT), ELISA (Cytokine Assays), Flow Cytometric Analysis (FACS), CD4, c-reactive protein, IL-6 and d-dimer were used.

2.5.6 Intervention efficacy analysis. Each RCT intervention explained that they evaluated the effect of mindfulness on the treatment separately. Some journals continued to follow up for up o 12 months after the intervention so then they could assess the long-term influence of the intervention that had been done.

3. Result

The literature search identified 15 journals that describe mindfulness management for psychoneuroimmunology in supporting the coping and resilience mechanisms of cancer patients. In the end, the 5 main theme findings from the synthesis have been summarized briefly as below.

3.1 Effect of mindfulness on psychological.

For the stress stage, according to Kingston et al (2015), they reported that the Mindfulness-based cognitive therapy (MBCT) group experienced a significant increase in awareness and a decrease in anxiety levels. Carlson et al. (2014) also stated that the most preferred program was Mindfulness-Based Cancer Recovery (MBCR) (55%) compared to the management of stress. The mindfulness group has been shown to experience improvements in mood disorders, stress, quality of life and personal growth as measured by the Profile of Mood States (POMS) and Symptoms of Stress Inventory (SOSI).

In the depression phase, the results of the study by Chiesa et al. (2015) showed a decrease in the level of depression measured using the proven HAM-D and BDI scores over the long-term period. This was more so in the MBCT group than in the psycho-education group. Kenne Sarenmalm et als (2017) study stated that the MBSR group experienced a significant increase in depression scores, with a pre-MBSR average using a HAD-score of 4.3 and a post-MBSR score of 3.3 (P = 0.001), compared to non-MBSR (P = 0.015). Kenne Sarenmalm et al's (2017) study states that the MBSR group experienced a significant increase in depression scores, with a pre-MBSR average using a HAD-score of 4.3 and a post-MBSR score of 3.3 (P = 0.001), compared to non-MBSR (P = 0.015).

In the fatigue stage, the research carried out by Bruggeman-Everts *et al.*, (2017) stated that fatigue decreased significantly in the Ambulance Activity Feedback (AAF) group and in the Web-based mindfulness-based cognitive therapy (eMBCT) group when compared to the psycho-education group. The relevant clinical changes in fatigue severity were observed in 66% (41/62) of patients receiving AAF therapy, in 49% (27/55) of patients receiving eMBCT and in 12% (6/50) of patients receiving psycho-education.

3.2 Effect of mindfulness on neurological.

The research conducted by Creswell *et al.* (2014) shows that there was an increase in posterior cingulate cortex rsFC with left dlPFC (p = 0.05). Mindfulness meditation training statistically changes IL-6, so mindfulness has been shown to increase the marker for the risk of inflammatory diseases.

3.3 Effect of mindfulness on immunology.

The research by Malarkey et al, (2013) shows that MBSR therapy carried out for 45 minutes / day for 8 weeks causes a decrease in the levels of CRP and IL-6. Hecht et al's (2018) study showed a decrease number of CD4 + T-cells in the 49.6 cell / µl MBSR group and in the control group there

was a 54.2 cell / μl difference from 4.6 cells (p = 0.85)

3.4 Effect of mindfulness on psychoneuroimmunology in supporting coping mechanisms.
One study explained and reported on coping mechanisms. The results showed that confrontational coping style, problem solving and positive assessment were positive and significant predictors of the tendency to seek social support during active care. The role of psychology is very necessary to make decisions when the patient is in trouble (Rankin et al, 2012).

3.5 Effect of mindfulness on psychoneuroimmunology in supporting resilience.
There were 5 studies that reviewed and reported on resilience. The patient's resilience score did not reach the threshold value. However, it was found that the resilience score in the HI-IPSC-C group was higher than in the LI-IPSC-C group. The HI-IPSC-C group also showed a decrease in the need for supportive care, in addition to improved mood and coping efforts [26].
Palacio et al (2018) showed that more than half showed high resilience, positive aspects of care, moderate care ability and low burden. RS-SC is a short and specific instrument for the self-reporting of resilience in patients with cancer in China. RS-SC has the potential to be used both in clinical practice and in research as an intervention for resilience (Ye et al., 2017).

4. Discussion

We conducted a systematic review using an RCT design and a quasi-experimental study. There were 15 studies that we included which examined the effect of the relationship between mindfulness and stress, depression, the inflammatory processes, psychology, neurology, immunology, coping mechanisms and resilience. In addition, including the heterogeneous types of mindfulness, the type of control group and duration of follow-up were also examined in this review. There are several important findings regarding the effect or effectiveness of mindfulness that will now be discussed in detail.

Mindfulness is a psychological intervention that is used to improve mood so as to reduce stress levels and anxiety. The program most favored by the patients with stage I, II, III breast cancer was MBCR (55%) compared to management stress. The mindfulness group has been shown to improve mood disorders, stress and quality of life [22]. There were no significant differences regarding the PA, MM, and HRVBF interventions because they were equally effective at reducing stress and the related symptoms [27]. The MBSR intervention showed that there were no significant improvements in their physical symptoms and mental health (p> 0.05). However, a significant increase was observed in the patients' quality of life (p> 0.05) [28].

Based on the MBCT intervention, the patients who experienced depression during treatment experienced a significant increase in the lessening of their depressive symptoms and mindfulness skills when compared to the control group [7]. The electro-cortical clinical work pathways with MBCT in multi-leveled depression are nonlinear and interdependent mechanisms, represented by the dynamics of mediated EEG synchronization [6]. Based on the HAM-D and BDI scores, as well as the quality of life scores and awareness, it showed a higher increase, which was especially evident over the long-term period more in the MBCT group than in the psycho-education group [8] [9]. In another study with breast cancer patients who underwent MBSR for 8 weeks, they experienced a significant increase in depression scores with a mean pre-MBSR HAD score of 4.3 and a post-

MBSR score of 3.3 (P = 0.001), compared with the non-MBSR HAD score (P = 0.015) [5].

Fatigue decreased significantly in the AAF and eMBCT groups compared to the psycho-education group. The relevant clinical changes in terms of fatigue severity were observed in 66% (41/62) of patients receiving AAF therapy, in 49% (27/55) of patients receiving eMBCT and in 12% (6/50) of the patients who received psycho-education [17].

The mindfulness of the neurological system shown in the 3-day intervention with a duration of 2.5 hours / day can reduce salivary cortisol reactivity and reactivate psychological stress after doing cognitive therapy. Mindfulness meditation training causes a rise in the posterior cingulate cortex rsFC with dlPFC (p = 0.05) and a statistically significant change in IL-6; mindfulness has therefore been shown to increase the marker of the risk of inflammatory diseases [23].

Mindfulness of the immunological system at this stage has been proven to improve mood, coping ability and social support in an effort to modulate immune function. There was a significant effect on the MBSR group related to mental health and quality of life compared to the control group and there was a significant increase of lymphocyte proliferation with phytohemagglutinin (PHA) and peripheral blood IL-17, but this did not significantly affect the lymphocytes (CD4 +, CD8 + and NK-cell) [3].

In this study, there are four factors that can be an influence, one of which the mechanisms must be adaptive. The first factor is positive beliefs or views. Meditation awareness is the patient's ability to calm and focus their attention on themselves, and at the same time, it is given a positive sentence. Depression and fatigue are increased through decreased pro-inflammatory cytokines and anti-inflammatory cytokines, mediated through the endocrine system and autonomous nervous system. The expression of genes is shown to indicate a decrease in inflammation and an improvement of the symptoms of the disease. In addition, through increasing the nerve growth factors such as BDNF, brain connectivity and the volume of gray matter in certain brains can increase and cause a decrease in depression, improve cognitive function and slow the progression of the disease.

The purpose of this systematic review is to analyze the clinical evidence of the influence of mindfulness interventions on psychoneuroimmunology in supporting coping and resilience mechanisms. Based on the results of the analysis, there are many positive effects resulting from mindfulness management. Based on a review of the journals, it was found that many mindfulness interventions stated the benefits related to the psychological disorders such as decreased levels of anxiety, depression, fatigue and improvement in quality of life. However, when followed up in the long term, it was found that mindfulness had no psychological effect. The mindfulness of neurology can reduce salivary cortisol reactivity and changes in IL-6, so mindfulness has been shown to increase the marker of the risk of inflammatory diseases. Against immunology, mindfulness as a psychological intervention can modulate immune function, resulting in a significant increase of lymphocyte proliferation with phytohemagglutinin (PHA), peripheral blood IL-17 and CD4.

There are several potential limitations associated with this systematic review, namely (1) the search is limited to published research, which might introduce the risk of publication bias; (2) there is a possibility that bias is introduced by the way that the studies are chosen or how the search criteria is determined and (3) what we consider to be the main outcome (psychology, neurology and immunology) is not always the same as in other studies.

5. Conclusions

Mindfulness-based meditation techniques are applied to deal with stress and exercise awareness. By practicing observing the sensations of the body, individuals can achieve a mindful condition in their daily lives, including when doing routine activities such as walking, eating, standing etc. The best results will be obtained through formal, mindful routine exercises such as body scan techniques, mindful checking in, mindful breathing and mindful informal practices. There are several types of mindfulness with differing effects on psychoneuroimmunology, but this cannot determine the type of mindfulness management that is the most effective. Mindfulness as a whole has an influence on psychoneuroimmunology, especially psychology. Further randomized research must be carried out by including more objective steps to explain the mechanism of mindfulness on psychology, neurology and immunology simultaneously in terms of supporting the patient's coping mechanisms and resilience.

THE EFFECT OF PROGRESSIVE MUSCLE RELAXATION ON ANXIETY: A SYSTEMATIC REVIEW

Maulana Arif Murtadho[1], Kusnanto[1], Lilik Herawati[2]
[1 2] Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia [3] Faculty of Medicine, Universitas Airlangga, Surabaya, East Java, Indonesia E-mail: maulana.arif.murtadho-2017@fkp.unair.ac.id

ABSTRACT

Anxiety in patients is often neglected, although the psychological burden experienced can affect health and care. The aim is to analyze the effects of progressive muscle relaxation to reduce the patient's anxiety level. Literature search uses pre-determined keywords through several electronic databases such as Scopus, ProQuest, and Science Direct from 2014 to 2019. All studies include access based on (1) randomized controlled trials, (2) case control studies and (3) pseudo experimental. There were 14 studies reviewed, our findings show that after 6 weeks of PMR, it can reduce anxiety levels. Progressive muscle relaxation interventions are very effective in reducing the level of anxiety in patients. Interventions are needed to reduce anxiety in patients.

Keywords: progressive, muscle, relaxation, anxiety

1. INTRODUCTION

Anxiety disorders are the most common psychiatric disorders experienced by everyone, male or female, old or young, and associated with a severe burden of disease (1–8). Anxiety experienced by patients often gets less attention from all walks of life, even though anxiety affects the psychic patients who undergo treatment. So that efforts are needed to reduce the anxiety that patients respond to by PMR

Progressive Muscle Relaxation (PMR) is a widely known relaxation technique introduced by Jacobson that aims to reduce residual tension and eventually reach the threshold without firing through a systematic process of tightening and relaxing the muscles with muscle contractions which will be followed by muscle relaxation (9–13). This study evaluates the effectiveness of PMR in reducing patient anxiety by reviewing all relevant PMR trials.

2. METHODS

2.1 Literature Search

Search for English-language papers published from 2014 to 2019 is conducted at Scopus, ProQuest, and Science Direct database. The combinations used are "Progressive", "Muscle", "Relaxation", and "Anxiety." Journal related issues, study reference lists included, and other relevant papers in the field were searched in an effort to find possible records. from identification

of records to inclusion following the principles of the PRISMA statement (14).

2.2 Study Selection

Regarding the selection of studies, the inclusion criteria are as follows: (1) using PMR as an intervention; (2) original articles published in peer-reviewed journals. Exclusion criteria are as follows: the study was conducted not on people who suffer from certain diseases

2.3 Data Extraction

Data extracted from this paper included: study authors, countries, total number of patients, gender of patients, primary tumors, duration of PMR sessions, duration of intervention, frequency of exercise, average adherence rate, follow-up, variables studied, measurements used, and main findings.

3. RESULT

A total of 13 studies were identified to be included in the review. The search for Scopus, Science Direct and ProQuest found a total of 275 articles. After checking for duplication, there were 164 articles. Of these, 81 studies were discarded because after reviewing the abstract did not meet the criteria. The full text of the 83 remaining articles was examined in more detail, it turns out that 70 studies did not meet the inclusion criteria as determined. Therefore, 13 studies were finally included in our systematic review.

Participants in all studies were measured at baseline, those in the intervention group were given PMR sessions conducted during the follow-up period, and all were measured during the endpoint assessment. In total, 1196 patients were analyzed. Apart from the large range of sample sizes (12–210)

Summaries of Included Studies

The study results from 13 journals, show that progressive muscle relaxation not only reduces anxiety in patients, but also increases self efficacy (7), decreases depression (6,7,13), reduces stress (1), stabilizes blood pressure and nadi (6), increases the pain threshold (1). And in our opinion, the best time given for performing PMR is 2 times a day 5-6 times a week for 2 weeks because anxiety scores mean a steady decline from 6.76 at the pretest to 3.0 ($t = 25{,}068$, $P \leq 0.001$) in the post test and 1.12 ($t = 22{,}679$, $P \leq 0{,}001$) at follow-up (4)

4. DISCUSSION

The purpose of this systematic review is to find out the benefits of progressive muscle relaxation related to reducing anxiety experienced by patients. The review revealed the limited research available in this field of study, which identified only thirteen relevant studies.

Anxiety is an individual's response to an unpleasant situation and is experienced by all living things in everyday life. Based on the concept of psychoneuroimmunology anxiety is a stressor that can reduce the body's immune system. This happens through a series of actions mediated by the HPA-axis (Hypothalamus, Pituitary and Adrenal) (17–19). Stress will stimulate the hypothalamus to increase the production of CRF (Corticotropin Releasing Factor). This CRF will then stimulate the anterior pituitary gland to increase ACTH production (Adreno Cortico Tropin Hormone). This hormone will stimulate the adrenal cortex to increase cortisol secretion. Cortisol is what will then suppress the body's immune system (20)

Progressive Muscle Relaxation (PMR) is a movement that tightens and relaxes the muscles consciously in one part of the body at a time to provide a feeling of physical relaxation. Progressive progression of tightening and relaxing muscles is carried out in a row, Progressive Muscle Relaxation pioneered Edmund Jacobson, a doctor from America in the early 1920s. (4,21)

Two of the studies included concerning patients with breast cancer (13,15), while others varied in the types of diseases that we often encounter in the community. The study conducted by Andreas had the highest number of participants with 210 but no known ratio of numbers between women and men, while with participants were only 12 people (16) So there are some potential limitations associated with this systematic review. Some studies do not know the comparison of the number of respondents, the ideal time for the duration of the intervention there is no specific standard, thus inhibiting generalization and comparing results.

5. LIMITATIONS

There are several potential limitations associated with this systematic review. Some studies do not know the number of respondents compared, the ideal time for giving an intervention there is no specific standard, thus inhibiting generalization and comparing results.

6. CONCLUSIONS

The results found that PMR is able to overcome the anxiety experienced by patients, and there are many other benefits. However, there is still no specific standard about how long PMR should be given to patients and how often it should be done. This technique is worthy of further investigation in the context of randomized controlled trials.

ABSTRACT:

Poor asthma control and exacerbation of asthma will lead airway remodeling and decerase pulmonary function. Non-pharmacological therapies such as breathing exercises and physical exercise can be applied for increasing asthma control and pulmonary function . Buteyko breathing technique is one of breathing exercises for asthma patients that use breath-holding techniques and nasal breathing. The aim of this study was to examine the effectiveness and safety of Buteyko breathing techniques in asthma patients by systematic review and with the PRISMA guidelines. Database Search Scopus, PubMed, Proquest, and Science Direct in the range 1998-2018 by using keywords Buteyko and asthma. The research method used in this study (1) randomized controled trial (2) quasi experimental. Eleven articles reported that Buteyko breathing technique significantly increased FEV1, PEFR, FVC, asthma control, control pause, quality of life of adult asthma patients. Buteyko breathing technique also reduces dipsneu, asthma symptoms, bronchodilator use, and inhaled corticosteroids use. Buteyko breathing technique can be used as one of the effective and safe breathing training methods on adult asthma patients

Keywords: *Buteyko, asthma*

1. Introduction

Asthma is a chronic respiratory disease that attacks all age groups, especially children [1]. Chronic respiratory disease is a major public health problem and it will remain a challenge for the future. However, this disease still receives minimal attention and care. Asthma management can be carried out both pharmacologically and non-pharmacologically. The goal of long-term asthma management is to achieve asthma control. Asthma control is needed to minimize the risk of exacerbation so then the asthma patients can carry out their activities optimally in their daily lives [1]. Poor control asthma can reduce the quality of life of asthma patients [1]. Poor control asthma and the exacerbation of asthma will lead to airway remodeling and decreased pulmonary function [2]. Decreased pulmonary function in asthma patients is caused by airway obstruction and the weakness of the respiratory muscles as a result of frequent inflammatory processes, dypsneu and the presence of obstacles in activity [3].

Non-pharmacological management was developed for completing the pharmacological methods in order to improve asthma control [4]. Non-pharmacological management can be done

through physical activity and breathing exercises [1]. The recommended breathing exercise for asthma is Buteyko [5]. The prevalence of asthma in the world is estimated to be 334 million people of all ages (Phillips, 2014); an estimated 235 million people live with asthma and in countries with a middle to lower income, around 80% of deaths are associated with asthma (WHO, 2018). In 2025, the prevalence of asthma in the world is estimated to reach 400 million people [8]. Research in the Asia Pacific shows that poor asthma control is at 21%, asthma that is not well controlled is at 59% and 33% of respondents revealed that their asthma symptoms appear at night, early in the morning or for more that a week [9]. Poor control of asthma is due to the type of asthma, co-morbidity, a lack of education by the health workers, a lack of regular monitoring of their asthma, a lack of control of the precipitating factors, poor adherence to treatment programs and a lack of regulating a healthy lifestyle such as smoking and a lack of physical activity and exercise [10]. Low physical activity can increase the prevalence of asthma due to decreased asthma control [11]. Asthma patients who do not do breathing exercises regularly can aggravate the symptom of shortness of breath when they are having an asthma attack because the patients do not know the correct breathing technique to use. This can cause a ventilation-perfusion imbalance in the lungs. Breathing training and physical activity or exercises that are not carried out by asthmatic patients have an impact on the weakness of the respiratory muscles so then there is a decrease in lung function. In addition to respiratory disorders and the symptoms of shortness of breath, their tolerance to activity decreases. One breathing technique can be done is Buteyko. The advantages of the Buteyko breathing technique include the control pause which can reduce excessive CO2 expenditure which will regulate breathing through the medulla respiratory center, producing nitric oxide (NO) which has bronchodilating effects. This reduces the breathing volume using a combination of increased abdominal muscles and the relaxation of the respiratory accessory muscles. Breathing length can restore the exchange of carbon dioxide, accompanied cerebral vasodilation as a result of an increase in oxygen and excessive CO2 expenditure [12].

The aim of this systematic review was to assess the effectiveness and safety of the Buteyko breathing technique in adult asthma patients.

2. Methods

2.1 Design

The design of this study was a systematic review of quantitative study approaches formulated to review the relevant experimental studies and to conduct comprehensive analysis. This systematic goal was developed based on the PICO (Patient, Intervention, Comparison, and Outcome) framework [13]. The systematic reporting structure used PRISMA (Preferred Reporting Items for Systematic Reviews and Meta Analysis)[14].

2.2 Inclusion and Exclusion Criteria

This systematic review established inclusion and exclusion criteria that focus on experimental studies that use a randomized controlled trial and quasi-experimental design. A feasibility study was used to describe the effectiveness and safety of implementing the Buteyko breathing technique in asthmatic patients using the language eligibility criteria with English abstracts. The year of publication was limited to the last 20 years, between 1998 and 2018. The criteria for the inclusion group were studies with adult asthma patients and the exclusion criteria were children and smokers, asthma patients who

were obese, asthma in pregnancy, having other lung diseases such as pulmonary TB, COPD, pulmonary carcinoma, hypertension, heart failure, epilepsy and musculoskeletal disorders.

2.3 Search Strategy

The systematic search of the PICO electronic data framework was carried out according to the PICO framework (Xiaoli Huang., Jimmy Lin., 2006). In the first step, we looked on the electronic databases of Scopus, Pubmed, Proquest and ScienceDirect to identify key articles and to identify the keywords by adjusting the key concepts: 1. Asthma patients, 2. Buteyko breathing technique and 3. Experimental studies. Our keywords were used to look for quotes and full articles, including the title, abstract, text and reference information. The second step was translating keywords into English to find the relevant articles in the electronic databases. The third step was filtering using the PICO framework to determine which articles passed for further review according to the topic. The complete search strategy was limited to the last 20 years between 1998 and 2018.

Table 1. Eligibility Criteria

Criteria	Inclusion	Exclusion
Study Design	Quantitative Approach Experimental Study	Qualitative Approach
Concept	Buteyko breathing technique	Yoga, gym, etc
Population	Asthma patient	Asthma with obesity, pregnant, another lung disease, heart disease, musculoskeletal disorder
Context	Adult asthma	Children
Language	English (*min. Abstract)	Full text without Abstract on English
Date range	≥ 1998- 2018/	< 1998

2.4 Quality Of Appraisal

The assessment of the quality of the articles to be reviewed was done using the quantitative study tool, the Critical Appraisal Skills Program (CASP). There were 10 different questions that considered the results of the qualitative studies, the validity of the studies and their uses (Critical Appraisal Skills Program, 2018).

3. Result

3.1 Study Selection

The search strategy was carried out by generating a total of 471 citations, of which the researcher deleted 217 duplicates. Following this, 210 items of existing literature were deleted during the first

screening because the title and/or abstract did not match the specified eligibility criteria; 33 full articles from the second phase of screening resulted in 11 articles being obtained for review.

3.2 Study Characteristics

The total of 11 studies reviewed from 2008 - 2018 were conducted in 7 countries: the UK, Egypt, India, Canada, New Zealand, Australia and the Philippines. The experimental studies included were randomized controlled trials and quasi-experimental.

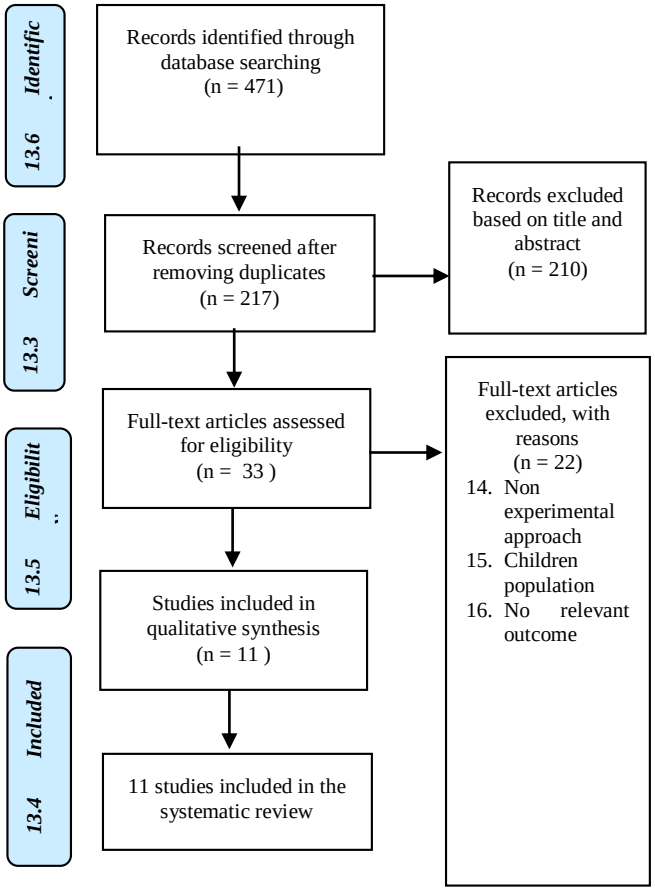

Figure 1. Flow Diagram

3.3 Result of Synthesis

The literature search identified 11 journals that explain the Buteyko breathing technique for asthma patients. Finally, the 2 main themes of the findings of the synthesis were summarized: Buteyko technique theory and Buteyko breathing technique

Buteyko Theory. The Buteyko breathing technique is a complementary therapy used to help asthmatics to prevent and control their asthma symptoms and to reduce or eliminate drug use[15]. The Buteyko breathing technique is a series of breathing exercises which consist of slow breathing and reduced breathing, combined with the time spent holding your breath, known as control pauses and extended pauses. These aim to reduce hyperventilation through a decreased frequency of breathing (Buteyko Technique - Buteyko Breathing Association, 2017).

The aim of the Buteyko breathing technique is to train patients who breathe excessively to be able to breathe properly. The Buteyko technique can also restore the patient's condition so then he can

breathe normally by exercising his breath, by breathing through the nose and by relaxing the diaphragm to achieve a normal breathing volume.

There is a theory underlying the development of the Buteyko breathing technique (Buteyko Technique - Buteyko Breathing Association, 2017). When asthma patients practise deep breathing, the amount of CO2 released will increase so the amount of CO2 in the lungs, blood and tissues becomes reduced. When asthma patients breathe too much air volume compared to what the body needs, the CO2 that comes out will also increase rapidly. This causes a chemical reaction that complicates the release of oxygen from the blood to the tissues of the body so then the tissue becomes deprived of oxygen. This results in the muscle layer surrounding the tissue reacting by contraction. CO2 deficiency causes the blood pH to become alkaline. Respiratory alkalosis is a clinical disorder that causes an increase in blood acidity (pH) due to alveolar hyperventilation (hypocapnia). Hypocapnia occurs because the elimination of CO2 exceeds the production of CO2 in the tissue. The increased pH is modified to a small degree by intracellular buffers. To compensate for the increased loss of CO2 and excess base, hydrogen ions are released from the buffer tissue, which further decreases the plasma bicarbonate concentration.

Buteyko Breathing Technique. The Buteyko breathing technique consists of relaxation and exercise. At the stage of relaxation, the body posture is as comfortable as possible, especially the upper body. This serves to relax the respiratory muscles and ribs slowly, namely when stretching the ribs outward during inhalation and the withdrawal of ribs inward during expiration. When practicing breathing exercises with asthma patients, it is recommended to breathe through the nose and not through the mouth (Buteyko Technique - Buteyko Breathing Association, 2017).

According to Buteyko theory, breathing through the nose will reduce the release of CO2. By relaxing the breathing muscles, the air insufficiency that occurs during the attack will decrease. In doing the Buteyko breathing technique, a chair and a room are as comfortable as possible for practice. It is best to do the exercises before eating or to wait at least 2 hours after eating. This is because digestion affects breathing. The important things that must be considered in carrying out Buteyko breathing techniques are:

1. Measurement of control pause

In doing Buteyko breathing exercises, first the ability to hold the breath (control pause) must be measured. After completing the exercise, the measurement of the control pause and pulse must be done again.

2. Posture

Good posture is very important to do the exercises properly, which can reduce shortness of breath when attacked by asthma. Using a chair that has a backrest allows them to sit upright and for their feet to touch the floor. This means that the body is in a condition that is as comfortable as possible. If you do not have a chair with a backrest, then the position of the head, shoulders and hips should be adjusted so then it is perpendicular.

3. Concentration

Focus on breathing, feel the air moving in and out of the nose and the different movements of the body when breathing and exhaling. The individual is recommended to concentrate on their breathing, because a person cannot change their breathing if they are not aware of how they breathe.

4. Shoulder relaxation

The shoulder is an important part in the effort to improve breathing in the event of tension and stiffness, which can cause difficulty in trying to raise the shoulder muscles when breathing, which affects the amount of air able to go into the lungs. The patients should try to be as relaxed as possible and let their shoulders relax and move naturally every time they breathe. Relaxation will help to regulate their breathing.

5. Monitor airflow

Feel the air coming out of the nostrils by placing a finger under the nose horizontally. The fingers should not be too close to the nostrils because this can interfere with the flow of air entering and leaving the nose. Shallow breathing is when you feel the air reaching your fingers. Start breathing again. This will help to reduce the amount of air each time that you breathe. This activity will increase the amount of breath carried out per minute which aims to reduce the volume of air overall. The warmer air that is felt less on the finger indicates that the successful decrease in air volume. Patients are expected to be able to continue breathing this way for 3-5 minutes. It is possible that the patient cannot complete the full 5 minutes when they first exercise.

Procedure [17]:

Step 1 – Beginning Control Pause (CP)

Step 2 –3 to 5 minutes of relaxed reduced-volume breathing or slow breathing

Step 3 – Maximum Pause (MP). The MP may be substituted with a CP if the MP is contraindicated due to the presence of kidney disease, epilepsy, hypertension or another severe chronic illness

Steps 2 and 3 were then repeated up to 5 times

Final control pause

4. Discussion

The Buteyko breathing technique helps to reduce the degree of dyspneu and it increases FEV1 and PEFR ($p = 0.001$) [18], which is supported by Grover (2014) and Mohamed, Riad and Ahmed (2013). The research conducted by Grover (2014) shows that the Buteyko technique also increased FVC. The Buteyko group showed an increase in quality of life and asthma control compared to the control group [20]. The effects of the Buteyko technique on asthma control are also supported by the previous research (Cowie *et al.*, (2008) and Mohamed, Riad and Ahmed (2013). Buteyko therapy can reduce both asthma symptoms ($p = 0.003$) and bronchodilator use ($p = 0.005$). There was no difference in FEV-isolation and the use of inhaled corticosteroids in both groups [15]. The results of the research conducted by [21] proves that the Buteyko Technique can improve asthma control from 40% to 79%, thus reducing the need for inhaled corticosteroids ($p = 0.02$).

The research conducted by Grover (2014) showed that the Buteyko breathing technique can increase FEV1, FEV1 / FVC and Peak Forced Expiration Flow through a control pause mechanism that can, in turn, increase the CO2 concentration. This will regulate the breathing through the medulla respiratory center, producing nitric oxide (NO) and a bronchodilating effect, reducing the breathing volume using a combination of increased abdominal muscle and the relaxation of the respiratory accessory muscles. A long breath can restore the exchange of carbon dioxide gas, followed by cerebral vasodilation as a result of the decreased oxygen and increased CO2 [12].

The research conducted by Mohamed, Riad and Ahmed (2013) showed that the Buteyko breathing technique can increase the peak flow of forced expiration, control pause and asthma control. The main cause of bronchospasms in asthma is a CO2 deficiency in the alveolar air, which results from hyperventilation and low metabolic activity. It can thus be concluded that hyperventilation is the main element in the etiology and pathogenesis of asthma (Mohamed, Riad and Ahmed, 2013).

The research conducted by Cooper et al. (2003) shows that the Buteyko breathing technique can reduce bronchodilator use but there was no difference with the Pranayama group in terms of bronchial responsiveness and pulmonary function through the mechanism of holding the breath at functional residual capacity and mouth-tapping at night. This refers to sleeping on the left side and preventing supine sleep because this can cause hyperventilation. Both of these techniques will increase the pressure of the arterial and alveolar CO2 [15]. Research conducted by Slader et al. (2006) and Villareal et al., (2014) showed that the Buteyko technique can improve asthma control and the quality of life of asthmatic patients through a normal breath blowing mechanism, where they breathe and then hold their breath until they first feel uncomfortable or want to breathe again. This time was recorded as a control pause. In healthy people, it can reach 50-60 seconds but in moderate to severe asthma sufferers, it often can only last for 1-3 seconds. Then this was followed by breathing slowly and not through the nose, which is shallow breathing. Then they proceeded with physical activity to increase the level of CO2. Increased CO2 will cause the dilatation of smooth muscles in the bronchial wall, bronchioles and alveolar so then perfusion ventilation balance occurs [20]. The Buteyko technique also teaches breathing through the nose because it will be able to bring in benefits such as filtering the air of allergens and dust pollution, humidification and producing nitric oxide which will promote airway bronchodilation. Research conducted by [21] showed that the Buteyko breathing technique can reduce the use of inhaled corticosteroid therapy.

Bowler et al, (1998) carried out a study of 39 patients. The patients were divided into two groups. One group was taught the Buteyko breathing technique and the control group was taught a course of asthma education, relaxation and diaphragmatic exercise. The study looked at the outcomes of medication use, quality of life, respiratory function and CO2. The results showed that those who were taught the Buteyko technique reduced their use of bronchodilators by about 90% in 12 weeks compared with 5% in the control group. The reduction in medication use was not associated with a reduction in quality of life. Lung function was unchanged in both groups. The study by McHugh et al., (2003) had the aim of assessing the impact of BBT on medication use in asthma. It followed 38 subjects over a 6-month period and found similar results to the first trial with an 85% decrease in bronchodilator use. The trial was run over a longer period for 6 months and this longer period was also able to demonstrate a 50% decrease in steroid use. The researchers concluded that Buteyko breathing therapy appears to represent a safe, efficacious alternative for the management of asthma. A general practice-based study by Opat et al., (2000), also conducted in Australia, randomized 36 adults with asthma and assigned them to watch either a Buteyko video or a nature video twice a day for 4 weeks. After 8 weeks, those who had watched the Buteyko video had reduced their use of bronchodilators by 60%. Both groups showed a significant improvement in their quality of life [21].

5. Conclusions

The Buteyko breathing technique significantly increases FEV1, PEFR, FVC, the control of asthma, control pauses and breath resistance and, overall, the quality of life of adult asthma patients. The Buteyko breathing technique also reduces the degree of dyspnoea, asthma symptoms, bronchodilator use and inhaled corticosteroids.

Diaphragm breathing and Pursed Lip Breathing: 5 repetitions twice/day, 6 days/week,6 weeks Spirometer	Group - Buteyko Breathing Technique (BBT) group-A showed a significant improvement in FEV1 and PEFR and a significant decrease in the levels of dyspnea, whereas PLBE within DE Group - B showed no significant changes in any of the three measurements. FEV1, PEFR (p= 0.001)
2	Comparison of the effects of Buteyko and pranayama breathing techniques on quality of life ; a randomized controlled trial - in patients with asthma Venkatesan Prem, Ramesh Chandra Sahoo and Prabha Adhikari (2012)	RCT	120 (18-60 years old) Group 1 : BBT (40) Group 2 : Pranayama Breathing(40) Group 3 : Control (40)	Independent variable: Buteyko Breathing Technique (BBT), Pranayama breathing . Dependent variable : Asthma Quality of Life, Asthma Control, pulmonary function test. (FEV1, FEV1/FVC)	Buteyko Breathing Technique (15 minutes/twice/ day for 3 months) Pranayama Breathing (15 minutes/2 times/day for 3 months) Spirometer Asthma Quality of Life Questionnaire Asthma Control Questionnaire	The Buteyko group showed better improvement trends (mean (95% confidence interval), P-value) in total. The Asthma Quality of Life Questionnaire score was better than the pranayama (0.47 (–0.008–0.95), P = 0.056) and control groups (0.97 (0.48–1.46), P = 0.0001). In comparison, between the pranayama and control groups, pranayama showed a significant improvement

						(0.50 (0.01–0.98), P = 0.042) in the total Asthma Quality of Life Questionnaire score.
3	Effect of two breathing exercise(Buteyko and Pranayama) ini asthma : a randomized control trial S Cooper, et al (2003)	RCT	90 (18-70 years old) BBT (30) Group 2 : Pranayama Breathing/PCLE (30) Group 3 : Control (30)	Independent variable: Buteyko Breathing Technique (BBT), Pranayama breathing/Pink City Lung Exerciser Dependent variable : Bronchodilator use, FEV1, asthma symptom	Buteyko Breathing Technique (twice/week for 6 weeks) Pranayama Breathing ((/2 times/week for 6 weeks)	The symptoms remained relatively stable in the PCLE and placebo groups but they were reduced in the Buteyko group. The median change in symptom scores at 6 months was 0 (interquartile range –1 to 1) in the placebo group, –1 (–2 to 0.75) in the PCLE group and –3 (–4 to 0) in the Buteyko group (p=0.003 for difference between groups). Bronchodilator use was reduced in the Buteyko group by 2 puffs/day at 6 months; there was no change in the other two groups (p=0.005). No difference was seen between the groups in terms of FEV1, exacerbations or the ability to reduce inhaled corticosteroids.
4	Effect of Buteyko breathing Technique on patient with bronchial	Quasi experimental	40 (30-50 years old) Group 1: Buteyko Breathing	Independent variable: Buteyko Breathing Technique (BBT),	Buteyko Breathing Technique 1st week: 4 times/week Weeks 2-6:	The study revealed there to be a significant decrease in asthma daily symptoms, a

	asthma Hasssan, et al (2012)		Technique. Group 2: control	Dependent variable : PEFR, asthma control	twice/week Peak flow meter	significant improvement in PEFR and the control pause test in group (A), while there were insignificant changes in group (B).
5	A randomised controlled trial of the Buteyko technique as an adjunct to conventional management of asthma Cowie, et al (2008)	RCT	129 (18-50 years old) Group 1: Buteyko (65) Group 2: Control (64)	Independent variable: Buteyko Breathing Technique (BBT). Dependent variable: asthma control, inhaled corticosteroid use	Buteyko Breathing Technique for 6 weeks Asthma control according to the Canadian Asthma Consensus	In the Buteyko group, the proportion with asthma control increased from 40% to 79% and in the control group, this increased from 44% to 72%. In addition, the Buteyko group significantly reduced their inhaled corticosteroid therapy compared with the control group (p ¼ 0.02). None of the other differences between the groups at 6 months were significant.
6	Effect of Buteyko method on asthma control and quality of life of Filipino Adults with bronchial asthma Villareal, et al (2014)	Quasi eksperi mental with approac hpretest-post test design	Sample: 16 adults with bronchial asthma (18-40 years old) Group 1: Buteyko Breathing Technique (BBT) Group 2: control	Independent variable: Buteyko Breathing Technique (BBT). Dependent variable: asthma control, quality of life	Buteyko Breathing Technique 3 times/day for 30 minutea every session for 4 weeks Asthma Quality of Life Questionnaire Asthma Control Questionnaire	The experimental group showed a significant improvement in the asthma control (p=0.029) and quality of life scores (p=0.006) after the 4 week period.
7	To study the effectiveness of buteyko	Quasi eksperi mental	46 (20-65 years old) Group A:	Independent variable: Buteyko	The duration of data collection was 6 months.	The results were calculated using a 0.05 level of

	breathing technique versus diagragmatic breathing in asthmatic Afle &Grover (2014)	dengan one gropu pre-test-post test design	Buteyko Breathing (23) Group B : Diaphragm breathing (23)	Breathing Technique (BBT)., Dependent variables: FEV1, FEV, FVC, PEFR	The time of the study was for 2 weeks. The duration of each treatment session was 60-90 minutes. Spirometry	significance. On the basis of the above statistical analysis, the p value for group A is less than 0.05. The intervention for group A was more effective than the intervention for group B.
8	Double blind randomised controlled trial of two different breathing techniques in the management of asthma Slader, et al (2006)	Double blind randomised controlled trial	57 (15-80 years old) Group 1: Buteyko Breathing Group 2: non-specific upper body exercise	Independent variable: Buteyko Breathing Technique (BBT), non-specific upper body exercise. Dependent variable: asthma control, quality of life, inhaled corticosteroid use.	Buteyko Breathing Technique (BBT), non-specific upper body exercise twice/day, 30 minutes every session for 30 weeks Asthma Quality of Life Questionnaire Asthma Control Questionnaire	Overall the QoL score remained unchanged (0.7 at baseline v 0.5 at week 28, p = 0.11 both groups combined), as did lung function and airway responsiveness. However, across both groups, reliever use decreased by 86% (p,0.0001) and ICS dose was reduced by 50% (p,0.0001; p.0.10 between groups).
9	Buteyko breathing techniques in asthma: a blinded randomised controlled trial Bowler, et al (1998)	Blinded randomized control trial	Sample: 39 pasien asma (12-70 tahun) Group 1: Buteyko Breathing Technique. Group 2: control	Independent variable: Buteyko Breathing Technique. Dependent variable: Medication use; PEF); forced expiratory volume in one second (FEV1); end-tidal (ET) CO2; resting minute volume (MV) and quality of life (QOL) score	Buteyko Breathing Technique once/day for 12 weeks Asthma Quality of Life Questionnaire Spitometry	No change in daily PEF or FEV1 was noted in either group. At three months, the BBT group had a median reduction in daily beta2-agonist dose of 904 (*P* = 0.002). Daily inhaled steroid dose fell By 49% (*P* = 0.06). A trend towards a greater improvement in the QOL score was noted for the BBT

						subjects (*P* = 0.09).
10	Buteyko Breathing Technique for asthma: an effective intervention McHugh, et al (2003)	Quasi-experimental	38 (18-70 years old) Group 1: Buteyko Breathing Technique Group 2: Control	Independent variable: Buteyko Breathing Technique. Dependent variable:: Beta 2 agonis use, ICS use, FEV1	Buteyko Breathing Technique for 6 weeks	No significant change in FEV1 in either group. The BBT group exhibited a reduction in inhaled steroid use by 50% and 2-agonist use by 85% 6 months from the baseline.
11	A Clinical Trial of the Buteyko Technique in Asthma as Taught Breathing by a Video Opat, et al (2000)	Quasi-experimental	36 (18-50) Group 1: Buteyko Breathing Technique. Group 2: Control (placebo)	Independent variable: Buteyko Breathing Technique. Dependent variables: Quality of life PEF, inhaled bronchodilator use	Twice/day for 4 weeks	Those assigned to BBT compared with the placebo had a p value of *p* = 0.0431, as well as a significant reduction in inhaled bronchodilator intake *(p* = 0.008).

[3]Faculty of Nursing and Midwifery Nahdlatul Ulama University, Surabaya, East Java, Indonesia
E-mail: nurul.hidayah-2017@fkp.unair.ac.id

ABSTRACT

Fluid restriction is become a major problem on clients undergoing hemodialysis with a percentage of nonadherence ranging from 10%-60%. Low adherence causes complications such as heart disease, cognitive function disorders, increased hospitalization and mortality. Interventions that can improve the adherence of fluid restriction in clients undergoing hemodialysis still need to be studied. The aims of this study was to evaluate and conclude the most effective interventions to increasing the adherence of fluid restriction in clients undergoing hemodialysis. Using electronic database including Scopus, ProQuest, and SpringerLink, limited year used 2009-2019, combining intervention, improve, adherence, fluid, restriction, hemodialysis as the search keywords 257 articles retrieved. Using matching keyword 15 articles determined to be systematic review. Psychosocial Interventions are the most frequently used and effective interventions to increase the adherence of fluid restriction in clients with hemodialysis. Psychosocial interventions including cognitive behavioral therapy, empowerment, motivation, communication and approaches through group support (health workers and the environment) have an impact on reducing stress, and improve the quality of life, so clients to be more adherence with treatments in hemodialysis programs. Psychosocial interventions are effective as interventions to improve adherence of fluid restriction in clients undergoing hemodialysis.

Keywords: intervention, improve, adherence, fluid, restriction, hemodialysis

1. Introduction

Chronic Kidney Disease (CKD) has become a major health problem in the world and it causes high morbidity and mortality and it constitutes a significant social and financial burden. (1). CKD patients with End Stage Renal Disease (ESRD) require renal replacement therapy *[2]*. Hemodialysis is the most common renal replacement therapy provided to patients with CKD (3). Patients undergoing hemodialysis must undergo significant adaptations related to fluid restriction, diet and drug dependence as well as psychosocial adaptations [4]. Fluid restriction is still a major problem in the care of CKD patients undergoing hemodialysis programs [5]. The comprehensive and collaborative effort of all health care teams with the main focus of care being the patients and their support system will be very necessary. The interventions that can increase the fluid intake restrictions in the CKD patients undergoing hemodialysis still need to be learned.

Rates of no adherence in hemodialysis therapy regimens around the world range from 8.5% - 22.1% and this rate has increased to 86.9%. The non-adherence to the fluid restriction ranges from 10 - 60% (6). In Japan and Europe, the non-adherence to the fluid restrictions increased from 9.7%

to 49.5%. CKD patients who are undergoing hemodialysis programs have increased in their rate of morbidity and mortality caused by the non-adherence to the fluid restrictions. Low adherence can lead to complications such as heart disease, cognitive dysfunction, increased hospitalization and mortality [7]. The negative effects of the non-adherence to the fluid restrictions mentioned above are a serious problem, so interventions to improve the adherence to the fluid restrictions need to be studied and developed.

The results of the previous studies showed that there was a significant effect from increasing the fluid adherence with the average change score during treatment [8]. There was a significant increase in the post-test score in the intervention group compared with the pre-test score after education related to the adherence of fluid restriction was carried out [3]. Results in other research also stated that after introducing communication solutions focused on fluid adherence, the average interdialytic weight gain of the patients decreased significantly, below the level that was considered to be an indication of adherence [9]. The results of the studies mentioned above inspired the researchers to evaluate the interventions used to improve the adherence of the CKD patients to the fluid restrictions when undergoing hemodialysis programs.

The purpose of this systematic review was to summarize the interventions that have been used effectively to improve the adherence of fluid restriction in hemodialysis patients so then it can provide meaningful information to both hemodialysis facilitators and clinical researchers.

2. Methods

The systematic review source search used electronic databases including Scopus, Proquest and Springer Link, with the limited year range used being 2009 - 2019 (10 years). The source search used the appropriate keywords (intervention, improve, adherence, fluid, restriction, hemodialysis) that were contained in the PICO framework [10] as shown in Table 1. This systematic reporting structure used PRISMA (*Preferred Reporting Items for Systematic Reviews and Meta-Analysis*), as shown in Figure 1. Based on the search results, 257 articles were retrieved and then 15 articles were finally selected to do the systematic review.

The systematic search of the PICO base of the electronic data framework was carried out in accordance with the PICO framework (Xiaoli Huang., Jimmy Lin., 2006). The first step as where we looked through the Scopus, Proquest and Springer Link electronic databases to identify key articles and to identify the keywords by adjusting the key concepts: 1. interventions to improve adherence, 2. patients undergoing hemodialysis and 3. fluid restrictions. Our keywords were used to look for citations and full articles, including the title, abstract, text and reference information. The second step was translating the keywords into English to find the relevant articles in the electronic databases. The third step was to filter using the PICO framework to determine which articles passed for further review according to the topic.

This systematic review established inclusion and exclusion criteria that focus on the interventions that can improve the adherence to fluid restrictions in hemodialysis patients including the language eligibility criteria of using English. The year of publication was limited to the last 10 years from 2009 - 2019. Further criteria for the inclusion group were studies in adult hemodialysis patients and the exclusion criteria were that they were peritoneal dialysis patients or child hemodialysis patients.

3. Result

The search strategy was carried out to obtain a total of 273 articles. The researcher deleted 253 articles because the title and abstract did not match the specified eligibility criteria. Of the 20 articles obtained, 5 articles were omitted due to duplication so 15 articles on the interventions used to improve the adherence to the fluid restrictions in hemodialysis patients were maintained for review.

The total of 15 studies reviewed from 2009 - 2019 were conducted in 8 countries: the USA, Iran, Turkey, Spain, Greece, China, Sweden and Lebanon. The overall research method was a quantitative study including educational, psychological, social, e-health and relaxation therapy interventions. Almost all of the articles used questionnaires in accordance with the theoretical constructs as instruments to measure the level of adherence of the patients undergoing hemodialysis programs in terms of fluid restriction. In addition, the adherence to the fluid restrictions of the patients undergoing hemodialysis can also be seen from the biological marker and the patient's IDWG (*Interdialytic Weight Gain*).

Tabel 1. PICO Strategy

	Keywords
P	CKD patients or hemodialysis patients
I	Hemodialysis
O	Improve adherence to the fluid restrictions

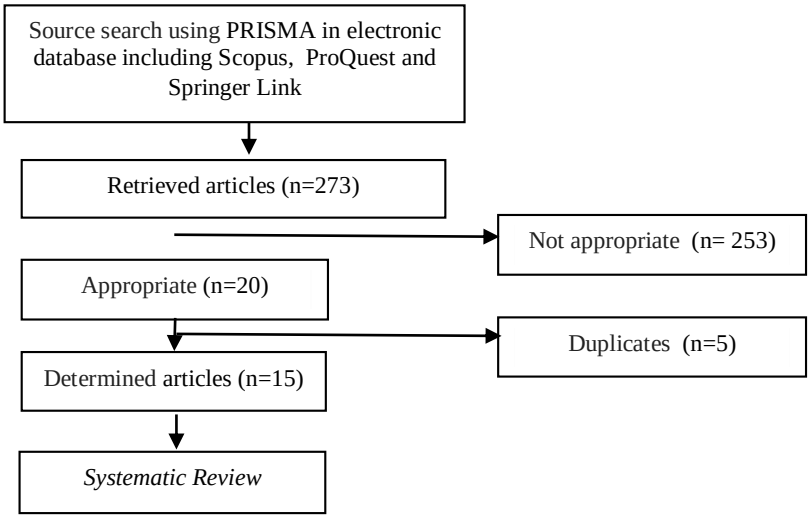

Figure 1. PICO strategy and the PRISMA source search in the electronic databases

The number of samples ranged from 17 to 237 patients undergoing hemodialysis. In the 15 articles, the respondents were around 18 - 65 years old and they had experienced being on the hemodialysis program for more than 3 months.

The interventions used to improve the adherence to the fluid restrictions in patients undergoing

hemodialysis found in 15 articles were educational interventions (education in a face to face meeting and video conference education), a psychological intervention, social approaches (social support and group support), e-health and relaxation therapy. Psychosocial interventions including cognitive behavioral therapy, empowerment, motivation, communication and social approaches through group support (health workers and the environment) were the most frequently used and these are as effective as interventions used to increase the adherence to the fluid restrictions in patients with hemodialysis.

Low adherence can result in complications such as heart disease, cognitive function disorders, increased hospitalization and mortality [7]. The negative effects of no adherence to the fluid intake mentioned above are immediate problems that must be followed up with efforts to improve the adherence to fluid restrictions.

The results of the study that was conducted stated that after being educated, there was a significant increase in the post-test score in the intervention group compared to the pre-test score, with a significance value ($p < 0.05$ and $p < 0.001$). Pre-dialysis weight and diastolic blood pressure were also reported to decrease significantly [3]. Level of knowledge is one of the factors that influences the adherence to fluid restrictions and the diet of the patients undergoing hemodialysis [3]. The existence of directed education regarding the fluid restriction for the patients is expected to increase the level of knowledge of the patients. This is so then the patients can understand the condition of their disease and try to adhere to the treatment. Research that was conducted by [11] said that there was a significantly increased level of knowledge, adherence and quality of life in the intervention group compared to the control group. Adherence is also reported to positively affect several dimensions in the quality of life intervention through education. This can help the patients to improve their diet and fluid management knowledge [12].

Based on the results of the studies[8][13][9][3], there is a significant effect from Cognitive Behavior Therapy (CBT) on increasing adherence to fluid restrictions [8]. The results of another study said that there was a significant positive effect from Behavioral Self-Regulation on interdialytic weight over time observed for the intervention group which showed the benefits of the intervention [5]. The systolic / diastolic blood pressure, interdialytic weight gain, hemoglobin and hematocrit levels differed and changed significantly between the groups before and after empowerment via the self efficacy intervention [14]. Significantly higher levels of adherence, lower levels of depression and anxiety and a better Health-Related Quality of Life (HRQL) score came after the Motivational Interviewing intervention [15]. The research that used Rational Emotive Therapy showed that it can effectively change the coping mode and mental state of the patient and then increase their adherence to fluid restrictions [13].

The results of the research report after introducing a Focused Communication Solution by the nurses showed that the average interdialytic weight gain of patients decreased significantly to below the level considered to be an indication of no adherence [9]. Social support also has a significant relationship with dietary adherence and the patient's fluid restriction within hemodialysis [16]. Support from a subgroup of patients is very clinically relevant to the adherence of fluid control of the patients undergoing hemodialysis programs [17].

The results of the studies that involved e-health showed that computer literacy applications can assess the ability to complete Personal Digital Assistant (PDA) tasks. This application was very helpful for individuals to use to monitor their own diet and fluid intake [18].

Previous studies have reported that after relaxation with the Benson relaxation method through the audiotape media, there was a significant difference in IDWG that showed the adherence to fluid restriction [19].

4. Discussion

After reviewing several articles, it can be seen that psychosocial interventions are the most frequently used and effective interventions that can increase the adherence to fluid restrictions in patients with hemodialysis. Fluid retention can cause dangerous conditions for patients such as edema of the lower extremities, pulmonary edema, hypertension and cardiovascular disorders. Therefore fluid management (restriction) appears to be important in CKD patients.

Psychosocial interventions including cognitive behavioral therapy, empowerment, motivation, communication and approaches through group support (health workers and the environment) have an impact on reducing stress and improving quality of life, so the patients to be more adherent with the treatments that are a part of the hemodialysis programs. Psychosocial interventions focus on how one thinks, behaves and communicates. Psychosocial interventions will help the patients to provide a cognitive assessment in addition to providing guidance on how to make decisions when determining a choice from the process of thinking independently. This will teach the patients to learn skills that are effective in terms of thinking, feeling, and behaving, thus their adherence to therapy will be more rational.

This study has several limitations, including the diversity of the psychosocial interventions found. It has not been focused on one intervention. The relatively long time for implementing the interventions is because it is related to behavior changes. The number of synthesized articles was also a limitation of this study.

5. Findings

Psychosocial interventions (cognitive behavioral therapy, empowerment, motivation, communication and approaches through group support) are effective as interventions to improve the adherence to fluid restrictions in patients undergoing hemodialysis. For the next systematic review, we can use more articles that have been published and more specific types of intervention. Psychosocial interventions can be a reference for improving the adherence to fluid restriction and this can be applied by the nurse or facilitator related to hemodialysis in practice.

E-mail : ramadhanners.sr@gmail.com

ABSTRACT

The purpose of this study to determine the effect of self-management education for compliance fluid intake in clients who undergo hemodialysis. This study used a design approach quasy experiment. Sampling technique used accidental sampling. The sample in this study were 24 peoples, divided into 12 respondents treatment group and the control group of 12 respondents. The treatment group was given self-management education interventions with the media calendar fluid management. The variable in this study were the knowledge, attitudes, actions and IDWG. Data were collected by using questionnaires and observation sheets then analyzed using the Wilcoxon Sign Rank Test with α of 0.05, Paired t test with α of 0.05and Mann Whitney U test with α of 0.05. Result study used 24 respondents showed between the pre and post in the treatment group showed a significant difference for knowledge, action and IDWG, but there was no significant difference for the variables attitude. Results of statistic test Mann Whitney U test showed no difference between the compliance component of the treatment group and the control that knowledge with p = 0.043, p = 0.005 attitudes, actions IDWG p = 0.017 and p = 0.007.

Keywords: self-management education, compliance fluid intake, hemodialysis

1. Introduction

In patients undergoing routine hemodialysis (HD), they often experience excess volume of fluid in the body, this is due to decreased kidney function in secreting fluid. Although CKD patients at the beginning of HD have been given health education to reduce fluid intake for a day, in the next HD therapy, patients often present with complaints of shortness of breath due to excess body fluid volume, namely an increase of more than 5% of the patient's dry weight [1].

The results of interviews with 10 clients who have undergone HD on February 1, 2016 at the Provincial Hospital of NTB, found that 7 clients claimed to not comply with restrictions on fluid intake. Clients do not understand about fluid restrictions, even though they have been given health education. Clients often experience shortness of breath and must undergo HD outside the predetermined schedule. The research conducted by [2] concerning factors related to patient compliance with Chronic Kidney Disease (CKD) undergoing hemodialysis at RSPAU Dr. Esnawan Antariksa Halim Perdana Kusuma Jakarta shows that compliance with CKD patients who undergo HD is influenced by age, education level, duration of CKD.

Limitation of fluid intake in CKD patients aims to prevent the occurrence of cardiovascular edema and complications. The water that enters the body is balanced with the water that comes out, either through urine or IWL. In limiting fluid intake, the fluid entering depends on urine output.

Daily weight is an important parameter monitored, in addition to accurate records of intake and output. The amount of intake is limited according to the amount of urine that is available plus insensible water loss (IWL). If there is excessive fluid intake during the period between dialysis, there will be a large increase in body weight [3]. One way to improve patient adherence in limiting fluid intake is by increasing the patient's understanding of the importance of limiting fluid intake in patients undergoing hemodialysis. Understanding good counseling material can influence the attitude of patients in caring for themselves so that patients are more obedient in limiting fluid intake.

Self-Care Theory by Orem found that humans have the ability to care for themselves (self-care agency). Self-management is the compliance and support partner of individuals in their treatment, knowledge and skills possessed to care for themselves, make decisions about their own care, identify problems, set goals, and monitor and manage symptoms. Self-management includes problem solving skills, decision making in response to signs and symptoms, and taking action, for example learning how to change behavior [4].

Self-care agency can be improved through a nursing agency in which there is a supportive educative system, one of which is through self-management education. In this study, researchers tried to provide education with fluid management calendar media (KPC). The fluid management calendar is a tool to monitor the development of the client's weight during HD. In addition, clients can plan or distribute fluid intake which will be consumed every day according to the doctor's recommendations.

2. Material and methods

2.1. Research design

The design was Quasi-experiment with pre-post test on control and intervention group.

2.2. Population and sample

The population in this research were all hemodialysis patients who experienced an increase of IDWG clients in the hemodialysis room of NTB Province Hospital, as many as 118 respondents and from which 24 respondents were obtained with accidental sampling. This research was conducted at the hemodialysis room of Provincial Hospital NTB on August 12 – October 4, 2016. Inclusion criteria in this research were clients who experienced increase of IDWG >4% and willing to be respondents, while exclusion criteria was clients who can’t read.

2.3. Variables

The independent variable in this study was self-management education. The dependent variable in this study was knowledge, attitudes, actions and IDGW clients undergoing hemodialysis.

2.4. Instruments

The instruments used in data collection were questionnaires of knowledge, attitudes, observation and body weight scale for IDGW.

2.5. Research procedures

In the first week the researcher collected respondents' data and chose respondents according to the criteria set by the researcher so that 24 respondents were obtained and the researcher measured the knowledge, attitudes, actions using questionnaires and IDWG measurements. In the 2nd week to

the 7th week the researchers gave intervention in the intervention group while the control group was not given. In the 8th week the researchers conducted a post test on the respondents.

2.6. Analysis

Data was analyzed by using IBM SPSS Statistic 24. Statistical analysis consists of two stages, namely descriptive and inferential analysis. Descriptive analysis includes the mean and standard deviation. Inferential analysis used Wilcoxon Signed Ranks Test for pre-test and Mann Whitney U Test for post-test to determine the different between the independent and dependent variables of control and intervention group. Confidence interval was 95% with alpha (α) = 0.05.

2.7. Ethical Clearance

This research has passed the ethical review and obtained an Ethical Approval certificate with No. 070.1/ 04/ KEP/ 2016 issued by Research Ethics Committee of NTB Province Hospital.

3. Results

Characteristics of respondents in table 1 showed the majority of respondents' age, both in the treatment group and the control group were in the range of 36-50 years which is equal to 58.3%, the sex in the treatment group respondents and the control group is dominated by men, the last education in the treatment group respondents is a college that is equal to 33.4% and the control group is high school is equal to 50%. The occupation of the treatment group respondents was dominated by the private sector, namely 33.3%, and the control group was dominated by respondents who did not work, namely 33.3%. Most of the respondents in the treatment and control groups had undergone HD <1 year.

Table 1. Characteristics respondents in both of group

Table 2 shows that in the treatment group there was an increase in knowledge scores, it can be seen in the pre-test data which showed that 1 respondent (8.3%) is in the less category, 2 respondents (16.7%) in the sufficient category and 9 respondents (75 %) were in the good category. Post-test data shows that the knowledge score of all respondents (100%) were in the good category after being given SME. While in the control group there is also an increase in the score of knowledge, this can be seen in the pretest data which shows that there was 1 respondent (8.3%) in the less category, 2 respondents (16.7%) in the sufficient category and 9 respondents (75%) in the good category. In the post test data the knowledge score contained 1 respondent (8.3%) in the sufficient category and 11 respondents (91.7%) in the good category.

For the treatment group there was an increase in attitude scores that were not significant, namely the positive category increased by 1 respondent. This can be seen in the pre-test data of the number of positive categories as much as 4 respondents (33.3%) and the negative category as many as 8 respondents (66.7%) in the post test data positive categories as much as 5 respondents (41.7%) and negative categories 7 (58.3%). Whereas in the control group there was no change in attitude score, this can be seen in the pre-test and post-test data which had a fixed attitude score, namely the positive category of 7 respondents (58.3%) and the negative category of 5 respondents (41.7%).

It is also showed that in the treatment group there was a significant increase in the score of action, it can be seen in the pre-test data which showed that 7 respondents (58.3%) in the category were sufficient, 5 respondents (41.7%) were in the good category. The post test data shows the score of action of all respondents (100%) in the good category after being given SME. While the control group did not experience a significant increase in score of action, it can be seen in the pre-test data which showed that 3 respondents (25%) in the less category, 3 respondents (25%) in the sufficient

category and 6 respondents (60%) in the good category. In the post test data the knowledge score contained 1 respondent (16.7%) in the less category, 3 respondents (25%) in the sufficient category and 7 respondents (58.3%) in the good category.

In addition, it is showed that in the treatment group there was a decrease in IDWG numbers, this can be seen in the pre-test data which showed that 12 respondents (100%) in the average category became 12 respondents (100%) in the mild category. While in the control group there is also a decrease in IDWG numbers in some respondents, this can be seen in the pre-test data which shows that 12 respondents (100%) were in the average category, in the post test data this became 6 respondents (50%) in the mild category and 5 respondents (41.7 %) in the average category and 1 respondent (8.3%) in the hazard category.

Table 2. Distribution of knowledge, attitudes, actions and IDGW of respondents before and after intervention

Variable	Treatment Group				Control Group			
	Pre test		Post test		Pre test		Post test

Total	12	100	12	100	12	100	12	100

Statistical results showed there was a significant difference between the pre-test and post-test knowledge in the treatment group with p = 0.007 while in the control group there is no significant difference between the pre-test and post-test. The Mann Whitney U Test showed p = 0.043, which means there was a significant difference in knowledge between the treatment groups given the SME compared to the control group not given the SME.

On the other hand, there was no significant difference between the attitude of the pre-test and post-test in the both of treatment and control group with p = 0.09 and 0.422 respectively. But the Mann Whitney U Test showed that p = 0.005, which means there were significant differences in attitudes between the treatment groups given the SME compared to the control group not given SME.

Statistical tests also showed significant differences in the respondent's actions between the pre-test and post-test in the treatment group with a value of p = 0.003 while in the control group there is no significant difference with the value p = 0.202. The Mann Whitney U Test showed p =

0.017 which means that there was a significant difference in the compliance measures of fluid intake between the treatment groups given by the SME compared to the control group not given the SME.

4. Discussion

The results of the study of knowledge variables showed that there was a difference in knowledge between the pretest and posttest in the group given self-management education intervention while in the group that was not given self-management education there was no difference between the pretest and posttest. The results also showed a significant difference between groups given self-management intervention in education and control groups. The results of this study are consistent with the research conducted by [5] stating that self-management education can improve patient knowledge. Another study conducted by [6] and [7] also states the same thing, that education about self-care can increase knowledge in the management and care of patients..

According to [8] the higher the level of education, the easier it is for individuals to understand a problem that arises in themselves or in the environment. The results of this study are in line with the research conducted by [9]. In patients who have a broader knowledge that allows patients to control themselves in overcoming the problems faced, they have high self-confidence, experience, and have a correct estimate of how to overcome the incident and easily understand what is recommended by health workers, which will be able to reduce anxiety so that it can help these individuals in making decisions.

The researcher assumed that the increase in knowledge scores in the treatment group was caused by higher levels of education. This is because many respondents have higher levels of education in the treatment group compared to the control group. The researchers also assumed that an increase in knowledge scores could be caused by continuous education given 8 times over 4 weeks.

The results of the attitude variable study showed that there were no significant differences between the attitudes of respondents in the pretest and posttest both in the groups given self-management education and control groups. The results also showed a significant difference between groups given self-management education and control groups. . The results of this study are not in accordance with the research conducted by [10] stated that self-management effectively increases behavior change and prevents the development of disease in patients with chronic kidney disease.

[11] explains that a person's attitude is built on three basic structures, namely cognitive, affective and conative. Cognitive is the representation of trust and confidence in a particular object. Affective indicates feelings and subjective emotional conditions for certain objects. This emotional feeling makes a person maintain his attitude although the attitude shown is not necessarily a positive attitude. While the conative structure is more directed at the tendency of actions and behavior of a person towards an object. This provides an overview and the reason why the respondent has a negative attitude and is positive.

Researchers assume that statistically there is no difference in attitude, but by looking at the accumulative data the client's attitude score it can be seen that there is a change in attitude scores but not much, this can be caused by the duration of 4 weeks of SME giving so that it is not enough to change one's attitude. Other factors can also be caused by filling out questionnaires filled out by respondents so that the level of validity is lacking, the condition of the hospital conditions that are not conducive can also cause the client to become unfocused when answering the questionnaire.

The results of the action variable study showed that there were significant differences between the pre-test and post-test actions in the group given self-management education intervention while in the group that was not given self-management education there was no difference between the pretest and posttest. The results of the study also showed a significant difference between the groups given self-management education intervention compared to the group that was not given self-management education.

[8] explains that a person's behavior is determined by predisposing factors which include beliefs, values, perceptions relating to one's motivation to act; supporting factors include the availability of health facilities and facilities; and driving factors include attitudes and behavior of health workers, families, or other officers who are a reference group of community behavior.

The researcher assumed that the increase in respondent's actions could occur because of the perception and belief that by adhering to fluid intake there would be improvements in his health condition and preventable complications. Family support is also influential in helping to regulate fluid intake and as a reminder that sufferers always adhere to prescribed fluid intake. The presence of fluid management calendar media also makes it easier for sufferers and families to remember and write down the fluid intake that has been consumed. In addition, sufferers can also evaluate how much fluid they have consumed and control how much fluid they consume.

The results of IDGW Variable study showed that there were significant differences between the IDWG pre-test and post-test in the group given self-management education intervention while in the group that was not given self-management education there was no difference between the pretest and posttest. The results also showed a significant difference in IDWG between groups given self-management education intervention compared to the control group. Data shows that all respondents in the treatment group experienced a decrease in the average IDWG value. The results of this study are supported by research conducted by [12] patients who received an educational intervention, and decreased IDWG2, 64 kg decreased to 2.21 kg and the level of adherence increased from 47% to 71%.

[13] suggests several factors that influence weight gain between two dialysis women, including fluid input, thirst, social support and self-efficacy. The results of research conducted by [14] state that there is a relationship between fluid input and weight gain between two dialysis times. Understanding and the patient's ability to regulate fluid intake that is close to the body's fluid requirements is needed to avoid the effects of excess fluid. The recommended daily intake of fluids for patients undergoing hemodialysis is the amount of urine plus insensible water losses [15].

[16] mentions thirst management in HD patients consisting of two strategies that are influenced by the patient's ability to choose and use thirst management effectively. The first strategy aims to reduce the amount of liquid entering in accordance with fluid restrictions. This method can be done by measuring the amount of fluid intake throughout the day or calculating the amount of liquid contained in fruits and vegetables. The second strategy aims to reduce thirst such as chewing candy, gum or using other saliva substitutes.

The researcher assumed the decrease in IDWG in the treatment group in this study apart from the routine dialysis process was also because of the client's ability to manage thirst and control the limitation of fluid intake consumed. The treatment group experienced a higher IDWG reduction than the control group, because the treatment group received self-management education interventions with fluid management calendar media whereas the client measures the liquid

consumed, which comes out every day for 6 weeks.

5. Conclusion

Self-management education using a management calendar fluids are able to increase knowledge, actions and client IDWG that undergo hemodialysis. While Self-management education with using a fluid management calendar has not been able to improve attitudes clients undergoing hemodialysis.

6. Acknowledgment

We would like to say thank you so much to all of respondents that were really cooperative in joining in the research and the President of NTB Province Hospital that supported this research very well.

THE EFFECT OF PROGRESSIVE RELAXATION THERAPY ON INSOMNIA ON OLDER ADULT

S Tauriana[1], Z 'Ulya[1], A N Izzati[1], I Choliq[1]
[1]Faculty of Nursing, Nurul Jadid University, Probolinggo, Indonesia
E-mail: s.tauriana-2018@fkp.unair.ac.id

ABSTRACT

One of the efforts made by the older adult to improve their welfare is to fulfill their basic needs. One of the basic needs is the need for sleep and rest, about 60% of the older adult experience insomnia or sleep disorders. Insomnia in the older adult can be overcome by non- pharmacological methods, one of which is progressive relaxation exercises. Progressive relaxation is a systematic physical relaxation of the head then down to the feet accompanied by a visualization suggestion that aims to deepen the relaxed state and is used to deal with sleep disorders. This study aims to identify insomnia in the older adult and analyze the effect of progressive relaxation therapy on insomnia in the older adult. This study used a Pre- experiment with the One Group Pretest Posttest approach, and the sampling technique used a total sampling of 29 people. Data analysis using paired T test. The conclusion of this study shows that there is an effect of progressive relaxation therapy on insomnia in the older adult. The results of the study as a basic guide or independent effort to overcome the quality of sleep, can be done alone or accompanied by a family

Keywords: Progressive relaxation, insomnia, older adult

1. Introduction

Insomnia is a sleep disorder that causes excessive drowsiness, if someone experiences insomnia then someone's sleep needs will be disrupted. Those who get insufficient sleep will experience physical and mental health problems, including; feeling tired, lack of concentration, reduced memory, less able to make decisions, irritability and not relax, nausea, dizziness, and increased the risk of accidents.

The Indonesian Ministry of Health stated that the elderly who experience sleep disorders per year are around 750 people. Insomnia is the most common disorder. Every year it is estimated that around 35-45% of adults report a serious sleep disorder. The prevalence of sleep disorders in the elderly is quite high at around 50%.

One of the non-pharmacological management in dealing with sleep disorders is progressive muscle relaxation therapy. Relaxation exercises can be used to enter the sleep state because deliberately relaxing the muscles forms a calm and relaxed atmosphere [1][2][3][4][5][6][7].

2. Research Methods

This was a pre-experiment research with one group pre-posttest design. Population were older adults listed at Psyandu Lansia (integrated health care center for older adults) N=48, at Posyandu Selobanteng Banyuglugur Situbondo, Probolinggo, East Java. Samples were older adults with insomnia. There were 29 older adults with insomnia involved in this research.

The independent variable was progressive relaxation therapy which run according to the standard operating procedure. The dependent variable was the level of insomnia which was collected by using an insomnia questionnaire. At first, the researcher gave an explanation to the prospective respondents about this research. If they are willing to become respondents, they were invited to sign an informed consent. After that, respondents should complete the questionnaire given by the researcher. When all had finished, the researcher rechecks the completeness of questionnaire to make sure that all item was answered. Statistical analysis was conducted with paired t-test with level of significance 95%.

3. Results

Table 1 had shown that all of respondents (100%) have an insomnia at a severe level before progressive relaxation therapy. After progressive relaxation therapy conducted, a half of respondents (55.17%) have an insomnia on a light level. There were only 7 (24.13%) respondents who still have moderate level of insomnia. Then, as many as 6 (20.7%) respondents were free from insomnia.

Table 2 had shown significant differences between respondent's pre and posttest score for the level of insomnia. Statistical analysis by using paired t-test shown p=0.000 which means progressive relaxation therapy has a significant effect on the level of insomnia on older adult. Mean score decreased from 3.00 (before intervention) to 2.03 (after intervention).

Table 1. The level of insomnia on older adult before and after intervention (n=29)

The level of Insomnia	**Before intervention**		**After intervention**	
	Frequency	**Percentage**	**Frequency**	**Percentage**
Not insomnia	0	0	6	20,7
Light	0	0	16	55,17
Moderate	0	0	7	24,13
Severe	29	100	0	0
Total	29	100	29	100

Table 2. The effect of progressive relaxation therapy on older adult with insomnia

Variable	*n*	*Mean*	*T count*	*T table (df=27)*	*ρ Value (CI=95%)*
Before intervention	29	3,00	7,641	1,703	0,000
After intervention		2,03			

4. Discussion

All of respondents have a severe level of insomnia before intervention. The older adult was more often experiencing sleep disorders, especially insomnia. Insomnia can be caused by many factors, such as stress and depression, anxiety, physical condition, uncomforted environment, response to disease, and unhealthy lifestyle. Some medication also can affect the sleep quality.

Insomnia is often associated with poor sleep habits. If conditions persist, fear of not being able to sleep can lead to vigilance. During the day, someone with chronic insomnia can feel drowsy, tired, depressed, and anxious. One way to overcome insomnia is by relaxation methods. This

technique is called progressive relaxation which is a technique to reduce tension in the muscles. Relaxation exercises can be used to enter sleep conditions because by deliberately relaxing the muscles will form a calm and relaxed atmosphere. Feeling relaxed is forwarded to the hypothalamus to produce a Corticotrophin Releasing Factor (CFR) then CFR stimulates the pituitary gland to increase the production of Proopiomelanocortin which causes beta endorphin as a neurotransmitter that affects the mood to relax and the production of encephalin by the adrenal medulla increases so that there is an increase in the number of older adult sleep fulfilment.

Based on a survey conducted by researchers in May that the level of insomnia in the older adult at the IHC was quite high. Sleep disorders experienced by the elderly are caused by dizziness that often suffers. This dizziness is felt because the elderly have a heavy burden in their daily lives, namely working in the fields from 7:00 a.m. to 5:30 p.m.

After progressive relaxation therapy all of respondents showed a decrease on the level of insomnia. Many of them have light level. There were only less than 25% who still have moderate level of insomnia. While the rest are already free from insomnia. Previous research conducted at BPSTW Ciparay Bandung also found that there were differences on the level of insomnia before and after progressive muscle relaxation therapy.

Progressive relaxation is self-teaching or instructional exercises that include learning to relax the muscle group systemically, starting with the facial muscles and ending in the leg muscles. This action usually takes 15 to 30 minutes and can be accompanied by recorded instructions that direct the individual to pay attention to the relaxed muscle sequence. The progressive relaxation techniques taught by researchers, include: instructing the older adult to lie down comfortably, take a deep breath, stretch the calves and toes, train the abdominal and chest muscles, clench their fists as hard as possible for a few seconds, tighten the neck and shoulders as if touching the shoulder, close your eyes as hard as you can, touch your lips. For the older adult, adequate sleep is very important, if the need for sleep is very less, it will have an impact on excessive drowsiness during the day and a decrease in quality of life.

Statistical analysis had shown that progressive relaxation therapy has an effect on the level of insomnia in older adults. It can decrease the level of insomnia. So that, it can be one of alternative interventions to treat older adults with insomnia. Progressive relaxation therapy can help older adults to express negative feelings into positive feelings, so they can change their unhealthy lifestyle which can interfere with their quality and quantity of sleep. During the intervention, the older adult expresses a good condition, calmness, and relax. Progressive muscle relaxation therapy which combined with a breathing technique that is consciously carried out and uses the diaphragm, allows the abdomen to rise slowly and the chest to fully expand. The breathing technique is able to provide a massage to the heart that is beneficial due to the rise and fall of the diaphragm, opening blockages and facilitating blood flow to the heart and increasing blood flow throughout the body. Increased blood flow can also increase nutrients and oxygen. Increased oxygen in the brain will stimulate an increase in serotonin secretion, making the body calm and easy to fall asleep. Based on this research progressive relaxation therapy is able to overcome insomnia disorders that occur in the older adult and can be used as a consideration in choosing interventions for health workers and the community, especially for the older adult who experience insomnia.

The population and samples desired by researchers in this study are limited in number so that the expected results are less than optimal, data collection methods carried out with questionnaires

and observations that require a longer time in its implementation influenced the attitude, patience, skills and subjectivity and psychological response of the researcher. A truly accurate study, of course, requires considerable time for the respondents to be examined. However, this research was conducted in just one month, which of course was considered less representative of the desired results, Researchers are still classified as beginner researchers and this research is the first study that affects the results of the study.

5. Conclusion

The level of insomnia in the older adults before progressive relaxation therapy in severe insomnia Posyandu. The level of insomnia of respondents after progressive relaxation therapy at the Posyandu was not insomnia, mild insomnia and severe insomnia. There is an effect of progressive relaxation therapy on insomnia in the older adult at Posyandu. The results of this study can be input or consideration as a nursing intervention for insomnia in the elderly. The results of this study hopefully can help improve nurses' knowledge in carrying out providing services in reducing insomnia for the elderly. For that we as nursing provide information about how to deal with insomnia in the elderly and in the community. Insomnia can be prevented by progressive relaxation therapy.

HEALTH BELIEF MODEL (HBM) AND ADHERENCE IN CHRONIC ILLNESS: A SYSTEMATIC REVIEW

I E Kurniasih[1], Soedarsono[2], L Hidayati[3]
[1] Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia

ABSTRACT

Adherence to treatment is an important component in the management of various acute and chronic diseases. Low levels of adherence to medical interventions are a common and very complex problem, especially for patients with chronic illness. This Systematic Review aims to describe the effect of Health Belief Model (HBM) based interventions on adherence to the treatment of patients with Chronic Illness. Article search using the PECOT framework in the database; Scopus, Science Direct, ProQuest, and Ebsco, are limited to the last 10 years; 2008 until 2018, the best 15 articles reviewed. Health Belief Model has been shown to be effective in describing medication adherence in chronic illness that require long-term therapy such as pulmonary TB, Cancer, Diabetes Mellitus, and others. The Health Belief Model (HBM) theory can be used as a theoretical reference in predicting behavior and making interventions to improve medication adherence to Chronic Illness.

Keywords: Health Belief Model, Adherence, Compliance, Chronic Illness

1. Introduction

Chronic disease is defined by the World Health Organization (WHO) as being of long duration, generally slow in progression and not passed from person to person [1]. The Global Burden of Disease study 2013 reported a substantial (42.3%) increase in the years lived with disability (YLD) from 1990 to 2013 [2]. This was overwhelming due to non-communicable diseases, with no infectious diseases in the top 20 leading causes of YLDs globally in 2013. Chronic condition multi-morbidity is high in developed countries [3] and the prevalence of it increases with age; Australian data indicates that around 40% of people aged over 44 years have chronic disease multi-morbidity, increasing to around 50% for 65–74 year olds, and 70% for 85 years or over [4]. Millions of Americans are living with at least one chronic disease, and while the majority have been prescribed medication to control symptoms-medication adherence is a widespread problem. Medication nonadherence varies by chronic disease, patient characteristics, and insurance coverage, and previous research has identified non-financial barriers including disease-related knowledge, health literacy and polypharmacy [4].

Medications are an essential part of chronic disease management. However, adherence to long-term therapy remains poor. The World Health Organization (WHO) defines adherence to long-term therapy as "the extent to which a person's behavior – taking medication, following a

diet, and/or executing lifestyle changes – corresponds with agreed recommendations from a health-care provider" . Poor adherence is considered a major drug-related problem and is associated with increased emergency-room visits, hospitalizations, and suboptimal clinical outcomes, all of which are associated with an increased burden on the health care system. [5].

Adherence is an often discussed issue nowadays. Also the World Health Organization (WHO) is concerned with the problem of poor adherence. In one of its reports the magnitude of adherence is described and examples for different adherence estimates for various chronic conditions are given. Data from Middle Eastern countries indicates that medication adherence ranges from 1.4% to 88% depending on the methods used to assess and quantify adherence [6]. Reasons for poor treatment adherence include disease characteristics and severity, treatment factors (e.g., treatment duration, number of medications, cost, frequency of administration), and medication side effects, among others. In addition, patients have their own beliefs and perceptions about medications, which can have a significant impact on their intention to take the prescribed medications [5]

Health education to patients of chronic diseases, both in the form of tailored patient education, or participation in health education seminars on general topics, have a profound effect on the patient's knowledge and understanding of the risk involved with carelessness about their health [6]. Health education and awareness is the most effective way to disseminate information and encourage people to adopt healthy lifestyles. Adoption of a healthy lifestyle not only helps in the prevention of diseases, but also in reducing the risk of complications resulting from these diseases. However, the most important role of health education is on patients of chronic diseases (most commonly, diabetes and hypertension) who routinely visit the PHC centers for follow-up and replenishment of their drug supplies [6].

Thus, the purpose of the education is for the disease to be managed by the patient and to improve the patients' quality of life (17). To reduce the complications of diabetes, some studies emphasize that healthcare workers should not merely provide knowledge to people, but take into account the perception of the risk as a central concept for understanding healthy behaviors and making changes in behavior. So, patients with diabetes need to properly understand the risk of diabetic complications and the structure of the Health Belief Model (HBM) with respect to constructs appropriate for intervention (18). HBM as a theoretical framework for this research, is one of the most effective models of health education, mainly focused on prevention of diseases and adoption of behaviors to avoid illness and disease chains and it is one of the important precise models which is used to determine the relationship between health beliefs and behaviors. The HBM posits that people will take action to prevent illness if they regard themselves as susceptible to a condition (perceived susceptibility), if they believe it would have potentially serious consequences (perceived severity), if they believe that a particular course of action available to them would reduce the susceptibility or severity or lead to other positive outcomes (perceived benefits), and if they perceive few negative attributes related to the health action (perceived barriers) [7]. The aim of this systematic review was to describe the effects of educational intervention based on the health belief model (HBM) on compliance behavior in patients with

chronic disease.

2. Methods

2.1. Protocol

This systematic review using Procedures outlined in the Preferred Reporting Items for Systematic-Reviews (PRISMA) were followed [8,9].

2.2. Eligibility criteria

Journal articles published in English from January 2008 to January 2018. Searching strategy using the PICO framework to identify the keywords.

2.2.1. Type of study design. The design of this study was a systematic review of quantitative study approaches formulated to review observational studies and relevant experimental studies and comprehensive analysis. Design of this study were quantitative studies, with observational methods that include cross sectional and cohort and experimental methods which include RCT and Non-randomized experimental studies. Journals written in English were induced.

2.2.2. Type of participants. Studies were included with adult patients (>18 years) with chronic diseases who get long-term therapy.

2.2.3. Type of interventions. Educational interventions based on the Health Belief Model (HBM) with exclusion criteria HBM-based educational interventions that have been modified with other interventions such as mindfulness, experimental learning or other interventions.

2.3. Information sources

Studies were identified by comprehensive searching of four databases namely Scopus, Medline, Proquest, and Science Direct.

2.4. Search

Search terms in the database using a combination of keywords (1) Health Belief Model AND (2) Adherence AND (3) Chronic Disease

2.5. Study selection

Titles and abstracts were independently screened by reviewer against the inclusion criteria. Reviewer assigned inclusion codes of yes, no or unsure. Full-text articles were then obtained and assessed for eligibility. The reviewers compared the screening results and discussed any disagreements regarding study eligibility.

2.6. Data collection process

The following data were extracted: the identity of studies, the setting of the study and the main results. Two authors (IEK and LH) were involved in data extraction, and after organizing results in a table, the findings were discussed and reviewed again. One review author extracted the following data from included studies and the other checked the extracted data. Disagreement is resolved by discussion between authors.

2.7. Data items

Reviewers used a customized form to extract study information to enable the evaluation of study characteristics, heterogeneity, and likely population impact through reach, effectiveness, adoption and

Implementation. The following data were extracted: (1) study country; (2) cohort characteristics; (3) study inclusion and exclusion criteria; (4) study design; (5) characteristics of the intervention and control groups; (6) details of the intervention; (7) setting in which interventions were adopted; (8) who implemented the intervention; (9) timing of follow-up assessments; (10) primary and secondary outcomes; (11) measurement tools; and (12) intervention effects on outcomes.

3. Result

3.1. Study selection

The search strategy was carried out by generating a total of 352 citations, which deleted 215 duplicates. 145 existing literature was deleted during the first screening because the title and or abstract did not match the specified eligibility criteria. 38 full articles from the second phase of screening and 16 articles were obtained for review. Study characteristics, including cohort information, intervention details, and outcome measures are described in Appendix A.

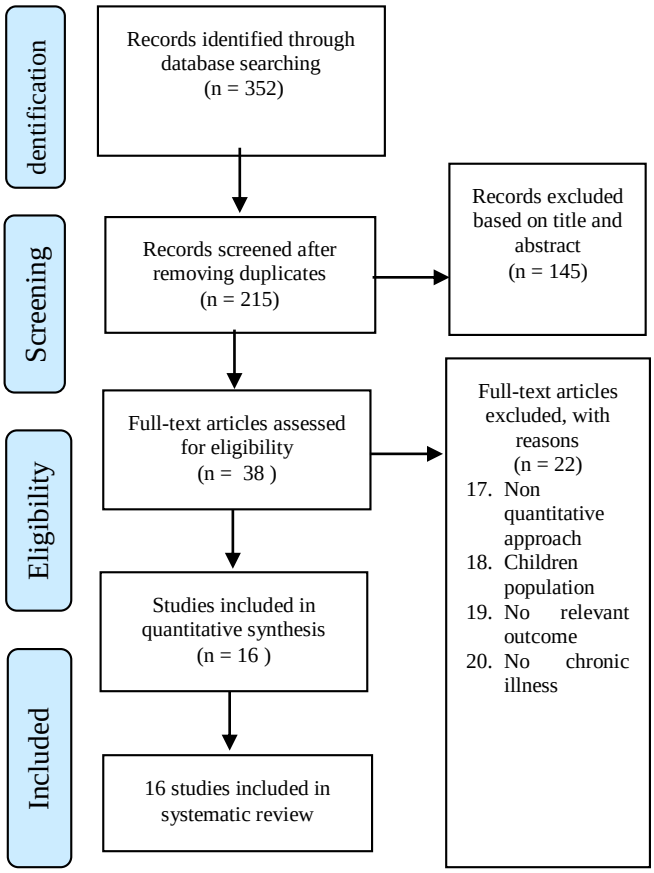

Figure 1. Study inclusion based on the preferred reporting items for systematic reviews

3.2. Study characteristic

The search strategy was carried out by generating a total of 352 citations, which deleted 215 duplicates. 145 existing literature was deleted during the first screening because the title and or abstract did not match the specified eligibility criteria. 38 full articles from the second phase of screening and 16 articles were obtained for review.

3.2.5 Type of participant. A total of 16 studies reviewed in 2008-2018 were conducted in 7 countries: UK, Iran, India, Turkey, China, Saudi Arabia and Malaysia. The research method used by several articles varied from Observational study include Cross Sectional (n=5) and cohort study (n=1), experimental studies include randomized controlled trials (RCT) (n=6) and quasi experimental (n=4). The total number of samples is 4,246 people.

3.2.6 Type of study design. All study adopted a Quantitative Approach Observational study and Experimental Study

3.2.7 Type of interventions. There were Health Belief Model (HBM) based education intervention. Further descriptions of the interventions, including timing and modality, are provided in Appendix 1.

3.3. Result of individual studies

Health Belief Model (HBM) in Pulmonary Tuberculosis. Research on the factors that influence compliance behavior in patients (TB) using the Health Belief Model (HBM) approach. The results showed that perceived threat variables, benefits, barriers, and self-efficacy accounted for 42% of the variance in adherence to therapy. The strongest predictor of adherence is self-efficacy. The results of this study also state that Health Belief Model (HBM) seems to be a suitable model in predicting therapeutic compliance in TB patients. Health Belief Model (HBM) can predict treatment compliance behavior in patients with TB [10–12].

A study conducted by [13]regarding the provision of psychological counselling and educational interventions guided by Health Belief Model (HBM), it results that after Health Belief Model (HBM) based counselling and education is given a significantly reduced rate of medication non-compliance among the intervention group through increasing Health Belief Model (HBM) constructs. The provision of psychological counselling and health education for Health Belief Model (HBM)-guided TB patients can be recommended in routine TB treatment strategies as an effort to improve compliance behavior in TB patients for the therapy given.

Health Belief Model (HBM) in Cancer. Study aimed at evaluating a Health Belief Model (HBM) based intervention in breast cancer patients in breast cancer screening. The study found that after 8 weeks of Health Belief Model (HBM)-based educational intervention, it was found that the average score of knowledge, perceived susceptibility, severity, benefits, barriers, self-efficacy, and behavioral intention related to Breast Self-Examination (BSE) and mammography in the intervention group increased significantly compared to the control group. The results confirm the efficiency and effectiveness of Health Belief Model (HBM)-based educational interventions on increasing factors that influence breast cancer screening behavior [14]. Study who stated that six months after being given Health Belief Model (HBM) -based education, 28.4% of women had undergone MMG, 69.9% had done BSE and 33.6% had undergone pap smear tests

[15]. Other study about factors affecting adherence in screening colorectal cancer also found that knowledge of colorectal cancer and Health Belief Model (HBM) constructs which included perceptions of susceptibility and resistance were significant predictors of compliance in conducting colorectal cancer screening, so it can be concluded that Health Belief Model (HBM)-based information-giving interventions can influence screening behavior for breast cancer and colorectal cancer patients [16].

A similar study the effectiveness of Health Belief Model (HBM)-based interventions in smokers in the prevention behavior of Oral Cancer. The results showed that after obtaining Health Belief Model (HBM)-based educational interventions there was a significant increase in the mean score of knowledge, perceived vulnerability, severity, benefits, self-efficacy, cues to act, and oral cancer prevention behaviors in the experimental group. In addition there were no significant changes observed in the mean scores of knowledge, perceived vulnerability, severity, benefits, self-efficacy, cues to act, and oral cancer prevention behaviors, in the control group, so it can be concluded that Health Belief Model (HBM)-based educational programs have a positive effect on oral cancer prevention efforts through increased knowledge, perceived vulnerability, severity, benefits, and self-efficacy [17].

Health Belief Model (HBM) in Diabetes Mellitus. Health Belief Model (HBM), which includes perceptions of vulnerability, severity, benefits, barriers and self-efficacy influences adherence behavior in the treatment of type 2 DM patients [18]. HBM-based self-efficacy education in DM type 2 patients. The results of the study stated that in the intervention group that was given education for 12 weeks (8 sessions, 2 sessions each) and evaluated after 6 months of intervention there was a decrease in sugar levels blood, lipid profile and anthropometric level and there was an increase in quality of life score [19]. HBM in DM education programs effective in improving adherence to nutritional type 2 DM patients. In the study of Dehghani-tafti, Saeed, Mahmoodabad, & Morowatisharifabad (2015), approve the efficiency of the health trust model in predicting self-care behavior compliance among DM patients, therefore it can be used as a framework for designing and implementing educational interventions in diabetes control plans. HBM-based diabetes self-management education is recommended for use as a health education intervention in patients with type 2 diabetes. [20], [21]

Other studies mention that after HBM-based interventions, all HBM variables differ significantly except the perceived threat. There is a significant linear relationship between self-efficacy and components of the health trust model after educational intervention in both groups [22]. It can be concluded that the administration of HBM-based educational interventions can improve adherence and effectiveness of therapeutic regimens in DM patients, thus influencing the stability of blood sugar levels and improving quality of life in type 2 DM patients.

4. Discussion

4.1. Summary of evidence

After reviewing several articles, it can be seen that health beliefs or beliefs are one of the individual factors that influence the compliance behavior of patients with chronic diseases that

require long-term therapy. Health Belief Model (HBM) -based educational interventions conducted on three chronic diseases with long-term therapy, namely Lung Tuberculosis, Cancer and Diabetes Mellitus resulted in the construct of the Health Belief Model (HBM) which included perceptions of vulnerability and seriousness, perceived benefit, perceived inhibition and self-efficacy can be used to predict patient behavior in seeking treatment and patient compliance behavior in carrying out treatment. The strongest predictor is self-efficacy, so the results of this study emphasize the importance of self-efficacy in adherence to the treatment that health educators should consider when developing programs to motivate patients to adhere to treatment.

In patients with pulmonary tuberculosis treatment adherence is the main determinant of treatment success. Non-compliance causes long periods of infection, recurrence, drug resistance which results in increased morbidity and mortality. One of the factors that affect non-compliance in TB treatment is a lack of knowledge about TB and its treatment. On the other hand, the patient trust is the main individual factor in influencing TB patient compliance, because belief is one of the decisive elements in shaping attitudes which ultimately affects someone to behave[13]. Research conducted by [11] also produced findings that HBM constructs can predict compliance behavior in patients with pulmonary tuberculosis. The provision of psychological counseling and education interventions based on the Health Belief Model (HBM), significantly reduced treatment non-compliance among the intervention groups through an increase in the construct of the Health Belief Model (HBM).

Beliefs about health and knowledge about breast cancer are two important factors that influence the delay in seeking treatment in patients with breast cancer, so to reduce this delay proper health education programs must be established [23]. The provision of a Health Belief Model (HBM) -based educational intervention has confirmed that the efficiency and effectiveness of interventions on increasing factors affecting breast cancer screening behavior through increased knowledge, perceived vulnerability, severity, benefits and self-efficacy [14].

Patients' perceptions and beliefs must be assessed as part of a patient-centered medication adherence intervention in patients with diabetes mellitus The provision of HBM-based education can improve compliance behavior and maintain normal blood sugar in type 2 DM patients [24] Self Efficacy, perceptions of vulnerability and resistance are each of the strongest predictors of influencing someone to behave obediently in patients with Diabetes Mellitus [25].

5. Conclusions

The Health Belief Model (HBM) has been shown to be effective in describing treatment compliance in chronic diseases that require long-term therapy such as pulmonary tuberculosis, cancer and diabetes mellitus. Provision of HBM-based educational interventions can effectively improve the adherence of patients to treatment through increasing patient confidence. The increase in perceptions of vulnerability and seriousness, perception of benefits, perceptions of barriers and self-efficacy on the disease will increase patient confidence, then will form a positive attitude. The existence of a positive attitude will encourage positive behavior too, in this case the behavior is obedient to treatment, so that the patient's confidence in his illness is one of the factors

that influence patients in behaving obediently to treatment.

Provision of Health Belief Model Education Interventions can be used as an alternative choice for health workers in providing education to patients, while for the next researcher, the Health belief model can be used as a frame of reference or framework in developing nursing interventions in an effort to improve patient compliance behavior with chronic diseases that get other long-term therapies such as hypertension, epilepsy, HIV, kidney failure and others..

Appendix A

Table A1. Summary Table of study characteristics

No.	The title and author of a scientific paper	Variables	Method	Result
1.	*Effectiveness of Health Belief Model on Oral Cancer Prevention in Men Smoker.* [17]	Independent: HBM-based educational intervention Dependent: Knowledge, perceived susceptibility, perceived severity, perceived benefits, perceived barriers, cues to action, self-efficacy and oral cancer prevention behaviors.	Design: quasi-experimental Samples : 200 smokers n = 100 HBM-based educational intervention group, n = 100 control group (without the HBM-based educational interventions) Instrument : questionnaire Analysis : T test, chi-square, paired t test.	- After getting an HBM-based educational intervention there is a significant increase in the average score of knowledge, perceived susceptibility, severity, benefits, self-efficacy, cue to action, and oral cancer prevention behaviors. - HBM-based educational programs provide a positive effect on behavior improvement for prevention of oral cancer by enhancing the knowledge, perceived susceptibility, severity, benefits, and self-efficacy.
2.	*Evaluation of Health Belief Model-Based Intervention on Breast Cancer Screening Behaviors among Health Volunteers* [14]	Independent: HBM-based educational intervention Dependent: Knowledge, perceived susceptibility, perceived severity, perceived benefits, perceived barriers for BSE (breast self-examination), self-efficacy for BSE, intention to behave on BSE, skills BSE, perceived benefits of BSE, perceived benefits of mammography, the intention to behave to mammography.	Design : Experimental study Samples : N = 240 women in the intervention group based education HBM, n = 240 women in the control group. Instrument : 1. *Noorizadeh questionnaire (2010)* 2. *Health Belief Scale models of champions* Analysis : 1. Chi- square Mann-Whitney	- The results showed that the average scores of knowledge, perceived vulnerability, severity, benefits, barriers, self-efficacy, and behavioral intentions regarding the examination of breast self-examination (BSE) and mammography in the intervention group improved significantly compared with the control group immediately after and two months after the educational intervention. - There are significant differences between the groups in the skills of BSE 2 months prior to the intervention, but there was no significant difference between the two groups in behavioral therapy and mammography 2 months after the intervention.

No.	The title and author of a scientific paper	Variables	Method	Result
				- The results confirm the efficiency and effectiveness of the HBM-based educational interventions on improving the factors that influence the behavior of breast cancer screening.
3.	*The impact of self-efficacy education based on the health belief model of in Iranian Patients with type 2 diabetes: a randomized controlled intervention study.* [19]	Independent: self-efficacy-based educational intervention HBM Dependent: - Knowledge about nutrition, health belief, quality of life - Glycemic control and metabolic include hba1c, blood glucose, lipid profile and anthropometry level	Design : *Randomized controlled intervention* Samples : N = 120 patients with type 2 diabetes mellitus in the HBM-based educational intervention group and n = 120 type 2 diabetic patients in the control group who received conventional education Instrument : 1. Blood samples 2. Diabetes knowledge questionnaire (DKQ-24) 3. HBM questionnaire 4. Quality of Life Questionnaire (DQOL) Analysis: 1. ANOVA 2. *Independent test* 3. *Chi-square test* 4. *Paired t test* 5. *Mann-Whitney test* 6. *Friedman repeated measure test*	- After being given education for 12 weeks (8 sessions, each session 2 hours) an evaluation after 6 months of intervention showed that there were significant differences in the levels of blood sugar, lipid profile and anthropometry level between the control and intervention groups. - Decreased levels of blood sugar, lipid profile and anthropometry levels found in the intervention group. - Score increased after a given educational knowledge in the intervention group. - An increase in quality of life scores in the intervention group after being given an education. - HBM-based educational interventions improve medication adherence in patients with diabetes mellitus type 2 which affects the stability of blood sugar levels and improved quality of life in patients with type 2 DM.
4.	*The Effect of*	Independent: Education	Design: Semi-experimental	- HBM-based education improves the

No.	The title and author of a scientific paper	Variables	Method	Result
	Education on the Early Diagnosis of Breast and Cervix Cancer on the Women's Attitudes and Behaviors Regarding Participating in Screening Programs [15]	about early diagnosis of breast cancer and cervical cancer based HBM Dependent: attitudes and behavior of women regarding participation in the program of early diagnosis, screening and training of cancer.	study Instrument: 1. *Champion's Health Belief Model Scale* 2. Form breast cancer risk evaluation 3. *Health Belief Model Scale for Cervical Cancer* 4. Pap-smear test Analysis: 1. *T- test* 2. *Mann Whitney test* 3. ANOVA	behavior of early detection of breast cancer and cancer of the cervix. - Six months after being given education, 28.4% of women had undergone MMG, 69.9% had done the BSE, and 33.6% had undergone a pap smear test.
5.	*Causes of Delay in Seeking Treatment in Patients with Breast Cancer Iranian Based on the Health Belief Model (HBM)* [23]	Independent: HBM variables which include knowledge, perceived susceptibility, perceived severity, perceived benefits, perceived barriers and cues to action. Dependent Behavior for the delay in seeking treatment.	Design : Cross-sectional study Sample: 80 breast cancer patients with a delay of <3 months and 80 breast cancer patients with a delay of> 3 months Instrument: HBM components Questionnaire Analysis: 1. *Descriptive analysis* 2. *T test* 3. *Chi-square* 4. Multivariate logistic regression	- Results of multivariate logistic regression showed that there was a significant correlation between perceived barriers OR = 1.48 (CI95% = 1.18 to 1.86), cues to action OR = 0.72 (CI95% = 0.55 to 0, 93), perceived vulnerability OR = 0.87 (CI95). % = 0.78 to 0.97), and the first symptoms OR = 0.259 (CI95% = 0.08 to 0.79) and delays in seeking treatment in patients with breast cancer. - Beliefs about health and knowledge about breast cancer are two important factors that affect delays in seeking treatment in patients with breast cancer in Kerman, Iran. - To reduce this delay, the appropriate

No.	The title and author of a scientific paper	Variables	Method	Result
				health education programs should be established. - The construct HBM can be used as a framework to predict the behavior of breast cancer patients in seeking treatment.
6.	*Complex relations among Health Belief Model components in TB prevention and care.* [26]	Independent: Components of the Health Belief model include: 1. Demography 2. Knowledge (knowledge) 3. Benefits (benefits) 4. Vulnerability (severity) 5. Severity (susceptibility) Dependent: 1. TB prevention behavior 2. Intention to seek TB treatment	Design: Cross-sectional study Instrument: 1. TB Knowledge Questionnaire 2. TB preventive behavior questionnaire 3. HBM questionnaire 4. Questionnaires intention TB treatment Analysis: *Path analysis* / Path analysis	- 6 constructs in HBM can predict medication adherence behavior in patients with TB.
7.	*The Effect of an Educational Program Based on the Health Belief Model on Self-Efficacy among Patients with Type 2 Diabetes Referred to the Iranian Diabetes*	Independent: health education Dependent: *self-efficacy* Health belief models and components	Design: Randomized control clinical trial Sample: 40 patients with type 2 diabetes in the intervention group and 40 patients with type 2 diabetes in the control group Instrument: 1. The questionnaire of health belief model of	- After the intervention all of the variables are significantly different than the perceived threat. A significant linear relationship between self-efficacy and health belief model components after educational intervention in both groups. - HBM-based educational interventions improve adherence behavior of

No.	The title and author of a scientific paper	Variables	Method	Result
	Association in 2014. (Vahidi, Shahmirzadi, Shojaeizadeh, and Haghani, 2015)		2. Self-efficacy questionnaire Analysis: *1. Chi - square* 2. Pearson correlation *3. Independent sample t-test* *4. Paired t-test*	patients with diabetes mellitus type 2 through increased HBM constructs.
8.	*Determinants of adherence to tuberculosis treatment in Iranian Patients: Application of health belief models.* [10]	Independent: HBM variables which include the perceived threat, perceived benefits, perceived barriers and self-efficacy. Dependent: behavioral treatment adherence.	Design: cohort studies. Sample: 297 TB patients. Instrument: interviews and questionnaires developed by the construct HBM and looked at medical records and medical cards that are used in the performance of medical checklists. Analysis: 1. Test data using Kolmogorov Smirnov normality. 2. ANOVA *3. Independent T-Test* 4. Multiple linear regression analysis.	- The results showed that the variables of perceived threats, benefits, barriers, and self-efficacy accounted for 42% of the variance in therapy adherence. - The most powerful predictor of adherence was self-efficacy - HBM seems to be a suitable model to predict therapy adherence in patients with TB. - The results of the present study emphasize the importance of self-efficacy in treatment adherence, which should be considered by health educators when developing programs to motivate patients to adhere to treatment,
9.	*Estimating the effect of lay knowledge and prior contact with pulmonary TB Patients, health-belief on the model in a high-risk*	Independent: lay knowledge and history of contact through HBM measurement constructs. Dependent: - Confidence in the perception of	Design: survey Sample: 500 people with a high risk of pulmonary TB transmission Instrument: Likert scale developed by every definition of variables Humanely the	- Experience direct interaction with pulmonary tuberculosis proved to have a significant relationship with the knowledge and confidence of the participants on the effectiveness of health behaviors. If participants had previous contact with pulmonary TB

No.	The title and author of a scientific paper	Variables	Method	Result
	population pulmonary TB transmission. [12]	threat, vulnerability perception, perception of seriousness. - Confidence in the health behaviors, perceived benefits and perceived barriers.	development of HBM Champion and Skinner Analysis: Logistic and linear regression analysis	patients, they are more likely to have a better level of knowledge, as well as specific health behaviors tend to regard as effective for the prevention or treatment of pulmonary tuberculosis. - Contacts previously found to have no effect on personal health threat. It also implies that when ordinary people have the experience of interacting with pulmonary TB patients, although prone to the development of pulmonary TB, they still think that they are not at risk of contracting this disease. In addition, our findings suggest that the perceived vulnerability of participants is higher than the perceived severity. This implies that the participants understand correctly that pulmonary TB is threatening illnesses and causes severe consequences. However, they do not consider themselves as having a high risk of infection, even if they live in neighborhoods with the highest risk of contracting pulmonary tuberculosis in Surabaya. This may be due to a lack of knowledge of participants about how pulmonary TB is transmitted from the patient to the health of the people. - The construct HBM can be used to predict the behavior of prevention and treatment in people with risk of contracting TB.

No.	The title and author of a scientific paper	Variables	Method	Result
				- Educational programs should be able to reconstruct people's misconceptions about pulmonary tuberculosis, thus bringing the perception of health risks so that not only focus on increasing knowledge of the layman.
10.	*Factor Associated with adherence to Colorectal Cancer Screening among Moderate Risk Individuals in Iran.* [16]	Independent: HBM variables which include susceptibility, seriousness, benefits, barriers, motivation, health and self-confidence. Dependent: The behavior of a screening for colorectal cancer.	Design: *cross sectional* Sample: 200 people with age above 50 years. Instrument: health belief model scale Champions (CHBMS) Analysis: Multiple logistic regression.	- Our findings suggest that knowledge of colorectal cancer, perceived susceptibility and resistance is a significant predictor of compliance for colorectal cancer screening. - Perceived vulnerability against colorectal cancer has the lowest percentage of all subscales. Participants who feel more vulnerable (OR = 2.99; CI 95%: 1:23 to 5:45) and reported a higher knowledge (OR = 1.29; 95% CI: 1.86-3.40) and those who reported fewer barriers (OR = .37; CI 95%: .21- .89), more likely to be screened for colorectal cancer. - Strategies to improve the knowledge and overcome the barriers at-risk individuals seems to be required. - Educational programs should be promoted to overcome the lack of knowledge and negative perception in the elderly Iran
11.	*Determinants of Self-Care in Diabetic Patients*	Independent: perceived susceptibility, perceived seriousness, perceived	Design: *cross sectional study* Sample: 110 patients with diabetes.	- Health belief model construction including perceived benefits, barriers, severity, vulnerability, self-efficacy,

No.	The title and author of a scientific paper	Variables	Method	Result
	Based on Health Belief Model [25]	benefits, perceived barriers, self-efficacy, social support. Dependent: *Self-care adherence behavior*	Instrument: a questionnaire about demographic data and questionnaire drawn up by the construct HBM, scale of family support, 11 items Toobert & Glascow scale of diabetes self-care. Analysis: Linear regression analysis	and social support predicted 33.5% of the observed variance of compliance self-care behaviors. Vulnerability and perceived self-efficacy has a positive effect on self-care behaviors; while the perceived barriers have a negative effect. Self-efficacy, perceptions of susceptibility and resistance of each is the most powerful predictor. - These findings agree the efficiency of health trust model in predicting compliance self-care behaviors among diabetic patients. - These findings realize the health belief model structures; therefore, it can be used as a framework for designing and implementing educational interventions in diabetes control plan.
12.	*Effects of Education Based on Health Belief Model on Dietary adherence in Diabetic Patients* (Mardani Hamuleh M * 1, Shahraki Vahed A2, 2010)	Independent: HBM-based education. Dependent: The construct HBM which include susceptibility, seriousness, benefits and barriers, patient adherence to a diet behavior and glycosylated hemoglobin.	Design: *Quasi-experimental study.* Sample: 128 diabetic patients were divided into 2 groups: the treatment group and the control group. Instrument: a questionnaire about demographic data and questionnaire developed by HBM construct as well as a questionnaire about patient behavior related to diet. Analysis: *1. Chi square*	The results showed that using HBM in diabetes education program is effective in dietary compliance among patients with type 2 diabetes.

No.	The title and author of a scientific paper	Variables	Method	Result
			2. *Wilcoxon.* 3. *Paired t test.* 4. *Simple t test*	
13.	*The Effect of Diabetes Self-Management Education, Based on the Health Belief Model, on the Psychosocial Outcome of Type 2 Diabetic Patients in Indonesia.* [21]	Independent: Diabetes self-management education, based on Health Belief Model (HBM) Dependent: *Self-efficacy, self-care behavior*, quality of life and glycemic control.	Design: *RCT with pre-test and post-test design.* Sample: 120 patients with type 2 diabetes were divided into 2 groups: the treatment group and the control group. Instrument: 1. DMSES (Diabetes management self-efficacy scale) 2. DDS (Diabetes distress scale) 3. SDSCA (summary of diabetes self-care activities) 4. DQOL (Diabetes quality of life)	- Diabetes self-management education based on HBM have a significant effect on the outcome psychosocial patients with type 2 diabetes. - This study has highlighted the importance of education in improving the psychosocial health of the patient. HBM approach to educational interventions, have significantly increased self-efficacy, self-care behaviors and quality of life, and reduce the level of pressure diabetes and their blood glucose levels. - Diabetes self-management education based HBM recommended for use as a health education intervention for patients with type 2 diabetes.
14.	*Psychological and Educational Intervention to Improve Tuberculosis Treatment adherence in Ethiopia Based on Health Belief Model: A Cluster Randomized Control*	Independent: Education and psychology-based interventions HBM Dependent: Behavioral treatment compliance.	Design: RCT Sample: 698 TB patients Instrument: - Knowledge and perception questionnaire compiled based construct HBM. - Kessler-10 item instrument. - Visual Analogue Scale	- Psychological counseling and educational interventions, guided by HBM, significantly reducing the level of non-compliance with treatment among intervention groups through increased HBM constructs. Provision of psychological counseling and health education for tuberculosis patients recommended guided by the theory of behavior could be incorporated into routine TB treatment strategy.

No.	The title and author of a scientific paper	Variables	Method	Result
	Trial. [13]		(VAS) Analysis: Multilevel logistic regression.	
15.	*The Association between Health Beliefs and Medication Adherence among Patients with Type 2 Diabetes* [18]	Independent: Health Belief Dependent: Medication adherence.	Design: cross sectional. Sample:217 patients with type 2 DM. Instrument: Expanded Health Belief Model Questionnaire Analysis: - ANOVA - Person correlation - Mann Whitney -	- The results showed that the construct HBM (perceived susceptibility, keseriuasan, benefits, barriers and self-efficacy) influence compliance behavior in the treatment of patients with diabetes mellitus type 2. - Perception and trust of patients should be assessed as part of treatment adherence interventions centered on the patient.
16.	*The Effects Of Education Based On Extended Health Belief Model in Type 2 Diabetic Patients: a Randomized Controlled Trial.* [24]	Independent: HBM-based educational Dependent: Compliance behavior, blood sugar levels	Design: RCT Sample: 120 patients with type 2 DM.	- HBM Award based education can improve compliance behavior and maintain normal blood sugar in patients with type 2 diabetes mellitus.

AROMATHERAPY EFFECTS IN CLIENTS UNDERGOING HEMODIALYSIS: A SYSTEMATIC REVIEW

Supriyono[1], Kusnanto[1], and O Soedirham[2]
Faculty Of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
Faculty Of Public Health, Universitas Airlangga, Surabaya, East Java, Indonesia

ABSTRACT

Complexity of problems in clients undergoing hemodialysis starts from a clinical and psychological perspective and requires appropriate and efficient intervention. The purpose of this systematic review is to find out the effects of aromatherapy on clients who undergo hemodialysis. The method used in this systematic review consists of 5 stages: (1) identification of instruments in the literature (database search); (2) identification of relevant literature based on title and abstract; (3) inclusion and exclusion criteria; (4) get full-text literature; (5) grading based on the literature component and analysis of selected instruments. The database used in the search for literature were Scopus, Proquest, ScienceDirect, BMC, Iranian Journal, PubMed by limiting the keywords "Aromatherapy" AND "Hemodialysis", published in the years between 2014-2017. Additional sources used were HerMed, Natural Medicine, Nephro Urology monthly. From the results of the study, it was found that aromatherapy can help overcome problems with sleep disorders, fatigue, pain, depression, pruritus, and anxiety. Aromatherapy with essential lavender which is the most dominant aromatherapy is given in the treatment process of patients undergoing hemodialysis.

1. Introduction

Chronic renal failure is a progressive and irreversible deterioration in kidney function which causes loss of the body's ability to maintain metabolic and electrolyte balance. In 2005, half a million people in the United States underwent hemodialysis. This number is expected to increase to 0.7 million in 2015. In 2011, it was reported that 35,000 Iranians needed dialysis and kidney transplants [1]. The incidence of chronic kidney failure increases from year to year. The number of chronic kidney failure in the world in 2009 in the United States has an average prevalence of 10-13% or around 25 million people affected by Chronic Kidney Disease. While in Indonesia in 2009 there was a prevalence of 12.5% or 18 million adults affected by chronic kidney disease. According to data from Peneftri (Indonesian nephrology union), it is estimated that there are 70 thousand kidney sufferers in Indonesia, but those detected suffering from terminal kidney failure from those undergoing dialysis (hemodialysis) are only around 4 thousand to 5 thousand. It is estimated that there are more than 100,000 patients who have recently undergone hemodialysis. Recent technological advances can improve hemodialysis (HD) clients with End Stage Renal Disease (ESRD) by prolonging the life of patients on dialysis, which can cause some physical and mental problems (e.g., fatigue, pain, itching, drowsiness, and depression) determined that 71% of dialysis patients suffer from lack of sleep. Given that sleep disorders occur depending on psychological factors and stress, anxiety and depression can affect the subjective quality of sleep of people undergoing dialysis. Anxiety is one of the disorders found in dialysis patients, which is associated with behavioral, psychological, physical and mental symptoms. Diseases and changes in the professional family, marriage, family and social life cause anxiety in these patients. Most dialysis clients continue to experience anxiety and distress about financial problems, sexual dysfunction, family responsibilities, and lack of freedom [2].

The therapies used in dealing with client problems that undergo HD are of various kinds. One of them is the use of aromatherapy. Aromatherapy is a therapy that relies on the sense of smell and touch which, in this case, is the skin. So far, the use of aromatherapy in the treatment of diseases

has been shown to be complementary and alternative medicine. In this systematic review, we will discuss the effectiveness of aromatherapy on psychological, clinical and health status for patients with hemodialysis. Aromatherapy refers to the provision of complementary therapies tailored to the dosage and type of aromatherapy given.

Aromatherapy is a form of alternative medicine using volatile plant material, widely known in the form of essential oils and various other forms that aim to regulate cognitive function, mood, and health. Aromatherapy is formed from various types of plant extracts such as flowers, leaves, wood, plant roots, bark, and other parts of the plant by making different ways by using and using their respective functions. There are many types of aromatherapy, such as essential oils, incense, candles, salt, massage oil, and soap. The types of plants used as extract are also very large, namely rosemary, sandalwood, jasmine, orange, basil, ginger, lemon, tea tree, ylang-ylang, and many more. There are many ways to use aromatherapy that have their own benefits. Inhalation aromatherapy is an essential oil that is inhaled to the lungs, which provides benefits both psychologically and physically. Not only does the aroma of essential oils stimulate the brain to trigger a reaction, but the natural ingredients found in essential oils at inhalation also provide therapeutic effects. There is also the use of essential oils that are applied to the skin. Essential oils applied to the skin can be absorbed into the bloodstream. One of the benefits of using topical applications is the effect that works directly on the desired body part. Massage is the best way to get the benefits of topical aromatherapy where there are therapeutic effects. However, excessive use also gives some concern about side effects, because the concentration of essential oils is very high, sometimes it can trigger irritation to the skin especially in pure essential oil ingredients. However, further research is needed to evaluate the efficacy and safety of the use of medicinal herbs. In addition, previous studies have shown that the level of complementary drug therapy (and especially medicinal herbs) in hemodialysis patients is very high even up to sixty percent of patients with end-stage kidney disease in one study. This is despite the fact that none of the treatments applied have been proven to be scientifically efficient [3].

2. Research Method

This Systematic review uses Preferred Reporting Item for Systematic Review and Meta-Analysis (PRISMA) guideline.

2.1. Literature Search Strategy

The scope of the literature is the use of aromatherapy in both combination and single intervention. The use of aromatherapy in question is via inhalation and topical. Aromatherapy is used in clients who undergo hemodialysis. Literature studied is in English and Arabic in order to increase the amount of literatur**e.** The database used in literature searches is Scopus, Proquest, ScienceDirect, Iranian Journal, PubMed by limiting the keywords "Hemodialysis" AND "Aromatherapy" AND "Effect", published between 2014-2019.)

2.2. Criteria for inclusion and exclusion

2.2.1. Study design. The study design is the inclusion criteria in this Systematic Review is a Random Controlled Trial (RCT) design that is published using English

2.2.2. Population. The population in this systematic review were all studies that describe patients who receive interventions for giving aromatherapy with or without a control group, men and women> 17 years old, and seeing the effect of aromatherapy on patients with hemodialysis.

2.3. Intervention

Various types of aromatherapy interventions that affect the psychological, clinical and health status

of patients with hemodialysis.

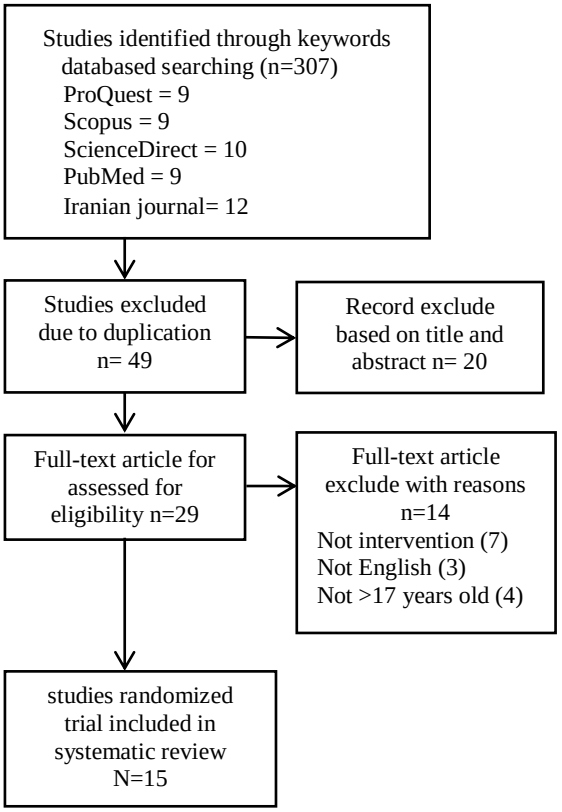

Figure 1. Flow diagram

2.4. Clinical results

The main objective of this systematic review is to look at the effect of interventions on aromatherapy on psychological, clinical and health status for patients with hemodialysis. Research is used without any time limit for the duration of the intervention.

2.5. Study selection

The standard protocol for selecting studies as suggested in the systematic review method guide, PRISMA. The steps taken were: removal of duplication; independent examination of titles, abstracts, and keywords and delete citations that are not relevant according to the inclusion criteria; if the title and abstract seem to meet the inclusion criteria and are in accordance with the objectives of the systematic review, the next step is the selection of journals with full text; the final step is choosing articles that use the Randomized Controlled Trial approach to reduce the risk of bias.

2.6. Data extraction

Data is extracted from each study that meets the requirements. The extracted data includes research characteristics, characteristics of aromatherapy, characteristics of results and summary of results.

2.7. Data analysis

The studies were grouped according to the effects arising from aromatherapy on psychological, clinical and health status for patients with hemodialysis. If possible, the research was then grouped

based on the time of follow-up and the type of control group.

3. Results

The research articles found 15 published journals from 2014 to 2017. Research was conducted in various countries with various methods. The research method found in the study was Randomized Controlled Trial (n = 6), Quasi-Experiment (n = 3), Clinical Trial (n = 4), Crossover Study (n = 1) and Non-equivalent comparison group pretest-posttest design (n = 1). The most widely used research design is the Randomized Controlled Trial. Then found 15 articles that were analyzed into a systematic review.

3.1 Population

The sample size of 15 studies used in this systematic review was the least 30 people divided into two groups, namely the control and intervention groups, with the age range 18-51 years, and the characteristics of the patients where the highest number of samples was 92 people were divided into two treatment groups also patients with hemodialysis with age> 18 years.

3.2 Intervention characteristic

Aromatherapy is a complementary intervention that is used to overcome health problems in clients undergoing hemodialysis. Aromatherapy used in the study as an intervention were lavender, rosemary, sweet almond, sweet orange, palm, bergamot and mustard greens. Most studies found used lavender aromatherapy. Lavender aromatherapy is used, given to clients with a variety of concentrations and different uses. But some studies combine lavender and other aromatherapy as well as lavender and rosemary aromatherapy.

3.3 Method of giving aromatherapy

The protocol for giving aromatherapy in each study is different. Aromatherapy is given through inhalation, topical or combined with massage or massage. Inhalation is the most intervention and is significantly successful in providing therapy to clients.

3.4 Effect on general health status

Health in general greatly affects the quality of life of clients undergoing hemodialysis. One study found a significant effect of using mustard inhaled aromatherapy 3 times a day for 5 minutes in 4 weeks measured using SF36V2 questionnaire [3].

3.5 Clinic Effect

3.5.1 Sleep quality. Improved sleep quality was found in RCT studies using essential lavender. It was found that the quality of sleep improved but the decrease in fatigue and sleep strength was not significant [4], combination lavender and bergamot 1:1 [5], essential lavender 5% [6]. The three studies in common using the lavender aromatherapy found significant results in improving sleep quality by measuring using PSQI and Quality Of Sleep Questionnaire.

3.5.2 Fatigue. Fatigue is a further problem that occurs in clients who undergo hemodialysis. Three studies have found that aromatherapy is a combination of lavender and sweet orange combination lavender and bergamot 1:1 [5] and a combination of 3 drops of lavender and rosemary 3: 3 [7]

significantly able to reduce fatigue by measuring using VAS fatigue Scale, BFI, and The Piper Fatigue Scale.

3.5.3 Pruritus. The research was developed using aromatherapy Palm with 1-2 droplets applied to the skin [8] and administration of sweet almond oil in pruritic areas as much as 5-10 cc [9] significant in overcoming the occurrence of pruritus in clients undergoing hemodialysis by measuring 5-D Pruritus Scale (Duration, Degree, Direction, Disability, Distribution) and Questionnaire of Pruritic Score.

3.5.4 Pain. Significantly 10% lavender aromatherapy essence [10], essential lavender aromatherapy lotion 100% [11], a combination of 1% lavender with 1% rosemary on 48cc oil with massage [11], a combination of 1% lavender with 1% rosemary on 48cc oil with massage [12], lavender essence by inhaling with a concentration of 10% for 5 minutes for 3 sessions of hemodialysis [13] can reduce pain by measuring Pain Scale and NRS (Numeric Rating Scale) VAS.

3.6 Psychological Effect

3.6.1 Depression. Depression is found in clients who undergo hemodialysis. Aromatherapy inhaled rosemary with a concentration of 2%[14], 5% lavender essential oil for 10 minutes [1], every time they undergo hemodialysis significantly decreases depression in clients with measurements of The Hospital Anxiety and Depression Scale (HADS), The DASS-21 for depression, anxiety, and stress.

3.6.2 Anxiety. The anxiety experienced by clients is related to HD processes. Application of an essential combination of lavender 5% and sweet almond [15] and 25% concentrate [2] tested significantly by measuring The Spielberger's State-Trait Anxiety Inventory.

4. Discussion

We conducted a systematic review using an RCT design to investigate the effect of aromatherapy on psychological, clinical and health status for patients with hemodialysis. We included 15 studies that examined the relationship between aromatherapy on psychological, clinical and health status in patients with hemodialysis. Including heterogeneous types of aromatherapy, type of control group and duration of follow-up. There are several important findings regarding the effects of aromatherapy on the psychological, clinical and health status of patients with hemodialysis which will now be discussed in detail.

Overall administration of aromatherapy has different effects on different types of aromatherapy in patients undergoing hemodialysis. The administration of aromatherapy refers to the dosage according to the type of aromatherapy. In general health status, there was an increase in health status. Health in general greatly affects the quality of life of clients undergoing hemodialysis. Health in general in the intervention group was better than the control group with a value of $p < 0.05$. The client is given a wet handkerchief dripped with mustard aroma and asked to breathe 3 times a day for 5 minutes in 4 weeks [3]

The clinical effects obtained by administering aromatherapy are improving sleep quality, decreasing fatigue, decreasing pruritus and decreasing pain. Improved sleep quality was found in RCT studies using essential lavender. Improves sleep quality ($p < 0.05$) [4]. It was found that the quality of sleep improved but the decrease in fatigue and sleep strength was not significant [5], There was a difference in the quality of sleep on the client. The intervention group had better sleep quality with a value of $p < 0.0001$[6]. The three studies in common using the lavender aromatherapy found significant results in improving sleep quality by measuring using PSQI and Quality Of Sleep Questionnaire. Fatigue is a further problem that occurs in clients who undergo hemodialysis. Three

studies have found that aromatherapy decreases fatigue ($p < 0.05$) [5], decreased fatigue with a p-value of <0.05 [7] significantly able to reduce fatigue by measuring using VAS fatigue Scale, BFI and The Piper Fatigue Scale. The research was developed using palm aromatherapy, which was found with a value of $p = 0.001$ [8] and with a lower pruritus rate in the intervention group with a value of $p < 0.05$ [9] significant in overcoming the occurrence of pruritus in clients undergoing hemodialysis by measuring 5-D Pruritus Scale (Duration, Degree, Direction, Disability, Distribution) and Questionnaire of Pruritic Score. Aromatherapy lavender inhalation effectively reduces pain in AVF clients who have a value of $p < 0.001$[10], lavender aromatherapy lotion can reduce the pain intensity of the installation of dialysis needles with a value of $p = 0.001$ [12], In the intervention group there was a decrease in headache with VAS measurements and $p < 0.001$ [13] Differences in pain intensity were found with better intervention groups, namely with values $p = 0.009$.

The effect of aromatherapy on patients undergoing other hemodialysis is psychological. Depression is found in clients who undergo hemodialysis. Aromatherapy inhaled decreased depression, anxiety and stress with a p-value of ≤ 0.005[14], Giving aromatherapy effectively reduces depression and anxiety with value $p = 0.005$ [1]. The anxiety experienced by clients is related to HD processes. Application of aromatherapy can decrease anxiety with p-value = 0.005 [15], The findings after the intervention decreased anxiety by measuring the Spielberger's State-Trait Anxiety Inventory with a value of $p = 0.009$ [2] Differences and decreases in anxiety in the intervention group were found compared to the control group with a value of $p = 0.001$.

The limitation of this review was references collected in this systematic review have not been tested elsewhere or research has been done in a different place. The environment and perceptions of each individual both client, family and nurse greatly influence the success of the therapy given. Searching for literature that is constrained by language is because there is one article that uses languages other than English. Resource constraints in translating English into Indonesian. The discussion used is still in the form of aromatherapy, in general, to deal with problems in clients who undergo hemodialysis so that it does not look specific to one aromatherapy.

5. Conclusion

This systematic review aims to find evidence of the effects or effects of aromatherapy use on clients of End Stage Renal Disease during hemodialysis. The search for literature is based on relevance and then evaluates the quality of the literature. The findings show the effects of aromatherapy on health in general, clinical effects such as decreased pain intensity, increased sleep quality, decreased fatigue and decreased incidence of pruritus, and psychological effects namely decreased depression and anxiety. But the weaknesses of the methodology, the small sample size, the short duration, and the challenges associated with blinding. The combination of aromatherapy with massage is the best intervention compared to others. However, there is a need for further research on the side effects of aromatherapy, the use of which is in the long term so that the right and useful dosage is obtained.

Table 1. Characterized of literature

Author	Study Design	Sample	Intervention	Control/ Comparation	Outcomes measures	Result
Muz et al (2017)	Randomized Controlled Trial	N = 62 The intervention group N = 27 and the control group N = 35	Aromatherapy in the form of sweet orange and lavender is given inhaled at a dose of 10mL with a dark bottle	General intervention	Visual Analogue Scale (VAS) PSQI Piper Fatique Scale	Aromatherapy decreases fatigue and improves sleep quality ($p < 0.05$)
Abdelghfar (2017)	Quasi Experiment	N=30	Giving Aromatherapy Palm with 1-2 droplets applied to the skin	General intervention	5-D Pruritus Scale (Duration, Degree, Direction, Disability, Distribution)	Based on 5-D pruritus scale, the effect of palm aromatherapy was found with a value of $p = 0.001$
Dehkordi et al (2017)	Clinical Trial	N = 56 With each group N = 28	The client is connected to a dialysis machine, given a piece of cloth smeared with three drops of damask rose oil with a constant density of 2% which is tied to the patient's collar, and the patient is asked breathe normally	Without intervention	The DASS-21 for Depression, anxiety and stress	Measurements of The DASS-21 found a decrease in depression, anxiety and stress with a p value of ≤ 0.005
Bicer et al (2017)	Quasy Experiment	The number of samples is N = 105 with the inclusion criteria of 50 clients	Clients are asked to breathe in aromatherapy a combination of lavender and rosemary 3: 3 in 3 drops	Give the placebo	VAS fatique Scale dan BFI	VAS Fatique Scale and BFI measurements were found to decrease fatigue with a p value of <0.05
Afrasiabifar et al (2017)	Randomized Controlled clinical Trial	N = 42 with intervention group N = 22 and	Clients are given sweet almond oil in the area of pruritus as much	Without intervention	Questionnaire of Pruritic Score	There were differences in each group with

		control N = 20	as 5-10 cc			a lower pruritus rate in the intervention group with a value of p <0.05
Barati et al (2016)	Randomized Controlled Trial	N=46	Clients are given sweet almond oil in the area of pruritus as much as 5-10 cc The client is given three drops of rose water (at a concentration of 25%) on a clean absorbent cotton handkerchief using a dropper every night before going to bed and also 15-20 minutes before starting a dialysis session	Without intervention	The Spielberger's State-Trait Anxiety Inventory	The findings after the intervention decreased anxiety by measuring the Spielberger's State-Trait Anxiety Inventory with a value of p = 0.009
Nesami et al (2017)	Randomized Controlled Trial	N = 72 with each group N = 36	Aromatherapy with 3 drops of lavender 5% essential oil for 10 minutes each time they undergo hemodialysis for a period of one month	General intervention	The Hospital Anxiety and Depression Scale (HADS)	Giving aromatherapy effectively reduces depression and anxiety with value p = 0.005
Atapour et al (2016)	Clinical Trial Study	N = 80 with each group N = 40	The client is given a wet handkerchief dripped with mustard aroma and asked to breathe 3 times a day for 5 minutes in 4 weeks	The client is given a wet handkerchief without aromatherapy drop	SF36V2 questionnaire	Health in general in the intervention group was better than the control group with a value of p <0.05
Kiani et al (2016)	Clinical Trial Study	N = 70 with each group N = 35	Clients are asked to breathe a combination of essential 5% lavender and sweet almonds which are dropped on cotton for 15-	General intervention	The Spielberger's State-Trait Anxiety Inventory	Differences and decreases in anxiety in the intervention group were found

			20 minutes placed on the client's neck			compared to the control group with a value of p = 0.001
Park et al (2016)	Non-equivalent comparison group pretest-posttest design	N = 30 with intervention group N = 17 and control N = 13	The client is given aroma massage with a mixture of lavender and bergamot essential oils in a ratio of 1: 1 diluted to 1% with 100 ml of jojoba carrier oil. Provided massage with a duration of 5 minutes before the client sleeps	Clients are given massage without using aromatherapy with the same duration and time as the intervention group	The Piper Fatigue Scale Quality of sleep Quantity Of Sleep	It was found that the quality of sleep improved but the decrease in fatigue and sleep strength was not significant
Aliasgharpour et al (2016)	Quasy Experiment Clinical Trial Study	N = 40 with each group N = 20	Aromatherapy intervention is three drops Aromatherapy mixture contains 10% lavender essence which is poured into cotton in a pouring container, and the patient is asked to breathe it before insertion of the needle for 5 minutes from a distance of 7-10 cm	General intervention	VAS Scale Pain	Aromatherapy lavender inhalation effectively reduces pain in AVF clients who have a value of p <0.001
Ghods et al (2015)	Crossover Study	N=34	Clients to be carried out by AVF are given 100% lavender essential aromatherapy lotion	Giving placebo is sterile water	NRS (Numeric Rating Scale)	100% lavender aromatherapy lotion can reduce the pain intensity of the installation of dialysis needles with a value of p = 0.001
Bicer et al (2015)	Randomized Controlled Experiment	N = 50 with each group N = 25	Aromatherapy given to clients is a combination of	General intervention	VAS pain Scale	In the intervention group

	Trial		1% lavender with 1% rosemary on 48cc oil with massage on the face area every day for 3 weeks			there was a decrease in headache with VAS measurements and p <0.001
Nesami et al (2014)	Randomized Controlled Clinical Trial	N = 92 with each group N = 46	The client is given the essence of lavender by inhaling with a concentration of 10% for 5 minutes for 3 sessions of hemodialysis	Clients are given aromatherapy without lavender	Vas Pain Scale	Differences in pain intensity were found with better intervention groups, namely with values p = 0.009
Lenjan et al (2014)	Clinical Trial	N = 60 with each group N = 30	Clients are asked to breathe lavender essential aromatherapy with 5% given to the cotton placed on the client's neck	General intervention	PSQI	There was a difference in the quality of sleep on the client. The intervention group had better sleep quality with a value of p <0.0001

ACUPRESSURE IN RELIEVING FATIGUE : A SYSTEMATIC REVIEW

Anisa Ain
Faculty of nursing, Universitas Airlangga, Surabaya,
Indonesia Email : anisa.ain-2017@fkp.unair.ac.id

ABSTRACT

Fatigue is a common symptom of patients with acute and chronic health problems. The complementary alternative therapy which commonly used to relieving fatigue is acupressure. The aim of this review is to explain the effects of acupressure on managing fatigue in various acute and chronic health problems. A systematic review of English articles using Fifteen journals from the databases such as Scopus, Science Direct, PubMed, and Pro-Quest were selected was performed using the search terms of acupressure and fatigue. Studies during which acupressure was applied as an intervention and assessed for its effectiveness on relieving fatigue were selected with the last ten years time limitation. The results of the study reported the positive impact of acupressure in relieving fatigue level with several cases, especially on patient with end stage renal disease, persistent Cancer-Related Fatigue, postpartum women, post-caesarean section, multiple sclerosis, chronic obstructive pulmonary disease, chronic back pain and migraine. From this review, health care providers should begin to incorporate acupressure into their interventions, especially in reducing fatigue in patients with various illness.

Keywords: acupressure, fatigue, acute, chronic, disease, health problem and complementary theraphy.

1. INTRODUCTION

Fatigue is a common symptom associated with a wide range of chronic illness (Whitehead, 2009). Fatigue can refer to a subjective symptom of malaise and aversion to activity or to objectively impaired performance. It has subjective health complaint that entails emotional, cognitive, and behavioral components (Lewis and Wessely, 1992). The symptom of fatigue is a poorly defined feeling, and careful inquiry is needed to clarify complaints of fatigue, tiredness, or exhaustion and to distinguish lack of energy from loss of motivation or sleepiness, which may be pointers to specific diagnoses (Mayou, 2002). Patients may complain of difficulty in carrying out normal activities of daily living, inability to work energetically or a feeling of tiredness even upon waking up (Kalra and Sahay, 2018).

Subjective fatigue is normally distributed in the population. The prevalence of clinically significant fatigue depends on the threshold chosen for severity (usually defined in terms of associated disability) and persistence. Surveys report that 5- 20% of the general population suffer from such persistent and troublesome fatigue. Fatigue is twice as common in women as in men but is not strongly associated with age or occupation. It is one of the commonest presenting symptoms in primary care, being the main complaint of 5-10% of patients and an important subsidiary symptom in a further 5- 10% (Mayou, 2002).

Patients generally regard fatigue as important (because it is disabling), whereas doctors do not (because it is diagnostically non-specific). This discrepancy is a potent source of potential difficulty in the doctor-patient relationship. Fatigue may present in association with established

medical and psychiatric conditions or be idiopathic. Irrespective of cause, it has a major impact on day to day functioning and quality of life. Without treatment, the prognosis of patients with idiopathic fatigue is surprisingly poor. Half those seen in general practice with fatigue the use of acupressure is based on meridian theory. Acupressure is rapidly gaining acceptance as a safe, cost-effective, noninvasive, and non- pharmacological form of therapy. Proposes that acupressure stimulates meridians, a network of energy path-ways throughout the body, to increase the flow of qi (bioenergy), subsequently altering the symptom experience. Acupressure is applied to specific points by the use of finger, hand, elbow, foot, and/or acupressure band, an elastic band with a protruding plastic button for stimulation of these pathways to increase the flow of qi (Parisi *et al.*, 2013). Studies testing the efficacy of acupressure for symptom management have been a focus of research, particularly during the last decade. However, no reviews have been pub-lished reporting the efficacy of acupressure for relieving fatigue in various illness.

2. METHOD

This systematic review using Fifteen journals from the databases such as Scopus, Science Direct, PubMed, and Pro-Quest were selected was performed using the search terms of acupressure and fatigue. Studies during which acupressure was applied as an intervention and assessed for its effectiveness on relieving fatigue were selected with the last ten years time limitation. The study consist of Randomized Controlled Trials (RCTs) and Quasi Experiments from several database sources such as Scopus, ScienceDirect, PubMed and Pro-Quest with the last 10 years time limitation (from 2009 to 2018). The keywords acupressure, fatigue, acute, chronic, disease, health problem and complementary theraphy.

Table 1 Inclusion chriteria

Design
* Randomized Control Trial (RCT)
* Quasi-Experimental Design
Population
* Patient acute and chronic illness
Intervention
* Acupressure
Outcomes measured
* Fatigue
Comparation
*Acupressure Intervention Versus No Treatment
* Acupressure Intervention Versus Placebo

The inclusion criteria are set to limit the scope of the systematic review. The inclusion criteria of this systematic review include the research using acupressure intervention on adult age.
The first step in the preparation of this sytematic review is the identification of 142 journals that have been collected from various databases based on the reviewer's defined keywords. The journals are selected according to predetermined inclusion criteria

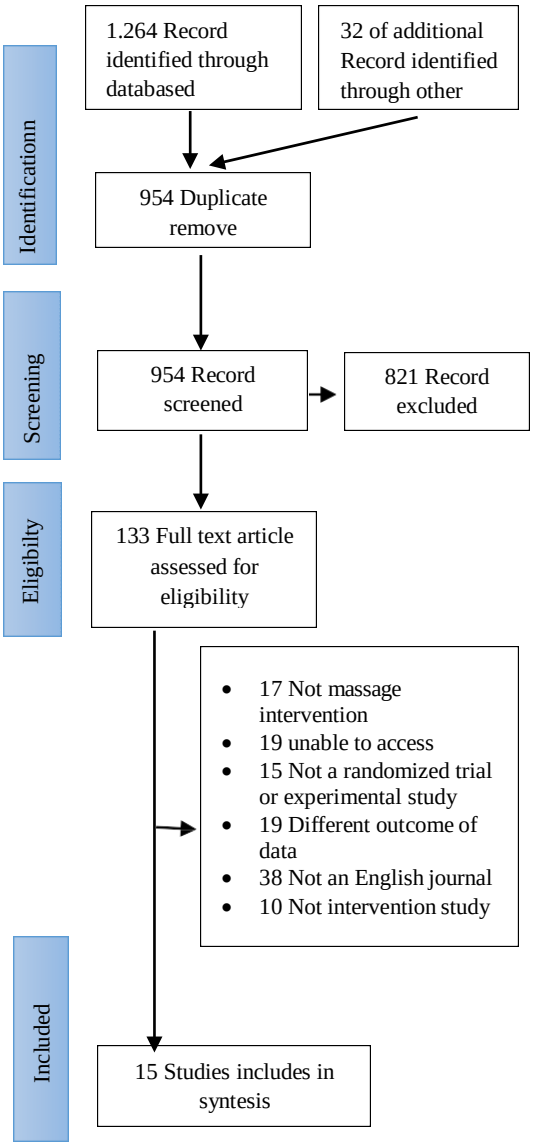

Figure 1. Flow of studies through the review

3. RESULT

Of the 15 research studies extracted, , three conveyed the use of acupressure to diminish the patient with end stage renal disease , five studies persistent Cancer-Related Fatigue. and the other studies includes postpartum women, post- caesarean section, multiple sclerosis, chronic obstructive pulmonary disease, chronic back pain and migraine.

Table 1. Description of the interventions and protocols used in the selected studies.

No	Author/year	Method	Case	Acupressure point	∑ Sample	Time
1	(McDougall and McDougall Jr., 2005)	QE	End stage renal disease	Combination St36, Sp6, K1, taixi	Acupressure (n = 28) Control (n = 28)	12 minutes 3 times a week For 4 weeks
2	(Tsay, 2004)	RCT	End-stage renal Disease	Combination K1, St36, GB34, Sp6	Acupressure (n = 35) Placebo (n = 35) Control (n = 36)	15 minutes 3 times a week 1 week

15	(Bastani, Sobhani and Emamzadeh Ghasemi, 2015)	RCT	Multiple sclerosis	The combination St36, Sp6, LI4	Acupressure (n = 50) Placebo (n = 50)	18 minutes 2 weeks (14 days)

*RCT : Randomized Controlled Trials
*QE : Quasi Experiments

3.1 The Effectiveness Of Acupressure On Fatigue In patient with end stage renal disease

Three study showed that acupressure can effectively reduce fatigue in patient with end stage renal disease. Patients with the end-stage renal disease (ESRD) who require maintenance hemodialysis often reported symptoms of fatigue.

Fatigue is viewed by health professionals as something that cannot be changed as it is part of the disease process (McCann and Boore, 2000). Thus, fatigue is rarely treated medically. However, medical treatment for ESRD patients may involve routine supplement of erythropoietin to correct anemia that may be related to the symptom of fatigue (Jhamb *et al.*, 2014).

Four acupoints were used to decrease fatigue, such as Yungchuan (K1) in both feet, Zusanli (St36), Yanglingchuan (GB34) and Sanyingjao (Sp6) in both legs. This study has shown that fatigue is a major concern. Results found that adjusted for differences in baseline fatigue, depression and sleep quality, patients in the acupressure group had a significantly lower level of fatigue (PFS) than patients in the control group (Tsay, 2004).

This study adds to previous research by supporting the positive effect of acupressure on the perception of fatigue. for hemodialysis patients. Participants in the study displayed a moderately severe level of fatigue. Moreover, many of these patients stated symptoms of fatigue began with the initiation of dialysis therapy, continued to experience post-dialysis fatigue that persisted during nearly all-waking periods. Patients managed symptoms of fatigue mainly through inactivity and sleep.

Acupressure techniques is noninvasive, safe and effective, can be easily taught to patients so that they can manage fatigue, and decrease adverse health outcomes to improve their quality of life. The findings of this study suggest that acupressure could improve fatigue (Eğlence, Karataş and Taşci, 2013)

3.2 The Effectiveness Of Acupressure On Fatigue In Patients With Cancer Underwent Chemotherapy

Cancer-related fatigue is the commonest symptom in cancer patients, with a high prevalence in most of studies. Side effects of medications and non-suitable relief of fatigue with medications, shifts the patients to complementary and alternative medicine like acupressure medicine.

Results of this investigation showed that acupressure in three points of L14, ST36 and SP6 has short-term effectiveness on the cancer-related fatigue of patients undergoing chemotherapy (Zick *et al.*, 2012). The study explored the effects of acupressure on fatigue and depression during transcatheter arterial chemoembolization in HCC patients. Acupressure contains eight auricular acupoints, including Yintang, Shenting, Cuanzhu, Taiyang, Jingming, Yangbai, Fengchi, and Baihui. Stimulating the Yintang, Cuanzhu, Taiyang, Yangbai, Fengchi, and Baihui acupoints can alleviate headache symptoms. Stimulation of the Shenting acupoints can raise vitality and improve dizziness. Stimulation of the Jingming acupoint can diminish tired eyes. Stimulation of the Fengchi acupoint can improve stiff neck, headache, dizziness, and fatigue (Lan *et al.*, 2015) .

3.3 The Effectiveness Of Acupressure On Fatigue In postpartum and post-caesarean section women

In particular, early postpartum mothers reported that maternal fatigue were high in childbirth. If the physical and psychological stresses of the postpartum period persist, they can have a negative impact on the mother and impair her adjustment to daily life, and negative feelings about the maternal experience are likely to lead to postpartum depression. Acupressure massage, which promotes the circulation of blood and lymph, mental stability, and relaxation of muscles, is thought to be effective in decreasing maternal obesity, edema, stress, and fatigue. Postpartum healthcare is one of the major issues in women's lives. Many study study find benefits of acupressure massage for postpartum women (Yeh *et al.*, 2017). This finding strongly suggests that meridian acupressure massage was effective for relieving fatigue in postpartum women.

Considering the average length of postpartum care center stay for postpartum women (1 week) and the time needed to perform a whole-body massage, we decided to apply meridian acupressure massage once a day for 90 min, over 5 days. Each meridian acupressure massage session consisted of a 5-min preparatory stage, an 80-min principal stage on abdomen, upper limbs, chest, abdomen, and lower limbs, side, back, and back and lower limbs), and a 5-min finishing stage (Jung *et al.*, 2017).

The other study showed auricular acupressure also can decreased fatigue symptoms of post-caesarean section women in early postpartum. No studies were found on the effects of auricular acupressure on fatigue, but two studies reported that acupuncture and acupressure of three acupoints (Zusanli, located at the anterior border of the tibia below the knees; Sanyinjiao, located at the medial border of the tibia above the ankle; and Hegu, located on the back of the hand between the thumb and index finger bones) reduced fatigue symptoms in women with cancer-related fatigue (Kuo *et al.*, 2016)

3.4 The Effectiveness Of Acupressure On Fatigue In patient with chronic obstructive pulmonary disease

The aim of the current study was to examined the effect of acupressure on dyspnea & fatigue among patients with COPD. The findings concluded that study group has statistically significant improvement in relation to dyspnea, respiratory rate and oxygen saturation than the control group (El-saadawy, 2013).

The demand for complementary therapies amongst chronic disease patients has gained significant momentum over recent years especially acupressure because it is safe effective method of treatment, with no side effect profile, which in part adds to its popularity amongst patients (Filshie, 2010).

Acupressure was applied by pressing in circular movements on the acupoint with the thumb finger. Seven acupoints were used in the current study which were: P6 (eiguan), St36 (Zusanli), CV 22 (Tiantu), BL3 (Feishu), Du14 (Dazhui), L1 (Zhongfu) & L10 (Yuji). The duration of each session

ranged between 20 – 25 min \ session, cosseting of 3 min of massage for neck and each shoulder to free the Qi and blood and 3 min for each acupoints to apply acupressure (El-saadawy, 2013).

3.5 The Effectiveness Of Acupressure On Fatigue In patient with chronic back pain

Lower back pain (LBP) is an extremely common health problem (Deyo, 2002). Lower back pain causes more global disability than any other condition. Disability-adjusted life years (DALYs) increased from 58.2 million in 1990 to 83 million in 2010 (Hoy *et al.*, 2014). It is causing an enormous economic burden in both developed and developing countries (Thelin, Holmberg and Thelin, 2008).

LBP is defined as a nonspecific condition that refers to complaints of acute or chronic pain and discomfort in the area between the lower posterior margin of the ribcage and the horizontal gluteal fold (Shmagel, Foley and Ibrahim, 2016).

LBP has a major negative impact on individuals health-related quality of life, including poor general health, psychological distress, sleep disturbances, disability and fatigue (Kovacs *et al.*, 2005). Fatigue limits functionality and can lead to social and psychological impairments. Fatigue is a symptom that can be particularly problematic for LBP patients, can complicate and disrupt recovery and delays optimal return to daily life and work (Sharpe, 2002)

Chronic low back pain (CLBP) has been associated with altered trunk muscle responses as well as increased muscle fatigability This study showed the positive effect of acupressure on the improvement of fatigue among female nurses with chronic back pain, immediately, 2 weeks, and 4 weeks after the intervention of acupressure (Movahedi *et al.*, 2017).

3.6 The Effectiveness Of Acupressure On Fatigue In patient in Women with Multiple Sclerosis

Multiple Sclerosis (MS) is the most prevalent neurological disease (Mao and Reddy, 2010). It is characterized by lesions and scarring of the protective myelin sheath of the central nervous system (CNS), leading to neuronal damage and axonal loss. It is more common in women than in men (Schwendimann and Alekseeva, 2007). According to a study in Multiple Sclerosis is unpredictable and is one of the major diseases affecting patients quality of life (Janardhan and Bakshi, 2002).

The course of the disease is uncertain and the clients with MS may face physical problems including muscle weakness, bladder and bowel dysfunction, problems with speech, and vision (Motl, Snook and Schapiro, 2008) and also hidden difficulties such as fatigue (Homorodean, Leucuta and Perju-Dumbravă, 2016). The patient's fatigue might be extremely debilitating and often causes one to have a sedentary lifestyle i.e. sitting, lying down or sleeping. Moreover, it has a great influence on all aspects of life, particularly on occupation, daily life activities, social relationships and self-care activities (Samuels & Ropper, 2010).

The experimental group were received acupressure, at the acupoints (ST36, SP6, LI4) and the placebo group, But at post- test, the results showed significant improvement of the mean scores of fatigue in the experimental group compared to the placebo group at immediately, two, and four weeks after the intervention (Bastani, Sobhani and Emamzadeh Ghasemi, 2015)

4. RESULT

From the results of the fifteen studies, acupressure is shown to reduce various fatigue patient with end stage renal disease, persistent cancer-related fatigue. And the other studies includes postpartum women, post-caesarean section, multiple sclerosis, chronic obstructive pulmonary disease, chronic back pain and migraine. This study shows that there are various acupressure points in relieving fatigue. Further research using combination with one or more other acupoints or using other methods would be very important for accelerating the process of healing for patients. Some experts believe that stimulation of points in acupressure prevents the transfer of acute stimuli and

increases the level of endorphins in the blood, and thus, causes pain relief. In some studies, it was also shown that massaging the placebo points could cause varying degrees of release and relaxation in the body, and consequently, affect the pain of muscle cramps.

Acupressure is a nonpharmacological theraphy that can cause the body to relax and is easy, safe and efficient. The who recognizes acupressure as a treatment to activate neurons in the nervous system, where it stimulates the endocrine glands and can turn on problematic. Zick, *et al* in breast cancer survivors found that the use of acupressure protocol was effective in significantly reducing fatigue; however, only relaxing acupressure was effective in also significantly improving sleep and quality of life (litzinger *et al.*, 2010). These effects are consistent with why one might select these points in an acupuncture protocol.

According to traditional chinese medicine theory, points used in the relaxing protocol were calming to the spirit (*Yin Tang*, *Anmian*, Ht 7), involved in the smooth flow of qi and emotions (LI 3), and involved in the formation of qi and blood (Sp6). Several of these points are commonly used in the treatment of insomnia (Deadman, 1998).

The stimulating protocol included the point involved in the formation of qi and blood (Sp6) but also included points to stimulate generation of qi and blood (St36), restore yang (LI4), *Tonify qi*/kidney/*Yang* (CV6, K3) and raise yang (*Du* 20). Several of these points are commonly used to increase energy and endurance (Deadman, 1998).

5. CLINICAL RECOMMENDATION

The systematic review begins to establish a credible evidence base for the use of acupressure in relieving fatigue. An evidence-base of reliable and valid evaluation is crucial for clinicians. In terms of the implication for nursing education, practice, and research, the review provides important evidence that acupressure uses a non-invasive, timely, and effective way. In addition, acupressure should be included in the nursing education curriculum to help students learn about the effectiveness of complementary therapies. Health care providers should have begun to incorporate acupressure into their practice to help patients who experience fatigue. before giving therapy, health care providers must have an official practice permit to ensure patient safety. they must also practice based on practical guidelines for acupressure management, because the incorrect application of finger pressure, the inaccuracy acupressure points and the inaccuracy selection of acupoint combinations may give different results to the patient.

6. CONCLUSIONS

The results of the study reported the positive impact of acupressure in relieving fatigue level with several cases, especially on patient with end stage renal disease, persistent Cancer-Related Fatigue, postpartum women, post-caesarean section, multiple sclerosis, chronic obstructive pulmonary disease, chronic back pain and migraine. This review shows that acupressure is a noninvasive, timely, and effective action in reducing fatigue in patients with various diseases.

7. LIMITATIONS

This study only contains the effects of acupressure in various patients with limited literary sources. we need to add other literature to support the results of the review, more special reviews are needed as evidence that acupressure can objectively relieve fatigue, for example from the biochemical and neuroimmunological dynamics of the human body.

ABSTRACT

Pursed lips breathing is a breathing technique used to resolve shortness of breath and breathing difficulties in COPD patients. Objective : To investigate the effectiviness use of PLB in exercise performance, ventilatory parameters, oxygen saturation and quality of life for individual during exercise in patients with COPD. Methods: the method used by searching through a database of the journal "Science Direct, Scopus, and Pro Quest". This search is limited to his journal starting in 2007-2018 Results: Literature search for completion of 608 journals. After reading the title and abstract on the inclusion and exclusion criteria, we finally included 15 relevant journals in the breathing control exercise. Study selection: This review includes random crossover studies, quasy experimental studies, mixed methodological studies and cross-sectional studies as a strategy to enhance the effects of PLB during exercise in patients with COPD. Data analysis: Systematic review adapted to PRISMA. Assessors analyze independent search results to find potential studies that meet the requirements and studies according to the title then the abstract is analyzed and only the journal meets the selected requirements. Conclusions: PLB effectively reduces ventilation parameters, increasing oxygen saturation and quality of life in patients with COPD.

Keywords: breathing exercises, pursed lips breathing, COPD

1. Introduction

Chronic Obstructive Pulmonary Disease (COPD) Often arises in middle age from smoking in a long time. Various risk factors such as smoking, air pollution, age and others[1]. Globally, an estimated 3 million deaths in the caused by this disease in 2015 i.e., 5% of all deaths worldwide in that year. Over 90% of COPD deaths occur in developing countries with weak economic levels. In Indonesia, the prevalence of COPD was 3.7% and increases with age and the incidence of COPD was higher in the males as much as 4.2%, whereas in women by 3.3%[2].

The impact of COPD on each individual Depending on the degree of complaints especially crowded and Decreased exercise capacity, characterized by airflow limitation due to obstruction of the airways. Because peripheral airway obstruction, the volume of water can Become trapped in the lungs[3], Secara general non-pharmacological therapy is given to Patients to manage, reduce

symptoms, improve lung function, cardiac work and improve the quality of life of Patients[4],

Pursed lips breathing is one of the very popular breathing techniques and is used for Patients with COPD. This breathing technique uses strategies pursed lips together when the exhalation [1].

Of the 15 studies recommend exercise PLB can do 6-10 minutes in a resting state can control and manage COPD Patients so well that PLB can reduce hyperventilation, increase of the diffusion of the alveoli, increasing improvement in lung function, working Decrease lung, lower respiration rate , stabilizing heart rate, lowering tightness and increase of oxygen saturation.

This study aims to Determine the effectiveness of the use of PLB in improving the ventilation parameters, oxygen saturation and quality of life ,

2. Method

2.1 Sources of Data and search

Systematic method used in this review begins with the selection of topics. Electoral population is used to search through the database of the journal "Science Direct, Scopus, and Pro Quest". This search is limited to journals starting in 2008-2018. Keyword English used is breathing exercises; pursed lips breathing; COPD, From the all journals have 15 journals on the topic. Fifteen of the journal Articles were then observed and performed Systematic Review

2.2 Study Selection

The review included a randomized crossover study, quasi-experimental study, a mixed methodological study and roomates across-sectional study aims to Evaluate the effects of PLB during exercise in Patients with COPD. The selected studies included Patients with the following characteristics: (a)ambulatory COPD Patients $\geq$ 40 years of age, smokers or ex-smokers $\geq$ 20 years; (B) a clinical diagnosis of COPD using spirometry criteria and GOLD criteria 2, 3 and 4 in a stable condition. (C) Absence: Client COPD status is unstable and with other comorbid diseases, The main intervention using PLB as a strategy to improve ventilation parameters, oxygen saturation and quality of life (QOL) for individuals during exercise in Patients with COPD,

2.3 Intervention

Data were collected and evaluated According to the criteria of inclusion and exclusion. Of Several journals, many interventions Independently Carried out with a different time. The duration of the intervention study intervention chest 10 minutes to 1 month.

a. Intervention 10 minutes to do the exercise PLB combination with other variables
b. Interventions for 1 till 4 weeks conducted exercises PLB combination with other variables

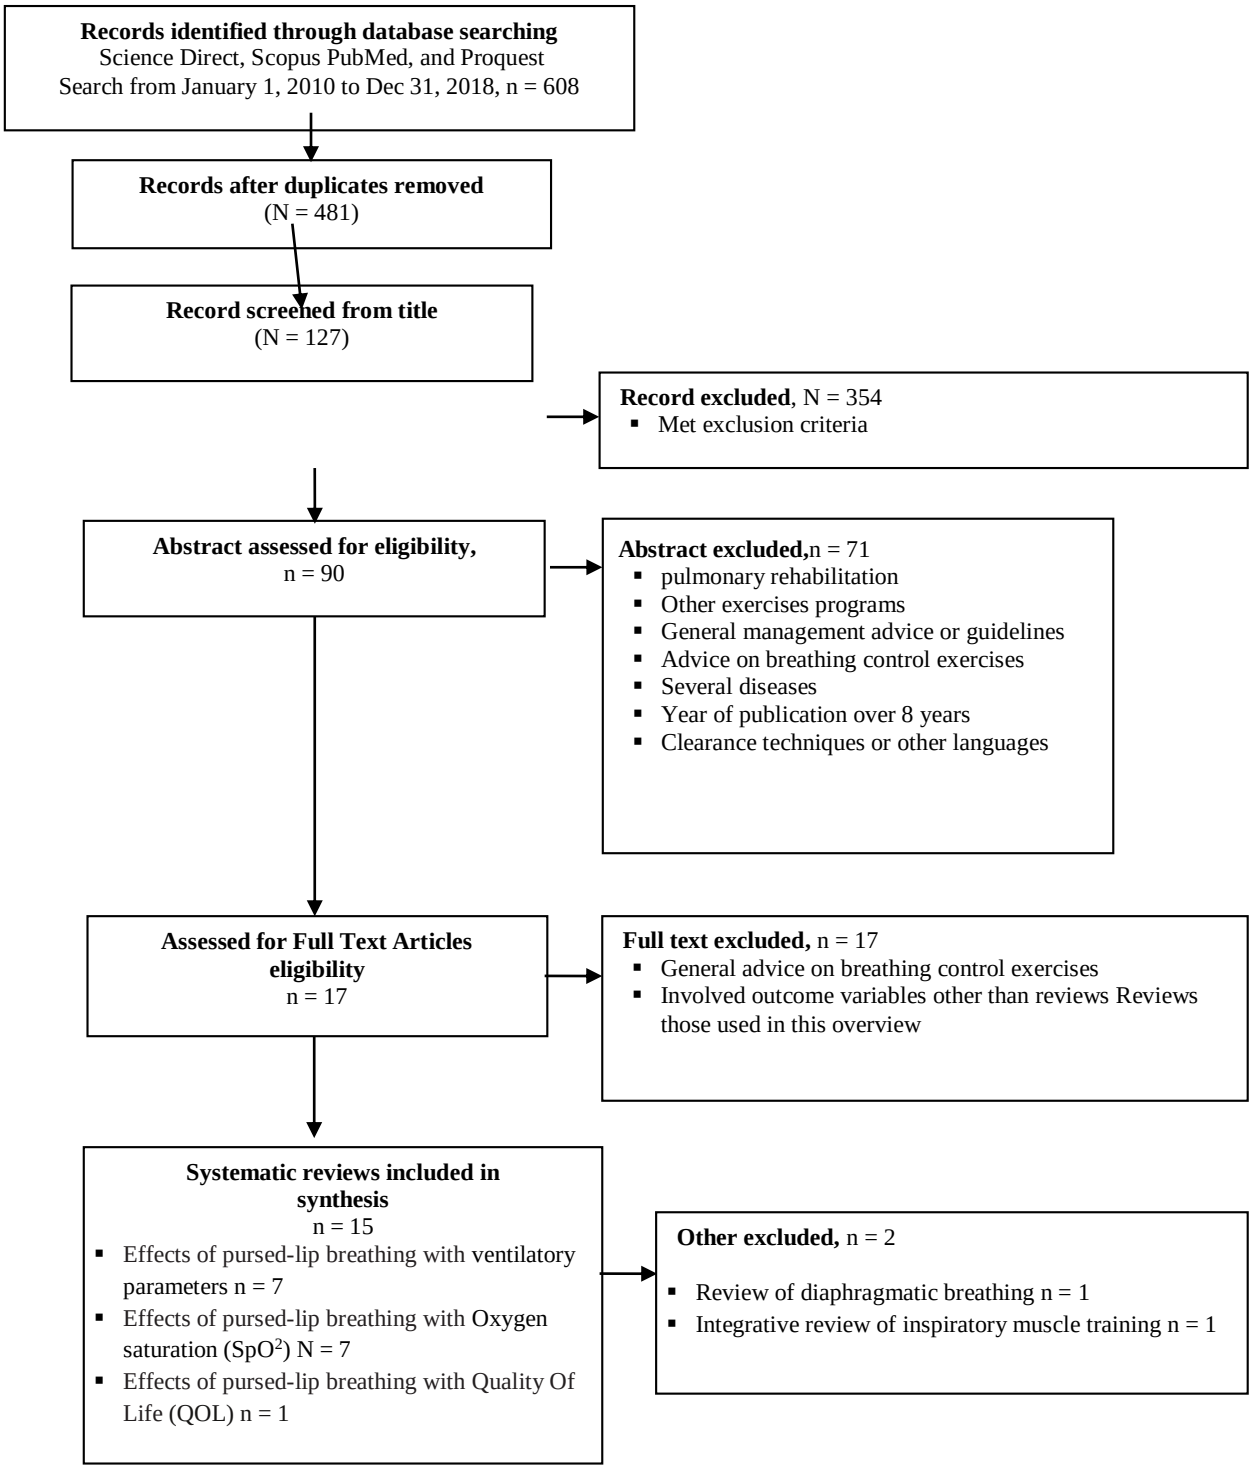

Figure 2 Flow chart of inclusion and exclusion process.

2.4 Data analysis

Systematic reviews in adjust to the Preferred Reporting Items for Systematic Reviews and Meta-analyzes (PRISMA). Appraisers analyze the results of an independent search to find any potential eligible studies. First, the study abstract is separated by title then Analyzed and only the selected journals qualify. Based on the abstract, the full article was Obtained for review, consideration, Analyzed and disputed on the feasibility study. In case of disagreement between the judge journals.

Systematic review which included organized and presented in one image. Figure 1 presents the information in a systematic search method selection. Table 2 Analysis overview effectiveness PLB on ventilation parameters, kinematics and muscle of breathing, shortness of breath, oxygen saturation (SaO2) and quality of life, Table 3 categorizes the description of the intervention and the authors' conclusion about PLB breathing control exercises on exercise performance, ventilation parameters, oxygen saturation and quality of life (QOL) Respiratory.

3. Results

Figure 2 shows the process of inclusion SR. Literature search identified 608 journals. After checking the titles and abstracts of the inclusion and exclusion criteria, we finally enter the relevant SR 15 on breathing control exercises. SR is based on complex interventions on exercise performance, ventilation parameters, oxygen saturation and quality of life and the authors have collected the data on different Reviews their pursed lips breathing exercises that exercise performance with variable, ventilation parameters, oxygen saturation and quality of life

In the subgroup analysis, there were effects found on ventilation parameters, oxygen saturation and quality of life, review diaphragmatic breathing and review inspiring muscle training not included as an exercise in this overview and therefore we exclude this SR, Furthermore, we exclude one-SR which was the previous updated version,

There is no effect on the SR-evaluation of shortness of breath / dyspnea, on relaxation techniques, exercise posture or muscle training.

4. Discussion

We-reviewed journal on the effectiveness of the quality of PLB to the ventilation parameters, oxygen saturation and quality of life in COPD Patients. The main result we show that, the effectiveness of PLB to the ventilation parameters, there are 18 independent variables are related, one journal no regard 1 to 3 variables related that the kinematics of the chest wall, as in kronisasi wall of the chest, shortness of breath , breathing patterns, respiration rate, work of breathing, improving the capacity of inspiration and dynamic hyperinflation. PLB effectiveness against oxygen saturation, there are seven independent variables related to and effectiveness of PLB to the quality of life there is one independent variable.

5. The effectiveness of the ventilation parameters PLB

respiratory ventilation explains the process of exchanging water between the environment and the lungs. Variables used to reflect Respiratory patterns are sensitive to changes in the frequency or volume of water diffused during respiration. Besides that, the pattern breathing Allows us to the study the mechanics and regulation of ventilation in the context of many factors that Affect supply oxygen, PLB effectiveness in regulating respiration in COPD Patients at rest - Significantly reducing respiratory frequency and increasing volume elasticity has been explained by authors such as Mende set al., Mayer et al., Borge et al., Laura et al.and others. Thus, this breathing pattern seems to be more effective than spontaneous breathing in COPD Patients.

Of the 15 journals there were 18 independent variables related, reported symptoms of decreased congestion, increased tidal volume and a significant Decrease in the frequency of breathing when using the PLB and Also There were no reports of improvement and Showed a significant decrease in respiratory frequency, Although there was no change in tidal volume. This finding supports the idea that not all Patients benefit from this breathing pattern. Author Associated improvement breathing pattern decreases end-expiratory lung volume(EELV),The author summarizes that a reduction of 3% to 4% in EELV in COPD Patients can be interpreted as a biomechanically favorable for inspiration. Low and higher tidal volume; The end result is Increased ventilation efficiency

5.1 Effect of PLB on kinematics and respiratory muscles

The breathing muscles are responsible for maintaining adequate ventilation. Strength and endurance of respiratory muscles can be assessed by measuring Several variables, such as maximum respiratory pressure (both inspiration and expiration), maximum voluntary ventilation, and transdiaphragmatic pressure, Dynamic measurement of the breathing muscles during the respiratory cycle is Achieved mainly by studying intrathoracic pressure (pleural pressure) measured in the esophagus and stomach pressure measured in the stomach area or, Alternatively, by plethysmography of the chest surface. Respiratory muscle function can also be evaluated by noninvasive (electrode surface) or invasive electromyography of the chest wall muscles (Mendeset al., 2018, [8–10,14].

The authors studied the work of breathing and the use of PLB during muscle ventilation in COPD Patients, observing significant reduction in gastric and pleural pressure during inspiration and improvement in breathing work. Enhancement of this is due to an increase of in the work of the chest wall (ribs) as a result of decreased work from the diaphragm, the which is the caused by more negative pleural pressure and Decreased gastric pressure during inspiration. Visser, besides confirming Reviews These results, Noted the use of abdominal muscles during the entire respiratory cycle and a significant Decrease in the diaphragm tension-time index. In another study, gastric pressure and surface electromyography were measured in COPD Patients, justifying Increased gastric pressure during expiration and contraction of all the abdominal muscles studied [15].

In summary, the PLB can be said to cause changes in the pattern of use of respiratory muscles, increase of the use of accessory muscles in the chest wall and increase of abdominal muscle activity throughout the breathing cycle while, at the same time, Decrease the use of the diaphragm muscle. All of Reviews These cause changes COPD patients to breathe more efficiently,

5.2 PLB on breathlessness

Patients with COPD, who perform PLB independently. Their findings suggest that the decrease breathlessness in patients due to reduced expiratory flow variability, leading to a decrease in the Bernoulli effect created by the air flow and thus reducing the tendency of the airways. Nevertheless, using the Borg scale to measure dyspnea in patients with COPD, compared to spontaneous breathing to PLB breathing and found that PLB-although improving ventilation, do not reduce the degree of dyspnea and even increased significantly in patients with PLB can be beneficial for patients with exercise [5,12].

5.3 PLB influence oxygen saturation (SaO2)

The author studied the oxygen consumption and clinical implications of having COPD Patients breathing exercises were put through with PLB Compared with spontaneous breathing. Studied changes in the volume of the chest wall lungs in COPD Patients do PLB. The authors observed that Patients Showed a significant reduction in end-expiratory lung volume (EELV), with a greater Decrease in obstruction. In addition, they Noted that Patients with COPD can perform Independently PLB.

Mechanically, EELV is the point of balance between the power of elasticity of the lung and the chest wall. The decrease EELV is an increase in the elasticity of the chest and potentially more energy for inspiration, which can occur passively as a result of the potential energy of the chest wall at the end of expiration. Effectiveness of PLB in PaO2, PaCO2 and oxygen saturation (SaO2) in COPD patients at rest and during exercise. At rest, they found a significant increase in PaO2 and SaO2 and a significant reduction in PaCO2; the result is the same for all patients. Patients feel the benefits of PLB. No significant changes in arterial gases during exercise was observed [5,13,16].

5.4 PLB influence on quality of life

Studies have shown that pulmonary rehabilitation, improves emotional function and increase of the sense of control that Patients of Reviews their condition. Reviews These are clinically significant improvements. Pulmonary rehabilitation is an important component of COPD management and was very helpful in quality of life related to health. We Evaluate the quality of life using the SGRQ [15–17].

6. Conclusion

Given the results reported in a systematic review, we conclude that PLB can improve

respiratory function in Patients with primary or secondary respiratory disease. Effectiveness PLB against the parameters of ventilation, oxygen saturation and quality of life in COPD patients is to improve the kinematics of the chest wall, as in kronisasi chest wall, work of breathing, improving the capacity of inspiration, oxygen saturation, quality of life and decreased shortness of breath, breathing patterns, respiration rate and hyperinflation dynamic in COPD patients.

ABSTRACT

The cause of poor sleep quality in hemodialysis patients is multifactorial, but one of the factors considered to be the cause is related to the timing of hemodialysis therapy. The purpose of this study was to determine the effect of differences in the timing of hemodialysis on sleep quality. This study uses search through electronic databases, which is Scopus, PubMed and Science Direct and Spingerlink which have been published without time limits using keywords ("dialysis" AND "shift" AND "sleep" AND "sleep" AND "quality"). Initial searches were found in 158 articles, and after going through the selection 8 articles were obtained. The schedule for implementing hemodialysis of patients with chronic kidney disease is divided into morning, afternoon, evening, night and rotation shifts. The main instrument used to determine changes in sleep quality in hemodialysis patients is by using The Pitsburg Sleep Quality Index (PSQI). Several articles also known to assess the level of daytime sleepiness, and restless legs syndrome. The average percentage of hemodialysis patients who experience poor sleep quality from each shift is approximately the same, which is around 40% -70%. The difference in the timing of the implementation of hemodialysis does not significantly influence the level of sleep quality.

Keywords: dialysis shift, hemodialysis, sleep quality.

1. Introduction

Hemodialysis is one of the renal replacement therapies for patients suffering from chronic kidney disease. Users of hemodialysis therapy reach 2.5 million or 80% of the 3 million people who use various types of kidney replacement therapy. Hemodialysis can prolong the life expectancy of patients with chronic kidney disease, but the therapy can have an impact on changes in the body's biological functions, one of which is a change in the quality of sleep [1]. More than 80% of patients undergoing hemodialysis have complaints of subjective sleep quality disorders [2].

The statement of the results of the study was also supported by the results of other studies that 73.9% of 142 ESRD patients undergoing hemodialysis therapy had poor sleep quality [3]. Sleep quality disorders that are often experienced by hemodialysis patients include insomnia, sleep apnea syndrome (SAS), restless legs syndrome (RLS), periodic limb movements (PLM) disorder and excessive daytime sleepiness (EDS) [2].

Disorders of sleep quality can cause emotional and physical problems in hemodialysis patients

[4]. Emotional problems that can occur in hemodialysis patients due to poor quality of sleep include increased irritability, confusion and cognitive decline that affect decision-making processes and problem solving [1],[5]. Physical problems that can be experienced by hemodialysis patients due to poor quality of sleep are fatigue, drowsiness, disruption of daily activities (especially during the day), impaired quality of life related to health (Quality of Life) and increased occurrence of morbidity and mortality [5].

The cause of sleep quality disruption in patients undergoing hemodialysis is multifactorial, but one factor that is considered to be the cause is related to the timing of the implementation of hemodialysis (dialysis shift). Patients with chronic kidney disease who undergo hemodialysis in the morning are believed to be more able to prolong life expectancy, but experience insomnia more often and can cause drowsiness and sleep during dialysis which lasts higher than patients who undergo hemodialysis at different times [4],[6].

Hemodialysis therapy during the day can cause disruption of the sleep wake cycle circadian rhythm, which can inhibit melatonin production at night [4], [7]. The implementation of hemodialysis at night at home is considered to be the most effective because patients do therapy as well as sleep at night so as to reduce drowsiness and excessive sleep during the day, but home hemodialysis facilities are not found in many developing countries [8].

The literature study using systematic review methods related to the effects of hemodialysis on sleep quality has been reviewed, but there is no systematic review that discusses the impact of the timing of hemodialysis (dialysis shift) on patient sleep quality. This systematic review seeks to review the research literature that deals with the influence of the timing of hemodialysis (dialysis shift) on the sleep quality of hemodialysis patients and knows the timing of hemodialysis which has the mildest sleep disturbance effect. Determination of the level of sleep quality in patients undergoing hemodialysis with different schedules in each literature obtained using a questionnaire that assessed sleep quality subjectively.

2. Method

This systematic review uses a guide based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyzes (PRISMA) guidelines [9].

2.1. Search strategy

Literature searches in this Systematic Review through four electronic databases, namely Scopus, PubMed and Science Direct and Springer link which have been published indefinitely. The keywords used are (1) dialysis shift, (2) hemodialysis (3) sleep quality.

2.2. Inclusion and exclusion criteria

2.2.1. Study Design. The study design that became the inclusion criteria for a systematic review was a design (1) clinical trial (2) a cross-sectional study.

2.2.2. Type of Participants. Participants in this systematic review were patients with chronic kidney disease who underwent hemodialysis and who were over 18 years of age

2.2.3. Output Measurement. The main output examined was subjective sleep quality in patients with

chronic kidney disease who underwent hemodialysis at different times, i.e. morning, afternoon, evening or night measured using the Pittsburg Sleep Quality Index (PSQI).

2.3. Study Selection

The protocol standard for selecting research studies is suggested in the PRISMA method for systematic review followed by screening by removing duplication, then the reviewer selects titles, abstracts and keywords, then removes irrelevant citations according to the selection criteria. The reviewer noted the reasons for choosing the research study including the selection of inclusion data. The selection of research studies that have been recorded by reviewers is then compared with each other to adjust their feasibility to the criteria set. Second, to minimize the risk of incorrect entry into the selection there are several research studies that have been applied or can be applied by reviewers to be included in the next review stage. The full text of the article is obtained if the title and abstract meet the inclusion criteria or if the feasibility study is clearly completed through joint discussions between reviewers.

3. Result

3.1. Literature search and selection

A total of 8 studies were identified to be included in the review. Searches from Scopus, PubMed, and Science Direct and Springer link found a total of 158 articles. After checking for duplication, a total of 98 articles were obtained. Of these, 67 studies were discarded because after a review the abstract did not meet the criteria. The full text of the 39 remaining articles was examined in more detail, apparently 21 studies did not meet the inclusion criteria as specified (Figure 1).

3.2. Study Characteristics

3.2.1. Population. This study involved 1,539 participants with the main inclusion criteria being patients with chronic kidney disease who underwent hemodialysis aged 18 years or older who were assessed for their sleep quality.

3.2.2. Outcomes. The main results assessed in this study were the subjective sleep quality level of chronic kidney disease patients undergoing hemodialysis with different times including morning, afternoon, evening or evening using the Pittsburg Sleep Quality Index (PSQI).

4. Analysis

4.1. Study characteristics

Table 1 contains the characteristics of the study from the results of identification of the literature used in systematic reviews. Eight literature used a cross-sectional study design. A total of 1,539 hemodialysis patients with a mean age of 56 years were involved in this study. These patients had undergone hemodialysis therapy for 65 months with a 4-hour implementation time for each hemodialysis procedure. Each patient can undergo hemodialysis 3 times a week which is divided into 3 or 4 different shifts, namely morning, afternoon, evening, night or rotation.

The entire assessment of subjective sleep quality in the literature uses the Pittsburg Sleep Quality Index (PSQI). Some literature also conducts daytime sleepiness assessments using Epworth

Sleepiness Scale (ESS). The assessment of the occurrence of restless legs syndrome (RLS) in hemodialysis patients is determined using the International Restless Legs Syndrome Study Group.

4.2. The effect of hemodialysis on subjective sleep quality.

Poor subjective sleep quality is a common problem in patients undergoing hemodialysis. Assessment of subjective sleep quality in patients undergoing hemodialysis was searched in all research articles using the Pittsburg Sleep Quality Index (PSQI) instrument. The results of subjective sleep quality assessment performed using PSQI showed that 40%-90% of hemodialysis patients experience poor sleep quality [2],[4],[6],[7],[8],[10],[11],[12]. In particular there are research results that show that 53% of hemodialysis patients experience subjective sleep quality problems from a total of 73.5% of the various types of sleep problems they have experienced (Table 3) [10].

There were 2 studies using the Epworth sleepiness scale (ESS) sleep scale to observe nap activity [2], [6]. One study showed that 28% of hemodialysis patients had long naps [2], whereas other studies showed that no long napping activity was found in hemodialysis patients with an average ESS = 2.37 [6]. From the two results of the study it can be concluded that the action of hemodialysis does not significantly affect the length of the patient's napping activity and the level of nap activity was not significantly affected by differences in hemodialysis therapy schedules ($p = 0.41$ and $p = 0.34$) [2],[6].

Assessment of the occurrence of restless legs syndrome (RLS) was also carried out using the International Restless Legs Syndrome Study Group in hemodialysis patients. The results obtained from the study amounted to 48% of 100 hemodialysis patients experiencing restless legs syndrome (RLS) [2]. Restless legs syndrome had a significant impact on sleep quality disorders ($p = 0.004$) and the occurrence of prolonged napping activities ($p = 0.005$), but were not significantly affected by differences in hemodialysis therapy schedules ($p = 0.52$) [2] (Table 3).

4.3. Effect of the timing of hemodialysis (dialysis shift) action on the subjective sleep quality

The timing of hemodialysis is considered to have an effect on the quality of the patient's sleep, but some results of the study state that the hemodialysis schedule has no effect on the patient's sleep quality.

This systematic review conducted a review of eight research literatures. Related to the schedule for implementing hemodialysis therapy, it can be divided into several times (shift), namely morning, afternoon, evening, night or rotation. In table 2 one literature study can be seen with 4 shifts and 2 shifts in hemodialysis time, four literatures studies with 3 shift hemodialysis schedules and two literatures studies with 3 shift hemodialysis schedules and rotational schedule. There are five research pieces of literature which show that hemodialysis time does not have a significant effect on the level of sleep quality of patients with a value of $p > 0.05$ [2],[11],[7],[12],[8].

The average percentage of hemodialysis patients who experience poor sleep quality from morning shift, afternoon, evening, night and rotation are more or less the same, which is around 40% -70% (Table 2).

There are three studies showing different results, namely there is a significant effect related to differences in the application of hemodialysis at the level of quality of sleep of patients [6],[10],[4]. One of the three studies stated that patients who took hemodialysis therapy in the evening had longer

sleep duration (p = 0.020) and took sleeping pills (p = 0.049) less than patients who took therapy in the morning or afternoon [6]. The results of other studies also stated that hemodialysis therapy in the evening has better sleep quality than other shifts (p = 0,000). Evening hemodialysis therapy had a significant effect on subjective sleep quality (p = 0.045), sleep duration (p = 0.000), sleep habits (p = 0.000) and sleeping drug consumption (p = 0.022) [10]. But there is a literature that states differently that patients who perform hemodialysis in the morning have better sleep quality than hemodialysis performed in the afternoon or evening (p = 0.01) [13] (Table 2).

5. Discussion

This systematic review is to determine the effect of differences in the timing of hemodialysis (shift dialysis) on the patient's sleep quality. Based on a review of 8 articles involving 1539 patients who routinely performed hemodialysis, the results showed that in general sleep quality changes occurred in patients undergoing hemodialysis.

Subjective measurement of sleep quality was conducted using the Pittsburg Sleep Quality Index (PSQI) in all articles shows that 40%-90% of hemodialysis patients experience poor sleep quality (Table 3). In addition, most articles state that patients taking hemodialysis therapy with a specific schedule or shift have the same level of sleep quality disorder, which is 40%-70% (Table 2) [2],[4],[6],[7],[8],[10],[11],[12].

Metabolic abnormalities in hemodialysis patients affect the increase in blood urea levels or uremia, thus causing beta 1 and 2 adrenergic receptors in blood plasma to significantly decrease. The decrease in beta adrenergic receptors has an impact on the decrease in levels of the hormone melatonin in the body that plays a role in regulation of the sleep cycle [14], [15]. Melatonin levels in hemodialysis patients are also influenced by the timing of hemodialysis therapy [14]. Hemodialysis therapy in the morning can cause excessive drowsiness during the day, which interferes with the wakeful sleep cycle in hemodialysis patients [16].

6. Conclusion

During the hemodialysis process, mononuclear cells produce interleukin 1 (IL-1), interleukin 6 (IL-6) and tumor necrosis factor (TNF) as a result of complement activation, interaction with dialyzer, and / or exposure to bacterial wall fragments (muramyl peptide). IL-1 is involved in the production of body heat (fever) and sleep induction. Fever and shivering generally occur during or after the dialysis process on a machine contaminated with endotoxin. IL-1, IL 6 or TNF produced by peripheral blood mononuclear cells in the bloodstream are considered as pyrogenic signals by the central nervous system (CNS).

The signal induces prostaglandin synthesis which represents the central mediator of a coordinated response that leads to an increase in the body's core temperature. Body temperature can also increase due to heat load from the hemodialysis procedure. This condition will stimulate the thermostat in the hypothalamus to activate the body's cooling system, thereby increasing the tendency to sleep during the day and will reduce the onset of sleep at night. Increased episodic body temperature due to hemodialysis procedures can change the tendency of sleep rhythms [18]. In the

end, reduced sleep onset at night results in a loss of time to produce melatonin at night so that the levels of the hormone melatonin decrease [14]. Decreasing levels of the hormone melatonin results in reduced sleep duration and difficulty maintaining sleep [17].

7. Limitation

The limitation in this systematic review is the assessment of the sleep quality of hemodialysis patients which is only limited subjectively by using a questionnaire without being accompanied by objective assessments, for example measuring oxygen saturation or using polysomnography (PSG). This systematic review explains the effect of the different timing of the hemodialysis action on the sleep quality of subjects with hemodialysis. In general, chronic kidney failure patients undergoing hemodialysis experience poor subjective quality of sleep. Hemodialysis patients undergoing hemodialysis therapy in the morning, afternoon, evening or evening have the same sleep quality. So that it can be concluded that the difference in the timing of the implementation of hemodialysis has no significant effect on the level of sleep quality of the patient.

INTERVENTION OF WALKING EXCERCISE TO REDUCE FATIGUE IN BREAST CANCER PATIENTS: SYSTEMATIC REVIEW

A Rufaida, E Yunitasari, I Krisnana
Faculty of Nursing Airlangga University, Surabaya, East Java, Indonesia
Email: anna.rufaida-2017@fkp.unair.ac.id

ABSTRACT

The occurrence of fatigue in breast cancer patients is a side effect that often occurs in patients after undergoing chemotherapy and radiotherapy. Rest does not always reduce fatigue. Many people think that cancer fatigue and cancer symptoms are very disturbing or troublesome. Even felt worse than pain. This fatigue can interfere with their social life, their work, and other activities they like. The purpose of this systematic review is to describe the effect of walking exercise intervention on reducing fatigue in cancer patients who have undergone chemotherapy and radiotherapy treatments. Article search uses the PECOT framework in the database; Scopus, ScienceDirect, ProQuest, and SpringerLink with limited year used 2015- 2019. In searching for articles, 115 articles were taken. Using matching keywords 20 article determined to be a systematic review. Walking therapy is an effective therapy that can reduce fatigue in cancer patients after undergoing treatment. Walking exercises can reduce fatigue in cancer patients who have chemotherapy and radiotherapy treatments.

Keywords: cancer, fatigue, walking exercise

1. Introduction

Breast cancer is the most common cancer found in women, with 25%, or 1,67 million new breast cancer cases occurring in 2012 [1]. There are many treatment methods for breast cancer including chemotherapy, radiotherapy, surgery, and immunotherapy, yet, these treatments may cause unwanted side effects that affect the patients' life quality. The medication used in the chemotherapy causes harmful symptoms like body pain, fatigue, nausea and vomiting, anxiety, depression, anorexia, insomnia, damaged skin and nails, suffocation, mouth ulcer, and other muscular nerve systems damages [1].

One of the most reported side effects of chemotherapy and radiotherapy cancer medication, as told by the patients, is fatigue. In this case, fatigue is caused by the cancer medication which affects the patients' condition before, during, and after the curing process [2]. A percentage of 41% of breast cancer patients have reported medium to severe fatigue during medication. Even years after the medication is finished, 30% of the patients could still experience the symptoms [3]. About 80 to 96 percent of the chemotherapy patients and 60 to 93 percent of radiotherapy patients also experience it [4]. This condition is reported to be the most disturbing condition that impacts the patients' quality of life and disturbs their daily activities [3].

There are ways to cure the post-medication fatigue that happens to a patient, which is to take

pharmacological and non-pharmacological therapy. One of the non-pharmacological treatments that can be applied is walking exercise. It can minimize the side effects results from the medication. Moreover, this method does not require much financial expense, while it has been proved to be one of the most effective interventions to reduce fatigue caused by cancer medication. Hence, non-pharmacological treatment can be considered as an alternative [5].

The objective of this systematic review is to acknowledge the effects of walking exercise therapy in breast cancer patients with fatigue symptom from the available quantitative studies to inform the patients, carer (family), and clinical research.

2. Method

2.1. Protocol

This Systematic review uses a guide based on the Preferred Reporting Item for Systematic Review and Meta-Analysis (PRISMA) [6].

2.2. Eligibility criteria

Journal articles published in English from 2008 to 2018. Search strategy using the PICO framework to identify the keyword.

2.2.1. Type of study design. All of these studies are experimental studies (including RCTs and non-randomized trials) that study the effectiveness of exercise exercises running on fatigue in breast cancer patients after treatment.

2.2.2. Type of participants. The studies studied included patients with breast cancer, patients after getting treatment and patients with fatigue.

2.2.3. Type on intervention. The intervention carried out was walking exercise given to breast cancer patients who had undergone treatment to reduce the occurrence of fatigue after treatment.

2.2.4. Type of clinical outcome. Fatigue is a problem that occurs after treatment of breast cancer patients.

2.3. Information sources

Studies were identified by searching electronic databases and scanning reference lists of articles. Three databases were systematically searched including Scopus, Science Direct, ProQuest, and SpringerLink.

2.4. Search

Search terms in the database using a combination of keywords (1) cancer (2) fatigue (3) walking exercise.

2.5. Study selection

The protocol standard for selecting research studies is suggested in the PRISMA method for systematic reviews followed by screening by removing duplicates, then two reviewers (AR and EY) chose titles, abstracts, and keywords, and then deleted irrelevant articles. The selection of research studies that have been recorded by two reviewers is then compared with each other to adjust their feasibility to the specified criteria. The full text of the article is obtained if the title and abstract meet

the inclusion criteria or if the feasibility study is clearly supplemented by joint discussions between reviewers.

2.6. Data collection process

The following data were extracted: author, year, journal, country, research arrangement, and main results. Two authors (AR and EY), are involved in data extraction, and after organizing the results in a table, the findings are discussed and reviewed. One review author extracted the following data from the included studies and other authors examined the extracted data. Disagreement is resolved by discussion between authors.

2.7. Data item

Information was extracted from each included study on (1) study identity (including the author's name, year of publication and origin of study); (2) study arrangements (including participant characteristics, interventions, presence of control groups as a comparison, intervention time, modality, frequency, setting, and implementation); (3) outcomes measure and tools; (4) major findings relevant for review.

2.8. Risk of bias assessment

Two reviewers independently evaluated the quality and risk of bias in each study according to the Cochrane Risk of Bias Tool. For research using the RCT design, the assessment uses RoB 2.0 which consists of 5 domains, namely: (1) the randomization process, (2) the deviation from the intended intervention, (3) missing results data, (4) measuring results and (5) Selection of reported results [7]. Non-randomized studies were assessed using ROBINS-I [8]. The ROBINS-I tool includes seven domains, where bias can be included in non-randomized studies or interventions (NRSI). The first two domains discuss the problem before the intervention comparisons, the third domain discusses the classification of the intervention itself and the other four domains discuss the problem after the intervention has begun [7]. Reviewers re-examine their final assessment and resolve disagreements through a discussion.

2.9. Data analysis

The study was grouped based on the intervention used and the study population. If possible, the study was then grouped based on the time of follow-up and the type of control group. All studies were individually assessed for levels of evidence using the National Hierarchy of Evidence (NHMRC) Board of Health and Medical Research (IV-I guidelines, with me being the strongest level of evidence).

2.10. Meta-analysis

Meta-analysis is not possible because studies are too heterogeneous in design and methodology, namely; in the type of intervention, type of control group, outcome measures used and time of follow-up.

3. Result

3.1 Study Selection

The search strategy that had been carried out resulted in a total of 115 citations, with 47 duplicates and 68 kinds of literature deleted in the first roll due to incompatibility between the articles' title and the feasibility criterion that had been set. There were 29 full articles from the second filtering process from which 12 articles were finally kept for a further review. Another 8 articles were obtained from the reference screening, thus, the final result consisted of 20 articles about exercise and fatigue cancer patients.

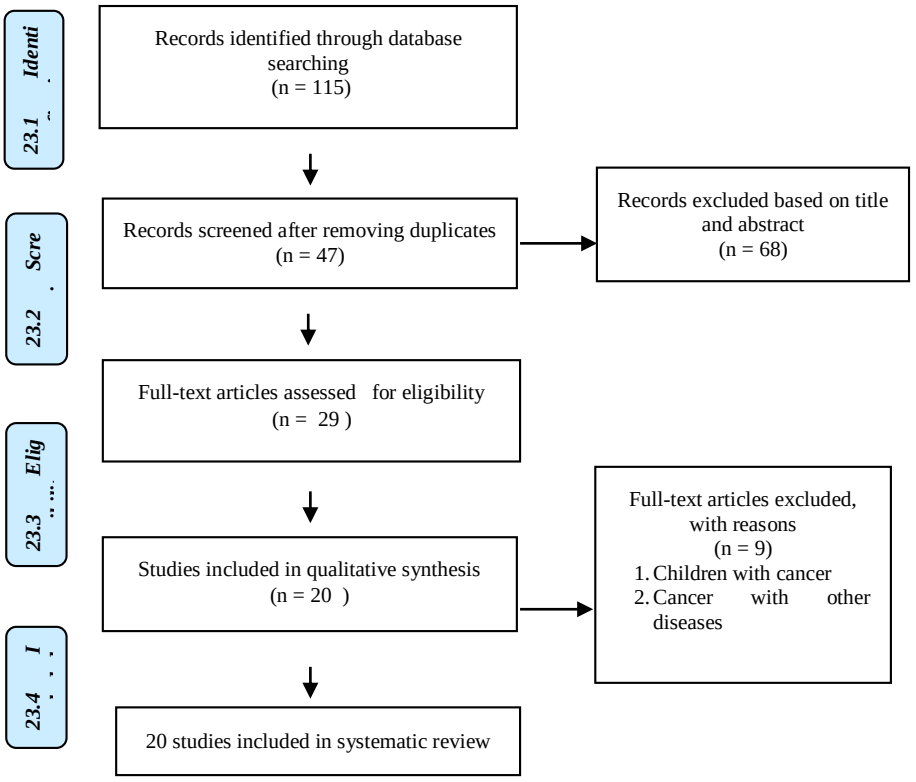

Figure 1. Flow Diagram

3.2 Characteristics Study

The 16 chosen studies, based on the 2008-2018 review, were carried out in 13 different places: England, Australia, America, China, Turkey, Amsterdam, New York, Taiwan, Thailand, London, Germany, Iran, and Korea. The quantitative method used in the studies covered mixed methods study, randomized controlled trials, quasi-experimental desgign, uncontrolled random group experiments, cross-sectional descriptive and comparative designs, cross-sectional study, retrospective analysis of archived data, and quasi-randomized trials.

3.3 Results synthesis

The literature research process had identified 20 journals defining the intervention of exercise to reduce fatigue in breast cancer patients who undertook chemotherapy and radiotherapy. Finally, it was found out in the journals that mild walking exercise could actually reduce fatigue

3.3.1 Walking exercise. Walking as an exercise is one of the most effective approved nonpharmacological interventions to reduce fatigue in connection to cancer [5]. This activity is accessible by everyone and a cheap option to recover from fatigue [4]. Walking exercise has significant effects. It is expected to be routinely done in mild to medium intensity to maintain functional ability and to reduce fatigue in women with breast cancer who undergo chemotherapy treatment [9]. The walking exercise intervention has been proven to effectively improve the physical activity which produces energy and reduces exhaustion. [5]

3.3.2 Fatigue. Fatigue is commonly reported by cancer patients and it often happens to patients who take medication [10]. It is a side effect that a patient could experience before, during, and after the medication therapy [2]. Some studies have demonstrated that there is a significantly high prevalence number of clinical fatigue during and after medication, but there are also some minor cases in which the fatigue does not get better; it even gives a paralysis effect months or years after the medication ended [2]. The fatigue caused by cancer medication can also agitate the medication process itself [9]. Hence, the occurrence of fatigue that happens after breast cancer patients take chemotherapy and radiotherapy medication must be treated sooner to prevent further possible harmful effects

4. Discussion

This systematic review was formulated to explore interventions for walking exercises to reduce fatigue in breast cancer patients undergoing chemotherapy and radiotherapy. There are 20 articles that have been identified to discuss issues that contain objectives that are consistent with this study. The research design used in this study included a quantitative approach, which was used in 19 studies, and 1 mixed method.

Effective exercise interventions can be carried out for patients who have undergone chemotherapy and radiotherapy [1,11]. A sports intervention suitable for cancer patients is walking exercise, which is generally recognized as an approach to recovery and to prevent a recurrence. This therapy needs to require assistance from the family or the closest person [12]. This exercise can be an inexpensive method to improve cognitive function in women with breast cancer carried out gradually by making a notebook of daily activities for physical activity and monitoring [2,13,14].

Physically active women experience higher psychological wellbeing, less fatigue, and faster recovery after treatment [15]. They will also feel fitter after walking exercise. The results of previous studies also said that there was no difference seen in fatigue for the intervention and control groups before walking exercise. However, after the intervention, the intervention group fatigue was lower than the control group and this difference was statistically significant [16]. Physical active motion during and after cancer treatment can help cancer sufferers reduce the negative effects after treatment and it is evident that walking exercise has a positive impact.

Regarding the search strategy, it is implemented in a broad context at an early stage, this review study has several limitations. (1) the results of this systematic review are based on secondary

findings from previous studies. Previous studies have not been explored thematically which could lead to several factors that have not been mentioned before. (2) Heterogeneity of study design.

The walking exercise can be used for complementary theory development. It has a possibility to be chosen as an alternative intervention that can be applied by a nurse to minimize fatigue or exhaustion. The use of walking exercise or doing another form of exercise in mild intensity demonstrates significantly good result in reducing fatigue in breast cancer patients. Its application as part of the intervention given by the nurses, this could increase society's impression on the health-care provided by nurses. Thus, it is logical to assume that this is because walking exercise is simple, evokes a comfortable feeling, and strengthens the interpersonal bond between a patient and the nurse. Besides, walking exercise induces very minimum side effects, requires very little financial expense, and can be done by the patient at home with the accompaniment of family members.

5. Conclusions

This systematic review is aimed to discover proofs of the effectiveness of walking exercise in reducing fatigue in breast cancer patients undertaking medical treatment. The results show that walking exercise can actually minimize fatigue in patients, as demonstrated in almost all of the previous studies. The limitations of the study include the small amount of sample, the short intervention duration, and the unavailable tryout from a different region. There needs to be a further study about the effectiveness of walking exercise in reducing fatigue in a bigger sample group and longer duration of intervention.

ABSTRACT

Diabetes Mellitus is a metabolic disease that cause its patient need a long life maintenance. Diabetes self care is an important part of diabetes care. It is complex and involves major lifestyle changes that need to become a part of patient's daily routine including self- monitoring blood glucose (SMBG), diet, physical activity, foot care, and taking prescribed medication. Diabetes self care requires high level of adherence to those lifestyle changes. The Information Motivation Behavioral Skill (IMB) model of adherence focuses comprehensively on the information, motivation), and behavioral skills factors that are conceptually and empirically linked to adherence This systematic review aims to describe how information, motivation, and behavioral skill can affect adherence in patient with Diabetes Mellitus. 15 best articles were found using PECOT framework in some databases; EBSCO, Science Direct, Scopus, and Journal of Universitas Airlangga. Those articles have been chosen based on some criteria. The Information Motivation and Behavior Skill Model of Adherence has been shown to be effective in describing medication adherence in Diabetes Mellitus. So it can be used as a theoretical reference in making interventions to improve medication adherence in patient with Diabetes Mellitus

Keywords: information motivation behavioral skill, adherence, diabetes mellitus

1. Introduction

Diabetes is a global public health challenge because of its high prevalence and associated mortality and morbidity [1]. The International Diabetes Foundation (IDF) in 2009 predicted an increase in the number of people with DM from 7 million in 2009 to 12 million by 2030 [2]. Diabetes Mellitus is a hyperglycemia disease characterized by absolute absence of insulin or a relative decrease in insensitivity of cells to insulin. In people with uncontrolled diabetes mellitus, there will be an increase in blood glucose (sugar), called hyperglycemia. Hyperglycemia that lasts for a long time will cause serious damage to the body, especially to the nerves and blood vessels. Therefore, it is important to control glucose levels in the blood of Diabetes Mellitus patients. Type 2 Diabetes Mellitus patients often have problems with adherence to the treatment of Diabetes Mellitus. A recent study revealed 1 in 3 patients did not take the prescribed Diabetes Mellitus drug [3]. The management of Diabetes Mellitus in everyday life is a complex activity and requires an understanding of self-care therapy regimens for people with Diabetes Mellitus

such as physical activity, diet, self-monitoring blood glucose (SMBG), and glycemic control [4]. These things are the personal responsibility of a person with Diabetes Mellitus. But most Diabetes Mellitus patients do not adhere to the therapeutic regimen.

Diabetes Mellitus can also be called a "Long life" disease because this disease cannot be cured during the life span of the sufferer. So that patients need "Long life maintenance" or long-term management. The success of a treatment, both primary and secondary, is strongly influenced by the adherence of patients with Diabetes Mellitus to maintain their health. With good compliance, primary and secondary treatment can be carried out optimally and the quality of health can still be felt, but if Diabetes Mellitus patients do not have self-awareness to be obedient, it can lead to failure in treatment which results in decreased health. Even due to non-compliance in maintaining health, it can have an impact on the complications of Diabetes Mellitus and can lead to death.

Information Motivation Behavioral Skills (IMB) is a model of adherence in predicting behavioral adherence with treatment therapy regimens. The IMB model includes three main constructs that influence behavioral change: Information barriers, motivation barriers (personal and social), and behavioral skill barriers *[5]*. If there is a deficit in the three constructions, it will reduce the consistency of behavior performance in adherence. The IMB model of adherence focuses comprehensively on the information, motivation), and behavioral skills factors that are conceptually and empirically linked to adherence [6]. The research question of this systematic review was how The Information Motivation and Behavioral Skill affects self care adherence in patients with Diabetes Mellitus. This systematic review aims to describe and summarize how information, motivation, and behavioral skill can affect adherence in patients with Diabetes Mellitus.

2. Methods

The method used in Systematic Review begins with the selection of the topic of Self-Care Adherence in patients with Diabetes Mellitus Type 2. Keywords in articles were searched in several databases such as EBSCO, Science Direct, Scopus, ProQuest and Journal of Airlangga University. Keywords used were “Information Motivation Behavior Skill Model of Adherence”, "Diabetes Mellitus Type 2", "Self-Care", and "Adherence". This search was limited to the last 10 years range from 2008 to 2018. It found 111 articles in EBSCO, 40 in Science Direct, 63 in Scopus, and 8 in the Journal of Airlangga University.

Articles were selected for review based on studies that fit the inclusion criteria. The inclusion criteria in this Systematic Review were English and Indonesian articles, Self-Care Adherence in Diabetes Mellitus Type 2 patients, and the research design were Qualitative Study with phenomenology approach, case study, ethnography, and focus group discussion. The 20 suitable articles reviewed.

3. Result

3.1 Study Selection and Eligibility Criteria

Figure 1 showed numbers of studies screened in this systematic review. The inclusion criteria were English and Indonesian articles, Self-Care Adherence in Diabetes Mellitus Type 2 patients, and the research design was a qualitative study with a phenomenological approach, case study, ethnography, and focus group discussion.

Further criteria were used to include or exclude studies for this review. Those criteria were primary outcome, primary outcome measurement, study design, and language or location. For primary outcome, the article must include diabetes (type 1 or type 2, not restricted to age group studied) with a primary focus on adherence to prescribed glucose-lowering regimens. Studies were excluded if they did not specify the medications evaluated or if the primary focus was not adherence. Primary outcome measurement criteria was that the study must include descriptions about barriers to self care adherence in patients with Diabetes Mellitus. Study design criteria was qualitative study with a phenomenological approach, case study, ethnography, and focus group discussion. Other quantitative studies were included if the study design was described. Articles were excluded if they were review articles, editorials, letters, opinion papers, general practice papers, meta-analyses, a dual publication, protocol-only paper, or were published outside the review's time frame. The last criteria is language or location, studies from all countries were included if published in English to allow for a global understanding of self-care adherence in diabetes.

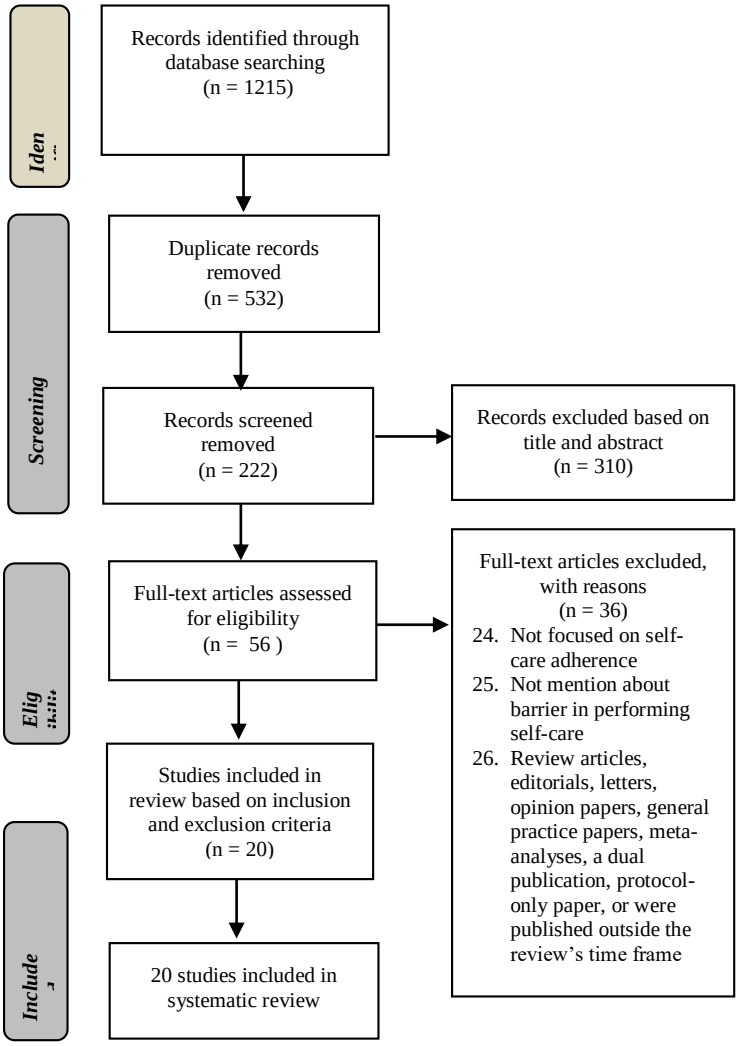

Figure 1. Flow Diagram

3.2 Study Characteristics

The studies reviewed in this article are 20 articles for self-care adherence in Diabetes Mellitus Type 2 patients. Research methods used by various articles ranged from qualitative studies with a phenomenological approach, case study, ethnography, and focus group discussion.

3.3 Result of Individual Studies

3.3.1 Information Barrier. Information barriers in patients with Diabetes Mellitus is a collection of relevant messages including the knowledge delivered related to self-care of Diabetes Mellitus which includes medication and glucose measurement, diet, activity, and foot care from health workers, advice from others, the media, etc. *[5]. A study conducted by Nelson et al., (2018)*

stated that information barriers that often occur in patients with Diabetes Mellitus includes the assumption that generic drugs are less effective than branded patent drugs and the disappointment felt when the treatment of diabetes does not have a fast effect.

Research of Woodcock, Gillam, & Frcp (2013) found that patients who knew about the condition of the illness and the complications that will be experienced. Most say they are afraid of comatose complications. In addition, most have received adequate information about Diabetes Mellitus Type 2 from doctors and nurses, but there was still a misperception about the information so that patients do not undergo self-care well. Patients stated the importance of ongoing care to treat diabetes. Nurses and doctors play an important role for that. Angelica et al. (2016) mentions Diabetes Mellitus patients have knowledge of Diabetes management. However, the knowledge possessed is very superficial and not applicative in their routines.

3.3.2 Motivation Barrier. In the study conducted by (Amico and Fisher, Fisher *et al.,* 2006) stated that adherence-related motivation refers to a personal and social motivation to follow one's regimen as prescribed. Personal motivation includes one's attitudes and beliefs about the consequences outcomes of both optimal and sub-optimal adherence. Social motivation includes perceptions of support for adherence behaviors from important others, as well as one's motivation to comply with their wishes.

This is in line with Rongkavilit *et al.* (2010) opinion that personal motivation includes positive or negative attitudes toward self-care compliance behaviors, perceived benefits of self-care, and perceived risks of self-care Diabetes Mellitus. Social motivation includes individual perceptions of social support from other people that are important for obedience and their desire to be obedient in carrying out self-care Diabetes Mellitus which includes Measurement of Glucose, Diet, Activity, and Foot Care.

Nelson *et al.* (2018) describe that feeling bored of consuming antidiabetic drugs is the most reported personal motivation barrier. In the Tristiana, Kusnanto, Widyawati, Yusuf, & Fitriyasari (2016) study mentioned the results of interviews conducted on April 18, 2014 at the Mulyorejo health center, it was found that 3 out of 4 patients stated that the patient was saturated with the routine they were doing that caused the patient to disobey their diet pattern and physical activity undertaken. Two patients say that they despair of suffering from Diabetes Mellitus, sometimes they do not want to eat because of fear of complications that will happen. A patient says to reduce the activity of gathering with his friends, a patient still would not accept if he was exposed to Diabetes Mellitus.

Social motivation can affect patients in performing self-care adherence. One of the supporting factors for patients performing self-care is family support. As stated by Mayberry & Osborn (2012), family support is essential in providing adherence effects to Type 2 Diabetes Mellitus patients. Costa (2012) in his research mentioned that partner and social-cognitive support is essential to adherence to SMBG in diabetic patients Mellitus Type 2. Halkoaho (2014) study found that people with type 2 diabetes thought the source of coping in the management of diabetes mellitus was self-acceptance of disease, adherence to self-care, knowledge of disease, and support from various parties including nurses.

3.3.3 Behavioral Skill Barrier. Behavioral skill barrier is an objective ability of individuals to adhere with task compliance and perceived self-efficacy to carry out self-care for Diabetes Mellitus. Obedience-related tasks include cues to take antihyperglycemic drugs and measure glucose, go on a diet, do activities, and perform foot care, strategies to minimize side effects every day, and strengthen self-compliance over time and in various different situations Liu *et al.* (2018) states that self-efficacy and coping strategies are factors that influence the compliance of patients with Diabetes Mellitus, stating that self-efficacy and coping strategies are factors that influence adherence to patients with Diabetes Mellitus.

Based on the review of the article, it can be argued that self-care therapy regimens for Type 2 Diabetes Mellitus in general are physical activity, diet, self-monitoring of blood glucose (SMBG), and glycemic control. However, most respondents did not adhere to the therapy regimen. Nelson *et al.* (2018) stated that the most frequently reported barriers to diabetes medication adherence in our sample were forgetting doses.

In Mogre, Abanga, Tzelepis, Johnson, & Paul (2017) research on adherence and factors associated with self-care behaviors in Diabetes Mellitus Type 2 patients in Ghana stated that dietary compliance, self-monitoring of blood glucose, and foot care were very low . Self-care is often done by patients was the exercise and measurement of blood glucose by health workers. Only 1 patient performed routine SMBG every day, 13.9% checked their legs daily and 9.6% who checked their shoes every day. The low rate of adherence to self-care is due to a low level of knowledge. Patients with low knowledge and women may need additional support to improve adherence to self-care behavior in patients with Type 2 Diabetes Mellitus.

A similar case occurred in Chourdakis & Kontogiannis (2014) study, which stated that the majority of patients (75.7%) reported regular nutritional intake but which were rich in fat. Most (90.3%) received prescribed medication, and 60.5% tested blood glucose concentrations accordingly but only 27.1% of the study population reported daily blood glucose levels. And only a third of patients are reported to have washed their feet every day for weeks. Thompson's (2014) study found that there was a difference between personal and cultural activity that affects activity for diabetes management.

4. Discussion

Diabetes Mellitus is a metabolic disease that cause its patients to need long life maintenance. Diabetes self-care is an important part of diabetes care. It is complex and involves major lifestyle changes that need to become a part of patient’s daily routine including self-monitoring blood glucose (SMBG), diet, physical activity, foot care, and taking prescribed medication. Diabetes self-care requires a high level of adherence to those lifestyle changes. However, most respondents did not adhere to the therapy regimen because of many factors that prevent patients from performing self-care.

Medication adherence is an important determinant of outcomes in patients with chronic diseases [14]. The Information Motivation and Behavioral Skill (IMB) model of adherence focuses comprehensively on the information, motivation, and behavioral skills factors that are

conceptually and empirically linked to adherence [6]. The model postulates that individuals are more likely to take health-related actions, such as diabetes self-care management behaviors, if they are well informed, highly motivated (personally and socially), and have adequate and appropriate behaviors, and thus, experience positive health outcomes [11]. So that in this case the Information Barrier, Personal Motivation Barrier, Social Motivation Barrier is estimated to influence the Behavioral Skill Barrier of Diabetes Mellitus patients in performing self-care. If behavioral skills can be done well, then Diabetes Mellitus patients can adhere to self-care.

Information barrier that affects patient adherence were diabetes knowledge, health education, and provider-patient communication. Motivation barriers such as health beliefs and social support are linked to adherence. Diabetes self-efficacy and coping strategies are identified as behavioral skill barriers that affect adherence in patients with Diabetes Mellitus. So, from this systematic review, the practical implication is it is confirmed that Information Motivation and Behavioral Skill Model of Adherence developed by Fisher et.al saying that information, motivation, and behavioral skill can affect adherence in patients. So, the outcome of this review is this model can be created as one of theoretical framework to develop nursing interventions in increasing self-care adherence in patients with Diabetes Mellitus.

This evidence-based review, while systematic, was not a meta-analysis, making it difficult to compare findings between studies. There is broad variability in baseline characteristics of the populations studied, which impairs the ability to generalize findings to other groups of individuals with diabetes. Another key limitation may be the systematic exclusion of study design. This study included some quantitative studies. It makes some information were not homogenous about barrier affecting self-care adherence in patient with Diabetes Mellitus.

5. Conclusion

The Information Motivation and Behavioral Skill (IMB) model of adherence focuses comprehensively on the information, motivation, and behavioral skills factors that are conceptually and empirically linked to adherence. It can be concluded that the information barrier which affects patient adherence were diabetes knowledge, health education, and provider-patient communication. Motivation barrier such as health belief and social support linked to adherence. Diabetes self-efficacy and coping strategies was identified as behavioral skill barrier that affects adherence in patients with Diabetes Mellitus.

Appendix

Table 2. Table of Article Analysis

Title, Authors, & Time	N	Design	Data Collection	Main Result
An empirical test of the Information , Motivation and Behavioral Skills model of antiretroviral therapy adherence [8]	200	Mix Method	Interview and Questionnaire	• The IMB model of ART adherence hypothesizes that adherence-related information, motivation and behavioral skills are the critical determinants of adherence behavior. • Simply stated, even a well-informed or highly motivated individual will have difficulty achieving and sustaining optimal adherence if he or she lacks the objective skills required to acquire or self-administer medication or feels incapable of performing such behaviors.
Applying the Information-Motivation-Behavioral Skills Model in Medication Adherence Among Thai Youth Living with HIV: A Qualitative Study [5]	10	Qualitative	Interview	• Data support the utility of IMB as a potential framework for understanding ART adherence in this population. • However, data indicate a consideration to expand the motivation construct of IMB to incorporate youths' perceived familial and social responsibilities and the need to adhere to medications for short- and long-term well-being of self, family, and society in a context of Buddhist values. • These modifications to IMB could be relevant in other cultural settings with more collectivistic worldviews.
Adherence During Antiviral Treatment Regimens for Chronic Hepatitis C A Qualitative Study of Patient-reported Facilitators and Barriers [15]	21	Qualitative	Interview	Three broad themes emerged: (1) missing doses and dose timing errors; (2) facilitators of adherence; and (3) barriers to adherence.
Assessing barriers to diabetes medication	237	Quantitative		The most frequently reported barriers were forgetting doses,

adherence using the Information-Motivation-Behavioral skills model [3]				thinking brand name medicine works better than generic medicine, not seeing immediate benefit, and feeling burned out with taking diabetes medicine.
Testing the information-motivation behavioral skills model of diabetes self-management among Chinese adults with type 2 diabetes: a protocol of a 3-month follow-up study [11]	250	Quantitative	RCT	• The concepts from the IMB model can easily be translated into intervention components • The IMB model adequately captures essential concepts which have been well supported in the literature to improve DSM behaviors, including information (e.g., diabetes knowledge), motivation (e.g., social support) and behavioral skills (e.g., diabetes self-efficacy).
Patient Characteristics Associated with Medication Adherence [16]	750,000	Quantitative		Medication adherence for those with one condition was higher in males, Caucasians, older patients, and those living in areas with higher education rates and higher income. In the total population, adherence increased with lower comorbidity and increased number of medications. Substantial variation in adherence was found by condition with the lowest adherence for diabetes (51%) and asthma (33%).
Determinants of Adherence to Diabetes Medications: Findings From a Large Pharmacy Claims Database [14]	218,384	Quantitative	Cohort Study	Sixty-nine percent of patients were adherent. Adherence was independently associated with older age, male sex, higher education, higher income, use of mail order versus retail pharmacies, primary care versus nonendocrinology specialist prescribers, higher daily total pill burden, and lower out-of-pocket costs. Patients who were new to diabetes therapy were significantly less likely to be adherent.
Medication Adherence with Diabetes Medication A Systematic Review of the Literature [17]	169	Systematic Review		• One hundred ninety-six published articles were reviewed; 98 met inclusion criteria. Factors including age, race, health beliefs, medication cost, co-pays, Medicare Part D coverage gap, insulin use, health literacy, primary

			nonadherence, and early nonpersistence significantly affect adherence. • Higher adherence was associated with improved glycemic control, fewer emergency department visits, decreased hospitalizations, and lower medical costs. • Adherence was lower when medications were not tolerated or were taken more than twice daily, with concomitant depression, and with skepticism about the importance of medication. • Intervention trials show the use of phone interventions, integrative health coaching, case managers, pharmacists, education, and point-of-care testing improve adherence.
Advantages to Using Social-Behavioral Models of Medication Adherence in Research and Practice [18]			Social-behavioral models can assist research and practice by consolidating the multitude of reasons for non-adherence into superordinate factors that drive adherence.
An Information–Motivation–Behavioral Skills Model of Adherence to Antiretroviral Therapy [6]			There is consistent and convergent empirical support for the IMB model's assertions concerning the roles of adherence-related information, motivation, and behavioral skills in understanding and promoting HAART adherence as well as for the hypothesized interrelations among IMB model components.
A situated-Information Motivation Behavioral Skills Model of Care Initiation and Maintenance (sIMB-CIM): An IMB Model Based Approach to Understanding and Intervening in Engagement in Care for Chronic Medical Conditions [19]			The sIMB-CIM offers an approach to applying the IMB model to a dynamic behavior that requires specific attention to the multiple systems that simultaneously influence an individual's decisions to enter and stay in CMC medical care. However, future rigorous evaluation is needed to demonstrate the added benefit of such an approach.
Patient Explanations for	15	Qualitative Interview	Results of the study are personal

Non-Attendance at Type 2 Diabetes Mellitus Self-Management Education : A Qualitative Study [20]				reasons in the absence of Diabetes Self-Management Education because of illness and they feel it less useful activities. As for the external factors that affect people with Type 2 diabetes do not follow Diabetes Self-Management Education is location, time, and duration Diabetes Self-Management Education
Family Support, Medication Adherence, and Glycemic Control Among Adults with Type 2 Diabetes Mayberry & Osborn (2012)	61	Qualitative	FGD	Family support is very important in providing adherence effects to the care of people with Diabetes Mellitus Type 2.
Home Alone : The Experience of Women with Type 2 Diabetes who Are New to Intensive Control (Kathleen M. Rayman, 2004)	14	Qualitative	Interview	There are 2 types of patient : Engagement As many as 57% of respondents included in the Engage class. In this class, respondents follow the rules of self-care and are consistent in performing self-care as a lifestyle. Pre-engaged. (43%) In this class of respondents do not consider diabetes dangerous. They are not serious in performing self-care. They assume that diabetes care management is not difficult.
Occupations, habits, and routines: perspectives from persons with diabetes Thompson (2014)	8	Qualitative	Interview	There are four themes inferred: "Changes over time"; "What to eat"; "Habits and routines"; and "Family: Occupational impacts" There is a distinction between personal bustle and culture that affects activity for diabetes management.
Psychological Well-being in Patients with Type 2 Diabetes Mellitus in Puskesmas Mulyorejo Surabaya (Tristiana, Kusnanto, Widyawati, Joseph, & Fitriyasari, 2016)	7	Qualitative	Case Study	• Patients with type 2 diabetes experienced a process of transition from a healthy condition in a state hospital. • The transition process began with the loss of a cyclic response affects patients with type 2 diabetes to control yourself and make the right decision for self-care. • Self-control will make patients with type 2 diabetes are able to adapt and engage with new experiences that

				become a new habit for patients with type 2 diabetes • Self-Care will facilitate the patients with type 2 diabetes in adapting to internal and external environment and make patients with type 2 diabetes have a positive outlook in life.
Type 2 diabetes patients' perceptions about counselling elicited by interview: is it time for a more health-oriented approach? [10]	15	Qualitative	Interview	People with type 2 diabetes think the source of coping in the management of diabetes mellitus is self-acceptance of disease, adherence to self-care, knowledge of disease, and support from various parties including nurses.
Qualitative study of an intervention for depression Among patients with diabetes: how can we optimize Patient–professional interaction? [22]	25	Qualitative	Interview	Constraints in compliance with self-care patients with Type 2 Diabetes Mellitus is the patient's problems, difficulties in therapy, and inability to cope with the changes that occur after illness for so long.
'A one-to-one thing is better than a thousand books': views and understanding of older people with diabetes [7]	13	Qualitative	interview	• Patients know about the condition of the disease and complications that will be experienced. Most of them said they are afraid of the complications of coma. • In addition, most have obtained adequate information about Type 2 Diabetes Mellitus of doctors and nurses, but there are misperceptions about the information that the patient is undergoing treatment with good self. Patients expressed the importance of continuous treatment to deal with diabetes. Nurses and doctors play an important role for it.
Diabetes Mellitus Client's Conceptions about The Treatment [23]	11	Qualitative	interview	Patients with Diabetes Mellitus have knowledge of diabetes management. However, knowledge is very superficial and not applicable in their routines.

PAT-932

EFFECT OF LAVENDER AROMATHERAPY FOR REDUCING DYSMENORRHOE

Erika Agung Mulyaningsih

INTRODUCTION

Many women or teens experience discomfort during menstruation, one of which is dysmenorrhea. Dysmenorrheal is a severe pain that starts several hours before or together with the onset of menstruation and lasts for 48 to 72 hours (Reeder, 2011 in Purwati 2015). This pain results in someone feeling disturbed and uncomfortable about all their activities, this causes a person to experience difficulty walking, no appetite, nausea, vomiting and even fainting. Besides the pain of menstruation (dysmenorrhea) can also disrupt the concentration of learning and force sufferers to rest so they cannot follow the learning process. The incidence of dysmenorrheal in the world is very large, in 2011 in the United States the prevalence of dysmenorrheal pain was estimated at 45% -90%. About 15% of adolescents report menstrual pain at a severe level and cause not to attend school. While in Indonesia, 55% of women experience dysmenorrheal (Proverawati and Misaroh, 2009 in Gustina, 2015). Whereas in East Java the number of reproductive girls who were 10-24 years old was 56,598 people who experienced dysmenorrheal and came to health facilities by 11,565 people (1.31%) (BPS East Java Province, 2010)

Lavender essential oil is thought to be an adrenocortical stimulant that stimulates menstrual circulation and has anti-convulsive properties. lavender is also useful as a sedative, relieves pain and changes the perception of pain (Lavabree, 1990 in Sun Hee Han, 2012).

In practice women who experience dysmenorrheal do not know the treatment techniques to reduce pain that is felt more safely. Based on the background above, the formulation of the problem that arises in this study is "How the Effect of the Use of Lavender Aromatherapy on Decreasing Pain in dysmenorrhea.

METHODS

In this study, the authors used a pre-experimental one group pre-post-test design design. The population in this study were all adolescents of MAN Jombang Class X and XI who experienced dysmenorrhea with an average of 40 adolescents experiencing dysmenorrhea on April 16 to May 13, 2018. The sample in this study were some adolescents who experienced dysmenorrhea in MAN Jombang Class X and XI that met 36 inclusion and exclusion criteria.

The sampling technique used in this study is Purposive Sampling. For the independent variable this study is lavender aromatherapy. While the dependent variable is a decrease in the scale of menstrual pain. The data collection technique in this study was to use a checklist.

Data processing and analysis is done using a computer program. The calculation was carried out to determine the effect of lavender aromatherapy on decreasing the level of dysminorrhea pain in adolescents MAN Jombang Class X and XI using the Wilcoxon test…

RESEARCH RESULT

The research results obtained in Lavender Aromatherapy Against the Decreased Level of Dysmenorrhea Pain.

Table 1 shows that the majority of respondents with the 12-15 year age category were 25 people (69.4%). Almost all respondents with menstrual length category ≤ 1 week in adolescents as many as 20 people (55.6%). based on the menstrual cycle almost all respondents with the menstrual cycle category ≤ 28 days were 24 people (66.7%). Based on the duration of dysmenorrhea, almost all respondents with a duration of <3 days of dysmenorrhea were 30 people (83.3%). Based on the handling of dysmenorrhea all 36 respondents with the category of dysmenorrhea treatment were left alone (100%). Table 2 shows that most (88.9%) before being given an intervention using lavender aromatherapy were moderate pain as many as 32 people and severe pain as many as 3 people. After being given an intervention using lavender aromatherapy it was found that most moderate pain was

18 people and mild pain as many as 17 people.

Table 1 Frequency distribution of respondents' general data

No	General data	Frequency	**Percentage %**
1	**Age**		
	8-11	11	30.6
	12-15	25	69.4

Wilcoxon singned ranks tes : P :0.000 . Z -4,491

Based on the results of the analysis using the Wilcoxon test at the level of significance obtained Z count -4.491a> Z table -1.96 the asymp value of sig. (2-tailed) where z count ≥ z table which means that there is influence or probability value ρ = (0,000) lower than significant standard α = 0.05 or (ρ

<α) which means H1 is accepted, H0 is rejected which means there is influence The provision of lavender aromatherapy to reduce pain in dysmenorrhea in adolescents of Jombang MAN level X and XI.

DISCUSSION

Degrees of Pain in Dysmenorrhea In adolescents of MAN levels X and XI, before the aroma of lavender therapy is given

Based on the results of table 4.7 above it is known that most (88.9%) before being given intervention using lavender aromatherapy were mild pain in 1 person (2.8%), moderate pain as many as 32 people (88.9%) and severe pain as much as 2 people (5.6%) and very severe pain in one person (2.8%).

According to Anurogo (2009), the causes of menstrual pain and cycle disorders can vary. Can be due to a disease process (such as pelvic inflammation), endometriosis, tumors or abnormalities of the location of the uterus, hymen or vagina not perforated, and stress or excessive anxiety. However, the most common causes of menstrual pain and cycle disorders are thought to be due to the occurrence of hormonal imbalances and abnormalities in the reproductive organs. Degree of moderate menstrual pain, most commonly experienced by adolescents, usually this pain feels pain that spreads in the lower abdomen, requires rest and requires painkillers, sometimes disrupting the activities of daily living. This feeling of pain is due to an increase in uterine contractions, as stated by Chang E, that the onset of menstrual pain is caused by an increase in the levels of PGE2 and alpha PGF2 in the blood which results in an increase in contraction and distortion of the uterus. So that there is a decrease in blood flow and oxygen to the uterus which causes ischemia and increased sensitization of pain receptors.

According to researchers the pain that appears is different because each person has a different coping mechanism where adaptive coping patterns will make it easier for someone to deal with pain and vice versa, a maladaptive coping pattern will make it difficult for someone to deal with pain. Coupled with the experience of each person is different in feeling the pain Someone who has managed to overcome pain in the past, and now the same pain arises, then he will more easily overcome the pain.

Based on table 4.1, it can be seen that the characteristics based on menarche, most of the respondents with the 12-15 year age category were 25 people (69.4%)

The sexual maturity (menstruation, physical maturity) is caused, among others, by the individual's physical condition, race, ethnicity, climate, way of life, and environment. Physical conditions that are poorly maintained or the disease experienced by a teenage girl can slow the arrival of menstruation. Apart from that external stimuli such as: sex films, sex books or magazines, temptations, and stimuli from men can result in sexual reactions and also result in sexual maturity faster than children naturally (Guntoro, 2009).

Adolescents are individuals who are experiencing a transitional period that gradually reaches sexual maturity, experiences a change of soul from childhood to adulthood, and experiences economic changes from dependence to be relatively independent. Therefore, it is important for adolescents so that they understand the conditions of physiological changes that occur and various changes, so that adolescent women can know health problems that can be overcome by themselves and they also know when these conditions should be further examined by experts.

Based on table 4.2 it can be seen that the characteristics based on menstrual length almost entirely of respondents with menstrual length category ≤ 1 week in adolescents as many as 20 people (55.6%) and ≥ 1 week as many as 16 people (44.4)

The above is not in accordance with the statement expressed by Wiknjosastro (2005), At that time the endometrium was released, while the lowest hormone expenditure - minimum ovarian hormones. Endometrium consists of 3 layers.

Normally the menstrual cycle is influenced by many things, such as the state of the environment has never provided a stimulus to adolescents to feel excessive stress, adequate nutrition of food, daily

activities are not too heavy.

Based on table 4.5 it can be seen that the characteristics based on the duration of dysmenorrhea are almost entirely respondents with the old category

Women with severe dysmenorrhea have high levels of prostaglandin during the menstrual cycle, this high concentration occurs for 2 days from the menstrual phase (Cunningham, 2008 in Rakhma, 2012)

According to researchers the perceived duration of dysmenorrhea pain will be different depending on the coping mechanism of each person where adaptive coping patterns will make it easier for someone to deal with pain and vice versa maladaptive coping patterns will make it difficult for someone to deal with pain, coupled with the experience of each person in pain different, someone who has succeeded in overcoming pain in the past, and when this same pain arises, then he will more easily overcome the pain ..

Effects of Lavender Aromatherapy on Decreasing Pain in Dysmenorrhea In adolescents MAN levels X and XI, after lavender therapy is given

Based on the results of table 4.9 it is known that most (50%) after being given an intervention using lavender aromatherapy were moderate pain as many as 18 people (50%). And after being given an intervention using lavender aromatherapy as much as 3 people with severe pain and changed to 0 people (0%) who had severe pain.

Provision of non-pharmacological methods is very important for patients who do not respond well to medication or experience problems due to side effects and patients who do not want to take drugs (Valiani et al., 2010). Hot compresses or hot baths, massage, relaxation (aroma of lavender therapy), distraction of physical exercise, and sleep enough to relieve primary dysmenorrhea. Heat relieves ischemia by decreasing contractions and increasing circulation. Changing the diet by reducing salt and increasing the use of natural diuretics, such as asparagus or leaf soup, can help reduce edema and discomfort (Bobak et al., 2004). Another heat therapy that can be used to reduce pain because dymenorrhea is by attaching a chili patch containing capsicum oleoresin to the lower back for 6 to 8 hours on the first day to the third menstruation. The heat sensation caused reduces pain, and is uncomfortable in the lower back area, lower abdomen to the area around the inner thigh. (Mulyaningsih, 2-17). Matched by Powell (2017) that when we breathe lavender aromatherapy oil, the chemical compounds contained in the aromatherapy oil will enter the bloodstream. In the end these chemicals will enter the limbic system, which is the nerve tissue in the brain that controls our emotions. Therefore, aromatherapy can change the perception of pain and also improve a bad mood. Aromatherapy works by affecting the work of the brain, olfactory nerves that are directly related to the hypothalamus, the part of the brain that controls the gland system that regulates hormones that affect body activity, and affects the work of the limbic system associated with blood circulation. Therefore, besides lavender aromatherapy is used to overcome the problem of pain, lavender oil can also be used to treat digestive problems, menstrual disorders and others (Veeder, 2007)

Relaxation using the aroma of lavender therapy will make the whole body in a balanced state, in a state of calm but not asleep, and all muscles in a relaxed state with a comfortable body position, with the muscle muscle relaxed, will reduce the level of pain felt and the researcher believes that after giving lavender aroma therapy, there was a change in the level of dysmenorrhea pain as well as the condition of the respondent, where the scale of pain responders almost entirely decreased, and the condition of all respondents seemed more relaxed, and no longer showed symptoms of dysmenorrhea at first, such as pain in lower abdomen and spread to the back, nausea, vomiting, no appetite, sweating, difficulty walking and even fainting.

From the description above, according to the researcher that relaxation of lavender aromatherapy is very important to find and choose an effective and easy method to reduce the level of dysmenorrhoea pain, because in treating dysmenorrhea pain can not only be overcome by pharmacological techniques, but can be done with non-pharmacological treatment , an activity that is safe for all women, namely by giving lavender aromatherapy by inhaling aromatherapy in a closed

room ...

The Effect of Lavender Aromatherapy on Decreasing Pain in Dysmenorrhea In adolescents MAN levels X and XI

The results of calculations using the Wilcoxon signed test application obtained Z count -4.491a> Z table -1.96 asymp value sig. (2-tailed) where z count ≥ z table which means that there is influence or probability value ρ = (0,000) lower than significant standard α = 0.05 or (ρ <α) which means H1 is accepted, H0 is rejected which means there is influence The provision of lavender aromatherapy to reduce pain in dysmenorrhea in adolescents of Jombang MAN level X and XI.

Based on table 4.7, it was found that from 32 (88.9) respondents almost all of the respondents before being given the intervention experienced moderate dysmenorrhea pain and when after being given the intervention decreased to mild pain by 18 people (50%). And a small percentage of respondents with severe pain as many as 3 people before being given an intervention and after being given an intervention to 0 people (0%).

This is in accordance with the statement expressed by Dr. Powell (2017), when we breathe lavender aromatherapy oil, the chemical compounds contained in aromatherapy oil will enter the bloodstream. In the end these chemicals will enter the limbic system, which is the nerve tissue in the brain that controls our emotions. Therefore, aromatherapy can change the perception of pain and also improve a bad mood. Based on medical research that has been done, aromatherapy can reduce stress hormone cortisol levels, slow heart rate, relieve pain, reduce inflammation and reduce anxiety and depression. Proven in table 4.7 the pain scale has decreased mostly (88.9%) before being given intervention by using lavender aromatherapy is moderate pain as many as 32 people and changed to 18 people (50%) with moderate pain. And before being given an intervention by using lavender aromatherapy as much as 3 people with severe pain and changed to 0 people (0%).

According to researchers that dysmenorrhea is pain that appears in the lower abdomen, spreads around the waist, this pain appears together with the onset of menstruation and lasts for several hours. Where to reduce pain that can be helped by medical therapy and non-medical therapy, the expression is relaxation using the aroma of lavender. Relaxation of the scent of lavender therapy is very important to find and choose an effective and easy method to reduce the level of dysmenorrhea pain, because in treating dysmenorrhea pain can not only be overcome by pharmacological techniques, but can be done with non-pharmacological treatment

The response of each respondent to pain that is felt is different. If in table 4.7 that has been explained above that before being given the intervention the respondent experiences moderate pain and after being given the intervention becomes mild and there is a constant. Most likely when the researcher gave the intervention the respondent had not felt the peak of the pain of the dysmenorrhea so that after giving the intervention the pain remained and there was no change. This is consistent with the opinion of Dawood (2006), which states that menstrual pain is felt most intensely on the first or second day of menstruation (24-48 hours), consistent with the time of maximum prostaglandin release in menstrual blood.

Differences in the level of menstrual pain with the same intervention, but changes in pain levels differ can be caused by differences in respondents' perceptions of pain and efforts to relieve pain. One of them is a method that can be used to deal with the pain of dysmenorrhea including pharmacological treatment, non-pharmacology, and surgical treatment. In accordance with the theory of Kasper et al (2005), that treatment of dysmenorrhea can be done with pharmacological and non-pharmacological techniques. The pharmacological approach to dysmenorrhea is best treated with NSAIDs or normal contraception. NSAIDs work significantly more effectively than placebo. Drugs that include NSAIDs include ibuprofen, naproxen sodium, and ketoprofen. While other non-pharmacological approaches that can be applied to treat menstrual pain are relaxation with aroma therapy. This non-medication and non-aggressive method is recommended as an appropriate choice for reducing pain. Relaxation is a safe, non-aggressive, easy to do method, causing very few and reversible side effects. Relaxation techniques that can be used to reduce pain include relaxation

therapy with aroma therapy (Valiani et al., 2010).

Researchers argue that after giving lavender aroma therapy, there are changes in the level of dysmenorrhea pain scale and the condition of the respondent, where the level of pain scale of respondents almost entirely decreased, and the condition of all respondents seemed more relaxed, and not

CONCLUSIONS AND RECOMMENDATIONS

Conclusion

The results of the study on the effect of the influence of lavender aromatherapy on decreasing dysmenorrhea pain in adolescents of MAN Jombang level X and XI can be concluded as follows:

1. During pre-intervention, lavender aromatherapy mostly experiences moderate-scale menstrual pain.
2. While the post value of lavender aromatherapy interference has decreased the level of pain from moderate-scale pain to mild-scale menstrual pain.
3. There is an effect of the administration of lavender aromatherapy to decrease the pain of dysmenorrhea in adolescents of Jombang MAN level X and XI

Suggestion

1. Theoretical

This study can be used to deepen learning about midwifery counseling and care in adolescents who experience dysmenorrhea. The aroma of lavender therapy has proven to be an alternative to reducing pain without drug administration.

2. Practical

a. For Educational Institutions

Educational institutions can use the results of this research as material in community service, both the service of lecturers and students. Through health education activities for adolescents both in the school environment and outside of school.

b. For respondents

For the next respondent that the provision of lavender aromatherapy can be used as an alternative method in the future that is appropriate and safe to reduce menstrual pain.

c. For further researchers

For researchers then the selection of samples to be done using a randomization technique to reduce the risk of research bias. In this study, there is a need for other control or comparison groups, such as the use of music therapy, gymnastics, bathing in warm water, chili peppers and others.

ABSTRACT

Uremic pruritus remains a distressing symptom afflicting chronic kidney disease patients although the prevalence has decreased in recent years. It is most commonly described as a daily occurence of itch and associated with poor quality of life, poor sleep, depression, and mortality. Current study proposed treatment for pruritus in topical use are not well defined. This systematic review of the literature is aimed to understand alternative topical treatments carried out in clinical trials for uremic pruritus. Scopus, ScienceDirect, Cochrane Library, CINAHL, and PubMed databases were sistematically searched from their inception to February 2019 with keyword limit 'uremic pruritus', 'topical treatment', and 'chronic kidney disease'. Fifteen articles that met the inclusion criteria have been clustered into 5 categories : emollient, aromatherapy (essential oil), lotion, ointment, and cream. The results showed that topical treatments alleviate uremic pruritus symptom while some of them followed by adverse reactions and particularly showed negative outcomes. In conclusion, patients with uremic pruritus have several options to choose topical treatment for their skin problem, and the most used is aromatherapy from various essential oils. Furthermore, future studies should evaluate the efficacy of topical treatments, compared one another and report data related to its safety used.

Keywords ***:*** *uremic pruritus, topical treatment, chronic kidney disease*

1. Introduction

A large number of patients with progressive kidney disease receiving hemodialysis therapy suffer from pruritus [1]. Despite being an annoyance, uremic pruritus (UP) can adversely impact the quality of life (QoL) and medical outcomes. Many challenges faced uremic pruritus include the protean manifestations of UP, a poor understanding of the underlying pathogenesis, non-standardized diagnostic tools, and poorly designed treatment trials [2].

The Dialysis Outcomes and Practice Patterns Study (DOPPS) is an international longitudinal study of dialysis patients which showed that 41.7% of patients reported moderate to extreme pruritus [3]. The most recent sizeable study of the prevalence of uremic pruritus included the DOPPS III data specifically from Japan, which reported an overall incidence of moderate to extreme pruritus of 44% [1].

Yet there is still a limited understanding of its pathophysiology and many hypotheses have been raised in previous years. Several hypotheses including increased systemic inflammation [4]; dysregulation of serum PTH, calcium, phosphorus levels, precipitated calcium phosphate crystals, iron deficiency anemia, μ-receptor alteration and neuropathy have all been suggested to cause uremic pruritus [5,6].

Effective treatment options are limited because of a low number of randomized, placebo-controlled trials with most of them reporting only limited therapeutic success. In addition, several times in the past, reports on putative effective novel treatment options were followed by studies with contradictory results. The lack of effective treatment modalities also results from a still incomplete knowledge of the underlying pathophysiological mechanisms. This review highlights the recent clinical and experimental findings focusing on the pathogenesis and current treatment options of UP [7].

Although several small studies have examined a variety of interventions especially in topical treatments, the efficacy of this intervention and the optimal treatments remain poorly defined. According to the researchers' knowledge, no systematic review has been conducted to assess the effects of topical treatment on uremic pruritus patients. To address this important knowledge gap, we systematically reviewed the literature and summarized the evidence for the major interventions for the topical treatment of uremic pruritus.

2. Methods

2.1. Eligibility Criteria

The methods adopted for this systematic review are consistent with the guidelines detailed on the PRISMA checklist [8]. Clinical trials (controlled or not) and semi-experimental clinical trials that investigated the effect of topical treatments (emollient, aromatherapy, lotion, ointment and cream) on the hemodialysis patients (aged ≥ 18 years), with advanced chronic kidney disease (CKD; stage ≥ 3 or on hemodialysis therapy) applied by massage and simple topical methods and assess the outcomes (pruritus score, pruritus severity, pruritus distribution, sleep quality, emotional disturbance, skin condition and function, blood biochemistry, quality of life and treatment satisfaction) were included. Review studies, case reports, case series, letter to editors and descriptive studies were excluded. The target population were all hemodialysis patients.

2.2. Search Strategy

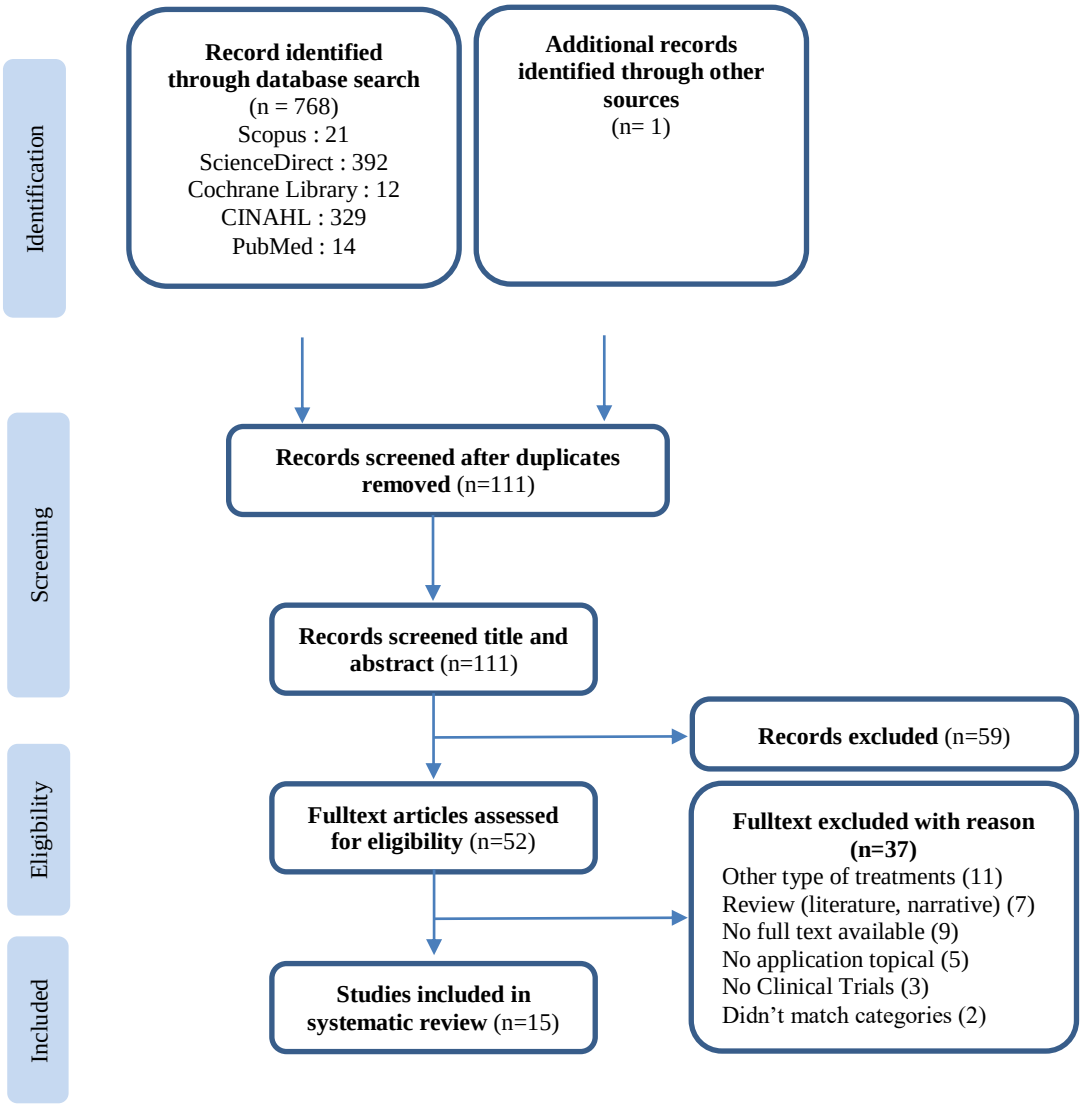
The searches were conducted by three independent researchers following consultation with a medical doctor, who gave advice in search strategy and the identification of search terms and treatment options. A combination of subject headings and MeSH terms was used as appropriate to cover the concepts of ‘uremic pruritus’, ‘chronic kidney disease’ and ‘topical treatment’. The electronic databases were searched from the inception of databases to March 8, 2019 and included international (Scopus, Science Direct, Cochrane Library, CINAHL, and PubMed). Only complete papers available in English were included. To ensure literature saturation, the reference lists of the included studies were studied and relevant reviews were identified through the search.

2.3. Selection of Studies and Data Extraction

The Prisma protocol was used to guide the systematic review, which is explain in Figure 1. The reviewers independently screened the titles and abstracts for eligibility adjusting to study protocol. The full text was then reviewed to confirm that the eligibility criteria were met and to extract the requisite information, which included the study characteristics (authors, year, design, sample), intervention details (comparison group, treatment groups, type of topical treatment, dose, treatment

frequency, administration method, duration per session, period of intervention) and measurements tools (outcomes, scale, comparison group, type of topical treatment and results) were also collected. Duplicate studies were removed. Reference lists of relevant articles were manually searched for any additional relevant studies.

Fig. 1 Flow diagram for trial selection and exclusion. Abbreviations: CINAHL, Cumulative Index to Nursing and Allied Health Literature;



Data extraction was performed in Microsoft Excel by 3 independent reviewers. The information gathered from each study included the following: title, first author, journal, year of publication, study population, period of intervention, characteristics of intervention and control, pruritus intensity measurement tool, pruritus intensity results pre- and post-intervention, and adverse drug reactions.

It was not explained how the ratio was determined of men and women in the sample population of each study. The range of samples varied between studies. Some studies provided incomplete information about the application of interventions such as administration of administration, route, dose, duration and frequency, time of application, and by whom the intervention was implemented.

The efficacy of the research results of each study was unclear, as evidenced by recommendations for use, not listed in the articles.

3. Results

3.1. Search Results and Study Selection

A total of 769 articles were retrieved from the initial search. Of the 111 non-duplicated studies in the title and abstract screening process, 59 were excluded because they had unrelated titles. Of the remaining 52 studies, 15 met the eligibility criteria. Of the 35 excluded studies, 11 used another type of treatment, 7 were review articles, 9 did not have the complete text, 5 were not applicable topically and 3 were descriptive studies and 2 could not be included in 5 categories [Fig. 1]. Table 1 is a summary of the studies.

3.2. Study Characteristics

The studies were conducted on 855 chronic kidney disease patients receiving hemodialysis therapy who suffer from mild, moderate and extreme pruritus. All the 15 included studies are a quasi-experimental design and are published in the English language [Table 1].

Characteristics of included studies are summarized in Table 1. The 15 trials included a total of 582 patients and examined 12 different types of topical treatment. Sample sizes ranged from 80 to 16 patients, with only 2 studies enrolling less than 20 participants.

All studies included adults 18 years or older. All 15 studies included hemodialysis patients. Seven studies measured uremic pruritus using a visual analogue scale; 2 studies using a verbal rating scale; 2 studies using quality of life questionnaire; 4 studies observed skin condition; 2 studies measured sleep quality; 1 study measured treatment satisfaction, 2 studies marked blood biochemistry and 6 studies using pruritus scale/score. Length of treatment varied across studies, but in general was short (range, 1 week to 8 weeks).

3.3. Topical Treatment Categories

All studies which from 12 types of topical treatment were clustered into five categories

Emollient. Two articles were studied in emollient to investigate the effects of baby oil [9] and emollient containing high water content [10] to uremic pruritus. One study using itching severity scale to measure pruritus severity[9]. Another one used various outcomes to be measured as pruritus severity, emotional disturbance, dry condition and blood biochemistry [10]. Overall, when emollient wascompared to placebo there was a statistically significant benefit in favor of the active treatment to reduce uremic pruritus while another outcomes emotional disturbance and skin condition.

Aromatherapy. Four studies examined the efficacy of aromatherapy to reduce uremic pruritus symptom. Four types of essential oil used in treatment uremic pruritus by topical application to skin, sweet almond oil[11], peppermint mixed with sunflower oi [12], lavender and tea tree oil diluted to almond and jojoba oil [13] and chia seed oil [14]. All studies measured pruritus severity using pruritus scale/scored questionnaire. All the aromas/oils given in range 1 drop to several milliliters. Overall, the aromas has statistically significant difference to control groups in alleviating uremic pruritus symptom.

Lotion. Three studies compared the effects of topical treatment in lotion preparation on uremic pruritus. Three types of lotion that used this treatment categories, dead sea mineral [15], pramoxine

[16], sarna and eurax lotion [17]. Of these, 2 studies measured pruritus severity using pruritus visual analogue scale. One of them measured some outcomes, skin condition, sleep disorder, treatment satisfaction and blood biochemistry [15]. For all, the results of lotion preparation for uremic pruritus were high significant impact in reducing symptom.

Ointment. Two studies explored the role of ointment to improved skin problem on uremic pruritus. Two kinds of ointment, capsaicin ointment [18] and tacrolimus ointment [19] that clustered to this treatment categories. Capsaicin 0,03% given daily while tacrolimus 0,1% given twice a day and all studies done for 4 weeks. The results of ointment preparation for uremic pruritus significant impact in reducing symptom in favor of capsaicin 0,03% meanwhile no significant difference with control group in tacrolimus 0,1% using and also tacrolimus had adverse drug reaction [warm sensation] which felt by more than half participants.

Cream. Four articles studied the used of topical treatment in cream preparation on uremic pruritus. There were three variety of this preparation in four articles study, capsaicin [20,21], sericin [22] and *gamma linoleic acid* [GLA]. All the cream given in range once to 4 times a day during range 2 to 6 weeks intervention. The level of pruritus was measured using VAS in 2 studies, VRS in 1 study and pruritus score in 1 study. Another outcomes also be measured for skin condition and quality of life. Overall, the result of studies statistically significant difference in favor of cream intervention to uremic pruritus severity, skin condition and part of quality of life. But there were adverse drug reaction in using sericin cream [erythema] and capsaicin [burning sensation, dryness and transient erythema] happened though in little mount.

4. Discussion

The main finding of our systematic review of treatments for uremic pruritus is that with the exception of the evidence for topical treatment in some types of preparation to burdensome symptoms in patients with chronic kidney disease receiving hemodialysis. This review of clinical trial articles found 15 relevant studies conducted on 855 hemodialysis patients suffering from uremic pruritus which could be clustered into five categories of preparation to simplify the alternative options therapy.

The most commonly used preparation categories that are used in the topical treatment of uremic pruritus was aromatherapy with various essential oils from at least 4 studies. Studies have shown a beneficial effect for essential oils to reduce pruritus in hemodialysis patients. Massage aromatherapy on women during delivery also has shown decreased levels of pruritus, it should be due to a similar duration per session and the design of the study. Most studies in this review measured pruritus severity using a visual analogue scale, pruritus score, verbal rating scale and skin condition in favor of topical treatment.

The studies showed a positive effect for aromatherapy on improvement of sleep quality in patients undergoing hemodialysis similar to the Cho, Karadag and Moeini studies on cardiac patients in ICUs this is due to similarities in methods of aromatherapy, duration per session, frequency of sessions, study design, used scale and type of used aroma [28, 29, 30]. Studies have demonstrated a positive effect of aromatherapy on depression in hemodialysis patients. In agreement of current a study conducted by Conrad shown a positive effect on depression of postpartum women [31], this is should be due to similar type of aroma and duration of aromatherapy per session.

Studies have shown a positive effect for aromatherapy on stress in hemodialysis patients

similar two systematic reviews which conducted by Kim and Hur Mh on middle-aged women and healthy adults, this was due to similarity in studies design, type of aromatherapy, and duration of aromatherapy [32,33]. The study that addressed quality of life showed a positive effect for aromatherapy on the quality of life in hemodialysis patients similar to a systematic review conducted by Fung on elderly patients with dementia. This was due to study design and the type of aromatherapies [34]. The only study found in this area indicated a positive effect of aromatherapy on a decrease in headaches in hemodialysis patients, in agreement of present results of a study that conducted by Cha on middle-aged women which shows a positive effect for aromatherapy on headache. [35] This was may be due to a dose of aromatherapy and design of study.

Despite a large trial literature examining multiple different interventions, the combination of flawed methodology, high risk of bias, small sample size, and study heterogeneity prevent the generation of robust treatment recommendations. High-quality studies are urgently needed to bridge this major gap between research output and identified patient priorities.

Some previous systematic reviews have attempted to evaluate individual treatments for uremic pruritus. The review have addressed the efficacy of acupuncture. Kim et al reviewed the literature regarding the effect of acupuncture on uremic pruritus. Six studies were included in the review, with various study designs including RCTs, uncontrolled observational studies, and a controlled clinical trial. The authors concluded that there was a lack of evidence to support the use of acupuncture for uremic pruritus.

This review study have addressed the efficacy of aromatherapy, emollient, cream, ointment and lotion preparation of topical treatment in hemodialysis patients included 15 studies. Another systematic review with a total of 44 articles: RCTs, quasi-RCTs, observational studies, open-label studies, and retrospective studies were included in Simonsen systematic review for treatment of uremic pruritus in general preparation. This review supported a trial of emollient containing high water content, capsaicin and sericin cream, dead sea mineral lotion, and other topical treatments [23].

Kim et al reviewed the literature regarding the effect of acupuncture on uremic pruritus. Six studies were included in the review, with various study designs including RCTs, uncontrolled observational studies, and a controlled clinical trial [24]. The authors concluded that there was a lack of evidence to support the use of acupuncture for uremic pruritus. The review supported omega-3 intake in patients with CKD with uremic pruritus. Gooding et al and To et al examined the literature with regard to capsaicin and ondansetron, respectively. Both reviews included varying causes of pruritus and were not exclusive to uremic pruritus.

Our analysis distinguishes itself from these previous studies in several important ways. First, we examined a broader range of treatments in order to better describe the full spectrum of trials evidence on the treatment of uremic pruritus. Second, we included only clinical trials (no descriptive) in our review. Such trials are the optimal study design for estimating treatment effects. This property is especially relevant when examining effects of therapy for a subjective symptom such as pruritus, in which the pathophysiology is not completely understood. We only included studies that used a well-validated tool for assessment of pruritus because otherwise it would be difficult to compare and generalize results across studies.

The systematic review conducted by Bouya et al [25] to determine the effect of aromatherapy on hemodialysis complications from the inception of the databases to 30 December 2017. A review

of the literature found 22 relevant studies conducted on 1087 hemodialysis patients. The most commonly used method was inhalation aromatherapy and the most common aroma used was lavender. Most studies have shown the beneficial effect of lavender on anxiety among patients undergoing hemodialysis [25].

The results of the reviewed studies demonstrate the beneficial effect of topical therapy on the pruritus and some related outcomes in hemodialysis patients with pruritus. The results showed that aromatherapy improved the quality of life in hemodialysis patients. The results of included studies suggest that dialysis health care team can use different topical therapy options (emollient, aromatherapy, lotion, ointment and cream) by using an appropriate dose (lavender, tea tree, sweet almond, dead sea mineral, chia seed, jojoba, peppermint, or sunflower oils; sericin, capsaicin, pramoxine, tacrolimus, GLA, etc.) as complementary therapies to reduce pruritus and related outcomes of dialysis (anxiety, sleep disturbances, depression, and stress) and improve the quality of life of hemodialysis patients as well as choice an appropriate dose and frequency of aromatherapy sessions in some complications due to limitation in number of studies required conducting more studies.

5. Conclusion

The results of the reviewed studies demonstrate the beneficial effect of topical treatment on uremic pruritus in hemodialysis patients. The results showed that aromatherapy is most common used for one of some types of the preparation, that alleviate uremic pruritus severity, repaired skin condition, and improved the quality of life in hemodialysis patients. Considering the complications and heavy cost of managing complications in patients undergoing hemodialysis, it appears that aromatherapy can be used as an inexpensive, fast-acting and effective treatment to reduce the complications in hemodialysis patients subject to further study to assure the safety and effectiveness of the procedures. As well choice an appropriate dose and frequency of topical treatment sessions in some complications due to limitation in number of studies required conducting more studies. The most important limitation of the present study was the variation of the topical treatment and doses used, which makes meta-analysis impossible for more accurate examination of the effect of the topical treatment on uremic pruritus.

Table 1
Description of the study characteristics, outcome, measurement, interventions and results.

No	Title (Authors, Year)	Study Characteristic 1. Design 2. Sample	Outcome and Measurement	Intervention i) Experiment Group (EG) : type, dose, frequency and administration method, duration per session, total number of sessions, total duration of intervention ii) Control Group (CG)	Results
1.	*Effect aromatherapy on uremic pruritus among Patients Undergoing Hemodialysis* [12]	1. Quasi-experimental (pretest-posttest one control group design) 2. Hemodialysis patients N=30	1. Pruritus scale from VAS score 2. 5 Domain pruritus scale	Aromatherapy consists of mix between two oils includes peppermint oil and sunflower oil, administered by topical massage method, given 1–2 drops, 2x/day, given in 15–25 min per session, for total 6 session during 2 weeks	Significant positive effect of aromatherapy to Uremic Pruritus. Aromatherapy revealed that (33.3%) had mild pruritus and (66.7%) hadn't pruritus
2.	*Efficacy of Topical Application of Sweet Almond Oil on Reducing Uremic Pruritus in Hemodialysis Patients: A Randomized Clinical Trial Study* [11]	1. Quasi-experimental 2. Hemodialysis patients N= 60	1. pruritic score at one week and two weeks post-intervention 2. pruritic score questionnaire	(i) EG (n = 22): Sweet almond oil (certified as traditional medicine and with a registration number for the production license), 5-10 ml once a day for 2 weeks; (ii) CG2 (n = 20): no intervention	Significant difference in the mean of pruritus severity pre-intervention (19.63-11.67), one week post-intervention (12.22-11.33), and two weeks post intervention (7.27-5.74) ($P < 0.05$) in the test group.
3.	*The effect of aromatherapy on hemodialysis patients' pruritus* [26]	1. Quasi-experimental (pretest-posttest) 2. Hemodialysis patients N=80	1. Pruritus 2. PSS (modified scale of the Pruritus Score Scale)	(i) EG (n=40), received aromatherapy massage using lavender, tea tree, almond and jojoba oils 5% solution, three times a week, a six-week aromatherapy by the investigators during dialysis sessions three times a week for a period of 7–15 min for each region of the pruritus, given during 7–15 min each session, 18 times for 6 weeks (ii) CG (n=40), received normal nursing care	Highly significant positive effect on Uremic Pruritus after applying aromatherapy, whereas control group difference was not found to be statistically significant
4.	*Sericin cream reduces pruritus in hemodialysis patients: a randomized, double-blind, placebo-controlled experimental study* [22]	1. Quasi-experimental 2. Hemodialysis patients with moderate to severe pruritus, *N*= 47,	(1) Four measurements: weeks 0 (pretest), 2, 4, and 6; (2) skin condition: SD27 used to test skin hydration, redness, and pigmentation; (3) pruritus: VAS; (4) quality of life: QoL and KDQOL-SF	(i) EG : The 2 sides of the participants' bodies served as experimental and control groups for testing. A cream containing sericin was used for the limbs on one side; twice a day for 6 weeks; (ii) CG : whereas a placebo was used for the limbs on the other side;	(i) Experimental locations: improvement in severity of pruritus; skin demonstrated reduced reddening and pigmentation (weeks 2, 4, and 6); increased hydration (weeks 4 and 6); placebo reduced redness on the leg (week 6) (ii) QoL: only scores on the pain subscale dropped; (iii) KDQOL-SF: total scores did not change significantly

5.	*Babyoil therapy for uremic pruritus in hemodialysis patients* [9]	1. Quasi-experimental 2. Hemodialysis patients N=63	(i) Two measurements of severity of pruritus (ii) ISS	(i) EG1 (n = 30): low-temperature baby oil (10∘C to 15∘C) at least once a day for 15 min each time over 3 weeks; (ii) EG2 (n = 31): room-temperature baby oil (24∘C to 26∘C) at least once a day for 15 min each time over 3 weeks; (iii) CG (n = 32): routine care; (iv) this method focuses on increasing moisture, while cold may reduce nerve conduction, inflammation, and chemical stimuli	Severity of Pruritus: EG1 and EG2 improved significantly more than the CG did in total ISS scores. EG1 and EG2 did not differ from each other
6.	*Effectiveness of Topical Chia Seed Oil on Pruritus of End-stage Renal Disease (ESRD) Patients and Healthy Volunteers* [14]	1. Quasi-experimental 2. Hemodialysis patients N=16	1. skin functions, namely trans epidermal water loss and skin capacitance 2. 6-point itch scale	i) EG (n=), topical chia seed oil containing moisturizers as oil-in-water lotion formula with concentration 4% ii) CG (n=) moisturizers without chia seed oil were used as placebo	The score of satisfaction was improved from 2.0 (at 2 weeks) to 2.8 (at 8 weeks). Statistically significant improvement of skin dryness observed at 4 weeks after treatment and maintained. Significant alleviation in lichenified brownish patches on the right dorsum of foot
7.	*Topical Capsaicin Therapy for Uremic Pruritus in Patients on hemodialysis* [18]	1. Quasi-experimental 2. Hemodialysis patients N= 34,	1. Evaluation of itching 2. Total scoring of pruritus = (severity of pruritus × distribution of pruritus) + sleep disorder scoring	(i) EG (n=17), received Capsian 0.03% ointment (capsaicin 0.03%, Goldaru, Iran), (ii) CG (n=17), received placebo (prepared in the Pharmacology Institute of Mazandaran University of Medical Science)	There is significant difference in pruritus scores after each week (1,2,3 & 4) between two groups. Measurement test showed that decreasing in pruritus severity in the study group was more than that in the placebo group
8.	*A Randomized Controlled Clinical Trial Comparing the Efficacy of Dead Sea Mineral-Enriched Body Lotion versus Two Types of Placebo in the Treatment of Cutaneous Dryness, Itching, Peeling and Tightness in Hemodialysis Patients (EDIT)* [15]	1. Quasi-experimental 2. Hemodialysis patients with moderate pruritus, N= 78,	(1) Two measurements: before the experiment (week 0) and 2wk after the experiment (week 2); (2) skin condition: itching, dryness, peeling, and tightness; (3) sleep disorders: 0 to 4 points; (4) treatment satisfaction: 0 to 4 points; (5) blood biochemistry values: serum potassium, calcium, PTH, chemistry, liver	(i) EG (n = 25, completed by 21 people): lotion containing Dead Sea mineral and mud (DS) and moisturizing ingredients; (ii) CG1 (n = 25, completed by 20 people): lotion (containing moisturizing ingredients but not DS); (iii) CG2 (n = 28, completed by 24 people): lotion (containing neither moisturizing ingredients nor DS); (iv) usage method: twice daily (once after showering) for 3weeks; (v) the study did not show efficacy of Dead Sea mud	(i) Skin conditions of the 3 groups improved significantly in every category (itching, dryness, peeling, and tightness). The changes in the experimental intervention (Dead Sea mud lotion) and the other 2 groups (the control groups) did not differ significantly; (ii) the 3 groups did not change significantly in sleep or treatment satisfaction; (iii) pruritus, dryness, sleep disorders, and treatment satisfaction were correlated; (iv) blood biochemistry values: no change

			function tests, and C-reactive protein (CRP)		
9.	*A pramoxine-based anti-itch lotion is more effective than a control lotion for the treatment of uremic pruritus in adult hemodialysis patients* [16]	1. Quasi-experimental 2. Hemodialysis patients (N=28)	1. % decrease in average VAS 2. 10-cm VAS	(i) EG (n=14, Topical 1% pramoxine HCl) 2x/day on all affected areas for 4 weeks (ii) CG (n=14, bland emollient) (Cetaphil) 2x/ day for 4 weeks	Pramoxine: 61%; control: 12%. Statistically significant for pramoxine HCl to alleviate uremic pruritus
10.	*Therapeutic Effect of Topical Gamma Linolenic acid on refractory uremic pruritus* [27]	1. Quasi-experimental 2. Hemodialysis and peritoneal dialysis patients (N=17)	1. Median VAS (mm) at BL & post in paired analysis 2. 100-mm VAS, Questionnaire	(i) EG (n=11); GLA 2.2% cream 30 mL/day (titrated up) 1x/day for 2 weeks (ii) CG (n=11); Placebo 1x/day for 2 weeks	GLA: 75 BL, 30 post; Placebo: 72.5 BL, 67.5 post. Statistically significant different, in favor of GLA, but adverse drug reaction exist for GLA: erythematous skin reaction (5.9%)
11.	*Lack of efficacy of tacrolimus ointment 0.1% for treatment of hemodialysis-related pruritus: A randomized, double-blind, vehicle-controlled study* [19]	1. Quasi-experimental 2. Hemodialysis patients (N=22)	1. % reduction in itch post 2. 10-cm VAS	(i) EG (n=11) Tacrolimus 0.1% ointment) 3x/week by investigator and 2x/day by patient for 4 week (ii) CG (n=11) Vehicle control for 4 week)	Tacrolimus: 77%; Placebo: 79%. Statistically not significant for using tacrolimus to uremic pruritus patients, while exist the adverse drug reaction Tacrolimus: warm sensation (67%)
12.	*Effect of skin care with an emollient containing a high water content on mild uremic pruritus* [10]	1. Quasi-experimental 2. Hemodialysis patients with mild pruritus, n = 20,	(1)Three measurements: weeks 0 (pretest), 2, and 4; (2) pruritus: VAS; (3) emotional disturbance: VAS; (4) dry skin and scratches: assessed by 2 clinical physicians; (5) blood biochemistry values: WBC, eosinophilic leukocytes, hematocrit, RBC, Hb, platelets, total protein, potassium, calcium, uric acid	(i) EG (n = 10): hydrogel containing 20% natural ingredients (e.g., aloe vera and vitamin E) and 80% water was applied to the skin twice a day for 2 weeks before stopping for 2 weeks; (ii) CG (n = 10): none; (iii) blood flow, dialysate flow rates, and artificial kidneys of the patients were not changed during the experimental stage; no medication was used; (iv) aqueous gel contains high amount of water and could reduce itching	(i) Severity of pruritus: EG changed at week 2, differing from the CG; (ii) skin dryness: EG changed at week 2, differing from the CG; (iii) skin scratches: EG changed in both weeks 2 and 4 compared with week 0, differing from the CG; (iv) emotional disturbance: EG changed at week 2, differing from the CG; (v) blood biochemistry values: the 2 groups did not differ within each group or between the 2 groups at the 3 points
13.	*Hemodialysis related pruritus: a double-blind, placebo-controlled,*	1. Quasi-experimental 2. Hemodialysis	1. % responders (from severe or moderate to mild or none)	(i) EG (n=9, Capsaicin 0.025% cream to 1) affected site 4x/day for 4 weeks	Capsaicin: 82.4%. Statistically different in treatments %, in favor of capsaicin with

	crossover study of capsaicin 0.025% cream [20]	patients (N=19)	2. 4-point VRS	(ii) CG (n=10, Placebo to 1%) affected site 4x/day for 4 weeks	higher effect. But there is adverse drug reaction Capsaicin: local burning and/or stinging, cutaneous erythema
14.	*Topical capsaicin for treatment of hemodialysis-related pruritus* [21]	1. Quasi-experimental 2. Hemodialysis patients (N=21)	1. degree of itching 2. 4-point scale pruritus	(i) EG (n=10), received capsaicin 0.025% cream were applied to the preselected site four times daily for 6 weeks. (ii) CG (n=11), vehicle control	All noted an improvement in pruritus from moderate or severe at the prestudy evaluation to minimal or no pruritus bythe end of the first study week. But there was adverse drug reaction : burning sensation, dryness and transient erythema
15.	*A randomized, crossover trial of Sarna and Eurax lotions in the treatment of hemodialysis patients with uraemic pruritus* [17]	1. Quasi-experimental 2. Hemodialysis patients (N=31)	1. % responders for comfort 2. 4-point VRS, 100-mm VAS	(i) EG (n=15, Sarna lotion for 1 week) (ii) CG (n=15, Eurax lotion for 1 week)	Sarna: 76.7%; Eurax: 76.6% Statistically no different in treatment, while the adverse drug reaction is existing for Eurax: sparse itchy rash (3.2%)

ABSTRACT

Benson relaxation is being used in a wide range of common physical and psychological problem conditions in treatment despite lack of consensus about their effectiveness in different patient categories. The aim was to systematically review the evidence of effectiveness benson relaxation in different patient categories. MEDLINE, PubMed, CINAHL, Ebsco, Elsevier ScienceDirect journals were identified from 2014 to 2019. Studies were reviewed and categorized based on the type of patient. We used PRISMA guidelines to assess the quality of the included reviews. The search produced 92 reviews: 15 were included, covering 17 unique RCTs and 8,683 unique individuals with various conditions. The evidence supports the use of benson relaxation to alleviate symptoms, both mental and physical, in the adjunct treatment of fatigue, acute and chronic pain, depression, sleep disturbance, and anxiety disorders in adults.

Keywords: benson relaxation, benson technique, benson relaxation training

1. Introduction

Pharmacological stress control methods are costly and usually accompanied complications. Recent research has focused on non-pharmacological techniques. Relaxation is one of most useful non-pharmacological techniques[1]. Relaxation technique as a kind of subjective stress management method decreased anxiety levels, mood disturbance, body discomfort, and autonomic nervous system's activity and at least it might affect the quality of sleep[2–5].

Herbert Benson MD, is the father of modern mind-body medicine. From the late 1960s onwards he demonstrated that the relaxation response brings about bodily changes that decrease heart rate, lower metabolism, decrease the rate of breathing and bring the body back into what is probably a healthier balance [6]. Benson's relaxation is one of the best muscular relaxations that effective on the pulse rate, respiratory function, and heart workload[7]. Benson's technique works by the alignment of the hypothalamus and decreasese the sympathetic and parasympathetic practices[8].

Benson technique creates a quiet environment that results in the reduction of muscle tension and increases the patients' attention. Benson relaxation is one of the most useful nonpharmacological techniques which reduce stress through impact on mental and physical conditions, depression, mood, anxiety, and self-steam[9,10].

Despite the expanding application of Benson relaxation, the evidence for their use and the appropriate indications are debated. The aim of this study is to provide a systematic overview of the effectiveness of Benson relaxation in different patient populations in order to identify the patient categories in which these interventions are indicated.

2. Research Methods

2.1. Inclusion and exclusion criteria

We performed a systematic overview of Benson relaxation. To be included the studies had to have the following characteristics: 1) randomized controlled trials or quasi experiment with Benson relaxation as the intervention 2) performed for treatment or prevention and 3) reporting any health outcome benefit. Unpublished dissertations and conference papers were excluded. As the aim of this study was to define indication areas, we did not restrict the search by patient population and number of RCTs reviewed.

2.2. Searching Strategy

Some Six electronic databases were searched: Proquest, CINAHL, Elsevier's Scopus, SpringerLink, ScienceDirect, PubMed. The databases were searched for advance search with English language publications using the following terms: "Benson AND Relaxation" or "Benson AND Technique" or "Benson AND training in combination with "RCT" or "randomized".

2.3. Study selection process

Reviews were independently selected by title and abstract by the authors. Any citation considered potentially relevant by at least one reviewer was retrieved in full text form in order to determine whether it met the selection criteria stated previously.

2.4. Data extraction and quality assessment

The systematic reviews were evaluated independently by the authors for both content and quality. They extracted data based on the PRISMA guidelines for systematic reviews[11]. If information was missing or data were incomplete, the authors of the review were contacted or the RCTs concerned were retrieved in order to give an overview as thorough as possible. To assess the quality of the systematic reviews, a checklist was created using the validated PRISMA guidelines[11]. Authors simplify assessment process with PRISMA as same as checklist that used in previous systematic review about mindfulness[12].

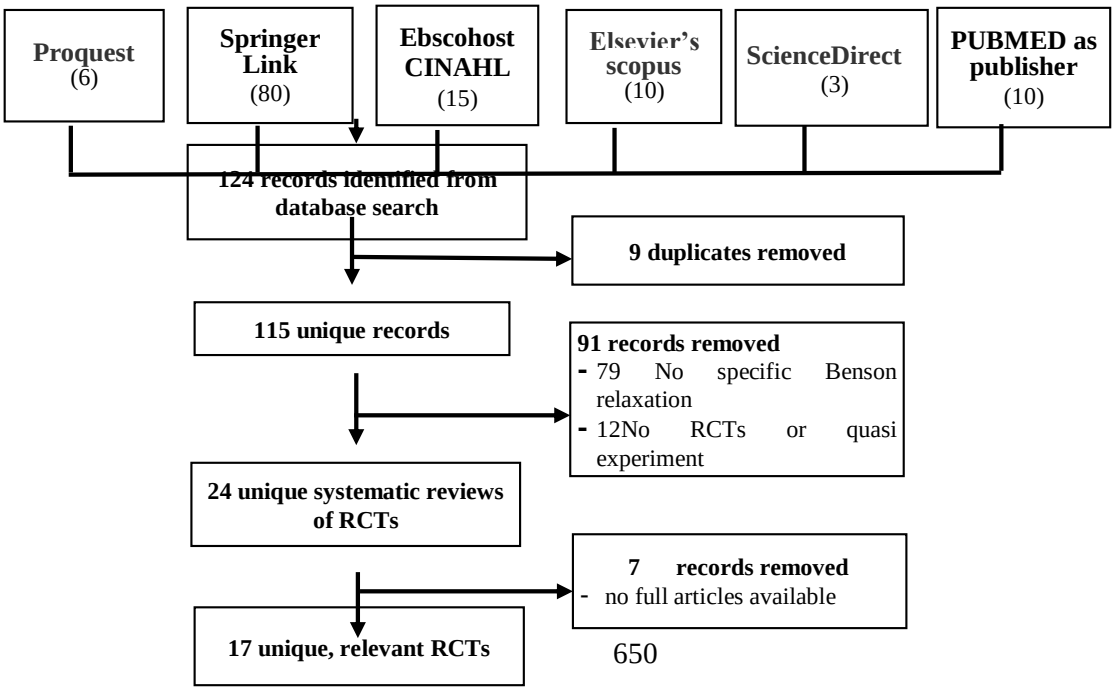

Figure 1. Flowchart.

Table 1. Quality assessment items based on the PRISMA criteria for systematic reviews

No	Questions	Item on original checklist
1	Was the objective of the review explicitly described with reference to the participants, interventions, comparisons, and outcomes (PICO)?	PRISMA item 4
2	Were study eligibility criteria (inclusion/ exclusion criteria) and study selection process reported?	PRISMA item 6+9
3	Was a comprehensive literature search performed?	PRISMA item 7
4	Was the search strategy reported for at least one database?	PRISMA item 8
5	Was a list of studies (included and excluded) provided?	
6	Was study selection and data extraction done by at least two independent authors	PRISMA item 10
7	Was the risk of bias of individual studies assessed and presented?	PRISMA item 12+19
8	Were also unpublished studies included (risk of publication bias)?	PRISMA items 15+22
9	If applicable, was the method for combining results appropriate?	PRISMA item 14+16
10	Were the strengths and limitations of the review addressed?	PRISMA item 25
11	Is the conclusion supported by the data, taking into account the quality of the studies?	PRISMA item 26
12	Were the findings interpreted independently of the funding source?	PRISMA item 27

2.5. Data synthesis

Intergroup comparison effects (improvement intervention vs control group) are reported unless otherwise mentioned. If the intergroup results were insignificant, we also looked at intragroup differences in order to see if the intervention had at least a pre-post effect (which is already incorporated in significant intergroup effects). The control group includes: wait list control (WL), treatment as usual (TAU) or active treatment (AT). The results are pooled by population to indicate what symptoms in these populations are amenable to Benson relaxation. Data synthesis was performed with random effects analysis. Furthermore, in order to be totally transparent, in the supplementary material a table is provided to show exactly the RCTs were included in this review.

3. Results

3.1. Study Selection

A total of 124 potentially eligible articles were identified, retrieved, and screened for potential inclusion. 9 articles were duplicate records. From the remaining 115 articles, 91 were excluded based on the abstract: 12 were not RCTs and 79 did not have Benson relaxation as intervention. Seven results were conference abstracts and not yet published. The full text of the remaining 17 articles was reviewed.

Table 2. Study characteristics.

Author (year)	Design	Population (number of Participants)	Intervention	Control intervention	Outcome measure
Hassanzadeh (2018)	RCT	Hemodialysis patients (105)	Benson relaxation	AT (Aromatherapy), TAU	Fatigue
Pasyar (2015)	RCT	Hemodialysis	Benson	TAU	Adherence,

		patients (86)	relaxation		Biomedical Markers
Poorolajal(2017)	RCT	Preoperatif patients (144)	Benson relaxatuon	TAU	Anxiety, Hemodynamic
Tahmasbi(2016)	RCT	patients undergoing coronary angiography (70)	Benson relaxatuon	TAU	Anxiety
Sajadi (2019)	RCT	Female nurse (72)	Benson relaxatuon	AT (systematic desensitization)	Anxiety
Araujo (2016)	RCT	Women with high-risk pregnancies (50)	Benson relaxatuon	TAU	Depression level
Seifi (2018)	RCT	Patients With Heart Failure (105)	Benson relaxatuon	AT (Nature Sound)	Fatigue
Masry (2017)	Quasi experiment	knee or hip replacement patients (100)	Benson relaxatuon	TAU	Night pain, sleep quality
Solehati (2015)	Quasi experiment	Post SC women (60)	Benson relaxatuon	TAU	Pain
Reig-Ferrer (2014)	RCT	Elderly (30)	Benson relaxatuon	WL	Psychological well-being, immune parameters
Mowla (2017)	Quasi experiment	Primary caregiver of children with chronic diseases (100)	Benson relaxatuon	TAU	QoL
Mahdavi (2017)	RCT	Hemodialysis patients (80)	Benson relaxatuon	TAU	Stress, Anxiety, Depression
Gorji (2014)	RCT	Hemodialysis patients (88)	Benson relaxatuon	TAU	stress, anxiety, pain perception
Calisi (2017)	RCT	Female Nurse (46)	Benson relaxatuon	WL	Anxiety, Depression, Well-Being, Work-Related Stress, Confidence
Barati (2016)	semi-experienced & practical research	Elderly (30)	Benson relaxatuon	AT (Jacobson relaxation, Combined exercises (Benson Relaxation+ Jacobson Relaxation))	elderly's depression, life quality
Kiani (2017)	RCT	Hemodialysis patients (105)	Benson relaxatuon	TAU	Anxiety
Paramban (2016)	Quasi-experimental design	Primigravid mothers (30)	Benson relaxation	TAU	Stress

TAU = treatment as usual ; WL = waiting list ; AT = active treatment

3.2. Data extraction and quality assessment

Characteristics of the study, patient population, intervention, control condition, and outcome measures of the 23 included reviews are shown in Table 2.The quality scores shown are those agreed upon after discussion. Nearly all reviews performed well on items related to the description of the objective, the literature search, and the study selection process (items 1–4). The list of included and excluded RCTs was not always complete (item 5). Although some reviews employed independent data extractors, many did not, and several were unclear about this item (item 6). Approximately half of the reviews assessed and presented the risk of bias of individual RCTs and the risk of publication bias (items 7 and 8)

Table 3. Quality assessment of included reviews.

3.3. Synthesis of results

The results of the reviewed RCT's and quasi experiment are summarized below, categorized by patient population. 17 articles were included, with a total of 1301 participants. The categories are healthy population, hemodialysis patient, perioperative patient, cardiovascular disease patient, pregnant women, and elderly.

3.4. Benson relaxation and hemodialysis patient

The search identified five unique RCTs that show the benefit of Benson relaxation for hemodialysis patients. The first research shows inhalation of lavender essential oil to reduce the level of fatigue in the patients undergoing hemodialysis was more effective than that of the Benson relaxation method. This perspective supports the idea of using complementary and alternative medicine, especially aromatherapy by lavender essential oil, to reduce the level of fatigue[13].

On the other hand participants receiving BRT for eight weeks experienced significant improvement in dietary and fluid adherence, as well as changes in their biomedical markers, such as blood glucose

and White Blood Cell (WBC) count. The study also states that the differences between the control and BRT groups regarding the biomedical markers, such as BUN, PO4, and IWG, indicated that BRT was effective in increasing the dietary and fluid adherence in HD patients[14].

Benson's relaxation method in text, our findings confirmed the effect of relaxation on stress and anxiety with several studies and the recommendations are mostly emphasized on long-term, regular practice. The most effects of relaxation works through the decrease of metabolism and strengthening of heart contractions, respiration, and blood pressure; and release of epinephrine on the sympathetic system of a patient's physiological condition. Thus, by teaching the nurses can benefit the patients can by lower cost and prevent from extra problems as it is easy to use and teach to all levels of patients[1].

We found a high prevalence of stress, anxiety, and depression among patients on HD. Benson relaxation helped patients compared to those who did not receive any intervention. Meanwhile, the changes in stress scores were significant. There is growing evidence to evaluation of the influence of Benson relaxation as a cost-effective and safe technique on different chronic disease Improving and preventing the patients' psychological problems as well as other chronic disorders through applying nonpharmacological interventions[15].

The mean of hemodialysis patients' anxiety level mark changes was significantly higher in relaxation method group than the other group after the intervention. It can be concluded that results of the present and almost other similar studies indicates the effect of Benson's relaxation method on patients' anxiety level decrease. A difference in fatigue or anxiety level is sometimes observed in other studies or usefulness of these methods on anxiety is not shown; the reason of these differences may be searched among the effect of various factors like intervention duration, method, dose or density of essence, few samples, evaluation tool, enough sensitivity of tool, education, age and psychotic factors which makes the difference in results of these studies. At last the using Bensons relaxation method is recommended for similar clinical conditions to control patients' anxiety[16].

3.5. Benson relaxation and perioperative patient

The use of Benson's relaxation technique is a safe and inexpensive method that is associated with a beneficial effect on preoperative anxiety and the hemodynamic status in patients who are candidates for undergoing a various kinds of surgical procedures such as CABG, CAG, PCI, and general surgery. The investigations have shown that relaxing music can significantly reduce heart rate, respiratory rate, and myocardial oxygen demand[17].

There was an improvement in pain scores among the study group subjects at one day postoperative while there was a statistical significant difference was existed between study and control groups regarding pain intensity at 3rd postoperative day after implementation of Benson's relaxation technique. Regarding sleep quality the current study results showed that an improvement in sleep quality scores among study group subjects than control group subjects after implementing Benson relaxation technique at one day postoperative and 3rd postoperative day[18].

Benson relaxation had the greatest effect on reduction of pain intensity in women after caesarean section. While in recovery, pain reduction was due to Benson relaxation intervention. There was a decrease in pain intensity as 2.34 cm in the group given Benson intervention compared to the control group as 0.93 cm. Some other studies found that this relaxation technique is effective in reducing pain[19]

3.6. Benson relaxation and cardiovascular disease patient

Anxiety is a common problem associated with invasive medical procedures, especially in patients undergoing coronary angiography. As an intensifier at cardiovascular reactions, anxiety poses significant risk to the health of patients undergoing angiography. Benson's relaxation technique reduced the level of anxiety in patients of the intervention group before coronary angiography. Furthermore, this complementary technique had a positive impact on the vital signs of these patients, while it decreased the physiological parameters of the vital signs[20].

The Benson muscle relaxation and nature sounds interventions reduced fatigue among the patients with HF compared with the control group. However, no difference was observed between the 2 intervention groups with regard to the reduction of fatigue. In all groups, the reduction of fatigue was observed after the comparison of the results obtained before and after the interventions. Since all 3 groups also received routine care, the reduction of fatigue could be associated with routine care and medication. However, in the intervention groups more changes were found in the score of fatigue compared with the control group, which could be a result of the relaxation and nature sounds interventions. In the Benson muscle relaxation, the score of fatigue was reduced after the intervention more than the control group. Apart from psychological effects, relaxation affects the sympathetic system, which consequently decreases the heart workload and improves the cardiac output as a main reason for fatigue[21].

3.7. Benson relaxation and pregnant women

This study has shown that relaxation as a nursing intervention was effective at significantly decreasing the levels of depression of hospitalized women with high-risk pregnancies. This study has shown that relaxation as a nursing intervention was effective at significantly decreasing the levels of depression of hospitalized women with high-risk pregnancies[22].

Level of stress among primigravid mothers was significantly reduced after practicing Benson's relaxation therapy that there is significant difference in the stress scores before and after Benson's relaxation therapy hence the research hypothesis (H1) has been retained[6].

3.8. Benson relaxation and healthy population

Nursing staffs expose to a high level of anxiety. Based on our results, Benson's relaxation and systematic desensitization were effective methods for decreasing in the nurses' anxiety in both state and trait dimensions. Moreover, there was no significant difference between two intervention methods regarding state and trait anxiety. Nevertheless, the mean of changes in anxiety score was higher in the systematic desensitization. The staff in medical workplaces are exposed to a variety of stresses and high risk for anxiety disorders. Therefore, delay in primary prevention, early diagnosis, and control of anxiety disorder caused continually of psychological effects[8].

On busy inpatient units, nurses typically use highly technical equipment and experience unpredictable workloads, with ever-changing sets of circumstances that often need reprioritizing; essentially there is not enough time to complete the tasks of caring for a patient with multidimensional needs. These conditions reduce opportunities for the nurses to take breaks for rest or nourishment. In the short term, this stress may lead to physical and mental fatigue, and often hinders productivity and job performance[10].Nurses can be excellent role models for stress reduction techniques and wellness strategies if their belief systems include personal wellness. Conversely, not having the knowledge and skill of practicing personal wellness decreases the nurse's ability to teach patients stress-

reduction strategies. Holistic nurses who practice compassionate self-care may be more capable of providing their patients with compassion and loving kindness.

Chronic diseases leave a significant effect on not only the afflicted children but also their parents. Chronic diseases in children may also influence their parents' or primary caregivers' quality of life (QoL). According to the results of this study, the QoL among primary caregivers of children with chronic diseases was affected by the intervention. One can infer the parents were suffering from role limitations due to ensuing emotional problems[23].

3.9. Benson relaxation and elderly

The aging process involves a decline in immune functioning that renders elderly people more vulnerable to disease. In residential programs for the aged, it is vital to diminish their risk of disease, promote their independence, and augment their psychological well-being and quality of life. Benson's relaxation technique or "tranquilization technique" used here produced an improvement in the quality of life and a modulation of the immune parameters in a group of elderly people residing in a nursing home. Given that it is an easy and economical intervention, it could be useful as a health resource in residential settings where its daily practice could offer medium and long-term benefits for the health and well-being of older adults[9].

Various relaxation programs regularly have effect on decreasing the elderly's depression. So it expected that various relaxation techniques such as Benson & Jacobson is used as effective practices & safe supplement &also as a non-medical treatment alongside other common treatments to reduce depression. According to the recent research findings & previous researches cab be resulted that effectiveness of regular relaxation schedule is irrefutable to improve the elderly depression with using treatment methods. It is recommended that regular relaxation programs & appropriate care for the elderly should be considered alongside other plans[24].

4. Discussion

This review provides an overview of more trials than ever before and the intervention effect has thus been evaluated across a broad spectrum of target conditions, most of which are common stress response. Study settings in many countries across the globe contributed to the analysis, further serving to increase the generalizability of the evidence. Beneficial effects were mostly seen in mental health outcomes: depression, anxiety, stress and quality of life improved significantly after training in Benson relaxation. These effects were seen both in patients with medical conditions and those with psychological disorders, compared with many types of control interventions (WL, TAU or AT).

There are several benefits of adding Benson relaxation to usual treatment. First, Benson relaxation are easy to implement and they allow patients to take a more active role in their treatment[16]. Second, there is little emotional and physical risk involved[14]. Third, the costs are relatively low as one trainer can lead a rather large group and most exercises can be done at home without the help of external means[9]. However, they do require commitment in both adherence and time of the patient.

Aim of this review was to assess in which populations Benson relaxation are effective, and in which not. Most insignificant effects found were based on studies using outcome measures that are only indirectly affected by Benson relaxation therefore no definitive conclusions can be drawn for these outcome measures. According to psychological theory, stress is usually caused by an external

factor which evokes fear, anger, or other states of discontentment. Stress is also experienced proportionately; the larger the discrepancy between the actual and desired situation, the higher the level of stress[15]. Apart from the initiating event, individuals themselves tend to magnify stress by worrying about the cause and consequences of the event, which often evokes more stress than the event alone. Support for this theory of stress reduction by coping with psychological stress factors is found in the demonstrated physiological effects of Benson relaxation. Blood pressure, heart rate, respiration rate and oxygen consumption had been shown to respond favorably to Benson relaxation. Similar physiological effects are seen in the relaxation response, it activates the autonomic nervous system to release endorphins and serotonin, and the parasympathetic response influencing endocrine and immune responses[12]. From the explanation, we learn that Benson Relaxation to regulate some body process has good effects on decreasing stress and improve health quality.

As one of the aims was to identify how different patient populations respond to Benson relaxation, we included a heterogeneous group of populations. However, even when we categorized them by diagnosis, some reviews included very heterogeneous populations themselves. Excluding these would cause us to miss 12 unique RCTs, so we defined a category 'mixed population' representing heterogeneous patient populations. Although we tried to report their results as clearly as possible, interpretation of this group's effects is difficult. Also, though Benson relaxation were considered equal in approach, the small heterogeneity of interventions could have resulted in some bias towards the null, thereby strengthening the validity of our findings of consistent effects of these interventions.

Future research will benefit from creative strategies that measure placebo effects and non-specific effects, and distinguish these from actual effects. Nevertheless, the reviews included in our overview are methodologically strong and demonstrate that Benson relaxation are effective for certain conditions. Since the available evidence demonstrates that Benson relaxation exceeds WL control, future research should probably focus on comparison with active treatment. Further research should also look more into the mechanisms whereby these therapies are efficacious.

5. Conclusion

Based on the results of this review, it was concluded that although there is continued doubt in the medical world towards Benson relaxation, the evidence indicates that Benson relaxation are associated with improvements in depressive symptoms, anxiety, stress, quality of life, and selected physical outcomes in the adjunct treatment of cardiovascular disease, hemodialysis, acute pain, pregnancy, preoperative period especially pre and postoperative, other mental disorders in healthy adults and elderly.

EFFECTIVENESS OF AROMATHERAPY AND HAND MASSAGE ON ANXIETY AND BLOOD PRESSURE IN HYPERTENSIVE PATIENTS : A SYSTEMATIC REVIEW

Rizky Asta Pramesti Rini
[1] Faculty of Nursing, Universitas Airlangga, Surabaya, East Java, Indonesia
E-mail: rizkyastapramestirini@gmail.com

ABSTRACT

Hypertension is systolic blood pressure equal to or above 140mmHg and or diastolic blood pressure equals or above 90mmHg. Stress and anxiety are the main risk factors for hypertension. Anxiety can stimulate the release of epinephrinehormone from the adrenal gland which can cause an increase in heart rate and narrowing of the blood vessels,to which it can increase blood pressure.Non-pharmacological treatment can be perfromed using aromatherapy and hand massage to determine changes in anxiety levels in hypertensive patients. In journal articles with Quasi-experimental, Randomized Controlled Trial (RCT), and non-randomized controlled design, cross-sectional and intervention studies were taken through a search tool with a database called Scopus, Pub med,Science direct using the PICO framework method. A total of 15 articles were selected according to the inclusion criteria involving 14,406 participants. Significantly, aromatherapy and hand massage had a positive effect to reduce anxiety levels in hypertensive patients. Systematic review is considered sufficient to know the effectiveness of aromatherapy and hand massage on reducing the anxiety and blood pressure levels in hypertensive patients. However, a systematic review assessment which focused on RCT research articlesis required to determine the effectiveness of aromatherapy and hand massage.

Keywords: aromatherapy, hand massage, anxiety, blood pressure

1. Introduction

Hypertension is the most common cardiovascular disease and is a major risk factor for global disease load (World Health Organization, 2017). Hypertension is a condition in which systolic blood pressure (SBP) ≥ 140mmHg or diastolic blood pressure (DBP) ≥ 90mmHg (Lili yang et al., 2018). Hypertension is a global challenge with high levels of morbidity and mortality. Hypertension is multifactor resulting from the influence of a combination between genetic and environmental factors. Modified risk factors of hypertensive patients who experience high emotions are the increase of developing mental health disorders, especially anxiety and depression. Anxiety is a significant cause of increased blood pressure and is an independent predictor of hypertension (Sharma et al 2016). According to Kretchy et al (2014) hypertensive patients have symptoms of anxiety, stress and depression and show the influence of negative emotions on the treatment of hypertension. Anxiety is the main response to stressors. In hypertensive patients, anxiety symptom is in the stage of the disease process. Anxiety factor can affect the severity of hypertensive patients. Anxiety is a form of unpleasant emotions, which can increase patients' psychological and physiological effects including abnormal heart rate, blood pressure (BP), heart output, and heart rate which can cause severe procedural complications and worsen CHD symptoms (Lijuan Mei et al.,

2015). Hypertension can be treated by pharmacological or non-pharmacological methods. Pharmacological treatment is long-term, used in treating hypertension in the form of diuretics, beta blockers, ACE inhibitors, angiotensin II receptor blockers, and vasodilators. Non-pharmacological treatment is used as a complement for pharmacological treatment. Thus, blood pressure can be controlled and maintained (Hikayati et al., 2012). Non-pharmacological treatment uses aromatherapy and hand massage to determine blood pressure changes and anxiety in hypertensive patients.

2. Method

2.1. Literature Search Strategy

The literature used in this Systematic review was obtained through 3 (three) electronic databases, namely: Scopus, Pubmed and Science Direct which published between 2006 and 2018.

The keywords used in the article search technique were "Aromatherapy", "Hand massage", "Anxiety", and "Blood pressure".

2.2. Inclusion and Exclusion Criteria

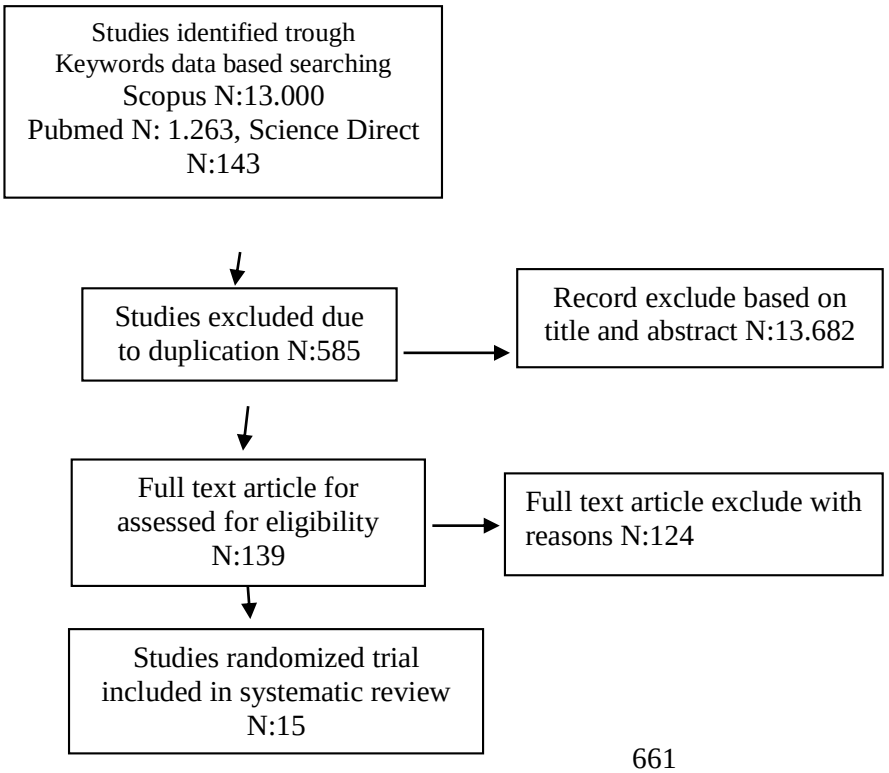
3.4.1. Design of the Study

The design of the study which became the inclusion criteria on this Systematic Review was *anxiety* and published in English.

3.4.2. Population

Population in this Systematic Review includes:

1. All studies indicated patients who received aromatherapy interventions and hand massage with or without a control group
2. Men and women > 25 years old
3. Finding the effect of aromatherapy and hand massage on anxiety in hypertensive patients



2.3. Intervention

Various types of aromatherapy interventions and hand massages which affected anxiety and blood pressure against various types of related diseases.

2.4. Clinical Results

The main result as well as the main objective of this systematic review was to know the effect of aromatherapy interventions and hand massage on anxiety and blood pressure. The studies contributed to this research were used without any limitation of time for the duration of the intervention.

2.5. Studies Selection

The standard applied to select the studies as suggested in the systematic review method guide was PRISMA. The steps were as follows:

1. Removal of duplication
2. Independent examination for titles, abstracts and keywords and removing irrelevant quotes according to inclusion criteria
3. If the title and abstract seemed to meet the inclusion criteria and in accordance with the objectives of the systematic review, the next step was selecting the journals with full text
4. The final step was selecting journals which used aromatherapy and hand massage to reduce bias.

2.6. Data Extraction

The data was extracted from each study which met the requirements. The extracted data included the characteristics of aromatherapy and hand massage toward anxiety, characteristics of results and summary of results.

2.7. Data Analysis

The studies were grouped according to the effects of aromatherapy and hand massage on anxiety. If possible, the studies were then grouped by time, follow-up and control group type.

3. Results

3.1 Literature Search and Studies Selection

In figure 1, in summarizing the search results and selecting the studies, this research adopted PRISMA guidelines (Liberati et al. 2009). The selection of journals based on the keywords used resulted in 14,406 potentially relevant studies, 585 duplications were deleted and 13,682 titles and abstracts found were traced. A total of 139 studies with full text were obtained with 124 studies excluded because they did not meet eligibility criteria, namely did not use English, not intervention. Eventually, 15 studies were selected for systematic review.

3.2 Population

The samples of 15 studies used in this systematic review indicated that the minimum number of the sample was 14 women with ages ranging from 18-20 years to parasympathetic autonomic activity, while the highest number of samples is 891 in hypertensive patients.

Patients with following conditions were involved as samples in this research: Hypertension,

Dementia, Coronary Angiography, Acute Coronary Syndrome, myocardial infarction, patients who would undergo surgical procedures, disorders of parasympathetic nerve activity.

3.3 Clinical Result Measures

Research indicated that result measures used to assess anxiety were: DASS (Depression Anxiety Scale), MMSE (Mini Mental State Examination), HARS (Hamilton Anxiety Rating Scale), VAS (Visual Analog Scale), SRAS (Self Rating Anxiety Scale), STAI (State AND Trait Anxiety Inventory) and AAS (Average Anxiety Score)

3.4 The Effect of Aromatherapy and Hand Massage on Anxiety

3.4.1. Aromatherapy

Inhaling essential oils has a direct and sustained effect on blood pressure during the day, and stress reduction. Essential oil has a relaxing effect to control hypertension (Kim et al., 2012). SAS scale can evaluate anxiety levels in hypertensive patients as much as 12% (Tie et al.2006). According to Zahra et al, (2014) Aromatherapy inhalation with lavender aroma could reduce anxiety in patients with myocardial infarction. Thus, health care providers, especially nurses, can use this inhalation scent to improve anxiety management after myocardial infarction.

3.4.2. Hand Massage

Hand massage effectively relieves anxiety without side effects among patients with coronary angiography (May et al., 2015). Hand massage is a simple, comfortable massage, and done with relaxation. For people who are experiencing stress, having difficulty maintaining a personal relationship with others, hand massage may be beneficial to reduce pain because it has a relaxing effect and reduces anxiety (kunikata et al., 2012). According to Nayoung et al (2015) hand massage and music therapy can reduce anxiety and improve sleep quality in elderly women.

4. Discussions

The researchers conducted a systematic review using RCT design, Cross sectional, non-random, and quasi-experimental to determine the effect of aromatherapy and hand massage on anxiety. Fifteen studies were examined to know the relationship between aromatherapy and hand massage. There are several important findings regarding the effectiveness of aromatherapy and hand massage, including:

4.1. Aroma therapy

Aromatherapy is a therapeutic use of essential oils from plants. Essential oils can be absorbed into the body through the skin or the olfactory system. Olfactory stimulation results in changes in physiological parameters such as blood pressure. According to Zahra et al (2014) after administration of aromatherapy, anxiety in the experimental group was significantly lower than the control group. There was a decrease in salivary cortisol levels of 0.02 µg / dL from 0.16µg / dL to 0.14µg / dL.

4.2. Hand Massage

Hand massage on autonomic activity and anxiety decreased significantly by ($P < 0.01$) (Kunikata et al 2012). Hamilton anxiety score in hand massage group showed that there was a significant decrease of ($P < 0.1$). After filling out the DASS -21 questionnaires, most (72.5%) of the

hypertensive patients were aware of the symptoms of complications regarding psychological symptoms, mild to severe depressive symptoms, anxiety 70% and 10% stress.

5. Conclusion

Aromatherapy and hand massage are complementary therapies which can be performed to reduce anxiety in hypertensive patients. In addition to pharmacological therapy, this therapy can be used as an adjunct to treat hypertensive patients.

PEER GROUP SUPPORT AND HEALTH EDUCATION ON SELF CARE BEHAVIOUR IN DIABETES MELLITUS PATIENTS

Ilkafah[1], Kadek Ayu Erika[2]
[1]Faculty of Nursing
[2]Hasanuddin University
E-mail: afa_ilkafah@yahoo.com

ABSTRACT

Diabetes mellitus is a metabolic disease that requires the complexity of therapy so that it requires self-management to control blood sugar. This study aims to determine of Peer Group Support (PGS) and health education on self-care behaviour in type II Diabetes Mellitus (DM). This research was a quantitative study with a quasi-experimental design, used two group design with pretest and posttest design. The sample was 28 respondents using total sampling method. They were divided into two groups by simple random sampling. The first group attended PGS for 4 meetings, the second group was only given counselling about DM for 4x. Measurement of Self care Behaviour using SDSCA (Summary Diabetes Self Care Activities), was carried out 2x pre and post-intervention. The results showed that there were differences in Self-care Behaviour in diabetes between peer group support and health education groups (p = 0.009). PGS is influential on the management of type 2 DM patients (p
= 0,000). It is expected that the health centre to form a special cadre for DM patients and for further research to use a larger sample with stress management modification for sufferers.

Keywords: diabetes mellitus, health education, peer group support, self care behaviour

1. Introduction

Diabetes is one of the most common chronic disorders that affect large numbers of human at all social and economic level, greatly increases the risk of cardiovascular diseases, and is the primary cause of death [1]. Patients with diabetes should be able to adapt to dietary changes, physical activity, medication and to manage stress. Patients are required to interact effectively with health care systems, family members and friends to provide support in managing the disease [2]. Peer support interventions attempting to address metabolic, treatment adherence, behavioral, knowledge and psychosocial outcomes have shown varying success[3].

Factors that affect the high blood sugar levels in patients are age, lack of physical activity and less understanding of the disease so that blood sugar levels can be controlled[4]. Diabetes mellitus affected almost 150 million people worldwide, and in the year 2025, the number of diabetic people is estimated to increase until 300 million. Meanwhile, other researchers in other studies estimated that in the year 2030 the number of diabetics will rise up to 366 million people from 171 million people in 2000[5]and it is predicted that the developing countries have their contribution which that

70 % of diabetic people are living there [6]. Indonesia is one of the developing countries, where the prevalence of diabetes mellitus is also increasing rapidly [7].

Diabetes as a chronic disease with the most complications requires independence from patients in managing their illness. If the patient is not able to independently consciously from himself then the possibility of disease is difficult to control[8]. One of the main aspects of diabetes care is self-care because self-care can improve patient health, reduce medical expenses and complications. Self-care describes the behavior of individuals who are carried out consciously and self-focused[9]. Diabetes self-care includes diet, medication adherence, regular exercise, monitoring of blood glucose levels and foot care[10].

Health education and support by groups of people with chronic diseases or peer group support (PGS) can reduce health behavior problems, reduce depression and contribute to improving the management of independent diabetes. The success of PGS is related to the sense of togetherness and sharing of life experiences with fellow DM people. Without the PGS, people with DM will feel alone, feeling that there is nothing they can share with their illness and no one understands themselves because only he feels that[11]. Support in peer provided through participation in groups can help patients manage their disease, especially managing diabetes self-care. This study aims to determine of *Peer Group Support* (PGS) and health education on the self -care behaviors in type II Diabetes Mellitus (DM).

2. Research Methods

This research study was quasi-experimental with a pre- and post-test design that was conducted in a developing Public Health Center in South Sulawesi, Indonesia, from July to December 2018.

According to the number of patients in the public health center where the sample calculation was conducted, 94 participants should be included to achieve 90% power, with a 1-sided level of 0.01 and a 10% - 15% anticipated drop-out rate [12]. The patients with diabetes type 2 were totally sampled; 18 participants were allocated to the PGS group and 18 participants were allocated to the Health Education (HE) group. For the final outcome analysis, we excluded six participants on the basis of the participants' request (n = 5) and due to incomplete returned instruments (n = 3), thereby leaving 14 participants for both groups (Fig. 1). The inclusion criteria were type 2 diabetes patients for at least one year, who had the commitment to take part in the complete study, and those who were fully alert and capable of reading and writing. The patients with ulcers decubitus and who were over 65 years of age were excluded because these conditions can disrupt their activities.

The respondent’s characteristic data served as an instrument for obtaining an overview of the factors related to self-care behavior. The data, which includes age and phone number, was collected using a participant characteristic questionnaire. The self-care behavior (SCB) scores was measured pre- and post-intervention for both groups using the Expanded Version of the Summary Diabetes Self Care Activities (SDSCA).

The SDSCA is a standard self-report scale to assess diabetes self-management. Ten items assessed the frequencies of specific self-management activities during the previous week; an additional three items assessed smoking. The respondents marked the numbers of days (0–7) on which the indicated behaviors were performed. The item scores could be averaged to the five subscales. All scale scores ranged from 0 to 7 with higher scores suggesting better self-management. The SDSCA has shown adequate reliability and validity in English [13]as well as for the German

samples[14]. In this study, the reliability coefficients were observed as follows (Cronbach's α; stratified by scale): general diet 0.89, exercise 0.74, blood-glucose testing 0.78 and foot care 0.72[13,15]. These tools were also translated into Bahasa Indonesia with a Cronbach's alpha coefficient of 0.79, which indicates high consistency.

The researchers recruited patients with type 2 diabetes according to the inclusion criteria and then allocated them either to the PGS group or to the health education group. Recruitment and intervention for the PGS group was conducted first until the desirable sample quote was achieved, followed by the recruitment and intervention of the participants for the health education group. This sampling method was applied to avoid data contamination and to ensure that the sample size was appropriate for the power analysis.

The aim and procedure of the study was explained to the patients and those who agreed to participate signed an informed consent form. The researcher then explained to the participants how to fill in the PGS and health education information. Furthermore, the group that taught PGS before the intervention were given the PGS guidelines. In the PGS group, there were two peer supporters that were diabetic patients who had been able to control the disease.

The peer supporters attended two-morning training sessions which were conducted by the research team. The sessions focused on the basics of type 2 diabetes and the issues relating to working within groups and confidentiality. Peer support meetings were held in the general practice premises at a convenient time for the practice staff, peer supporters and participants. The practices offered various daytime or early evening sessions, depending on the patients' preference. There was also a "frequently asked questions" (FAQs) system. That is, at the end of each session, the group fed back questions to the research team who compiled written answers based on the feedback from all groups. The FAQs from all groups were combined and sent back to the groups for the next session. Both interventions were given four times each week. The researchers measured the outcomes two times, namely before the intervention (pre-test), and four times after the interventions (post-test).

The data entry and statistical analysis was performed using the SPSS 21.0 statistical software package. The data was presented using descriptive and analytical statistics. Chi-square and independent t-test were used for the homogeneity test of the participants' characteristics between groups[16] in which a p value > 0.05 was considered to be similar between the group characteristics. The data obtained was analyzed using a paired t-test and independent t-test with a significant level of $\propto < 0.005$.

3. Results

Eighteen participants were in the PGS group and 18 participants were in the health education group. Four participants in the PGS group and health education group dropped out during the intervention (Figure 1). The characteristics of the participants at baseline have been presented in Table 1, showing that the two arms were balanced and similar statistically.

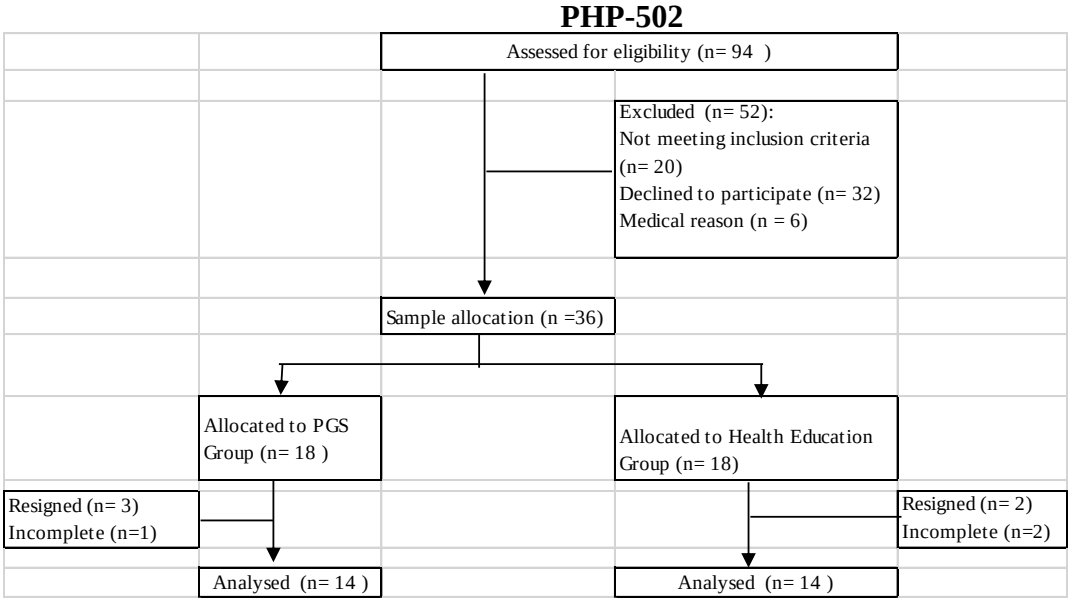

Figure 1. Study flow.

Table 1. The characteristics of the participants (n = 28).

Variables	PGS		Health Education		P Value
	n	%	n	%	
Age in years (Mean, SD)	50.53	6.32	50.08	7.13	0.106
Sex					0.564
Male	2	7.1	5	17.9	
Female	12	42.9	9	32.1	
Level of education					1.000
High School	8	28.6	9	32.1	
University	6	21.4	5	17.9	
Employment					1.000
Employer	4	14.3	6	21.4	
Employee	3	10.7	2	7.1	
Unemployed	7	25.0	6	21.4	
BMI categories					0.875
Underweight	1	3.6	4	14.3	
Normal	10	35.7	10	35.7	
Overweight	2	7.1	0	0.0	
Obesity	1	3.6	0	0.0	
Duration of illness					0.986
1-3 years	3	10.7	1	3.6	
> 3 years	11	39.3	13	46.4	
Marital status					1.000
Single	3	10.7	2	7.1	
Married	9	32.1	10	35.7	
Widow/widower	2	7.1	2	7.1	

Note: Statistically significant $\alpha \leq 0.05$ using an independent t-test & Chi-square test

Table 2. SCB score between the PGS group and health education group (*Mean of total score* ± *SD*).

Time	PGS	Health Education	Mean difference (95% CI)	*t* value	*P* value
Pre-test	52.40 ± 0.64	52.54 ± 0.61	0.14	0.674	0.698
Post-test	64.14 ± 0.89	60.71 ± 0.82	3.98	7.221	0.001

Table 2 shows the description of the differences in self-care behavior. A significant difference was found between the PGS group and the HE group with a mean difference of 3.98 (99% CI, P = 0.001). These results indicate that PGS more effectively improved the self-care behavior of the patients 4 times after the intervention.

Table 3. SCB score differences based on the SCB domains before and after the completion of Peer Group Support and health education (*Mean* ± *SD*).

SCB Domain	Peer Group Support (n=14)	Health Education (n=14)	*t* value	*P* value
General diet	3.02 ± 0.54	2.51 ± 0.56	3.556	0.042
Exercise	4.12 ± 0.67	2.99 ± 0.14	5.211	0.001
Blood-glucose testing	1.61 ± 0.28	1.02 ± 0.21	1.428	0.322
Foot care	3.08 ± 0.33	2.01 ± 0.36	3.209	0.021

Note: Statistically significant at an $\alpha < 0.005$ with Independent t-test.

Table 3 shows the measurement of the SCB score difference based on the SCB domains. The scores for the exercise domains were the highest.

4. Discussion

The majority of the participants in all groups were female with an age of 50 years and over. The duration of illness in all groups was almost equal. This indicates that this problem might be more prevalent among females than males. The youngest participant was 43 years, which is much younger than in the Western Urban China population[17]where the youngest diabetic patient was 60 years old (range of 60 – 79 years). The participants' education levels were almost equal in the two groups as the most appropriate statement to compare the impact of the intervention strategy among the two groups[14,18]. Most of the study participants (68 %) in the two groups were married. This situation is expected, as their family can support and motivate the participants in doing the self-care behavior which will lead to increase the patients' adherence to following the program.

Before conducting the study, the respondent's commitment was asking. Therefore, among the two groups, there are eight respondents has dropped out for the intervention. The reason that the respondents could not continue the intervention was because there were families who had died and who had to go out of the area for 2 weeks. There were also those who had dropped out because they followed their husband who had suddenly migrated outside of the area.

Based on the results, the support from both the groups and their peers is more effective at increasing the self-care behavior in the PGS group that received it four times. This was better than those who only received health education. The researchers concluded that PGS significantly increases the self-care behavior in patients with type 2 diabetes mellitus. A study conducted in China found

that peer support in primary care can enhance knowledge, improve self-efficacy, and decrease BMI, systolic blood pressure, diastolic blood pressure and both fasting and 2-hour post-prandial blood glucose [19]. Besides that, peer support also reported that it can improve the clinical outcomes that include the HbA1C, cholesterol concentration, systolic blood pressure and wellbeing score [15]. Another study with another patient found that with breast cancer, peer support can provide a higher quality of life compared to others [18].

The highest score in the SCB level based on domain in this study before both of the interventions was observed as being focused on exercise. Exercise is an easy thing for the respondent to do. The respondents only need to jog or walk every morning for about 30 minutes and without spending much money. In addition, there are a lot of programs available from public health centers that are near to their home. They have taken part in joint exercises every week.

Both PGS and health education are effective at improving self-care behavior. Besides that, both of them can enhance the knowledge of the participants. This is supported by the previous study in that knowledge can be improved through training and education and the educational model involving the active role of the participants. This results in improving their knowledge significantly and steadily as a basis for their behavior changing [20].

In the PGS group, there were 2 volunteers serving as support for the respondents who still poor at diabetes self-care. With the presence of volunteers who were able to manage their disease well, they are expected to be able to have a vicarious experience. Vicarious experience is a way to improve the management of independent diabetes from the experience of success that has been shown by others. It is a role in peer group support that is used as modeling for carrying out an action. Modeling is generally weaker than personal success when carrying out actions (enactive attainment). With a model that can be imitated and supported, the patient finds it easier and is more motivated to follow the behavior of the model.The success of PGS is related to the sense of togetherness and the sharing of life experiences with others [4]. With the existence of PGS, the patients can feel a sense of togetherness with the others who have the same condition as themselves. They can learn of the solutions to the problems that they experience so then their self-care behavior can improve.

This study has several limitations and shortcomings, such as the implementation of PGS, which is one group of PGS for as many as 14 participants. The groups should have been made where there were eight or nine people in one group. This happened because of the limited number of participants and teams of nutritionist and pharmacists from the developing public health center. In anticipation of these limitations, the researchers provided the PGS implementation and taught it directly in order to assist the participants with filling out the self-care behavior questionnaires and the list of the respondent's problems. This was to allow them to discuss it with the teams and volunteers. Additionally, the researchers presented two volunteers to facilitate the 14 respondents so then they could accommodate the questions and discussions from the respondents.

5. Conclusions

PGS is more effective at improving the self-care behavior in patients with diabetes mellitus than health education. The results of this research can be used as a reference in the treatment of diabetes self-management. This is because PGS is a social treatment that is easily performed by nurses, family, health educators and patients. Therefore, PGS can be used as a preferable standard procedure. This research can be continued with a larger sample and over a longer period of time than

in the present study.

BODY ALTERATION OF PATIENTS WITH TUBERCULOSIS WHO GET MEDICATION AT THE PUSKESMAS

Suprajitno[1]
[1]Nursing Department of Blitar, Poltekkes Kemenkes Malang
E-mail: bedonku@gmail.com

ABSTRACT

Patient with Tuberculosis who already experience 6 months of treatment may felt body alteration. The study was aimed to illustrate the body alteration of Tuberculosis patients who get medication at the Puskesmas. The design used cross sectional. The samples were 141 tuberculosis patients who got medication at the Puskesmas in Blitar which was selected by simple random sampling. The variables were height, weight, urine color, feeling of boring related to the medication and willingness to stop drinking the medication routinely. The data was collected in the patient's house on August - November 2018. The data was collected by instruments of height gauge, weights, and interview form. The data were analyzed descriptively. The results have shown the most changes were in the physical such as the weight loss, the red urine, and nausea. The patient's nausea causes a decrease in intake and has an impact on the patient's weight that goes down. It is important for nurses in Puskesmas to provide medical services and information through health education before the first medication.

Keywords: tuberculosis, body alteration, puskesmas

1. Introduction

The eradication of tuberculosis in Indonesia has been an intention and aim since 2011 [1], but positive new tuberculosis patients found through x-rays and sputum examinations are always going to be there. New patients receive intensive medication at the Puskesmas for a minimum of 6 months and they periodically perform a sputum examination as part of their ongoing evaluation. Patients with tuberculosis getting their medication at the Puskesmas are given additional food that aims to maintain their nutritional status and increase their endurance during medication.

Tuberculosis patients feel the weight losses every time that they measure their weight before taking the medicine at the Puskesmas. Weight and height is an important measure to use to assess body mass index, so then their proper nutritional needs can be determined. Health workers always record these results in the patient's medical record, but they never evaluate the physical and emotional alterations. Physical alterations and the feelings of patients due to medication also do not get the attention of the health workers. The alterations that appear, for example, can include a thin body and feelings of being bored while taking the medication. The purpose of the study was to illustrate the alterations in the bodily condition of the tuberculosis patients who get their medication at the

Puskesmas.

2. Material and methods

The design used was a cross-sectional approach. The researcher sampled as many as 141 tuberculosis patients who were receiving medication from the Puskesmas in Kabupaten and Kota Blitar who were selected through simple random sampling. The variables included height, weight, urine color, the feeling of boring related to the medication and the willingness to stop drinking the medication. The place of the data collection was at the patients' homes between August and November 2018. The data was collected using instruments; the collection tools were height gauges, weights and interview forms. The data was analyzed descriptively.

3. Results

The study results have been presented in Tables 1 and 2.

Table 1. Characteristics of the tuberculosis patients in Kabupaten and Kota Blitar on August – November 2018 (n = 141)

Description	Age (years)	Height (cm)	Weigh t (kg)	BMI	Chest (cm)	Waist (cm)
Minimum	15	141	30	11.02	60	53
Maximum	87	177	78	31.64	96	92
Average	48.98	159.30	47.38	18.61	75.26	68.83
Standard deviation	16.43	7.38	8.49	3.16	7.26	7.24
Skewness	-0.02	-0.01	0.19	0.33	0.41	0.63
Kurtosis	-0.71	-0.77	0.67	1.38	0.23	1.51

Table 2. Body alteration of tuberculosis patients in Kabupaten and Kota Blitar on August – November 2018 (n = 141)

No.	Alteration and feelings of the patient	f	%
1	Patient's perception of body condition:		
	a. Very thin	31	21.99
	b. Thin	99	70.21
	c. Normal	10	7.09
	d. Obese	1	0.71
2	BMI category:		
	a. Underweight	68	48.22
	b. Normal	71	50.35
	c. Overweight	1	0.71
	d. Obese	1	0.71
3	Urine color:		
	a. Red	116	82.27
	b. Not red	25	17.73
4	Nausea:		
	a. Yes	55	39.01
	b. No	86	60.99
5	Feeling bored the medicine:		
	a. Yes boring	16	11.35
	b. Not boring	123	87.23
	c. Not filling	2	1.42
6	Thinking to stopped of medication:		
	a. Yes want to quit	13	9.32
	b. Do not want to quit	126	89.36
	c. Not filling	2	1.42

4. Discussion

The lowest age found among the tuberculosis patients was 15 years old (Table 1) and they had been living with their family. Four patients (2.84%) were adolescents aged 15 - 18 years who had a high school level of education, according to the guidelines of *Pengendalian Tuberkulosis di* Indonesia (Tuberculosis Control in Indonesia)[2][3]. The parents of the adolescent patients suffered from tuberculosis three years ago and were now cured. This situation illustrates that transmission easily occurs between family members. However, the prevention of transmission is also easy for the families to do. The families have five tasks in terms of health, namely recognizing health problems, deciding to choose what actions to take, caring for their sick family members, modifying the environment for their sick family members, and utilizing health care facilities [4]. The main task of the families who have family members suffering from TB is to prevent transmission, to increase immunity by immunization, to provide adequate nutrition, to create an environment that can break the chain of transmission, and to support the patient care at the Puskesmas[5][6]. The families' task where there are family members suffering from tuberculosis are to recognize the symptoms of a cough if it does not heal for two weeks, weight loss, night sweats, and a reduced appetite [7]. This task is in line with the role of protecting the family members, namely by preventing and medicating the tuberculosis patients. The family tasks need to be supported by knowledge and their attitude [8].

The analysis results (Table 1) illustrates that the body mass index of the TB patients was

normally distributed and that there were no outliers, therefore the quantitative analysis can be continued[7][9]. The body mass index of the tuberculosis patients was largely in the thin and normal category, according to the patient's perception of their own condition (Table 2) which is that they felt very thin, thin and normal. Perceptions of the bodily condition are according to the patient's feeling that their weight has decreased. Body mass index and the patient perception of their bodily condition is not a barrier to being medicated, although medication failure (death) has occurred in patients who are underweight [3].

The interview results about the nutrition given by the family to the patients were adequate, in that they were being given carbohydrates, vegetables, proteins sourced from eggs, freshwater fish, beef and chicken. The family statement was supported by the Puskesmas' nurse's statement, in that every month they have been given an additional protein meal in the form of canned milk as much as 1 kg from the Puskesmas. The purpose of supplementary feeding was to maintain the patient's immune system during the giving of the medication. The role of the family was to prevent a decrease in the body mass index and to prevent medication failure by providing adequate nutrition [1][10].

During the course of taking the tuberculosis medication, the patient's urine becomes red and they may feel nauseous (Table 2). These changes are the side-effects of Isoniazid (INH), Rifampin (RIF), Pyrazinamide (PZA) and Ethambutol (Myambutol)[11]. Urine discoloration and nausea have been realized by the patients and families because they (patients and families) already have been receiving health education from the Puskesmas nurses before starting the medication. The health education for the families results in an increase of the patient's vitality by the use of traditional herbal from the temulawak rhizome, which can increase lymphocytes [12] and act as a bactericidal [13]. The family said that the patients were also given ginger processed drinks every day to increase their vitality.

The treatment received by the tuberculosis patients causes boredom and they think about stopping the medication (Table 2). Such feelings and thoughts are caused by the medication at around 6 - 9 months. The patients who are not bored and who do not think of stopping their medication are larger than those who are bored. The interview results from the patients who are bored are where the patients must be careful with their behavior. For example, when eating and drinking in public areas. The patients who are not bored say that the disease needs to be treated so then it does not spread to people around them or to their colleagues [14][15].

5. Conclusion

Body alteration is (1) where the body becomes thin, there is red urine and nausea, and (2) a few of the tuberculosis patients were feeling tired of taking the medication and they were thinking of stopping taking the drugs. The bodily alterations and feelings of the patients must be a concern of the Puskesmas nurses who provide the medication. The patients must be given health education before the first dose of medication.

ABSTRACT

Summary Guidance for Daily Practice (SGFDP) is a media used to discuss and share knowledge to prevent foot ulcer in patients with Type 2 Diabetes Mellitus (T2DM). The aim was to know the influence of applying SGFDP to fasting blood glucose levels and foot care behavior. The study was quasi-experimental utilizing a pretest-post-test with a control group design. The sample obtained was 232 respondents through consecutive sampling. The data collected using observation sheets and the Nottingham Assessment of Functional Footcare (NAFF) questionnaire. The results were analyzed using the Wilcoxon and Mann-Whitney tests. The results showed a significant influence from SGFDP on foot care behavior. The application of SGFDP as an approach to prevent foot ulcers in patients with T2DM by discussing and sharing knowledge, and utilizing a foot ulcer prevention simulation with foot exercises. Sharing information and the attention given by the nurses in the form of regular meetings can increase patient knowledge and induce behavior changes in the DM patients to encourage them to take positive actions such as maintaining their diet and doing physical activities.

1. Introduction

Diabetes mellitus (DM) is a metabolic disease characterized by an increase in blood sugar levels. This occurs due to abnormalities in insulin secretion, insulin action or both [1]. DM is one of the most chronic diseases experienced by people in the world. DM patients are susceptible to nerve and vascular damage which can result in a loss of the protective sensation in the legs, poor circulation, biomechanical changes in leg and skin trauma [2]. The impact that can occur if it is not treated can occur because the development of ulcers is known in diabetic patients to be preceded by a history of trauma (neuropathy) or vasculopathy[3]. DM-related complications are a major cause of morbidity and mortality, and they have a serious impact on the quality of life of the patients[4]. Foot ulceration and subsequent lower limb amputation are common and serious chronic complications for DM patients [2].

It is estimated that in 2035, the global prevalence of DM will increase to nearly 600 million [5]. In Indonesia, DM patients are known to have increased from 1.1% in 2007 to 2.1 percent in 2013. The province of East Java, with the prevalence of DM based on a doctor's diagnosis and symptoms, is 1.2% and 1.6% respectively [6].The four main objectives of service providers include health promotion, disease prevention, patient care and meeting the patient's needs. The management of DM patients in the physical aspect with early education is about DM, the monitoring of routine blood sugar levels, diet, how to use the health facilities, physical exercise and the importance of foot care [7]. The role of the nurses is to prevent the risk of ulcers related to DM through education, demonstration and monitoring about foot care.

SGFDP is a summary of suggested guidelines for daily practice summarizing the essence of the prevention and management of foot problems in DM patients as part of a more complete guide on foot care consisting of the identification of risky feet, the inspection and routine checking of feet at risk, health education for patients regarding foot care, routine footwear care and identification and the handling of pre-ulcer signs in DM patients that can be performed in the daily health services[3]. This summary is intended for health care providers around the world who are involved in treating diabetics. The purpose of the research was to determine the influence of applying SGFDP on fasting blood glucose levels and foot care behavior.

2. Research methods

a. 2.1.Research design, population, sample, and variables

The design was quasi-experimental with a pre-post-test control group design. The population in this research consisted of all outpatients with DM in 3 Primary Health Services. The samples obtained totaled 232 respondents (116 in the treatment group and 116 in the control group) with consecutive sampling. This research was conducted at Palembang in South Sumatera from October 9th - December 20th 2018. The inclusion criteria in this research were 1) low risk DM patients, 2) a DM history of more than 10 years, 3) can communicate verbally well, and they are able to read and write and 4) taking DM therapy in the form of oral subcutaneous therapy. The exclusion criteria were 1) patients with DM who experienced cognitive impairment and 2) DM patients with foot ulcers. The independent variable was the application of SGFDP and the dependent variables were fasting blood glucose levels and foot care behavior.

b. 2.2.Instruments

SGFDP used the modules as form of media to give to the respondents. The module of SGFDP consists of information about DM, diet, the behavior of people with DM, foot care behavior with exercise and psychosocial education to reduce stress in DM patients. The instrument focused on fasting blood glucose levels was an observation sheet and foot care behavior was measured using the NAFF questionnaire by [8], which was modified by [9] and translated into the Indonesian language. The number of questions totaled 27 using a Likert scale with a score of 0-3. We obtained a range of scores from 0 to 81; the higher the score, the better the DM foot care behavior. This questionnaire was tested for validity and reliability with a Cronbach's alpha value of 0.720.

c. Research procedures and analysis

This research was carried out in collaboration with the existing program activities in the primary health service in order to increase the knowledge of the DM patients through empowerment and health education. The research has passed the ethical review and obtained aEthical Approval certificate No. 208/UN2.F12.D/HKP.02.04/2018 issued by the Health Research Ethics Committee of Faculty of Nursing Science, Universitas Indonesia. The research was conducted in the treatment group by providing SGFDP with select modules at 3 meetings over 3 weeks. The first week was to provide health education about DM and the screening of the respondents with the risk of foot ulcers. The second week was explained as the ideal diet and behavior of people with DM, and the third weeks was on teaching prevention of foot ulcers through a demonstration of foot exercises and monitoring. The control group was given information about DM through a module that had been

made by the researcher. The data was analyzed busing IBM SPSS Statistic 24. The statistical analysis used a Wilcoxon Signed Rank and Mann-Whitney U test. The confidence interval was 95% with alpha (α) = 0.05.

3. Results

The characteristics of the respondents in Table 1 shows that the majority of the respondents in both groups were in the age group of the elderly and that the majority were female. The last level of education for both groups was high school and the majority of respondents in both groups did not work. The majority of the income in the control and treatment groups was >2.6 million. The majority of the respondents in the control group had had DM for 14-15 years and the treatment group had had DM for 10-13 years.

Table 1. Characteristics of the respondents in the control and treatment groups of patients with DM (n=232)

Characteristic	Control Group		Treatment Group	
	n	%	n	%
Age				
Adult (30-40 year)	16	13.8	27	23.3
Elderly (41-50 year)	100	86.2	89	76.7
Sex				
Male	44	37.9	50	43.1
Female	72	62.1	66	56.9
Education				
Elementary School	19	16.4	23	19.8
Junior High School	26	22.4	39	33.6
Senior High School	54	46.6	46	39.7
University	17	14.7	8	6.9
Work				
Does not work	72	62.1	85	73.3
Private	26	22.4	23	19.8
Government employees	18	15.5	8	6.9
Average income				
<1.5 million	43	37.1	39	33.6
1.5-2.5 million	28	24.1	32	27.6
>2.6 million	45	38.8	45	38.8
Long suffer from DM				
10 – 13 years	49	42.2	83	71.6
14 – 15 years	67	57.8	33	28.4

The results of the analysis of fasting blood glucose in the control and treatment groups at the pre-test and post-test showed that all of the respondents had differences in the mean and std. deviation. The results of the data obtained using the Wilcoxon Signed Ranks test on fasting blood glucose in

the pre-test and post-test of the control group showed no change in the results between the pre-test and post-test of the respondents. The test results showed p>0.05 which was 0.11, which means that there was no significant difference. The treatment group showed p<0.05 which was equal to 0.013, which means that the pre-test and post-test in the treatment group had significant differences. The results of the post-test carried out using the Mann-Whitney U test on fasting blood glucose data in the control and treatment groups was 0.836 which equals p>0.05. It can be concluded that there were no significant differences in the results of the post-test data in the control and treatment groups (Table 2).

Table 2. Distribution of blood glucose and foot care behavior in the control and treatment groups of patients DM (n=232)

Variables	Control Group		Treatment Group	
	Pretest	Posttest	Pretest	Posttest
Glucose				
Mean ± SD	47 ± 29.153	72 ± 29.396	29 ± 8.344	.9 ± 14.62
Wilcoxon Signed Rank Test	0.11		0.013	
Mann-Whitney U Test		0.836		
ıre Behavior				
Mean ± SD	3 ± 7.489	28 ± 9.878	)2 ± 7.889	42 ± 8.254
Wilcoxon Signed Rank Test	0.274		0.003	
Mann-Whitney U Test		0.001		

)5 (Wilcoxon Signed Rank Testand Mann-Whitney U Test)

The results of the foot care behavior analysis in the control and treatment groups in the pre-test and post-test showed that all of the respondents had differences in the mean and std. deviation. The results of the data obtained using the Wilcoxon Signed Ranks test on foot care behaviornint the pre-test and post-test of the control group showed no change in the results between the pre-test and post-test of the respondents. The test results showed p>0.05, which was 0.274 which means that there was no significant difference. The treatment group showed p<0.05, which was equal to 0.003, which means that the pre-test and post-test in the treatment group had significant differences. The results of the post-test foot care behavior data using the Mann-Whitney U Test in the control and treatment groups were 0.001 which means p<0.05. It can be concluded that there were significant differences in the results of the post-test data between the control and treatment groups (Table 2).

4. Discussion

The SGFDP approach explains the basic principles of the prevention of foot problems in DM patients[3] and it seeks to prevent ulcers in patients at risk wih DM by providing integrated and adequate foot care[10]. Prevention bases in the Guidance For Daily Practice (SGFDP) include risky feet identification, risky inspection and routine foot checks, patient health education about foot care, appropriate footwear care and the identification of pre-ulcerative signs.

One risk factor of DM was age, especially for those older than 40 years. This is because at that age, there is an increase in glucose intolerance[11]. In old age, bodily functions are physiologically decreasing because the aging process causes a decrease in insulin secretion or resistance. Therefore the body's ability to control high blood glucose is not optimal. The aging process causes a decrease in insulin secretion or resistance, resulting in a macroangiopathy, which can affect the decrease in blood circulation, one of which is in the large or medium blood vessels in the legs.

Gender is one of the factors associated with the occurrence of DM, where women who have experienced menopause tend to be more insensitive to insulin. Diabetes in general, for men, comes faster than it does for women. Women can be protected from diabetes until they reach menopause because of the influence of the female hormone estrogen, which is a reproductive hormone that helps to regulate blood sugar levels in the body. The results of a study conducted by [12]showed a higher prevalence of the incidence rate of T2DM in women than in men. Women are more at risk of developing diabetes because physically, women have a greater chance of increasing their body mass index. Post-menopausal monthly cycle (premenstrual syndrome) syndrome makes the distribution of body fat more easily accumulated due to the hormonal processes, so therefore women are more at risk of developing T2DM[4].

Education level has an important role in increasing the knowledge of DM. The majority of the residents did not know about DM. Knowledge can have an important role in the prevention of DM in the community. Education can influence a person, including a person's behavior and lifestyle, especially in reference to motivating people to participate in developments. In general, the higher the education level of someone, the easier it is for them to receive information[13].

The respondents who suffered from DM needed to do more physical activities. In T2DM, exercise plays a major role in regulating blood glucose levels. Muscle contractions have properties such as the production insulin and increasing the permeability of the membrane to glucose in the contracting muscle[1]. At the time of exercise, insulin resistance is reduced, whereas insulin sensitivity increases when inactive. This is not a permanent effect. Therefore, exercise must be carried out continuously. Physical activity can be in the form of diabetic foot exercises. Exercise is very beneficial for improving blood circulation, losing weight and improving insulin sensitivity as it will improve the glucose levels in the blood.

Hyperinsulinemia (10fEU/ml) can cause atherosclerosis, which has an impact on vasculopathy which makes the legs prone to DM ulcers[15]. In addition, it is often accompanied by an increase in triglyceride and plasma cholesterol levels which will result in poor blood circulation to the tissue, which appears in the decrease of the dorsalis pedis artery pulse (<60 x/m) and decreased ankle brachial index (<0.9), resulting in ulcers that usually start from the tip of the leg[14]. All of the respondents in this study had suffered from DM for more than 10 years. Foot ulcers are especially common in DM patients who have suffered with the disease for 10 years or more. If their uncontrolled blood sugar levels are not seen to, then this will result in vasculopathy and neuropathy.

Physical activity is included in this research in the form of DM foot exercises. Physical activity increased the sensitivity of the insulin receptors in the active muscles [16]. The main problem that occurs in T2DM is the occurrence of insulin resistance which causes glucose to not enter the cells. When a person engages in physical activity, there will be a muscle contraction which will eventually make it easier for glucose to enter the cell [17]. This means that when a person is engaged in physical activity, it will reduce the level of insulin resistance and this will eventually reduce their blood sugar

levels. There are other factors that influence blood sugar levels. In addition to SGFDP implementation, there are several things that cause one's blood sugar to rise, namely a lack of exercise, an increased amount of food consumed, increased stress and emotional factors, weight gain and age, and the impact of treatment from drugs, such as steroids [18].

The driving factor was the factor obtained from the closest person to the patient and the social support given to the individual, such as their family, friends and teachers, and especially in this case, the health workers who can strengthen the behavior of SGFDP management. With the support provided by the closest people to them, it is expected to encourage behavior change in the patients [19]. In terms of the prevention of injury in T2DM patients, foot care behavior is carried out in accordance with SGFDP, which consists of the identification of risky feet, the inspection and routine examination of risky feet, health education for patients about foot care, routine foot care and the identification of pre-ulcer signs in DM patients [20].

The level of education of a person is very influential on any changes in attitude and behavior related to healthy living. Higher levels of education will make it easier for a person or community to absorb information and to implement it in their daily behavior patterns and lifestyle, especially in terms of health. Based on the information obtained by the researchers through questioning the respondents, the respondents said they always tried to maintain good foot care behavior in accordance with the principles of SGFDP so then further foot injuries can be prevented.

This is because of the intervention given by the researchers in the form of SGFDP through daily practice guidance that explain the basic principles of the prevention of foot problems in DM patients to prevent ulcers in patients at risk who have DM. Foot problems in DM are one of the more serious complications. Foot problems are the main source of suffering and costs for the patients and they also place a considerable financial burden on health care and on society in general. Strategies include prevention, patient education and close foot monitoring [3].

DM Patients with peripheral neuropathy also have a history of foot ulceration or lower limb amputation, foot deformity, poor foot hygiene and inappropriate or inadequate footwear. Furthermore, routine inspections and checks of at-risk feet should be conducted at least once a year to identify those at risk of foot ulceration. Patients who have any of the risk factors must be examined more frequently. These include a history of ulcers, previous amputations, end-stage kidney disease, social isolation, access to poor health care, walking without using a pedestal and a regular foot examination concerning vascular status, skin, footwear and an assessment of neuropathy[10].

Health education for patients about foot care is presented in a structured, organized and repeated manner, both verbally and through media channels. This plays an important role in preventing foot problems. Patients with DM must learn how to recognize potential foot problems and they must be aware of the steps that they must take when problems arise. One of the sports recommended for people with DM is foot exercises[9]. Gymnastic foot stretches aims to smooth the blood circulation that is disrupted. This is because leg exercises can strengthen the leg muscles. This is in accordance with [22], who stated that DM foot exercises aim to improve blood circulation so then the nutrients can get to the tissues smoother. It can also strengthen the small muscles, calf muscles and thigh muscles, and overcome the limitations of joint motion that often experienced by DM patients. This is supported by theories involving endoneuria blood flow, increased nitric oxide synthesis and increased Na + / K + -ATPase activity with given training efforts [23].

Regular footwear, improper footwear and barefoot walking with insensitive feet are the main causes of foot ulceration. Patients with a loss of sensation should be taught about protection and the appropriate use of footwear so then the use of footwear at any time, both inside and outside the room, is paired with the identification of pre-ulcer signs in DM patients characterized by redness or pain [3].

The limitations in this study were that it was limited in terms of the time available and the intervention in the treatment group was for 3 weeks. Patient changes and any developments will be more visible if the intervention is carried out over a longer time period.

5. Conclusion

SGFDP explains the basic principles of preventing foot problems in patients in a manner that can be carried out in a session once a week and re-evaluated after 3 weeks by discussing, sharing knowledge and undergoing foot ulcer prevention simulation using foot exercise. Sharing information and the attention given by the nurses with regular meetings can increase patient knowledge and behavior changes in the DM patients to encourage them to take positive actions. This was proven to prevent foot injury in patients with T2 DM. SGFDP can be done regularly to train the DM type 2 patients to maintain a good lifestyle including good food, a balanced diet, exercise and regular activities. The next researchers could improve the treatment of SGFDP based on culture and by evaluating the qualitative results.

ABSTRACT

Perceptorship is a learning method that involves more experience in conveying their knowledge to someone who is less experienced. Perceptorship is a very important part of a hospital organization that is applied during new employee orientation, mutation and rotation, as well as guidance for school students who undergo field work practices. The purpose of this study is to analyze factors that affect implementation of perceptorship in the hospital and to give recommendation of monitoring and evaluation perceptorship as well. The Journal had searched towards multiple database: DOAJ, Sage, Proquest, Medline, Google Scholar, Science Direct. It used limited time in June 2013 to September 2018. From 1517 article, only 15 articles that suitable with the inclusion criteria. Systematic reviews obtained from 15 medical journals showed various factors that influence the application of perceptors in hospitals.

Keywords: perceptorship, health, hospital area, systematic review

1. Introduction

Preceptorship is a learning method that involves those with more experience conveying their knowledge to someone who is less experienced[1]. The preceptor becomes a model or role model in preceptorship activities while simultaneously providing expert advice to the preceptee. In the preceptorship process, there is encouragement, guidance, support, and advice to help the preceptees in their organizational development and personal development. Preceptorship is in the form of advice relating to practices in the workplace including role models in one-to-one groups and organizations[2]. Preceptorship is a very important part of a hospital organization that is applied during new employee orientation, mutation and rotation, as well as in the guidance for school students who undergo fieldwork practices.

In the implementation of preceptorship, there are often various obstacles including unrecognized receptors, guidance schedules that not match with the work time of the preceptor, unbalanced preceptor-preceptee ratios, a lack of understanding of the learning methods, and a bad working environment. Based on the research at the University of Newcastle, new nurses admitted that they were stressed when it came to adapting, namely due to a lack of communication with the health team in their new workplace. New nurses, after completing the orientation period, still needed support through the program of preceptorship and this increased the retention of new nurses by 29% (from 60% to 89) and by 9.5% it decreased the nursing vacancies[3].

Preceptors in hospitals need to carry out an evaluation of the implementation because there are still problems with the guidance system, such as the preceptor ratio with the preceptee, the requirements as a supervisor and besides that, it requires an increase in the quality and competency of the preceptor to produce competent preceptees.

This study was aimed at analyzing the factors that influence the implementation of preceptorship in the hospital.

2. Research Methods

The literature search was carried out using several major databases such as PROQUEST, ScienceDirect, DOAJ, SAGEPUB, MEDLINE, and GOOGLE SCHOLAR by entering the keywords preceptorship, health, hospital area, and systematic review. The papers were critically reviewed and the relevant data was extracted and synthesized using an approach based on Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA). The time limit used was June 2013 to September 2018. From the 1,517 articles obtained, only 15 articles met the inclusion criteria. The inclusion criteria for the articles were 1) that they had a RCT research design, 2) that they mentioned the factor variables that influence preceptorship, 3) that the sample was made up of health workers in a hospital and 4) that the parameters assessed included the intensity of applying the preceptorship.

From the 15 literature items, various factors have been found to influence the application of preceptorship, among others, including the level of education, preceptor experience, partnership, learning methods and work environment. The parameters used to measure the application of patient safety goals were obtained through questionnaire instruments, checklist observation sheets and interview sheets.

3. Results

3.1 Level of education

Burke et al[4] explained the problems that arise in the guidance process of undergraduate students in hospitals, namely the use of language and instruments that are less objective in evaluating student competencies. Chang et al[5] suggested that the use of portfolio applications can easily be accessed by the nursing undergraduate students. The ease of access makes the students motivated by and within the preceptorship process. Carmel et al[6]explained that for postgraduate students, their care should be focused on guidance to increase their self-confidence and specific competencies in accordance with the specialization of the program. Colleen et al[7] explained how to organize and prioritize work, communication and leadership for postgraduate students.

3.2 Preceptor's experience

Lee-Hsieh et al[8] explained the experience of preceptors in developing the Clinical Teaching Behavior Inventory (CTBI) instrument. The instrument is very effective when applied in a nursing student preceptorship. Adam et al explained the experience of the preceptor in carrying out the homecare process as applied in the learning process. This is very useful for the preceptee because it provides a real picture of the process of providing nursing care based on the experience of the preceptor.

3.3 Partnership

Blegen et al[9] explained that preceptors and preceptees must establish good partnership relationships so then they can have an effective period of mutual time throughout the preceptorship process. Chen and Lou[10] explained that the strategy of guidance in a multidimensional manner is done by adding guidance time to the course at a certain point in time. Forneris and Peden-McAlpine[11] explained that a good relationship in reference to preceptorship can encourage the preceptee to think critically, discuss, ask questions and increase their curiosity about the material that has been delivered.

3.4 Learning methods

Lazarus[12] described the effectiveness of the Five Minute Preceptor and SNAPPS learning methods in the context of the feedback learning method by evaluating the learning outcomes in the preceptorship process. Omer et al[2] explained that mentoring can increase the confidence and independence of the preceptee when it comes to developing themselves in the learning process. Kowalski and Cross[13] explained that residency programs can improve their leadership skills and the ability to communicate effectively with the nursing students.

3.5 Work environment

Hyrkas and Shoemaker[14] explained that commitment, rules and discipline in the work environment had an effect on the preceptorship process when it came to forming good habits in the preceptee. Chen et al[15] explained that the process of collaboration between health workers in the work environment can provide learning and allow for training in collaborative actions for the preceptee. Mwafulirwa[16] explained that the existence of a delegation and supervision process in the work environment can provide the preceptee with the chance to conduct monitoring and evaluation as well as the chance to create follow-up plans for the actions taken.

4. Discussion

The preceptee education level influences the guidance and preceptorship process. The preceptors must be able to analyze the competencies that must be achieved by the preceptees so then they can optimize their abilities, creativity, and innovation during the preceptorship period[4][5][6][7].

Based on the research, it can be seen that the experience of the preceptor is very influential on the learning process during the preceptorship. For this reason, someone who is a preceptor is expected to have work experience according to their field or expertise for at least 2 years in a row so then they can integrate their knowledge and experience into the preceptorship process[8].The partnership establishes good relations through the preceptorship so then it can have a positive impact on the learning process. This can increase curiosity in the preceptee's understanding[9][10][11].

Creativity in the context of the learning method has a positive impact on the preceptorship process. The various learning methods that can be applied include coaching, mentoring, Five Minute Receptor, SNAPPS and residency[12][13]. The work environment has a positive impact on the preceptee when it comes to forming a conducive work environment as a good provision if they become employees in the company[14][15][16].

5. Conclusion

The systematic review obtained from 15 medical journal articles showed the various factors that influence the application of preceptors in hospitals. The factors include the level of education, experience, support, guiding model and work environment. The type of instrument that is often used is the Clinical Teaching Behavior Inventory (CTBI).

DEVELOPMENT OF NURSING COST AND NURSING SERVICE WEIGHTS FOR MALAYSIA DIAGNOSIS RELATED GROUP (MY-DRG®) IN A TEACHING HOSPITAL IN MALAYSIA

Nor Haty Hassan[1,2], Syed Mohamed Aljunid[1,3] Amrizal Muhd Nur[1]
[1]International Centre for Casemix and Clinical Coding, Faculty of Medicine, UKM,
[2]Department of Nursing, Faculty of Medicine, UKM
[3]Department of Health Policy and Management, Faculty of Public Health, Kuwait University. Kuwait

ABSTRACT

Traditionally the hospital costing and charging system in Malaysia do not present the value of nursing care provided to patients during their stay in the hospital. The aim of study is to develop the nursing costs and service weights for Universiti Kebangsaan Malaysia Medical Centre (UKMMC) using the casemix system, MY-DRG®. Two methods of calculation that are nursing hours and unit cost of nursing per patient per day of stay were used. A cross sectional descriptive study was conducted among discharges from 2009 to 2012 using retrospective data obtained from the casemix database. A combination of step-down costing and activity based costing method for hospital costing was used. A total of 85,042 discharges were grouped into 704 MY-DRG®. The hospital data were obtained from five departments: Finance, Human Resource, Nursing Management, Maintenance and Health Information, UKMMC. Total cost of nursing services for each group of MY-DRG® was calculated and the costing data was trimmed using lower trim point and high trim point method. The results showed that cost of nursing services is higher in calculation of nursing cost based on nursing hours compared to cost per patient per day of stay. The outcome of this study is both methodologies can be implemented and recommended to the health policymaker.

Keywords: nursing cost, nursing service, malaysia diagnosis related group

1. Introduction

Nursing services are known to be the largest component in inpatient care [1]. Nursing care is also a continuous activity that never stops. It begins with the patient's admission until the patient can be discharged from the hospital. It is a 24-hour service with a heavier nursing workload during the day compared to at night. The nurses spend almost 60% of their time with patients in critical wards and 54% in the medical and surgical wards [2]. Furthermore, the contribution of the nurses was found to constitute about 30% of the overall hospital costs and 44% of the nursing care cost for the inpatients [3]. The traditional method of hospital payment based on the 'room and board' rate gave the impression that the amount of nursing care is equally distributed among all patients, causing the cost of nursing care to become an unseen variable [4]. Taking into consideration the major contribution of nursing services in patient care, in addition to the current rise of hospital costs and limited healthcare resources, nursing researchers began to study the relationship between nursing services

and nursing cost [5], [6]. Many countries worldwide have progressively conducted nursing cost calculations with variations in the study samples and study output [7].

Currently, the healthcare billing system in Malaysia is inadequate in terms of estimating the economic value of nursing services. This is because the traditional costing method based on room rates or by the patient's age category (adults or children), and the patient's length of stay has been used to charge for the nursing services. This type of charge neglects the severity or complexity of the patient's illness when in fact, the severity or complexity of the patient's illness is directly related to the cost of care as more nursing care may be needed. Therefore, the traditional costing method could result in either an under- or over-charging of nursing services, which could ultimately give rise to improper hospital reimbursement. A study by Welton and Fischer compared the hospital charges based on 'room and board' charges and based on nursing service intensity respectively. Welton and Fischer's study found that charges which were based on nursing service intensity was found to be more accurate and thus reduced the risk of underestimating the nursing cost [8]. Another factor which may influence the hospital cost and charges is the use of highly qualified Registered Nurses (sometimes nurses holding a Bachelor's Degree) in providing patient care. Using over-qualified nurses may raise the nursing costs, as payment for a Registered Nurses' salary will contribute to a higher portion of the hospital budget. This was also proven by Welton and Fischer, who discovered the differences in relation to cost of using services from a mixed category of nurses. The contribution of Registered Nurses on salary and hours of care is high which can be as high as 25.5% of the hospital expenditures annually [9]. This is in line with the findings of a study by Mark et al., which stated that the costs increased when many Registered Nurses were hired in the hospital [10]. Nonetheless, although the salary of Registered Nurses was high and found to contribute to the high cost of treatment, experienced and educated nurses are highly important for a positive patient outcome [11].

The definition of the cost of nursing services has multiple meanings, according to the methodology used and the results produced[12]. Nursing cost can be determined or measured in several ways such as nursing cost per patient, per patient day, per patient care hour, per acuity-adjusted patient day, per Diagnosis Related Group (DRG), an average nursing wage, nursing hours or per visit [12], [13], [14]. A casemix system is a new approach used to calculate based on the different types of DRG. Service weights were used to measure the common resources consumed by the patients in each DRG group [15]. For example, a DRG with a service weight of 4.0 is a service that consumed quadruple times more resources than DRG with a service weight of 1.0 [16]. It is useful to obtain information on budget spent for patients in different DRG groups[17]. Other similar terms in relation to service weights are, service intensity weights, service cost weights and relative weights [18], [19], [16]. Nursing intensity weight (NIW) was created to adjust the relative weights for each DRG for hospital reimbursement and for the adjustment of the payment system so as to reflect the nursing resources [16], [20]. Relative weights have been used to construct the payment based on DRG using the formula mean cost of a DRG compared with the mean cost for all DRG[1]. Cost weight is also defined as the average cost of the DRG level compared to the average cost across all DRG groups [15]. Specific components of cost weight are known as service weights or ratios. They are used in nursing, laboratory and radiology costs [21].

There were limited studies in Malaysia, which determined the cost weights for services. The pharmacy service weights were determined by Ali Jadoo et al. (2015) and found that the pharmacy service weights ranged between 3.78 and 11.80 [22]. In a recent study by Roszita et al. (2016) on

laboratory and radiology service weights, the laboratory service weights were between 1.6896 to 5.9609, while the radiology service weights ranged between 1.6336 and 2.8461 [23]. Internationally, a study by Knauf et al. (2006) found that cardiology cases have an average NIW of 3.11 and orthopedic cases have an average NIW of 2.26 [1]. Apart from reporting merely the crude cost weights, it is also crucial to determine if there was any 'overestimation' or 'underestimation' of the cost weights. Overestimation occurs when the estimated cost weight is higher than the actual cost weight. Conversely, underestimation is when the estimated cost weight is lower than the actual cost weight [21]. The general objective of this study was to estimate the nursing resources used by the inpatients by linking the calculation of the nursing cost with the Malaysia Diagnosis Related Group (MY-DRG®) casemix system.

2. Research Methods

2.1 Study population and designs

This study is an economic evaluation study that employed a cross-sectional descriptive study design conducted entirely at the Universiti Kebangsaan Malaysia Medical Centre. In 2002, UKMMC became the first medical centre in Malaysia to introduce the casemix system for managing their patients. The main purpose of its development was to enhance the quality and efficiency of hospital services. UKMMC uses the MY-DRG® grouper, which is the customized version of the United Nations University (UNU)-Case Based Group (CBG) casemix system[25]. MY-DRG® is a patient classification system that belongs to the casemix system that is being used in Malaysia. All of the discharges in the casemix system database from 2009 to 2012 were included as the study subjects. The total study subjects comprised of 90,581 discharge cases and they were grouped into 708 MY-DRG®.

2.2 Data collection tool

Hospital information data from 2011 were used and compiled to complete the costing template. This information was essential to assist in the calculation of the nursing cost and nursing service weights. Five departments of UKMMC were involved and the hospital information data required was as follows. From the Finance Department, there was the the total of the expenditure of purchased items for the last five years, in addition to the operating costs and annual staff salary. The Nursing Management Department looked into the number of nurses. The Human Resources Department involved the number of staff. For Health Information, there was the number of inpatient days, the number of discharges, the number of outpatients and the average length of the stay (ALOS). The Maintenance Department provided the hospital floor area.

2.3 Data analyses

The data was gathered and input into a database using SPSS version 22 for the costing and statistical analyses. The advanced statistical analysis using multiple linear regression was carried out to determine the factors that might influence the nursing cost. All analyses were done using IBM SPSS version 22 and a p value of <0.05 was considered to be statistically significant.

2.4 Costing analyses

Costing method using a combination of step-down and activity-based costing were carried out to obtain the nursing cost and nursing service weights. Nursing hours were used as a basic component in the calculation of the nursing cost. There were eight steps to follow in order to develop the nursing cost:

2.4.1 Method one: calculation of nursing cost using nursing hours.

Step 1: Calculation of nursing hours per year per nurse
Step 2: Calculation of nursing hours per patient per day of stay of each cost centre (medical, surgical, obstetrics & gynecology, pediatrics)
Step 3: Data trimming using the L3H3 method
Step 4: Calculation of the nursing hours for each MY-DRG®
Step 5: Calculation of the mean nursing hours for each MY-DRG®
Step 6: Calculation of the nursing service weights per MY-DRG®
Step 7: Calculation of the hospital nursing based rate (HNBR)
Step 8: Calculation of the nursing cost per MY-DRG®

2.4.2 Method two: calculation of nursing cost using unit cost of nursing per patient per day of stay.

Step 1: Calculation of the cost of nursing per patient per day of stay
Step 2: Calculation of the mean nursing cost per MY-DRG®
Step 3: Calculation of the nursing cost MY-DRG®
Step 4: Calculation of the nursing service weights for MY-DRG®

3. Results

3.1 Patient characteristics

The data was obtained from the retrospective data analysis of the discharged inpatients in the casemix system database of UKMMC. The data was trimmed using a low trim point and a high trim point (L3H3) to determine the inliers (MY-DRG® within the standard length of stay), in addition to noting any outliers (MY-DRG® with the non-recommended standard length of stay) based on ALOS for each MY-DRG®. As a result, there were 85,042 ‘inliers’ with 704 MY-DRG® included in the study. The remaining cases were identified as ‘outliers’ comprising 5,539 cases. Many discharged inpatients were within the age range of 20-29 years (21.2%; 18,071/85,042), followed by 30-39 years (17.6%; 14,967/85,042), <10 years (13.4%; 11,370/85,042) and 60-69 years (12.5%; 10,600/85,042). There were more female inpatients (59.4%; 50,497/85,042) compared to male inpatients (40.6%; 34,545/85,042). The mean length of stay for the inpatients was 5.3 (5.52) days.

The majority of inpatients treated in UKMMC were from medical (58%; 49,353/85,042), followed by surgery (22%; 18,767/85,042), obstetrics & gynecology (O&G) (19%; 15,985/85,042) and the least case type was from the pediatrics discipline (1%) (937). The discharged inpatient cases were also categorized into several severity levels. The distribution of the cases according to severity showed that out of 85,042 cases, 48,149 (56%) of the inpatient cases treated in UKMMC were severity level I, despite UKMMC's nature as a teaching hospital to manage more complex patients. Subsequently, there were 25,278 cases (30%) from severity level II and 11,615 (14%) from severity level III. Discharged inpatients in the casemix system database were coded according to body system

called casemix main group (CMG). Based on the distribution of CMG from 2009 to 2012, the highest frequency CMG for discharged inpatients of this study was CMG 'O' (Deliveries groups), totaling 15,985 cases (19%). Accordingly, CMG 'W' (Female reproductive system groups) was the second highest CMG with 8,842 cases (10%) and least CMG was from CMG 'T' (Substance abuse & dependence groups) 62 cases (0.07%).

3.2 The nursing cost and nursing service weights according to discipline

3.2.1 The nursing cost and nursing service weights for medical. The top five highest nursing cost and nursing service weights in the medical discipline have been identified in Table 1. As apparent in the table, four of the cases were from CMG F (Mental health and behavioral group). The table below also shows that method 1 had a higher nursing cost compared to method 2.

Table 1. Nursing cost and nursing service weights for medical – comparisons of method 1 and 2

MY-DRG® code	MY-DRG® description	Method 1		Method 2	
		Nursing cost (MYR)	Nursing service weights	Nursing cost (MYR)	Nursing service weights
F-4-13-II	Bipolar disorders including mania - moderate	6,129	4.9871	5,311	4.3604
F-4-10-I	Schizophrenia - mild	5,252	4.2737	4,787	3.9301
F-4-10-II	Schizophrenia – moderate	4,949	4.0272	4,763	3.9104

3.2.2 The nursing cost and nursing service weights for surgery. The top five highest nursing cost and nursing service weights in the surgical discipline consisted of different types of cases, all of which were from severity level III. It is notable from table 2 that the MY-DRG® group with the highest nursing cost and nursing service weight was G-1-11-III (Ventricular shunt - major). The table below also showed that method 1 had a higher nursing cost compared to method 2.

Table 2. Nursing cost and nursing service weights for surgery - comparison of methods 1 and 2

MY-DRG® code	MY-DRG® description	Method 1		Method 2	
		Nursing cost (MYR)	Nursing Service weights	Nursing cost (MYR)	Nursing service weights
G-1-11-III	Ventricular shunt - major	9,694	7.8880	8,532	7.0046
M-1-03-III	Spinal fusion procedure - major	8,120	6.6074	7,047	5.7857
U-1-20-III	Other ear nose mouth & throats operations - major	7,974	6.4890	6,953	5.7083
J-1-20-III	Simple respiratory system operations - major	7,111	5.7865	6,264	5.1426
G-1-10-III	Craniotomy - major	6,831	5.5584	5,926	4.8657

3.2.3 The nursing cost and nursing service weights for obstetrics & gynecology (O&G). The top five highest nursing costs and nursing service weights for O&G have been listed in Table 3. As apparent in the table, the highest nursing cost and nursing service weight was in MY-DRG® group O-6-10-III (Caesarean section - major). The table below also shows that method 1 had the higher nursing cost compared to method 2.

Table 3. Nursing cost and nursing service weights for O&G – comparison of methods 1 and 2

MY-DRG® code	MY-DRG® description	Method 1		Method 2	
		Nursing cost (MYR)	Nursing service weights	Nursing cost (MYR)	Nursing service weights
O-6-10-III	Cesarean section - major	2,515	2.0467	1,457	1.1959
O-6-10-II	Cesarean section - moderate	2,019	1.6430	1,152	0.9459
O-6-11-I	Vaginal delivery with fallopian destruction &/or dilation & curettage - minor	1,741	1.4172	1,002	0.8225
O-6-10-I	Cesarean section - minor	1,738	1.4149	981	0.8057
O-6-11-II	Vaginal delivery with fallopian destruction &/or dilation & curettage - moderate	1,676	1.3640	957	0.7861

3.2.4 The nursing cost and nursing service weights for pediatrics. The top five highest nursing cost and nursing service weights according to pediatrics have been listed in Table 4. The nursing cost and nursing service weight were the highest among the cases that were grouped under MY-DRG® P-8-08-II (Neonate birth weight>2499 grams with respiratory distress syndrome & congenital pneumonia - moderate). The table below also shows that method 1 had a higher nursing cost compared to method 2.

Table 4. Nursing cost and nursing service weights for pediatrics - comparison of methods 1 and 2

MY-DRG® code	MY-DRG® description	Method 1		Method 2	
		Nursing cost (MYR)	Nursing service weights	Nursing cost (MYR)	Nursing service weights
P-8-08-II	Neonate birthweight >2499 grams with respiratory Distress syndrome & congenital pneumonia – moderate	1,300	1.0582	1,003	0.8234
P-8-15-I	Neonate birthweight >2499 grams with aspiration syndrome - mild	1,255	1.0218	978	0.8025
P-8-16-II	Neonate birthweight >2499 grams with congenital/perinatal sepsis - moderate	1,254	1.0206	978	0.8025
P-8-17-III	Neonate birthweight >2499 grams with complex operation - severe	1,192	0.9702	912	0.7486
P-8-14-I	Neonate birthweight >2499 grams with complex congenital	1,116	0.9084	858	0.7045

abnormalities - mild

3.2.5 Comparison of nursing cost from method 1 and method 2. Table 5 below shows the results of the analysis using a paired-sample t-test. There was a statistically significant difference in nursing cost for (method 1 using nursing hours = 1230.500, SD = 913.284) compared to nursing cost (method 2 using cost per patient per day = 1220.949, SD = 907.662), t (85041) = 7.495, p<0.001 (two-tailed). The mean difference in nursing cost was 9.552 with a 95% interval ranging from 7.054 to 12.051.

Table 5. Comparison of methods 1 and 2 for nursing costing

	Data	N	Mean Nursing cost	Std. Deviation	t	df	Sig. (2-tailed)
Nursing cost	Method 1 (Using nursing hours)	85042	1230.500	913.284	7.495	85041	0.00
	Method 2 (Using cost of nursing per patient per day)	85042	1220.949	907.862			

4. Discussion

The main objective of this study was to develop the nursing costs and nursing service weights to enable the nursing department to estimate the nursing resources used by the inpatients, using the casemix MY-DRG® hospital classification tool used by UKMMC. This study is the first of its kind in Malaysia. This study provided two approaches in the calculation of the nursing costs and nursing service weights. Throughout this study, the greatest challenge faced was in the calculation of the nursing costs using method one, which was the calculation of the nursing costs based on nursing hours, in which it was very time-consuming as several approaches were required to obtain accurate results. There is ample evidence from the previous studies to show that there are different kinds of methods that can be used for nursing costing. Riewpaiboon et al. (2007) and Negrini et al. (2004) suggested that a variation in results might be obtained from the different costing methods, depending on the requirements and interests of the users [24], [25]. Although the diversity of costing methods may create some confusion among the researchers in choosing the most suitable or appropriate one [25], the differences in the methodologies may also benefit by giving a wider choices for the users to pick from.

In the other study, CMG was used to determine the variability of nursing hours [26]. CMG was also used to compare the cost weight between per diem (per day) and according to the nursing workload [21]. In this study, two methods were used for the costing analysis. The first method was based on average nursing hours per MY-DRG® to obtain the nursing cost and nursing service weights. On the other hand, in the second method, the calculation was based on the cost of nursing per patient per day of their stay. The findings showed that each method produced different nursing costs and nursing service weights. This concurred with several previous studies, which showed that different nursing costs come from different methods and study samples. Ultimately, the

methodologies used in this study have their own strengths, such as the development of the nursing cost and nursing service weights wholly based on MY-DRG®. In addition, the type of costing analysis applied in this study was a combination of the step-down and activity-based costing approach. As demonstrated, this is a new approach in the costing of nursing services. To the extent of the researcher's review, there has been no study conducted so far using a combination of step-down and activity-based costing linking nursing costing information within the casemix system.

In this study, there were 85,042 of cases grouped into 704 MY-DRG® from 2009 to 2012. The strength of this study was in its ability to analyze the information from a large sample of 85,042, making it feasible to estimate the nursing cost and nursing service weights for almost all MY-DRG® groups in UKMMC. The total of the study samples was quite similar to a study done by Gong et al. (2004) describing Chinese hospital activity using the Australian casemix Diagnosis Related Group (DRG) [27]. In the study by Gong et al., there were 84,028 records which were grouped into 529 DRGs involving three public hospitals in Chengdu over a year [27]. It was realized at the time that there was a lack of previous nursing studies done on costing analysis in relation to the casemix system or DRG. The trimming process in this study was based on the low trim point and high trim point (L3H3) method. There are two types of 'outlier' (an unusual case): the inpatient's length of stay which was much longer or shorter than the average (a stay outlier) or a cost that was much more or much less than the average for that group (a cost outlier) [27]. Pertaining to this study, the stay outlier was chosen to be used in the trimming process.

From the 85,042 cases, the majority of patients 50,497 (59.4%) were female while there were only 34,545 (40.6%) male patients. This may be due to the common cases of the case main groups (CMG) being from CMG O (Deliveries groups) and CMG W (Female reproductive system groups). The descriptive analysis showed that the the majority of cases were female within the age group of 20-29 and 30-39, classified as severity level I and II (pregnancy and child birth). It was also revealed that episiotomy was the second top ten highest frequency for procedures (below routine chest x-ray). O&G cases were not included in the level I highest cost. In addition, vaginal deliveries were classified at the lowest cost. The findings from the descriptive analysis involved the following positive assumptions: that these cases are primigravidas or elderly primips which require admission; that their very short LOS is to do with the specific care for normal deliveries and that most if not all nurses working in the delivery rooms and postnatal wards are midwifery trained. This contributes positively to the short LOS. This is in line with a study done by Saperi et al. (2005) to determine the complexity of cases in UKMMC, which found that the majority of cases at severity levels I and II were from pregnancy, childbirth and puerperium cases[28]. The numbers of inpatients according to age group were 20 to 29 years old (21.2%), 30 to 39 (17.6%), below 10 years old (13.4%), elderly 60 to 69 years old (12.5%) and 50 to 59 years old (10.8%). The average length of stay for the inpatients was 5.3 (5.52) days. The average length of stay could not be compared due to differences in the methodology of the studies such as the sample characteristics and study settings. The majority of inpatient cases in UKMMC were from the medical discipline, in which 58% were from severity level I cases. Most of these cases were schizophrenia, bipolar disorders, dementia, childhood mental disorders etc. These cases recorded the highest LOS for severity level I (mean LOS of 20.81). There are at least two factors that could influence the long LOS. Firstly, the cases could have been referred from other hospitals at a fairly severe stage. Secondly, there is also a probability that the majority of the nurses are not trained in mental health nursing and there is also the fact that there are fewer doctors trained

in psychiatry compared to other specialized areas. Based on the distribution of psychiatrists in Malaysia according to the state in 2018, the total number of psychiatrists in Malaysia was 410, which is only 0.02% of the Malaysian population [29]. Furthermore, Douzines et al. (2012) stated that the highest LOS could also be influenced by medical problems related to psychiatric inpatients [30]. For example, arterial hypertension commonly occurs in a patient with bipolar disorder and endocrine or metabolic diseases for schizophrenia patients. This finding is consistent with a study done by Amrizal et al. (2005) on costing the cardiology cases where the findings showed that cases of medical cardiology were higher (86.5%) than surgical cardiology (13.5%) [31]. The higher cases were from severity level I compared to severity levels II and III [31].

Diagnoses and procedures are vital in the casemix system. The most common procedure done on the inpatients was a routine chest x-ray. A chest x-ray is a common investigation required in the early assessment of several cases and it is also used as part of a routine investigation for pre-operative cases and for patients 35 years old and above. The procedure may require being done more than once, such as where there is a respiratory problem or in hemodynamically unstable cases. The most common diagnosis was spontaneous vertex delivery. There were a number of cases in CMG O (Deliveries groups) and CMG W (Female reproductive system groups). The results of the study also showed that the highest number of cases in UKMMC was from O-6-13-I (Vaginal delivery - mild) to the amount of 6,045 cases.

There is high variability in the nursing time between Diagnosis Related Groups [15]. Evidence also proven that nursing activities are highly heterogeneous within Diagnosis Related Groups [32]. Pertaining to this study, the result of both methodologies showed that this study could determine the variability of nursing cost and nursing service weights for every MY-DRG®. In method one, the variability of nursing activities within MY-DRG® was presented using the variability of nursing hours per case in each MY-DRG® that was involved in step two (calculation of nursing hours per patient per day of stay of each discipline) assisted by the length of the stay. This finding was supported by the study done by Jenkins & Welton (2014), who found that variations in the nursing hours for similar patients were between 0.36 to 13 hours for 247 Diagnosis Related Groups [14]. Both authors used the nurse and patient database as a measurement tool for nursing time. In method two, the cost of nursing per patient per day of their stay was used as a basic requirement to obtain the nursing cost per MY-DRG®. Thus the limitation of this method was that the variability of nursing cost was limited per MY-DRG®. Both methods provided the variability of nursing cost and nursing service weights across the 704 MY-DRG® comprised of 85,042 cases. However, some studies may have other views on using DRG to calculate the nursing cost. Mølgaard (2000) argued that determining the extent to which DRG system reflects the nursing cost can be steep[33]. Similarly, Finkler (2008) suggested that DRG is not an appropriate approach to determine the nursing intensity or the variability of the nursing resources consumed by each patient, which was strongly supported by Welton et al. (2009) who stated that the use of an average cost instead of a 'patient-specific' cost would be not feasible to measure the actual nursing care time or cost differences [5], [34].

Both methodologies employed by this study used the length of stay as the cost driver to differentiate the nursing cost for each MY-DRG®. This type of method is strongly supported by Schreyögg et al. (2006), who stated that the allocation of hospital costs to cases could use the length of stay as an allocation base when there are no other specific allocation criteria [19]. In some studies, the use of nursing activity was the most preferable rather than the length of stay in reflecting the

variability of nursing resources consumed by the patients[7]. The authors further stated that when using the calculation model based on the length of stay and not on the nursing activities, this would lead to more homogenous groups. This is as most of significant part of variation was not being measured. Even though some of the patients had a similar diagnosis across the DRG groups, they might required different needs related to nursing care [35]. Although the use of the nursing activity database has been found useful (Welton, Zone-Smith & Fischer 2006; Welton et al. 2009), such databases may not be feasible in this study because the nursing database has yet to be kept and recorded. This is because the nursing information is based on nursing care time and the resources used for each inpatient [16], [34].

Although the calculation of the nursing cost in this study used average nursing hours and nursing costs, the study findings could actually reveal the variability of nursing costs within MY-DRG® for specific case types, namely medical, surgery, pediatric and O&G cases. This information is essential compared with differentiating the nursing cost within and between similar nursing units or wards for each patient. In contrast, Tillet & Senger (2011) stated that there are different demands of the nursing services from unit to unit and from patient to patient[36]. Correspondingly, the evidence has suggested that nursing care and nursing cost are highly variable within and across similar units[37].

The findings from this study would enable nursing to distinguish between the nursing cost and nursing service weights for every MY-DRG®. MY-DRG® is a more powerful approach in that the study results were able to show the variability of nursing care based on nursing service weights that determined the differences in the nursing workload among the different types of illnesses and severity level. This methodology could be applied by the local healthcare settings because of the nursing data that records the nursing hours of the nursing services done for every inpatient. The advantage of linking the nursing cost and DRG system was that nursing costs are a more applicable nursing cost that can be determined further by the severity level of the patient. Unfortunately, the majority of hospitals in Malaysia have yet to officially implement the casemix system in their hospital management. Therefore, the other option for hospital costing is to impute data using a computerized costing system that is highly accurate but higher in cost[5]. In other developed countries such as the United States, the nursing database is readily available for use as a source of information to determine the economic value of nursing care [34].

Direct and indirect nursing services provided to the patients in the different types of nursing services were also not determined at this stage. Some of the studies used classifications such as value and non-value nursing to differentiate between the types of nursing care [2]. As stated by Chiang (2009), the nursing care activities performed for the patients consisted of direct care and indirect care. Direct care is easily determined based on the hours of care, but not the indirect nursing care, such as telephone calls, documentation or meeting with doctors and the family. This is since the estimated times spent on those activities was and is challenging to measure [12]. Thus, the direct and indirect nursing care for patients could only be estimated. The standard nurses working hours were comprised of direct and indirect nursing care for the patient. On the other hand, Penner (2013) described that ‘hours per patient day indicates the amount of direct nursing care time that an inpatient requires per day [38]. The second method of nursing costing was more straightforward as it required fewer steps to follow compared to the first method. It began with determining the nursing cost per patient per day, furthering the statement that the nursing cost between MY-DRG® groups was differentiated according to the ALOS of each MY-DRG®. The choice of method depends on the requirement of the

user, and whether they are to use the higher or lower rate of nursing cost for their settings. Since method one tends to produce higher nursing costs, the results presented can be re-evaluated and re-adjusted by recalibrating the nursing cost and nursing service weight.

Besides, both methods have successfully developed the nursing cost based on MY-DRG®. As viewed by Laport et al. (2008), the nursing cost could still be developed without using DRG based on two approaches, namely the calculation of nursing costs using the average nursing cost per patient per day and a calculation based on the nursing workload [15]. Contrary to this, Wilson et al. (1988) commented that the inconsistent methodology used might produce problems when making the comparison [39]. Through the observation of the results, it was anticipated that there would be some differences between the nursing cost and nursing service weights developed using nursing hours and cost per patient per day of their stay.

When comparing both methods, it showed that the method of calculation using nursing hours consistently gave a higher nursing cost compared to method two, which used cost per patient per day of their stay. The first method to obtain the nursing cost was derived from the nurses' working hours a year based on their standard working hours a month. Nursing hours per patient per day of their stay is the basic component of the calculation. Any overtime, extra duties and annual leave was excluded from the calculation. Although both methods can be used due to the rising of hospital services nowadays, the one with the higher estimation may be appropriate to use for hospital reimbursement purposes.

In general, the results of the nursing costs and nursing service weights from the surgery discipline were higher compared to other disciplines such as medical, O&G and pediatrics. The higher nursing cost and nursing service weight across the surgical discipline were because the patients may need more nursing interventions, both pre-operatively and post-operatively. For instance, pre-operatively, they may require an immediate x-ray, lab investigations, a blood transfusion and rigorous preparation physically before an operation including shaving, the cleaning of specific areas, an intravenous drip and drug administration. Post-operatively, in the acute phase, the patients may need frequent observation such as taking their vital signs and monitoring the wound for bleeding so as to prevent post-operative complications. Post-operatively, for most major surgeries, the patients are nursed in bed for at least 1 to 2 days depending on the severity. During this time, all of their hygiene needs will be taken care of. This was agreed on by Welton, Zone-Smith & Fischer (2006), who stated that the increased level of severity indicates the increase in the level of nursing intensity [16]. Furthermore, Knauf et al. (2006) stated that the scoring of nursing intensity was usually the highest in two peak times; admission or surgery [1].

This study has identified that CMG F (Mental health and behavioral groups) had higher nursing costs and nursing service weights compared to other MY-DRG® across the medical disciplines and case-types. CMG F also had longest length of stay with a mean length of stay of 16.50 (11.41) days with the maximum length of stay being 63 days compared to other CMGs. The findings are supported by Wilson et al (1988), who stated that length of stay is typically different in different parts of the country [39]. This was as suggested by a study done by Auffarth et al. (2008), comparing psychiatric inpatients stay in the United States and in a German hospital [40]. The result from the study by Auffah et al. stated that the average inpatient stay for mental health patients was shorter in the United States compared to Germany. This was due to the cultural differences and diversity of the health system [40]. Furthermore, mental health patients have a longer length of stay as they have a

more chronic condition compared to acute cases. Therefore, there are not much nursing interventions or procedures that need to be done unless they are in the acute stage of illness.

In the calculation of the nursing costs using method one, the nursing cost was higher due to the nursing hours. Nursing activities for mental health patients are more focused on observing, monitoring behavior and documenting the necessary information throughout their hospitalization. Furthermore, both methods of calculation are involved in the use of their length of stay data. Thus the resulting nursing cost is prone to be higher in mental health cases. Cases from the caesarean section and in terms of vaginal delivery were among the highest nursing costs. This was agreed on by Welton, Zone-Smith & Fischer (2006), as differences in nursing hours occurred for the cesarean section, where the average nursing hours were 6.1 and for vaginal delivery, 5.2 nursing hours per day of nursing care was the average [16].

The difference in nursing hours was expected as a surgical procedure may require more nursing interventions such as an assessment, the administration of an analgesic and wound care. Results from pediatrics showed that P-8-08-II (Neonate birth weight >2499 grams with respiratory distress syndrome & congenital pneumonia - moderate) was higher in terms of nursing cost compared with the other departments. The results in this study were difficult compared with other studies; for example, Knauf et al (2006) defined pediatric DRG groups as neonates who were dying within one day, who had been transferred < 5 days of birth and who had a birth weight < 750 grams [1].

5. Conclusions

Nursing has a major function in the management of patient care. This study provides results in the form of nursing costs and nursing service weights for every MY-DRG® of the casemix system, UKMMC. The findings of this study also indicate that the nursing costs and nursing resources consumed by inpatients across the different MY-DRG® can be successfully determined using the casemix system. The results showed that the cost of nursing services was higher when the calculation of the nursing costs was based on nursing hours (method one) compared to a cost per patient per day of their stay (method two). The outcome of this study is that both methodologies can be implemented and recommended to the health policymaker.

ABSTRACT

The objective of this study was to describe time-motion and comparisons of spending time between senior and junior nurses use the direct care tool during nursing action in intensive care unit. This study was conducted during three months for 34 professional nurses. Six investigators directly observed and measured of time on each nursing direct care action that applied by the nurses. There were 40 types of direct care nursing were observed from 30 nurses. The most common nursing direct care in the intensive care unit was an invasive procedure such as injection and inserting an intravenous needle. The longest mean time of duration is personal (bathing) with an average time of 14.33 minutes. The shortest average duration of time is respiratory procedure for use of a nebuliser with a mean time of 1.43 minutes. So based on the study, the minimum nursing hours per patient day is 365 minutes (6.08 hours) and the maximum time is 542 minutes (9.03 hours) per day with direct-care mean score is 495 minutes (7.82) hours per day. Spending time was not significantly different between senior and junior nurses in time motion (p.02).

Keywords: time motion study, intensive care unit

1. Introduction

Nursing management consists of two important parts, including nursing leadership and the management of patient care [1]. A time motion study is one of the components involved in the management of patient care [2]. Taylor explained that time motion studies can be described as detailed observations of the time that is needed to perform specific tasks [3]. For example, there was nursing direct care and indirect care (called nursing action). Organizing health services which include nursing actions is very complex, thus demanding that the health workers follow standards of knowledge and science [4]. Good standards that are followed by the productivity of health staff will create quality nursing care [5]. Time motion is one measure of the performance achievement that is based on set standards. Nurses are the spearhead of patient care. This represents a crucial and limited resource; the effectiveness and efficiency of the nurses is important in the promotion of safe patient care and hospital quality performance. Types of clinical department include pediatrics or surgery;

they are significantly associated with the demands on the health care staff [6]. One of the various types of nurses includes emergency nurses that usually work in the emergency or high care rooms such as an Intensive Care Units. Spending time in the high care unit is challenging, where the nurses have to struggle to devote time to critical patients. It is argued that complex nursing care can cause a heavy nurse workload. As a result, they may neglect part of the nursing actions [1]. On the other hand, a study by Orique, Patty and Woods found that there was no significant relationship between nurse workload and missed nursing care [7]. This study conducted a time and motion study to investigate an evidence-based concept on how high care unit nurses spend their time and the differences in spending time between the senior and junior nurses.

2. Method

The study was conducted on an Intensive Care Unit (ICU) for three months in a hospital in Indonesia. Six professional students who were characterized participated in the study. They undertook an observation of each shift rotation in the research unit. The observation was undertaken on 30 nurses who contributed a substantial amount of care. To measure the patients' demand of nursing care, we applied a time motion study form. First, we identified all nursing actions in the ICU using a daily log form. Second, based on the list of direct nursing care, we made a list of the time motion study observation sheets that consisted of some of the nursing actions, then plus the observation time and motion study. The observation sheet was comprised of six components of direct care nursing action (DCNA): 1) observation and monitoring that provided nine DCNAs, 2) self-care which consisted of eight DCNAs, 3) diet, food and drink which consisted of seven DCNAs, 4) medication which consisted of seven DCNAs, 5) somatic therapy which consisted of five DCNAs and 6) health education which consisted of four DCNAs. To keep a representative sample of the patients, we involved all of the patients in ICU in the intensive care acuity system. We determined all high care nurses regarding the requirements of their training and especially their competency. The data was analysed using the Statistical Package of v. 20 (IBM SPSS). The categorical data was provided as a distribution. The continuous variables have been summarized as means. They were analyzed using the dependent t test as a measure of the comparison of the time spent between the senior and junior nurses. The comparison was conducted based on all DCNAs that have been collected and calculated on the total time required.

3. Results

A total of 30 nurses were observed in the Intensive Care Unit (ICU). The observation was applied to the nurses who provide direct nursing care services (direct care) to the patients. A number of 34 patients were used during the observation.

Table 1. Profile of the nurses

	F	%
Ages		
18-40	25	73
40-61	9	27
Gender		
Male	11	31
Female	23	69
Education		
Diploma	17	50
Bachelor	17	50
Length of work		
≤ 15 years	29	85
>15 years	5	15
Training		
5-8 times	18	52
>8 times	16	48

Table 1 showed that the majority range of the participants' for age were 18-25 (73%). There were more females (69%) than males and the length of work was always less than 15 (85%) years. It can be seen in the table that the nurse should have training requirements. Almost 50% of the nurses had intensive care unit nursing care training.

Table 2. Profile of the patient's intensive care

	F	%
Ages		
18-40	17	48.5
41-60	18	51.5
Gender		
Male	15	43
Female	20	57
Length of stay		
Min	9	
Max	16	
Mean	12	

Table 2 shows the profile of the patients in the intensive care unit. All acuity patient classifications have been provided for the total and intensive care. As can be seen in Table 2, the patients' characteristics described the ages of the patients as being more than 41 years old at 48.5%, while those less than 40 years old made up 51.5%. Females made up 43% and males made up 57%. Next, the length of the stay of the patients was for a minimum of 9 days, a maximum of 16 days and an average of 12 days.

A list of the daily logs of the nursing actions that were observed by the professional nurses included injecting, counting of infusion drops, calculating fluid balance, personal hygiene like bathing the patients, measuring blood pressure and other vital sign examinations, providing medication and giving health education. The distribution of the DCNA spend time can be seen in Table 3.

Table 3. Direct care nursing action distribution in intensive care

CDNA	Mean	Min	Max
Personal hygiene	14.33	4	39
Oxygenation	3.00	3	3
Injection of medicine	3.00	2	3.6
Suction	2.31	2	5
Extubating	3.6	3	5
Wound care	7.00	3	14
Take blood sample	12.00	3	20
Diagnostic examination	12.66	11.7	20
Oral hygiene	3.00	1	5
Syringe pump application	2.50	1	3
Tracheostomy care	7.83	4	16
ECG examination	3.58	2	5
Infuse pump application	2.67	1	4
NGT management	3.40	3	4
Bronchial washing	2.71	2	4
Heating Up	9.50	5	14
X-Ray Preparation	2.33	1	12
NGT application	5.50	5	6
Replacing infusion flabotle	1.00	1	1
Colostomy Care	3.20	3	4
Replacing DC	6.00	5	7
Infusion fluid observation	1.29	1	2
Replacing of bandages	3.33	2	4
Infusion remove	3.67	2	7
Remove IV needle	10.40	8	15
Nebulizer therapy	1.43	1	2
Nursing supervision	13.50	12	19
Feed the patient	2.25	2	3
New patient hand over	13.40	14	16
Apply computer monitor	4.25	4	5
Family Heath Education	12.30	10	14.00
Blood Pressure measurement	3.02	2.7	3.5
Health assessment	11.22	9.20	12.00
Heart rate and temperature	2.02	2.5	3.05
Fluid Balance	13.20	12.20	14.03

Table 3 shows that there were 35 types of direct nursing care in the intensive care unit. In the table, we have also provided the mean, minimum, and maximum nursing action spending time.

Table 4. Distribution of direct care nursing spend time

Distribution	Times
Maximum direct care nursing	14.33 minutes
Minimum direct care nursing	1.43 minutes
Maximum direct care nursing	9.03 hours per day
Minimum direct care nursing	6.08 hours per day
Mean score direct-care	7.82 hours per day

It can be seen in Table 4 that the longest mean time of duration was for personal hygiene (bathing) with an average time of 14.33 minutes. The shortest average duration of time was the respiratory procedure for the use of a nebuliser with a mean time of 1.43 minutes. Based on the study, the minimum nursing hours per patient in a day was 365 minutes (6.08 hours) and the maximum time was 542 minutes (9.03 hours) per day with the direct-care mean score being 495 minutes (7.82) hours per day.

Table 5. Spending time between the senior and junior nurses

Group	Mean	Sd	t	Sig
Senior	5.8415	5.492	.038	.970
Junior	5.7955	5.420		

Table 5 describes that the group means between the senior and junior nurses are statistically different. On the other hand, the value in the "Sig. (2-tailed)" row is more than 0.05 where, looking at the group statistic table, we can see that the nurses who had junior experience were doing the same as the senior nurses in terms of spending time. This study found that there were no significant differences regarding spending time that was compared that resulted in $t = 0.038$, $p = 0.970$.

4. Discussion

As seen in the two tables above (Tables 1 and 2), the number of nurses is 30 while the average number of patients per day is 12. This shows that the number of nurses who provide nursing care to patients with intensive acuity is not balanced. A study found that staffing patterns may not balance when achieving patient outcomes in an intensive pediatric care setting with a high acuity patient level [8]. It can be reported that there are an average of 12 patients (71%) out of 17 beds available in the ICU per day (see table 2). It could indicate that there needs to be more activities and services in the inpatient care from the nurses. The results of the analysis of the average patients per day in the ICU can be categorized as high care. It is recommended that the ideal value for the average number of patients is no more than 85% per day [9],[10].

There were 35 types of Direct Nursing Action (DNA) that were observed and listed based on the daily logs in this study. Other studies found that the majority of the nursing staff spent the most time on direct care interventions, particularly in the domain of basic physiological care like personal hygiene and fluid requirements [11],[12]. Within one working day, the intensive care nurses spent an time of 469.50 minutes or 7.8 hours providing nursing services directly to their patients. Huber explained that on average, it took eight hours for the nurses to provide direct nursing care to the patients in the intensive care category [9]. Direct care activities in the intensive care unit tend to be complex, but the workload could be handled by nurse practitioners such as professional nurse students (senior student), where they commonly helped by checking vital signs, suctioning, positioning the patients, replacing the infusion bottles and providing nutrition through a Naso Gastric Tube (NGT). The direct nursing care activities that should be carried out by the nurses are thus reduced.

As can be seen in the results of the senior and junior nurse comparisons, there were no significant differences between them. The majority of the nurses spent their time with the intensive

care patients, which did not change. The work patterns commonly applied functional methods. A study conducted by Westbrook et al found that there was no multidisciplinary care team work among the health staff in nursing care [11],[13]. The task time distribution was similar; the junior nurses tended to do simple tasks and the senior nurses did the more complex tasks. However, the average time spent was not significant different. Looking at the direct care nursing categories of the junior and senior nurses, 'services that were not differences', which may due to the similar complexity of the tasks between both of them. This also may be caused by the frequency distribution of patient classification according to the bed occupation rating.

Another reason for this is that it may be due to the distribution of the patients in intensive and total care (89%) with an average of 10 patients per day. For intermediate care, there is was a mean of 2 patients per day. This is because the ICU has a focus on dealing with critical patients whose conditions are unstable and who thus require extra supervision and treatment [10], [14] such as patients with severe trauma, post-major surgery and who are experiencing critical complications of various diseases.

Direct care such as medication tasks have been observed in this study. However, indirect care like professional communication that consumed a lot of time was not considered to be observed in direct care nursing actions. Mendoza and Heredero suggested that both digital and manual communication is very important to develop institutional relationships [15]. In this study, this may improve nursing action services. In the nursing professional relationship, communication is required in the sustainable nursing process [16].

ABSTRACT

Early Warning Score is an early detection system that deterioration the patient's condition which aims to prevent worsening of the patient's condition. Based on observation that have been made, there is a incompatibility with implementation of the clinical response and the Standard Operating Procedure that has been determined. The purpose of this study was to analyse the factors related to the implementation of the Early Warning Score at a Private Hospital in Central Indonesia. This research was conducted using a quantitative descriptive correlational method with cross sectional design. A total sampling technique was applied by recruiting 55 nurses. Factors related to implementation clinical response EWS were measured using questionnaire and non behavioural observation with record analysis. Chi-Square test was applied to identify the correlation of the factors. The result of this study revealed that there was no relationship environmental factor (p=0.261), workload factor has no relationship (p=0.818), equipment availability factor has no relationship (p=0.276), and knowledge factor has no relationship (p=0.276).

Keywords: early warning score, implementation factor of early warning score, clinical response

1. Introduction

An Early Warning is an assessment standard for monitoring changes in the physiology that consists of six parameters for documentation consisting of the vital signs of the adult patient and any additional oxygen use. The score of the National Early Warning Score (NEWS) counted from the seven elements were recorded. If the score of NEWS is high, then there are more major physiological changes being experienced by the patients. More major changes in the physiology from outside the normal range have made the physiological condition of the patients worse [13].

When the patient's condition worsens, then the nurse must do an intervention that is also known as a clinical response. The phenomenon found from the observation from January until April 2018 done in a Private Hospital in Central Indonesia found that some nurses did not conduct a clinical response EWS according to the Standard Operating Procedure determined by the hospital.

Gordon and Beckett [5] conducted an audit on the documentation on the Scottish Early Warning Score System (SEWS) for the night shift and found that only 21% of the night shift graph was completely and had correctly documented SEWS. The 55% from the graph had no calculations

and 21% of the results from the graph had the wrong calculations. The observation of the parameters often ignored respiration frequency, temperature and neurological status. The same result was obtained by Kolic, Crane, McCartney, Perkins and Taylor from 70 patients that were in care in the ward; between 18,9% had the correct EWS score [7].

Rose and Clarke said that the intervention given by the health staff was often incorrect and in some cases, the health staff even neglected EWS, causing a high workload [12]. Besides their workload, according to Philips Healthcare, the clinical response implementation of EWS was influenced by other factors such as the environment, knowledge and the decreased awareness of the nurses about how important vital sign monitoring is. Some of the study results made the researcher realize that some of the factors can affect the implementation of the clinical responses to EWS [11]. Based on the phenomenon found, this study aims to analyze the factors related to the implementation of the Early Warning Score in a Private Hospital in Central Indonesia.

2. Methods

This study was a quantitative research with a correlational design. The sample population of this research consisted of nurses who worked in one of the wards. The sample used for this study consisted of 55 respondents using the total sampling method. The respondents for this study must have followed the EWS training and not been on leave. The instrument for this study consisted of a questionnaire that was modified and developed by researcher. The researcher modified the questionnaire using a pilot study. The pilot study was conducted to determine how suitable the condition of the hospital was. The questionnaire consisted of 37 statements and used a Likert scale that consisted of the workload factor, environmental factor, knowledge factor and equipments availability factor. Furthermore, this study also conducted a record's analysis using an observation sheet that was arranged according to the operational standard procedure clinical response of the Early Warning Score (EWS). Based on the validity test and reliability test, we obtained an r Alpha for knowledge of 0,701 and the result showed that the questionnaire was valid and reliable with an r Alpha $\geq$ 0,70. This study is related to human research, so the researcher had to conduct an ethical review. This study underwent an ethical review and was approved by the Research Ethical Committee Faculty of Nursing Pelita Harapan University letter No. 006/RCTC/EC/R/SHMN/V/2018.

The retrieval of the data was conducted from 2nd – 15th July after we had approached the respondents in the Hospital and gave them an informed consent form which explained the purpose of the study. After the respondents agreed to be respondents and they had given their informed consent, the respondents answered a questionnaire and the researcher conducted a documentation study for each of the respondents with the view of integrating their notes and the observation sheet. The respondent's questionnaire was answered and then collected. It was checked, and then it was computerized for analysis.

The data analysis done consisted of univariate and bivariate analysis. Univariate analysis aims to view the frequency distribution of each of the variables. Bivariate analysis used the Chi-square test to view the relationship between the environmental factor, workload factor, knowledge factor and equipment availability factors with the clinical response implementation in a Private Hospital in Central Indonesia.

3. Results

This study results showed that for sex, the majority of nurses on the wards in a Private Hospital in Central Indonesia were female. Based on the age of the nurses, for age range, the majority were early adults (26-35 years). Based on the education of the nurses, having a diploma degree was the majority education. Based on the length of work, the majority had worked for 1-5 years in the Private Hospital in Central Indonesia. For the percentage of the characteristics of the respondents, the results can be seen in Table 1 below.

Table 1. Respondent Characteristic's of the Clinical Response Implementation of EWS in a Private Hospital in Central Indonesia

Category	Frequency (n)	Percentage (%)
Sex		
Female	49	89,1
Male	6	10,9
Total	55	100
Age		
Teenager (17-25 years)	7	12,7
Early Adult (26-35 years)	46	83,6
Adult (36-45 years)	2	3,6
Total	55	100
Education Degree		
Diploma (DIII)	28	50,9
Bachelor	3	5,5
Ners	24	43,6
Total	55	100
Length of Working		
<1 years	4	7,3
1-5 years	43	78,2
>5 years	8	14,5

Total	55	100

Table 2. Data of the Clinical Response Implementation of EWS in a Private Hospital in Central Indonesia

Category	**Frequency**	**Percentage (%)**
Clinical response implementation of EWS		
Accordance of SOP	30	54,5
No Accordance of SOP	25	45,5
Total	55	100

Table 2 shows the results of the analysis which indicates that 55 nurses were the respondents for this study. The nurses who implement the clinical response according to standard operational procedures of EWS according to the hospital made up 30 respondents (54,5%) while 25 respondents (45,5%) did so but not according to the standard operational procedure EWS set up by the hospital.

Table 3. Frequency distribution of the factors related to the implementation of EWS in a Private Hospital in Central Indonesia

Variable	Total (n)	Percentage (%)
Environment Factor		
Conducive	23	41,8
No Conducive	32	58,2
Total	55	100
Workload Factor		
Light workload	35	63,6
Heavy workload	20	36,4
Total	55	100
Equipment Availability Factor		
Adequately	21	38,2
Inadequately	34	61,8
Total	55	100
Knowledge Factor		
Good	21	38,2
Poor	34	61,8
Total	55	100

Based on Table 3, the results of the environment factor showed that 32 respondents (58,2%) were categorized as not being in a conducive environment and that 41,8% were categorized as being in a conducive environment. The distribution frequency result for the workload showed that most of the 35 respondents (63,6%) were categorized as having a light workload and 20 respondents (36,4%) were categorized as having a heavy workload. The distribution results of the equipment availability factors showed that 21 respondents (38,2%) were categorized as having adequate equipment and 34 respondents (61,4%) were categorized as not having adequate equipment.

Table 4. The relationship between the environmental factor with the clinical response implementation of EWS in a Private Hospital in Central Indonesia.

		No accordance of SOP		Accordance of SOP		p-value
		N	%	N	%	
Environment	Conducive	13	56,5	10	43,5	0,261
	Not Conducive	12	37,5	20	62,5	
	Total	25	45,5	30	54,5	

Based on Table 4, it can be known that there is no relationship between the environmental factor with the clinical response implementation of EWS in a Private Hospital in Central Indonesia (p value = 0,261).

Table 5. Relationship between the workload factor with the clinical response implementation of EWS in a Private Hospital in Central Indonesia.

		No accordance of SOP		Accordance of SOP		p-value
		N	%	n	%	
Workload	Light	15	42,9	20	57,1	0,818
	Heavy	10	50	10	50	
	Total	25	45,5	30	54,5	

Based on Table 5, it can be known that the nurses' workload has a p value = 0,818. This means that the results showed there to be no relationship between the workload with the clinical response of the implementation of EWS in a Private Hospital in Central Indonesia.

Table 6. The relationship between the equipment availability factor with the clinical response implementation of EWS in a Private Hospital in Central Indonesia

		No accordance of SOP		Accordance of SOP		p-value
		N	%	n	%	
Equipment Availability	Adequately	12	57,1	9	42,9	0,276
	Inadequately	13	38,2	21	61,8	
	Total	25	45,5	30	54,5	

Based on Table 6, the conclusion was obtained that equipment availability has no relationship with the clinical response of the implementation of EWS because the p value = 0,276.

Table 7. Relationship between the knowledge factor with the clinical response of teh implementation of EWS in a Private Hospital in Central Indonesia

		No accordance of SOP		Accordance of SOP		p-value
		N	%	n	%	
Knowledge	Good	12	57,1	9	42,9	0,276
	Poor	13	38,2	21	61,8	
	Total	25	45,5	30	54,5	

Based on Table 7, it can be known that there is no relationship between the nurses' knowledge with the clinical response of the implementation of EWS in a Private Hospital in Central Indonesia.

4. Discussion

The monitoring of the Early Warning Score is an important thing that must be done by a nurse because the Early Warning Score (EWS) is an initial step for the detection of a signal worsening patient condition. When the patient's condition gets worse, the nurses need to have a clinical response. In fact, the implementation given by the nurses frequently is not exact and sometimes for some of the cases, the nurses neglected doing EWS because of their heavy workload. Although EWS is important, but there are some factors that can contribute to adverse events that happen to patients where there is a worsening of their physiology such as the environment, workload, equipment availability and knowledge.

4.1. Environment Factor with the Implementation of a Clinical Response

The results of the univariate analysis showed that 32 respondents (58,2%) categorized the work environmental factor as not being a conducive environment. The results of the bivariate analysis using a Chi-Square test showed there to be no relationship between the environmental factor with the implementation of a clinical response EWS in a ward in a Private Hospital in Central Indonesia. This study was therefore not in accordance with the theory because p value = 0,261. This can happen because observation study by researcher showed the hospital has light exposure and room arrangement supported for monitoring of EWS. Furthermore, security staff always standby to maintain serene rooms as the patients can be affected by stress, annoying feelings and a burnout in the nurses that can affect the implementation of a clinical response [4].

The result of study was not in accordance with Abdullah in that the physical environment or work environment was focused on everything around the employees (facilities and infrastructure) that influence the employees when carrying out the tasks that are the employee's responsibility [1].

The results are supported by the documentation study that showed that 58,2% agreed about the environment not being conducive. The implementation of a clinical response in the ward in a Private Hospital in Central Indonesia can work because the ward has enough lighting and because they have arranged the room in order to do monitoring. More specifically, Anggraeny said that a comfortable, safe, and conducive working environment is one of the most important things for hospital management to consider as part of an effort to increase the quality of nursing care [3].

4.2. Workload Factor with Implementation Clinical Response

The results of the univariate analysis showed that 35 respondents (63,6%) assumed that the workload of the nurses was categorized as a light workload. Based on the bivariate analysis of the workload factor, the results showed that there was no relationship between the nurses' workload with the implementation of a clinical response EWS with a p value 0,818 as evidenced by the Chi-Square test. This can be happen because of the even distribution of tasks equally in the wards in the Private Hospital in Central Indonesia. Workload factors also affect nursing care quality, especially susceptible nurses where they have concerns about patient safety such as the patient fall incident rate, decubitus and medication errors [8]. The distribution of the tasks equally meant that the nurses could arrange their time and assume responsibility of the tasks that given. Other than that, the amount of patients handled by the nurses in the Private Hospital in Central Indonesia was no more than seven patients, where seven patients are the maximum amount that can be handled by a nurse [8].

4.3. Equipment availability with the Implementation of the Clinical Response

Based on the bivariate analysis, it was found that equipment availability factor also had no relationship with the implementation of a clinical response EWS in a Private Hospital in Central Indonesia. This is because the p value that was obtained by the Chi-Square test was 0,276. No relationship was found between the equipment availability factor with the implementation of a clinical response of EWS. This can happen because the equipment for the assessment of EWS is always available in every nursing station such as a thermometer, stethoscope, sphygmomanometer, and an oximeter. Equipment availability can be factor that supports the implementation of a clinical response EWS in a hospital [6].

Equipment availability is supportive of the implementation of nursing care. Infrastructure, human resources and a lack of equipment will inhibit care giver quality [9]. Lacking equipment or lacking drugs when need can affect the handling of the patient and this can impact on patient condition. This is because the response time of the nurse is made slower [3].

4.4. Knowledge factor with the Implementation of a Clinical Response

The knowledge level of the nurses about EWS is still in the poor category according to the univariate analysis. The p value knowledge factor 0,276 means that there is no relationship between the knowledge factor with the implementation of the clinical response EWS. This result can be affected by the nurses in the ward getting regular training, having their knowledge evaluation about EWS every three months and if the hospital did an audit of the EWS implementation every month. The training aspect and evaluation can be affected by the knowledge that the nurses have [2].

Knowledge is close related to education level and degree. It is expected that the high education level of a person means that they will have extensive knowledge [10]. The quality and performance of a nurse related to giving nursing care is affected by knowledge [9].

The limitation of this study is a lack of references such as articles, journals, and text books that support the results of the study, specifically about the factors related to the implementation of a clinical response EWS in Indonesia. The data obtained was mostly from abroad and it was not specifically about the factors involved in the implementation of a clinical response.

5. Conclusion

In summary, the implementation of a clinical response EWS influences some of the factors such as knowledge, workload, equipment and the environment. This study showed there to be no relationship between the four factors with the implementation of a clinical response EWS. The results of this study describe the implementation of a clinical response EWS where the method used was observation. Therefore for future research about the implementation of EWS, there needs to be a larger population and more behavioral observations. This is so then the results of this study can be completely accurate.

DISCHARGE PLANNING IMPROVING THE INDEPENDENCE LEVEL IN ACTIVE DAILY LIVING AMONG POST-OPERATIVE HIP FRACTURE PATIENTS

A Aris[1] and N A Kadir[2]

[1]Faculty of Medicine, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia
[2]Training Institute of Ministry of Health Malaysia (Nursing) (ILKKM), Melaka, Malaysia

ABSTRACT

This study aimed to examine the effectiveness of discharge planning on patients with a hip fracture in Malaysia. A randomized controlled trial was conducted involving 58 patients aged 50 and above (intervention=29, control=29) in the orthopedic wards of Hospital Melaka, Malaysia. Those in the intervention group received discharge planning which was comprised of health education activities in the form of pamphlets and oral lessons within 24 hours of admission up until discharge while the control group only received the routine discharge practice. The outcomes measured were the duration of their stay in the ward, the date of readmission and their fall rates and daily activity after one month post-discharge. The data was analyzed using the Mann-Whitney U and Chi-square tests. The findings showed that the intervention group had a shorter duration of stay in the ward ($U=254.00$, $p=0.008$) and a higher level of independence in daily activities than the control group ($U = 205.00$, $p = 0.001$). The control group resulted in 100% of the subjects not being capable of being independent in their daily living compared to 75.9% in the intervention group ($p= 0.005$). Therefore the discharge planning focuses on the health education component needs that are to be considered for practice.

1. Introduction

Hip fractures are common among the elderly. It is well known that this incidence often occurs in this population due to osteoporosis and falls [1].Globally, the average age of the elderly when they get a hip fracture is between 75 and 79 years old [2]. However, in Malaysia, the occurrence of this fracture was reported to be as early as 50 years old and above in every 90 per 100,000 adult population in 1997 [3]. Most of the hip fracture cases in Malaysia were due to falling [4]. According to Lee and Amir [5], the probability of a hip fracture increases to more than 100% for every 10 years after turning 50 years old.

Hip fracture is considered serious because it can affect the quality of life of the elderly [6].The main treatments for the hip fracture are surgeries such as the dynamic hip screw, hemiartoplasty or total hip arthroplasty [1]. However, elderly patients with a hip fracture often require a long stay on the ward and readmission within three months after discharge due to the failure of the rehabilitation process [7] and recurrent falls [8]. Most importantly, the majority of patients are not able to perform at least one activity of daily living (ADL) after surgery [9].

Discharge planning is crucial for the hip fracture patients as they need continuous care in order to maintain and improve their health status even after being discharged from the acute care phase in the hospital [10]. Health education, the critical component in the discharge planning, helps these patients to adapt to the transition process from the hospital to their home [11]. It also provides ideas to the patients and their family on how to continue with the health care after discharge [12]. Previous studies have shown that elderly patients who had their discharge planned since the first day of their admission had a shorter hospital stay, a reduced rate of readmission and fall and increased ADL after discharge [8]. In addition, the patients were also found to be able to maintain their independent functioning status in ADL after they were discharged [13].

However, the effectiveness of the discharge planning on the hip fracture patients in Malaysia is unknown because the previous studies were conducted in other countries such as Taiwan [14]. Furthermore, most of the previous studies have only included hip fracture patients aged 60 years old and above [10] whereas in Malaysia, the hip fracture incidence occurs as early as age 50 [3]. Therefore, this study was conducted to examine the effectiveness of the discharge planning in Malaysian patients. The objective of the study was to examine the differences in the length of hospital stay, the readmission and fall rate and the ADL between the elderly patients who received discharge planning and those who did not receive it.

2. Research Methods

2.1. Design

This study was conducted using the randomized controlled trial design. It involved two groups; the intervention and control group. The intervention group was provided with discharge planning whilst the control group continued with the routine practice of discharge where the nurses only provided the patients with a leaflet that contained the do's and don'ts after the surgery before they were discharged.

2.2. Participants

All of the patients admitted to the orthopedic wards in Hospital Melaka (Ward D1, D2, D3 and D4) diagnosed with a hip fracture were included in this study if they were aged 50 years old and above, if they were able to communicate in the Malay language and had Malaysian citizenship, if they had undergone either a total/hemi arthroplasty or if they had a dynamic hip screw and if they had family to take care of them at home after they were discharged. However, they were excluded if they had been diagnosed with dementia and were staying in the intensive care unit after the surgery. This study was approved by two ethics committees; Universiti Kebangsaan Malaysia Medical Center (Reference No: UKM PPI/111/8/JEP-2017-664) and the Ministry of Health, Malaysia (Reference No: KKM.NIHSEC/P17-2003(6)).

2.3. Intervention

The patients in the intervention group were given a leaflet developed by Murphy *et al* [15] within 24 hours after they were admitted to the ward. The leaflet contained information about hip fractures, the different types of surgery, the patients' expectations after the hip surgery and post-surgery self-care. The information in the leaflet was also explained orally to the patients by the researcher. The explanation took 15 minutes for each patient. The health education was given again over the phone based on the patient's request when the patient was still not yet discharged from the hospital. The researchers' contact number was given to the patients for this purpose.

2.4. Measure

The outcomes measured in this study were the length of the hospital stay, the rate of readmission and fall, and ADL within a month after discharge. All of the measures were obtained from the patient's medical report except for the ADL, which was obtained through a phone call using The Barthel Index questionnaire [8].The author reported that the questionnaire had a result of 0.89 and 0.95 for the test and retest reliability between the rates respectively. It consisted of 10 items with a 5-point Likert scale response format. The total score for all items was between 0-20. A total high score indicated that the patient could perform the ADL independently. The total score was also categorized as follows: 0 to 3, high dependent; 4 to 7, full dependent; 8 to 12, moderate dependent; 13 to 19, low dependent and 20, independent [16]. The reliability of the questionnaire for the current study was α 0.949.

2.5. Sample size

The calculation of the sample size for this study was conducted using a two mean formula and this was based on the average of 8 and a standard deviation (SD) of 10.39 from the previous study [8]. Through this calculation, a total of 52 people were required for this study; 26 for the intervention group and another 26 for the control group. However, in order to overcome the possibility of a reduction in the sample size due to attrition, the total number of the samples required was 58 people (additional 10%).

2.6. Randomization

Patients who met the eligibility criteria were given an explanation of the study as well as the study information sheet. If the patient was interested in participating, then a written consent form was obtained from the patient. All consenting patients were then divided into the control or intervention group according to the number that they received in a sealed envelope (n = 29 Intervention, n = 29 Control).

2.7. Data Analysis

Data was analyzed using IBM SPSS version 21. A Chi-square test was conducted to examine the difference in the subjects' demographic and clinical characteristics between the intervention and control groups. Due to non-normal distribution of the data, the Mann-Whitney test was used when comparing the length of their hospital stay, the rate of readmission and falls and ADL between the intervention and control group. On the other hand, descriptive analysis was performed to describe the level of dependency in the ADL for each group. This was followed by a Chi-square test to examine the difference in the level of dependency between the two groups. Prior to this test, the five categories of dependency level were collapsed into two categories (dependent vs. independent) due to an insufficient number of samples in some of the cells. P value<0.05 was used to determine the significant findings.

3. Results

A total of 58 eligible patients agreed to participate in this study. The retention rate of the study samples was 100% as none of them withdrew throughout the study (Figure 1). The demographic characteristics of the study samples have been presented in Table 1. In both groups, the majority of the subjects were aged 70 years old and above, were a widow or widower and were not working. The majority had also attended primary/secondary school and had an income ≤RM1000. On the other hand, the intervention group had more male (51.7%, n=15) and Malay subjects (75.9%, n=22) whereas in the control group, most of the subjects were female (72.4%, n=21) and Chinese (58.6%, n=17). The results of the comparative analysis indicates that the subjects between the two groups were not significantly different in all of their demographic characteristics (p>0.05) except for the race variable (X^2 = 14.724, p = 0.001). Based on the Cohen table [17], the size of this difference is large (phi = -0.669).

Table 2 shows the clinical data of the subjects in this study. The majority of the subjects in both groups had hypertension/heart disease, had fractured the inner capsule and had been injured in a low impact mechanism. However, the number of the subjects with hypertension/heart disease, inner capsule fracture and with a low impact of injury was higher in the control than in the intervention group. However, there were no statistically significant differences of the clinical data between the groups ($p > 0.05$).

As shown in Table 3, the length of the hospital stays for the intervention group were lower (Mean rank = 23.76; Md = 9.00) than that of the control group (Mean rank = 35.24; Md = 10.00) and this difference was found to be significant ($U = 254$, $p = 0.008$). The effect size of the difference was 0.34, indicating that the difference was moderate [17]. Similarly, the subjects in the intervention group were more independent in performing their ADL (Mean rank = 36.93; Md = 16.00) than the subjects in the control group (Mean rank = 22.07; Md = 12.00). The difference was also statistically significant ($U = 205$, $p = 0.001$). Based on Cohen's table [17], this difference was moderate (0.44). On the other hand, the readmission and fall rates were not significantly different between the two groups ($p > 0.05$).

The findings for the level of dependency in ADL categories have been presented in Table 4. The intervention group had more subjects who were independent (24.1%; n = 7) and with low dependence (55%; n = 16). In contrast, the control group had more subjects with moderate dependence (44.8%; n=13), fully dependent (13.8%; n=4) and highly dependent (3.4%; n=1). None of the subjects in the

control group reported being independent in their ADL. Table 5 shows that there was a significantly greater number of subjects who were independent in the ADL in the intervention than in the control group ($p = 0.005$). The phi value was -0.370, which indicates a moderate size of difference based on the Cohen table [17].

4. Discussion

The results showed that elderly patients with a hip fracture who received the discharge planning had a significantly shorter length of hospital stay and a higher independence level in ADL than the control group. When the level of ADL was categorized as dependent vs. independent, a significantly larger number of the patients in the intervention than the control group reported that they were independent in their ADL. On the other hand, all patients in the control group were not independent in their ADL. However, the significance difference between the two groups in this study was not found for the rate of readmission and fall.

This study found that the discharge planning was effective at shortening the length of hospital stay in elderly patients with a hip fracture in Malaysia. This finding is similar to the finding in previous studies [8]. As with Huang and Liang [8], this study provided a leaflet containing information on the hip fracture, the types of surgery and post-surgery, and self-care of the hip bone surgery to the subjects soon after they were admitted to the hospital. According to Walker [19], written information about and the expectations after surgery along with personal care encourages the patients' involvement in their post-surgery self-care. As a result, this may have allowed the subjects of the intervention group in this study to start their ambulatory process earlier and thus they were discharged earlier.

Previous studies have also shown that the discharge planning reduced the rate of readmission in elderly patients with a hip fracture [8]. In contrast, this study did not find a similar result. In this study, the rate of the readmission for the intervention and control groups was two and zero respectively. Although the rate was different, it was not significant. This could be due to the small sample size. According to Grove, Burns and Gray [20], with a large sample size, the ability of the statistical test to detect a significant difference is high even if the size of the difference is small.

Unlike the readmission rate, the finding for the fall rate in this study is similar to that of the previous studies that did not find there to be a significant difference between the intervention and control group [21]. In this study, there were no incidences of fall reported by the subjects in the control and intervention group respectively. As for the rate of readmission, the non-significant difference in the fall rate between these groups may also be due to the small size [22].

Providing health education is an important component of discharge planning as it facilitates the patients being independent in their ADL after discharge [14]. Previous findings have demonstrated that patients who received discharge planning had higher independence level in ADL than the patients who did not receive discharge planning[23]. These findings are consistent with the current study. Previous studies also reported that a greater number of patients who received the discharge planning were independent in performing their ADL compared to those who did not have their discharge planned. This finding is also similar to that of the previous studies [18].What is surprising in this study is that all subjects in the control group were dependent on others for their ADL whereas in previous studies, there were patients who were independent in the ADL too [14]. This difference may be explained by the fact that the ADL in this study was measured a month after the discharge whereas the previous studies made the measurement three months after discharge. Without discharge planning, the control group in this study may need a longer time to be independent in their ADL.

It should be noted, however, that discharge planning in this study only focused on the implementation stage (health education) without the other stages (assessment, diagnosis and prescription)[24]. Therefore, the leaflet was general and not individualized according to the patients' needs. Furthermore, the follow up stage was conducted within one month after the patients were discharged whereas Fukui et al. [25] suggests that a longer period between 6 months to 1 year is

required in order to see the patients' progress. In addition, the study had a small sample size which may have caused the study power to detect the significant difference to be weak [26].

Nevertheless, it is recommended that the discharge planning should be introduced and practiced by the nurses when caring for elderly patients with a hip fracture who had undergone a surgery. In order to do this, the nurses' knowledge on discharge planning should be strengthened by their nursing organization. This is required as strong knowledge may enhance the nurses' skills and efficiency in handling the patients' discharge planning [27]. The head or clinical nurse should provide workshops related to discharge planning for all nurses in order to enhance their understanding of the interdisciplinary relationships [28]. A sufficient number of nurses, however, is needed to implement the discharge planning.

In addition, a similar study using a larger sample size is warranted. This study also needs to be performed for longer period starting with the assessment stage so then the health education content can be given according to individual needs. The patient's readmission and fall rate and ADL should be measured in the various stages – 3 months, 6 months and 1 year - in order to see the differences in the achievement of ADL after the surgery. Furthermore, the inclusion of other dependent variables such as the mortality rate and quality of life are also recommended in order to examine the wider impact of discharge planning.

5. Conclusion

The study found that the discharge planning was effective at shortening the length of the hospital stay and it also increased independence in the ADL. Therefore, discharge planning should be considered to be integrated into the nursing practices. However, future research involving a larger sample size and all stages of discharge planning as well as other dependent variables that, when conducted for a longer period, are warranted to examine the effectiveness of the discharge planning.

VARIOUS SELF EFFICACY BENEFITS PROGRAM IN BIOLOGICAL, PSYCHOLOGICAL, AND SOCIAL ASPECTS OF PATIENT WITH TYPE 2 DIABETES MELLITUS : A SYSTEMATIC REVIEW

A Mufidah[1], N T Septiana[1], T A Firmanti[1], N Fajriyah[1]
[1]Magister of Nursing, Faculty of Nursing, Universitas Airlangga, Surabaya
E-mail: ainul.mufidah-2018@fkp.unair.ac.id

ABSTRACT

There are various benefits found in type 2 diabetes patients using self efficacy, one of which is related to quality of life and glycemic control. We analyzed some of the literature related to self efficacy in type 2 diabetes starting from the biological, psychological and social aspects. Literature search through databases uses the PRISMA approach from: Scopus, SageJournal, Proquest, and Pubmed limited for the past 6 years; from 2014 to 2019 and 12 articles were selected from 168 articles found. This systematic review found five programs combined with self efficacy, namely DSME, Self care behavior, self-care management, HbA1c control management and behavior modification. Most of the results of the study showed the impact of self-efficacy intervention programs to increase HRQoL, decrease HbA1c, level diet and self-care behavior. The recommended that educational interventions be carried out to improve patients'self-efficacy to better deal with stress in their lives.

Keywords: education, self efficacy, intervention program, diabetes mellitus type 2

1. Introduction

Diabetes is a chronic condition that is associated with a number of severe complications that represents public health. It has a substantial burden that affects all age groups throughout the world. As many as 30 million people worldwide were diagnosed with diabetes in 1988. In 2000, the prevalence of diabetes increased to 150 million, with the International Diabetes Federation (IDF) estimating the prevalence of diabetes as 371 million in 2012[1]. The complexity of diabetes mellitus and its complications affects the working life of the patients, in addition to their interpersonal relationships, social activities, physical and mental status, and thus it can damage their quality of life[2].

Quality of life relates to an individual's sense of well-being, which naturally arises from a person's subjective evaluation of the positive and negative aspects of his life related to "their goals, expectations, standards, and problems. This is a broad concept that is complexly influenced by a person's physical health, psychological state, personal beliefs, social relations and their relationships with prominent features of their environment ”[3].

For several years, the self-management of structured peer support programs for chronic diseases have been given as a means of strengthening activation, understanding the patients' own role

in the care process and having the knowledge, skills and confidence to take on that role[4]. Peer support refers to the support of someone whose knowledge comes from their own experience with specific conditions. The World Health Organization considers this particular support promising as an effective approach to diabetes management. Face-to-face programs are one of the most important peer support models with the Chronic Disease Self Management Program (CDSMP) developed by the University of Stanford to be one of the most widely used[5].

One of the key factors involved in achieving active self-care is self-efficacy, which is a construct of social cognitive theory that focuses on one's self-confidence in carrying out the behavior given. Several studies have documented the relationship between self-efficacy and social care diabetes cognitive theory which also emphasizes the interaction between individual factors and the environment in shaping behavior[6],[7]. More and more research shows that self-care behavior affects glycemic control. But only a few patients do full self-care behavior according to the recommended level. It is important for diabetes that service providers must understand the factors that influence self-care behavior[1],[8].

2. Methods

2.1 Search strategies and study selection

This systematic review use a PRISMA review (Figure 1). The literature search was conducted in four databases such as Scopus, SageJournal, Proquest, and Pubmed with limited results for the last 6 years from 2014 to 2019. The key words used in the literature search were self-efficacy, self-care management and type 2 diabetes mellitus.

2.2 Types of studies

This systematic review aimed to identify the various benefits obtained in type 2 diabetes patients using self-efficacy. Many of the research studies that have been conducted with various types of research methods are cross-sectional predominantly. There were also quasi-experimental methods and RCTs used.

2.3. Criteria for inclusion and exclusion

The inclusion criteria for this article were articles that use English and that describe self-efficacy programs for the self-care management of patients with type 2 diabetes mellitus.

2.4. Participants, Interventions, Comparisons, Results and Study Design (PICOS)

The feasibility of the study was assessed using the PICOT approach: the participants were patients with type 2 diabetes mellitus, the intervention used programs combined with self-efficacy, namely DSME, self-care behavior, self-care management, HbA1c control management and behavior modification. The results looked at the increased HRQoL, decreased HbA1c , level of diet and self-care behavior.

3. Results

The total articles collected were 12. After reviewing the results, we found 5 programs combined with self-efficacy, namely DSME, self-care behavior, self-care management, HbA1c control

management and behavior modification.

3.1 Self-efficacy (knowledge, understanding, skill, and behaviors self management)

A 1-year prospective cohort study was conducted in diabetes tertiary hospital clinics affiliated with universities in Bangkok between April 2010 and July 2011. The initial group of 594 diabetic patients recruited for the study used a three-step approach. First, using the information in the medical records, the clinical patients were examined at the time of their visit if they met the inclusion criteria (having type-2 diabetes mellitus, being treated with insulin, age> 20 years). The exclusion criteria were having more than five comorbid conditions, being pregnant or lactating, using contraceptive pills, being infected with HIV, having a psychiatric illness and refusing participation [9].

Second, eligible patients went through random selection using random numbers. Finally, the patients were selected voluntarily and gave consent. The recruitment process took about 4 months to complete After the informed consent of the patient was obtained (month 0), the patients in both groups were followed every 3 months for the year at the end of months 3, 6, 9 and 12. In addition to month 0's self-efficacy test, the interview self-efficacy questionnaires were repeated at the 3-monthly visits of 3, 6 and 9 respectively. Using the pre-design information sheets, the data on AE and near misses in the periods 1-3, 4-6, 7-9 and 10-12 Months were collected at each 3, 6, 9 and 12 visits. At each visit, the patients were interviewed by a nurse from a different clinic and by staff trained on the research objectives, methods, patient rights, self-efficacy questionnaire and the application information sheet about AE [10].

During the 1 year follow-up period, there were 47 AE reports and 367 almost failed from within both groups. In the low self-efficacy group, around 39 AEs were reported, equal to 2.12 events per 100 person-months. With the exception of one case that experienced two AEs in months 7-9 and months 10-12 months, the rest of the group only experienced one event in more than a year. The distribution of incidents was quite level because there were 11, 8, 11 and 9 events in months 0–3, 4–6, 7–9 and 10-12, respectively. Nearly 80% of events occur at home, while only 18% occur in public places. Nearly 43% occurred after dark, between 10:00 a.m. and 6:00 a.m. The program first presented with dizziness (14.6%), fainting (12.7%) and syncope (7.0%). After an emergency or hospital visit, the most common diagnosis was hypoglycemia (84.6%), followed by hyperglycemia (7.7%). Other diagnoses included diabetic ketoacidosis and severe hypoglycemia. About 16 cases were received (41.0%). There was no permanent disability or death [1].

3.2 Relationship between self-efficacy, self-care behavior and glycemic control

The participants were given a set of DMSES-Malay Language and SDSCA-Melayu Version questionnaires. Clear written and oral instructions were given about how to fill in the questionnaire. They were asked to circle or check which option suited them the most. The participants were encouraged to seek clarification from the investigators at any time if there were questions. They were also reminded to answer the questionnaire themselves rather than getting help from their accompanying family members. The participants were given a pen to fill out a questionnaire in the corner of the clinic equipped with tables and chairs. The researchers ensured that the participants did not interact with each other when answering the questionnaire. On average, the participants needed about 10 to 20 minutes to complete the questionnaire. After it was finished, they submitted the questionnaire to the investigators who then examined the responses for completeness [8].

420 patients with T2DM were approached and invited to enter the study room. Of these, 22 patients (5.2%) refused to participate and 58 patients (13.8%) did not qualify to enter the study because they did not meet the inclusion and / or exclusion criteria. Therefore the level of recruitment for this study was 81%, giving a total of 340 patients who met the requirements with T2DM who completed the questionnaire [8].

This study showed a high average self-efficacy score (7.33) and the participants were found to be the most effective at tasks related to drug intake and they were the least efficacious at testing their blood glucose. This finding is comparable with the studies conducted in a hospital setting in Malaysia which showed an average self-efficacy score of 7.57 where the highest score was for drug intake. In contrast, the study population was the least effective at meal plans [11].

Similar findings were found in a Jordanian study that showed an average self-efficacy score of 7.26 with the highest score for efficacy focused on taking medication. The participants were least confident when doing physical activity. A possible explanation for the highest self-efficacy being for drug intake is that this is a direct task that does not require much effort to do. A low self-efficacy score when conducting blood glucose testing in our study population highlights the need to educate patients about blood glucose self-monitoring (SMBG) to increase their self-efficacy at performing the task [12].

3.3 Efficacy of the self-management education program

The intervention consisted of a 2.5-hour workshop once a week for 6 consecutive weeks. The group consisted of 8 to 15 people per participating center. All of the workshops were facilitated by two leaders, one of whom was diabetic or an adult caregiver with T2MD. The other was a health care professional. Ordinary care for T2DM is mainly provided by professional primary care and diabetes education is usually offered by the nurses individually [5].

The n = 594 individuals were recruited randomly to the intervention (n = 297) and the control group (n = 297). Overall, n = 62 participants were lost to the follow-up. Learning took place between September 2011 and December 2014, with 80% of the participants attending at least 4 sessions. The participants had an average age of 63.9 years and 59.8% were men. The average time since the diagnosis of the disease was 9.9 years. The two study groups had similarities in terms of age, time from diagnosis and comorbidity, but a higher percentage of men were observed in the intervention group. In the beginning, 45% of participants had HbA1c levels of ≥ 7%, while levels of ≥8% were seen in 18% of the samples; 2 years after the follow-up, no significant differences were observed between the intervention and control groups in terms of the changes in HbA1c or in the secondary cardiovascular outcomes such as blood glucose that controlled both pressure and cardiovascular risk [5].

After a 2-year follow-up, no differences were found in the HbA1c evolution between the patient interventions and controls. Likewise, there were no effects seen in other clinical outcomes, such as the risk of heart disease. In addition, a downward trend was observed in primary care and emergency department visits, with the intervention group presenting lower values than the controls. The consumption of drugs also declined in the intervention group. The intervention significantly strengthened the patient's self-efficacy, specifically related to disease control. The only habitual diet presented little but fruit consumption had no clinically significant difference. The participants

reported high satisfaction with the program [13].

4. Discussion

This systematic review aimed to identify articles focused around self-efficacy programs for patients with type 2 diabetes mellitus. The reason for conducting this systematic review was related to type 2 diabetes mellitus as a major cause of chronic morbidity and mortality worldwide. The treatment of type 2 diabetes mellitus requires a process that is long; the patients need good self-management strategy to manage the disease. We need to know what self-efficacy intervention programs we can use to manage the disease. From the results of a review of 12 articles, all of them showed that self-efficacy intervention programs had a positive impact on type 2 diabetes mellitus patients. Most of the results of the study showed that the impact of the self-efficacy intervention programs improved blood sugar control and quality of life, and increased the level of physical activity, self-efficacy, skills and knowledge related to self-management. These results were obtained from 4 articles relating to improving quality of life [10,14–16]. There were 4 articles that explained the improvement of self-management skills and knowledge. There were 4 articles that explained the effects of lifestyle changes (increased physical activity and exercise performance) [2,8,17,18]. This result was obtained from 2 articles related to the decline in the publication of exacerbations and hospitalization.

5. Conclusion

The self-intervention program can be used as an effort to improve self-management skills for controlling HbA1c and improving the quality of life of patients with type 2 diabetes mellitus. The role of nurses in this case is as educators and facilitators in implementing self-efficacy interventions. Nurses are expected to be able to provide good education about self-efficacy in patients with type 2 diabetes mellitus including the treatment of diseases based on adequate coping behavior, including controlling blood sugar, activity and diet. The patients should actively participate in applying self-efficacy to their disease.

ABSTRACT

Infestation of ectoparasites, especially insect infestations is a factor that can threaten the health of the community, one of which is Pediculus humanus capitis. In Indonesia many occur in school children who live in dormitories. This study aimed to identify correlation between female student behavior and infestation *Pediculus Humanus Capitis*. One of the modern islamic boarding school in the district of Banjar, South Kalimantan province was chosen as the place of research. The study design used cross sectional. The sample total of 211 second grade junior high school students in boarding schools selected by total sampling. The questionnaire used was the KAP (knowledge, attitude, practice) adaptation questionnaire that had obtained permission and had been tested by experts, will be analysed by Pearson correlation test. The result was the infestation of *Pediculus Humanus Capitis* experienced by female student was corelated by the level of knowledge of female student *Pediculus Humanus Capitis* with $p<0.05$, and was influenced also by the practice of female student in personal and environmental hygiene with $p<0.05$. The incidence of infestation of *Pediculus Humanus Capitis* in the islamic boarding school is influenced by the knowledge and practice of female student.

Keywords: pediculusu humanus capitis, behavioral, female student

1. Introduction

Infestations of *Pediculus Humanus Capitis* can threaten the health of the community[1]. *Pediculus Humanus Capitis,* known as head lice, usually cause interference for adults and especially school children[2]. Pediculus humanus capit is generally spread through direct transition, such as with by head contact with an infected person, or by contact with clothes, hair combs, hats, towels, or other personal items as an agent[3]. Diseases caused by the infestation of *Pediculus Humanus Capitis* are still categorized as overlooked diseases, and many are found throughout the world, especially in developing and poor countries[4][5]

Epidemiologically, the spread of pediculus humanus capitis is more common among children, especially school children living in hostels. This risk behavior is influenced by the habits of children in maintaining personal and environmental hygiene, and inadequate hostel facilities. Pediculus humanus capitis occurs throughout the world, according to the Center for Disease Control and Prevantion (CDC) in the United States. Their data shows that 6-12 million people are infected each year[6]. In developed countries such as Norway, the incidence of *Pediculus Humanus Capitis* at

97.3% occurs in elementary school children[7]. Pediculus humanus capitis is generally common in school children around the world, according to the latest data that reported that more than 12 million girls, especially in the age range of 3-11 years, had experienced an infestation of *Pediculus Humanus Capitis*. The highest prevalence (59%) was found in developing countries and tropical countries[8]. The incidence of infestation of *Pediculus Humanus Capitis* in Indonesia was found in many school children.

This study conducted a preliminary study of 20 female students who had all experienced an infestation of *Pediculus Humanus Capitis*. The average student experienced an infestation of pediculus humanus capitis when entering Islamic boarding schools. Based on the results of the interviews with the female students on the incidence of infestation by *Pediculus Humanus* Capitis, it was foun that it was because of the behavior of the female students, their lack of knowledge and because of the habits of the female students such as borrowing accessories that are personal like a comb or hair band, the habit of the students to wear a headscarf when their hair was still wet, and some of the students said that they often wet their hair but that they did not use shampoo.

The infestation of *Pediculus Humanus Capitis*can leads to psychological disorders in teenagers, namely shame, isolated inferiority, fear, and even frustration due to the stigma of people who consider *Pediculus Humanus Capitis* to be synonymous with poor hygiene, poverty, and a lack of attention from the parents of the sufferers[10]. The psychological impact caused by this disease can affect the quality of their sense of self, both in performance and in the learning achievements of the students who are infested[12].

Nursing actions carried out to prevent the occurrence of infestations of *Pediculus Humanus Capitis* are namely by increasing the behavior of the students related to prevention. It is hoped that the students can change their behavior so then they can prevent the infestation of *Pediculus Humanus Capitis* in Islamic boarding schools. One way to do that is by fostering the confidence and intentions of the female students related to clean and healthy behaviors[13]. This study aimed to determine the relationship between the behavior of the female students in terms of the prevention and treatment of infestation with the incidence of infestation of *Pediculus Humanus Capitis*.

2. Research Methods

This study utilized a cross-sectional design using primary data. The data collection was conducted during February 2019. The population was made up of all female students who were in grade 2 in a junior high school in Pondok Pesantren Darul Hijrah Puteri Martapura Banjar District, South Kalimantan, with a total sample of 211 people who fit the inclusion and exclusion criteria. The female students were grade 2 juniors aged 13-15 years who were at a boarding school. This research was conducted by asking the students to agree to be respondents, and then by giving them an explanation of the research and an informed consent form. This study used a questionnaire consisting of knowledge and behavior. This questionnaire was copied and modified from the KAP (knowledge, attitude, and practice) questionare following the details of the framework provided by Lazarus. It consisted of 27 questions; 15 questions were about knowledge and 12 were about practice. The answer choices used were true and false. The questionnaire that was carried out was tested to determine the validity using the Pearson product moment test. Bivariate analysis was used in this study to determine the relationship between the behavior of the incidence of infestation by *Pediculus Humanus Capitis* and the Pearson correlation test was used to determine the relationship between

knowledge and the incidence of infestation *Pediculus Humanus Capitis*, and the presence of female practices on the incidence rate of infestation *Pediculus Humanus Capitis*.

Infestation of *Pediculus Humanus Capitis*	8	3,8	3,8	1 time
	49	23,2	27,0	2 times
	39	18,5	45,5	3 times
	22	10,4	55,9	4 times
	93	44,1	100,0	Countless
Independent (Behavioral)				
Knowledge	20	9,5	9,5	Deficient
	80	37,9	47,4	Moderate
	111	52,6	100,0	Good
Practice	99	46,9	46,9	Deficient
	59	28,0	74,9	Moderate
	53	25,1	100,0	Good

Table 1 presents that the incidence rate of the infestation of *Pediculus Humanus Capitis* an it indicates that it was dominated by countless categories of 44.1%. Student behavior including knowledge about the understanding, prevention and treatment of *Pediculus Humanus Capitis* was dominated by the good category, which was 52.6% while the moderate category was 37.9%. The practice of female students in preventing the infestation of *Pediculus Humanus Capitis* as well as of maintaining personal hygiene and the cleanliness of the room (hostel) was dominated by the poor category at 46.9%.

Tabel 2. Results of the Pearson correlation test on the infestation of *Pediculus Humanus Capitis* with knowledge

		Infestation of pediculus humanus capitis	**Knowledge**
Infestation of *Pediculus Humanus Capitis*	Pearson Correlation	1	.496**

Practice	Pearson Correlation	-.176*	1
	Sig. (2-tailed)	.010	
	N	211	211

*sig < 0,05 shows significance

Table3 presents that the relationship between knowledge and *Pediculus Humanus Capitis* infestation events is sig <0.05 (.010).

4. Discussion

Knowledge is the result of knowing from someone after doing in the form of sensing through smell, taste and touch. Human knowledge is obtained through the senses[14]. Knowledge is the result of knowing and this happens after people have sensed an object[15]. There are six stages in the creation of knowledge, namely: knowing, understanding, application, analysis, synthesis and evaluation. In this case, the female students know about *pediculus humanus capitis* and how to transmit it, and they understand the forms of transmission. However, the female students have not yet been able to apply their understanding of *pediculus humanus capitis.* This is because the female students are still unable to practice a conductive environment to non-transmission because of the situation or condition not being supportive. Many factors influence a person's knowledge. The first factor is the education factor. Knowledge generally can be obtained from the information conveyed by the parents, so the parents' education has a strong influence on the knowledge gained by the female students about pediculus humanus capitis. Employment, regarding the work of the parents of the female students, is very influential on the process of accessing the information needed by the female students about *pediculus humanus capitis*. There are also socio-cultural factors, culture and habits in Islamic boarding schools that can affect the knowledge, perceptions and attitudes of the female students towards the prevention of *pediculus humanus capitis*. Based on the previous research, an increase in knowledge can change a person's attitude when they are conducting preventative practices in reducing the incidence of infestation of *Pediculus Humanus Capitis*[8]. A person's knowledge about *Pediculus Humanus Capitis* also influences the treatment and prevention of a person's risk of being infected with *Pediculus Humanus Capitis*[16]. Providing health education can also increase one's knowledge about *Pediculus Humanus Capitis*[13]. In a study where it was found that the knowledge was good enough about *Pediculus Humanus Capitis*, there were still many infestations due to their lack of attention to the health of the skin, especially the scalp[7]. It can be concluded that the good knowledge about *Pediculus Humanus Capitis* that is obtained by a person is very influential in terms of preventative medicine and in the prevention of the risk of *Pediculus Humanus Capitis* infestation. However, not all who have good knowledge understand the health of the skin, especially

the scalp, so they still experience infestation.

The female students' personal practices also affect the frequency of the occurrence of infestations of *pediculus humanus capitis*, as evidenced by the habits of the students who borrow and lend personal items. Human behavior comes from impulses that exist while encouragement is an effort to meet the needs that exist in humans. Human behavior does not occur sporadically (arising and missing at a certain moment), but there is a sense of continuity between one act and the next [14]. Moreover, practices are one of the factors that can cause an infestation of *Pediculus Humanus Capitis*. Based on the research conducted by Yinklang (2018), they stated that increasing knowledge can change a person's attitude in doing prevention practices to reduce the incidence rate of infestation of *Pediculus Humanus Capitis*. Personal hygiene practices are also an important key in determining the spread of *Pediculus Humanus Capitis*, such as increasing the knowledge so then it can change the practices of maintaining cleanliness. Maintaining personal hygiene includes the frequency of washing their hair, using shampoo, the habit of combing their hair, the habit of changing their headgear (veil) and changing their bedding; poor habits referring to the aforementioned can be a cause of infestation of *Pediculus Humanus Capitis*. Environmental hygiene also greatly affects infestation, such as a humid environment and a hot room temperature, which can cause the development and infestation of *Pediculus Humanus Capitis*[17].

The habits of teenage children who live in a dormitory, sometimes involving a group of peers (peer goroup) as a container for adjustment, often results friendship, which is the hallmark of the nature of the interactions – there is a certain closeness. The assumption is that the personal belongings of one's friends are legitimate if borrowed, which are used together with their group mates, and that it is common to consider so. The results of the previous studies indicated that the behavioral factors refer to where you are able to control your behavior but where you are not supported by the surrounding environment, such as having dorm roommates who still likes to borrow personal items, friends who do not want to treat pediculus humanus capitis, those who borrow a pillow or blanket, and those who maintain a less clean environment around the dormitory. The previous research states that personal hygiene behavior is an important key to determining the spread of infestation of *pediculus humanus capitis*[18].

5. Conclusion

Based on the statement above, there was a relationship between the behavior consisting of knowledge and the practices of female students on the incidence of infestation by *Pediculus Humanus Capitis*pitis in the boarding school of Darul Hijrah Puteri Martapura. This was due to the behavior of the female students regarding their personal hygiene and the cleanliness of the environment. Teachers and health workers are expected to develop a health promotion strategy based on this research for the inspection and prevention of an infestation of *Pediculus Humanus Capitis*so so then the incidence of infestation by *Pediculosis* in boarding schools may be reduced.

BEHAVIOR USING GADGET IN CHILDREN AGES 3 TO 5 YEARS

Tiara Lani[1], Pudji Lestari[2], and Eka Mishbahatul M.Has[1]

ABSTRACT

The gadget is a tool that has many uses that contain various applications and information about everything, this technological advancement makes someone able to spend hours in front of the gadget screen. Currently the use of gadgets is not only for adults but also for children. This study aims to identify the use of gadget in children aged of 3 to 5 years. This research is descriptive exploratory research design with a sample of 184 respondents children aged 3 to 5 years in the area of the village of Jawa, South Kalimantan. Data collection using a questionnaire Adult Involvement In Media Scale (AIM) adaptation that had obtained permission and had been tested by experts. The data taken are attitudes and time use of gadgets. The result attitude of parents in the use of gadgets to children was 69.8% including the adequate category and 87.5% children spent more than one hour a day with a gadget. Parents should have rules for using gadgets in children to prevent health problems or addiction to gadgets.

1. Introduction

A gadget is an object or tool that is created specifically with the aim of helping things to become easier and more practical. Examples of gadgets include laptops, smartphones, ipad and tablets [1]. Gadgets are not only used by adults, but they are now also used by young children under the age of five (Rideout, 2013). Fun gadget applications and programs have become friends for children. According to the research by[2], the result of their study was that children can spend their time in front of the screen for 4 hours per day. This is contrary to the opinion of [3] which states that children should only be in front of a screen <1 hour every day. Children aged 3 to 5 years should do social activities together with thir peers, family members and the surrounding environment[4].

In 2014, according to the Indonesian Ministry of Communication and Informatics (KEMKOMINFO), gadget usage in Indonesia is high, based on the survey results that 98% of internet users are children and adolescents. A study in Kuwait and the US revealed that children use mobile devices jointly with their parents or close family [5]. The results of the study shows that as many as 90% of parents download special applications for their children[6]. Based on an experimental study conducted in Martapura city focused on 20 parents of children aged 3 to 5 years old in the area of South Kalimantan, a total of 85% of preschoolers spend more than 1 hour every day on gadgets and as many as 15% of children use gadgets during the holidays.

Parents need to limit the gadget use of their children. An excessive use of gadgets may lead to addiction. Gadgets addiction in children can be seen from several signs such as tantrums when asked

to stop playing gadget, not responding to parent's calls, and academic performance decreases because the child is no longer interested in the school learning material [7]. The purpose of the study was to find out the usage duration of gadgets in children and the parents' knowledge of gadget use in children aged 3 to 5 years.

2. Material and Method

This study was a descriptive exploratory study and the data was collected through cluster sampling[8]. The rsearch was done at *Kampung Java* in South Kalimantan. As many as 184 participants consisting of mothers and their children were involved in the research. Parents or children with limitations such as speech and hearing impairments and psychological disorders were not included in this study. The research participants were given questionnaires related to knowledge and the duration of gadget use.

The independent variable was the parent's behavior related to gadget usage in children and the dependent variable was gadget usage in children aged 3 to 5 years. The researcher explained the purpose of the study going forward. The researcher asked for their willingness to become respondents and they then asked the parents to answer the questionnaire given to them. This research obtained a letter of ethical research No. 1274-KEPK Faculty of Nursing, Universitas Airlangga.

3. Results

Table 1. Results in terms of knowledge

Respondent's answer	n	(%)
Right	160	86.95
Wrong	24	13.05
Total	184	100

Table 1 shows that the parents' knowledge about the use of gadgets in children aged 3 to 5 years has been included in the good category because 86.95% or 160 respondents answered the questions correctly.

Table 2. Results for the time using the gadget

Usage duration	**n**	**%**
1 jam	26	14.1
>1 jam	158	85.9
Mean		2.6 jam/hari
Minimum		1 jam/hari
Maximum		6 jam/hari

Table2 shows that gadget usage for children aged 3 to 5 years is dominated by >1 hours usage (85.9%). Fewer children use gadgets for under an hour (14.1%)

4. Discussion

The parent's knowledge influences the care of the children with the process of growing and educating children, provide protection and care for children. The parents need to have knowledge about the gadget safe duration for children. In this study, most of the parents have good knowledge, but the duration of the use of gadgets in children is for more than 1 hour a day. This is because the parents consider gadgets to be a form of technology that is hard for children to avoid. Sometimes the screen time restrictions made by the parents means that they have to face their child crying. This drives the parents to provide gadgets to their children despite their knowledge about the benefits of gadget time restriction. The determination of a complete attitude is influenced by the knowledge, thoughts, beliefs, and emotionak state of a person. The factors that can influence attitudes are socio-cultural conditions[10]. A way to measure or assess one's knowledge is to use a scale or questionnaire[11].

The parents must consider how much time is allocated to playing with gadgets in children aged 3 to 5 years old. The ideal duration for preschoolers to use gadgets is 30 minutes up to 1 hour a day[12]. The American Academy of Pediatrics recommends no gadget use for children aged of 0 to 3, while children aged 3-5 years should be given a limit of around 1 hour per day. This goes up to 2 hours per day for children aged 6-18 years. However, Indonesian parents mostly let their children use gadgets 4 - 5 times more than is recommended. The parents should be aware that screen time in children can affect their health[13]. The health effects that can occur in children under the age of 5 include obesity[14]. Social and emotional development is also influenced by the use of gadgets because the children feel comfortable in front of the gadget so the children forget about the surrounding environment[15].

5. Conclusion and Suggestion

The parents' behavior related to gadget usage, especially knowledge in children, was good but the screen time for children aged 3 to 5 years was dominated by more than an hour per day. It was expected that parents and public health workers have a strategy in terms of health promotion about the impact that can be caused by the extensive use of gadgets at an early age.

Parents must have rules about how much time allowed is allocated for the use of gadgets by children aged 3 to 5 years. The parents' knowledge of the use of gadgets is a a good basis for making decisions and determining the actions against problems.

6. Appendiks

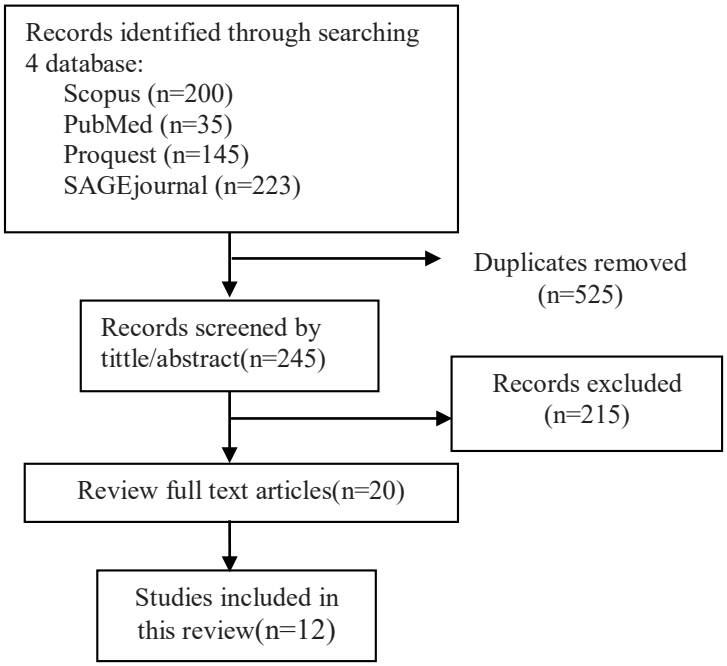

Figure 1. PRISMA flow diagram

Table 1. studies that form the basis of systematic reviews

Author	Type of study	Partisipants	Interventions	Outcomes
[1]	A prospective cohort study	n=157 group low self-efficacy n=153 group high self-efficacy	• Self-efficacy (knowledge, understanding, skill, and behaviors self management)	1. In DM patients with high self-efficacy, the incidence of errors in insulin use is lower than DM patients with low self-efficacy. 2. There is an influence between giving education about self-efficacy in patients with DM, compared with patients who are not given education
[6]	Cross sectional	n=137	• Diabetes self-care • Self-efficacy • Social support • Glycemic control	1. Diabetes self care has a direct effect on glycemic control 2. Self-efficacy and social support do not directly influence glycemic control
[15]	Cross sectional	n=200	• Self-efficacy • Self care activities	1. There is a positive correlation between self-efficacy and self-care activities (diet, exercise, and general self-care, foot care, medication) 2. There is a negative correlation between depression and self care activities (diet, exercise, and general self-care, foot care, medication)
[18]	A cross-sectional, descriptive study	n=75	• Self-efficacy • self-care behaviours • glycaemic control	1. Glycemic control in men is better than in women, when undergoing combination therapy participants experience poor glycemic control. 2. The total value of self-efficacy affects diabetes self-care significantly. 3. Self-efficacy in regulating the blood glucose has a strong influence on glucose control.
[8]	a cross-sectional study	n=340	• self-efficacy • self-care behaviour • glycaemic control	1. There is a positive relationship between self-efficacy and self-care behavior. 2. The high value of self-efficacy is associated with good glycemic control.
[2]	Quasi eksperimen	N=115 (n control=22, n=93)	• Ability to discriminate • Adult Sensory Profile (AASP)	1. No significant differences were found between patients with control of diabetes mellitus and healthy groups with qualities of any life domain 2. Patients with uncontrolled glycemic levels report a lower quality of life compared to

				patients with controlled diabetes mellitus 3. Patients with uncontrolled glycemic quality of social life were significantly lower compared to patients with diabetes mellitus
[19]	qualitative	n=8	• Multiple daily insulin injection treatment regimens	1. Changes in HbA1c levels, insulin regimens and body weight are likely to be affected by HRQoL for diabetic patients. 2. A simple treatment regimen (fewer injections) will lose weight and will have a positive impact on HRQoL
[4]	Descriptive	n=319	• the Diabetes Self-Efficacy Scale	1. The diabetes self-efficacy scale is a reliable, valid instrument for determining patient self-efficacy and providing appropriate care. 2. It can be suggested to investigate and evaluate the consistency of the scale by applying it to sample groups representing different socio-economic levels.
[17]	A cross sectional	n=123	• Self-efficacy, • self-care • glycemic control	1. Self-efficacy is associated with higher levels of diet, exercise, blood sugar. Self-management behavior and use of oral hypoglycemic drugs (OHA) were significant independent predictors of glycemic control of HbA1c <7% (53 mmol / mol). 2. The findings can serve to help doctors have a better understanding of the extent to which they have an influence on self-management behavior, which will ultimately lead to better glycemic control and thus can increase HbA levels 1c.
[5]	RCT	n=297	• Efficacy of a self-management education programme • Primary care to patients with type 2 diabetes	1. Decreased HbA1c is difficult to obtain in adequately controlled patients. On the other hand, increasing awareness of one's illness can increase disease control self-efficacy. 2. These findings, accompanied by a reduction in drug consumption and the level of use of health care, highlight that ordinary care will benefit by incorporating certain aspects of SDSMP.
[16]	Cross sectional	n=80	• Self-efficacy	1. The impact of stress on blood sugar and quality of life related to patient health can be influenced by their self-efficacy 2. Educational interventions are carried out to improve patients'

				self-efficacy to better deal with stress in their lives
[3]	cross-sectional	n=165	• self-efficacy • validation management diabetes	1. Higher levels of self-efficacy in lifestyle management were found in patients diagnosed at least 1 year to 15 years and aged> 65 years and the poorest efficacy found in men <65 years. 2. The results support the validity and reliability of IT-DMSES. This scale can be used in clinical research and practice to monitor type 2 self-management diabetes over time.

SCREENING BASED ON ANDROID WITH FRAMINGHAM RISK SCORE FRAMEWORK IN PATIENTS WITH CORONARY HEART DISEASE RISK (CHD): SYSTEMATIC REVIEW

Fatimah Zahra[1], Kusnanto[2], Padoli[3]
[1]Magister of Nursing, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
[2]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
[3]Surabaya Health Ministry Polytechnic, Indonesia
E-mail: fatimah.zahra-2017@fkp.unair.ac.id

ABSTRACT

In Indonesia, early or preventive detection of carciovascular heart disease (CHD) is largely ignored. Health workers are more focused on treatment and rehabilitation measures. The Framingham Risk Score (FRS) prediction model is used, to predict the occurrence of cardiovascular events in 10 years later. The purpose of this systematic review is to find out the effectiveness of screening based on android in patients with CHD risk. The literature searches for several major databases such as scopus, pubmed, and science direct databases from 2012 - 2018 were search for the relevant keyword. All included studies were access base on (1) randomized controlled trials, (2) cohort studies and (3) cross sectional. 13 out of 150 papers were included. An increase in adherence to patients after obtaining an android application. Framingham Risk Score is very sensitive to determine the risk of coronary heart disease in 10 years later for men and women. In conclusion, android-based screening can be used as a reference for early detection of coronary heart disease in 10 years later. Independent screening applications in patients can increase independence and reduce disability and mortality rates in patients with CHD risk for 10 years later.

Keywords: screening, android, framingham risk score, coronary heart disease

1. Background

Coronary heart disease (CHD) is a leading cause of death and disability worldwide [1] Globally, heart disease causes 31% (7.4 million) of deaths among those with CHD [2]. Coronary Heart Diseases (CHD) are widely accepted to be the most serious health care problems in developed countries [3]. The estimation of risk can theoretically be used to raise the population's awareness of CHD, which is that it causes a significant burden of morbidity and mortality. It is necessary to communicate the CHD risk efficiently in a public health setting[4]. However, the situation in primary care is not the same, particularly concerning the choice of methods used for calculating or classifying cardiovascular risk [3].

The Framingham risk score (FRS) is a simplified and common tool for the assessment of the risk level of CAD over 10 years [5]. FRS is the most applicable method for predicting a person's chance of developing cardiovascular disease (CHD) in the long term. This is because the risk score gives an indication of the likely benefits of prevention [5]

The current CHD screening application is widely used and it has a significant impact on early detection and improving quality of life. It can support the patients in their self-care and drug management. The patients can also access their electronic health records on their mobile devices, and they are activated and empowered to participate more in their own health care and in the management their long-term conditions[6]. We aimed, in this study, to find out the effectiveness of screening patients with a CHD risk.

2. Methods

The author searched the Scopus, Science Direct and Springerlink databases with the keywords "Screening", "Android", "Framingham Risk score" and "Coronary Heart Disease" and obtained 150 articles. The search was done by limiting the articles to 2012 - 2018 in terms of publication.

The inclusion criteria created by the authors were as follows:

1) Patients do not have a CHD history
2) Screening based on the Framingham risk score
3) Android application
4) Quantitative studies with a randomized controlled trial, cohort or cross-sectional design

The exclusion Criteria were as follows:

1) Patients who have been hospitalized
2) Early detection using a clinical examination
3) Qualitative studies.

3. Results

Figure 1 shows the literature search method. The search engines found 150 articles that were then selected based on the topic and research variables to find 185 appropriate articles. They were then re-selected according to the research variables to get 96 articles. Re-selection using the inclusion criteria narrowed it down to 13 articles. We then performed a critical appraisal to review the content, design and research method.

The research in this systematic review was diverse and taken from various countries. Two studies were conducted in Iran (15%) and Malaysia (15%). The studies conducted in China totaled three (23%) and there was one each in Europe, Australia, America, Spain and Japan. One study (7.6%) used a Randomized Control Trial design study and only five studies (38.4%) used a Cross-sectional Study design. Seven studies (54%) used a Cohort design study.

The sample size varied from 174 people to 73,277 people. One research study focused on android applications and 12 other studies focused on the Framingham risk score for patients with coronary heart disease risk in order to predict of coronary heart disease (CHD). One study focused on improving treatment adherence and cardiovascular lifestyle[7]. Eleven other studies focused on examining the risk of coronary heart disease using the Framingham risk score framework for the prediction of coronary heart disease in the next 10 years. One study focused on comparing the Framingham risk score and WHO[8].

There are many similarities between the studies that focus on a CHD risk assessment using the Framingham risk score framework. [9] compared the Framingham risk score before and after calibration to find out the different functions and to assess the utility of the framework. This was

confirmed by the research of [5], who conducted an evaluation of the Framingham risk score for measuring the risk of heart disease in patients with metabolic syndrome. Whereas the research of[10] sought to determine which metabolic syndrome fully reflects the CHD probability of the next 10 years based on the Framingham risk framework

Culture can also influence the differences in the research results. Some researchers have tried to compare this [11] by assessing the risk of CHD in multiethnic groups between Asian and Caucasian women. Individuals have also examined the performance of FRS in the Middle East[4] as well as[12], who examined the validity, convergence and sensitivity of FRS in diabetic patients in China. Because FRS was first performed on Caucasian ethnicities, some researchers wanted to examine its effectiveness if it was carried out in ethnic Asian, Mongoloid and Middle Eastern countries.

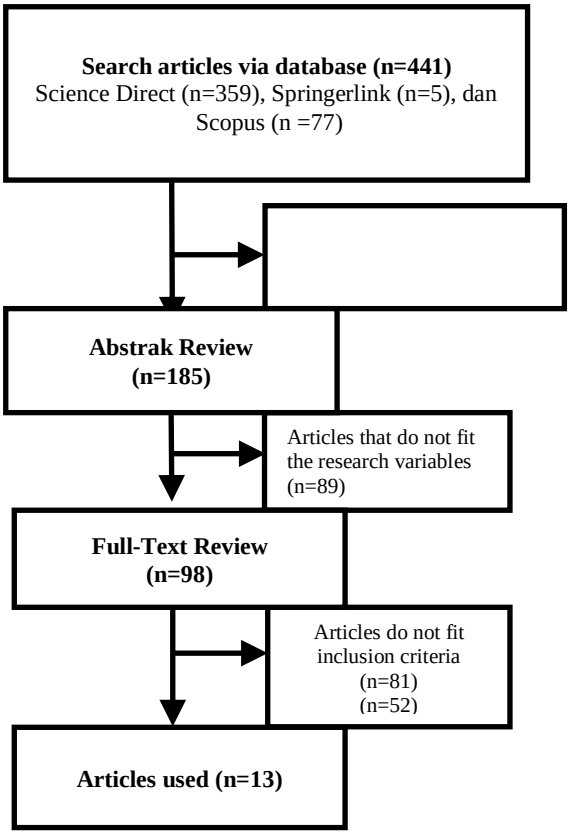

Figure 1 - Review of the literature method

Apart from ethnicity, the underlying problem affecting CHD is socio-economic. Predicting the risk of cardiovascular disease (CHD) in low-income urban residents in metropolitan Malaysia is one example of this[13]. Whereas[14]perfected this by exploring the correlation between socio-economic status and lifestyle on the incidence of CHD.

The development model of the Framingham risk score to improve the sensitivity of early CHD predictions was carried out by [15]. [16] compared the FRS (Framingham Risk Score) and Suita score (prediction model of Japanese CHD) because of reports of low FRS capabilities related to predicting coronary heart disease (CHD) in Asian populations.

4. Discussion

The Framingham risk score is a framework used for predicting heart disease in the next 10 years. Many countries have conducted research to test the framework. Standard risk factors (age, systolic blood pressure (SBP), total and high-density lipoprotein cholesterol, smoking and diabetes melitus) were measured at baseline and they are significantly related to the incidence of CHD [4]

His study[4] stated that the Framingham CHD framework is effective in terms of the ranking of individuals and that it can be used to measure risk and guide in terms of preventive care.

But in a population-based study of older adults, the Framingham risk score poorly discriminated between persons who experienced a CHD event and those who did not [9]. The overall Framingham risk score was significantly greater in men than in women, $P<0.001$, whereas this opposed the events during follow-up [3]. This was also confirmed by the study of[9] stating that traditional risk factors remain the best predictors of CHD events.

This is similar to the results of a study by [3] which stated that in both sexes, there is a difference in sensitivity but that the level of sensitivity is greater in women than in men. The results were in contrast with [10], which states that FRS has better results in men than women.

[11] examined the sensitivity of FRS in men and women in Asia, which stated that Asian women have a lower risk of CHD compared to Caucasian women.

Previous studies have also found there to be a lower performance of risk prediction based on the FRS associated with increasing age, but they didn't examine how CHD risk prediction might be improved among older adults. [9]. The performance of the FRS may be worse in the very old, with adults aged 85 years or older. In the present analysis among older adults, the FRS underestimated the absolute CHD risk, particularly in women [9].

Although FRS is a useful framework for predicting the risk of CHD, it also has several limitations that should be considered before applying its results to a population. First of all, the FRS is an estimation framework and it cannot be used as part of a medical examination. Secondly, because of the under-representation of a young population in the original cohort, the FRS may be an imprecise tool in this population. Thirdly, the FRS did not include several other potential CHD risk factors like a family history of CHD or diabetes [5]

This caused [16] to try to compare FRS with Suita. The result was that there were differences in the scores of the two, which were superior in terms of scoring in the Japanese population in terms of predicting the risk factors for the next 3 years. Whereas CHD risk predicted using Framingham is more sensitive when it comes to distinguishing the clinical risk groups in China [12]

The Malaysian studies concluded that health care expenditures, which are costs related to other diseases, and a loss of productivity due to CHD would worsen the situation of low-income urban populations[13]. Thus, public health professionals and policy makers must make a great effort to formulate public health policies and community-based interventions to minimize the possibility of high CHD mortality and morbidity among the residents of low-income cities by making CHD predictions as early as possible.

e-Health solutions have been shown to improve self-management, adherence to lifestyle modification, and medical therapy [7]. Smartphone apps have the potential to address the complexity of non-adherence behavior regarding both medical treatment and lifestyle modifications [7].

Finally, further information concerning the interventions and their results could be obtained by evaluating the changes in the CVR in both older persons (with a high risk and different levels of RF) as well as in younger persons (with a low risk but certain levels of 'treatable' RF) [3]. Although smartphones as a medium to improve health are still relatively new in the world of health, there have been many studies and significant results that show that they improve adherence and create positive life changes in patients[7].

It is expected that in the future, developing countries can take preventive measures against coronary heart disease by developing smartphone applications so then they can reduce mortality, morbidity and maintenance costs in hospitals.

5. Conclusion

The Framingham risk score is a framework for predicting CHD in the next 10 years. While there are pros and cons regarding its sensitivity between men and women, the Framingham risk score can be used globally. It is expected that future technological developments will be able to shift CHD to the digital era by using an Android smartphone so then FRS can reach more people. Mortality and morbidity can also be prevented by improving the preventive measures.

THE ROLE OF ENGAGEMENT FOR DECREASING TURNOVER INTENTION: A SYSTEMATIC REVIEW

N Dewanti, K N Beni, M M Prakosa, S W Purwanza, and I Yanriatuti
Master Student, Faculty of Nursing Airlangga University,
Surabaya E-mail: nisa.dewanti-2018@fkp.unair.ac.id

ABSTRACT

Engagement is an important aspect of organizational effort which can make employees express themselves physically, cognitively, and emotionally while working. "Engaged" employees will show how much they truly fulfill their job role and it is hoped that this will reduce turnover. This systematic review aims to examine the role of engagement to reduce turnover intention. The search was conducted in five databases, namely Scopus, ScienceDirect, PubMed, Emerald, and Researchgate using keywords 'engagement', 'turnover intention', and 'intention to stay'. The search identified 15 relevant articles published between 2014-2018. The result shows that engagement decreases turnover intention directly and as a mediator. Nine articles explained engagement as fully mediating role to reduce turnover. Variables that fully mediated by engagement are job characteristics, self-efficacy, job satisfaction, respect, decisional involvement, job and personal resources, psychological capital, training satisfaction, and person-organization fit. However, psychological capital and job satisfaction also acted as mediation between engagement and turnover intention. This study suggests that engagement can be used as a strategy to reduce turnover rates because engaged employees will continue to immerse themselves in work so that they have a little negative thinking such as leaving the organization.

Keywords: engagement, turnover intention, intention to stay, employee

1. Introduction

A stable workforce in an organization becomes a competitive tactic that is expected to be more vital in the future. Turnover among employees will always be a popular research topic among management researchers[1]. Employee turnover is still a global problem within organizations. A high turnover rate can result in a decrease in organizational competitive advantage, staff morale, work productivity, and the work quality of the employees[2]. Employee turnover also results in a loss of direct and indirect costs in the company, which can result in poor reputation, productivity, and organizational effectiveness. Direct cost losses usually relate to recruitment costs, training costs, and costs due to position vacancies, and indirect costs are associated with the increasing workload on the coworkers and the negative image of being a reputable company with high employee turnover[3]. Because of the negative impact caused by turnover in employees, it is necessary to find a way to keep employees in the organization.

Some studies report that one way to reduce turnover intention is by increasing engagement. Engagement is an important aspect of organizational effort which can make the employees express themselves physically, cognitively, and emotionally while working[4]. Work engagement describes the psychological condition of positive people who feel satisfied with their work. They feel very involved in their work, and this will have a positive effect on improving their mental and physical health and work performance, and this can reduce absenteeism and the turnover rate[5]. Engaged employees who have a positive energy will always be immersed in their work and so they will not have time to think negatively on matters like leaving the organization. The issue is in accordance with the theory of engagement where work will determine how long the employee lives in the organization. If the employee is doing the work then he will not intend to leave the organization at that time[1].

Based on the description of the background, the purpose of the current study was to systemically review and synthesize the evidence of the role of engagement to decrease employee turnover intention.

2. Research Methods

2.1. Search strategy

Systematic searches were carried out in the following databases: Scopus, Science Direct, PubMed, Emerald, and Researchgate. An extensive search for articles published from 2014 to 2018 was conducted. The keywords included ‘engagement,' ‘turnover intention,' and ‘intent to stay.' The search was done using a combination term of Boolean terms AND quotes. The research must use cross-sectional methods, longitudinal studies and a literature review of design reviews in order to answer the research questions. Additionally, only studies written in English were used for the current study.

2.2. Selection criteria

An article was included if it met the following criteria: 1) including research that discusses the influence or role of engagement on the turnover intention of employees, 2) measurements of engagement, 3) measurements of turnover intention, 4) original research and 5) including the employees as system users or study subjects. There was no limit as to the type of work and location of the data collection for the participants because the focus of the search was the influence or role of engagement. An article was excluded if it met the following criteria: 1) the results of the study do not explain the role of engagement on turnover intention and 2) they were theses, abstracts, or parts of a conference process.

2.3. Data extraction

The following data elements were extracted: author, year, country, theoretical framework, study design, sample, measurement, scoring, reliability, validity, analysis and the results of the study and whether it was significant or not significant. We extracted the outcomes used to evaluate the

effectiveness of the engagement for decreasing turnover intention. In the case of disagreement, differences were resolved through a discussion with all of the authors.

3. Result

3.1. Selection of studies

The search resulted in a total of 5,957 studies: 195 from Scopus, 55 from PubMed, 1117 from Science Direct, 25 from Researchgate and 4590 from Emerald. Of these, 47 manuscripts were relevant to engagement and turnover intention and they were screened using the inclusion criteria. The review process for the selected articles developed in three stages, including the title review, abstract review, and full-text review. Fifteen studies were maintained after screening for quality. All of the studies were quantitative. The retrieval and screening process has been summarized in Figure 1.

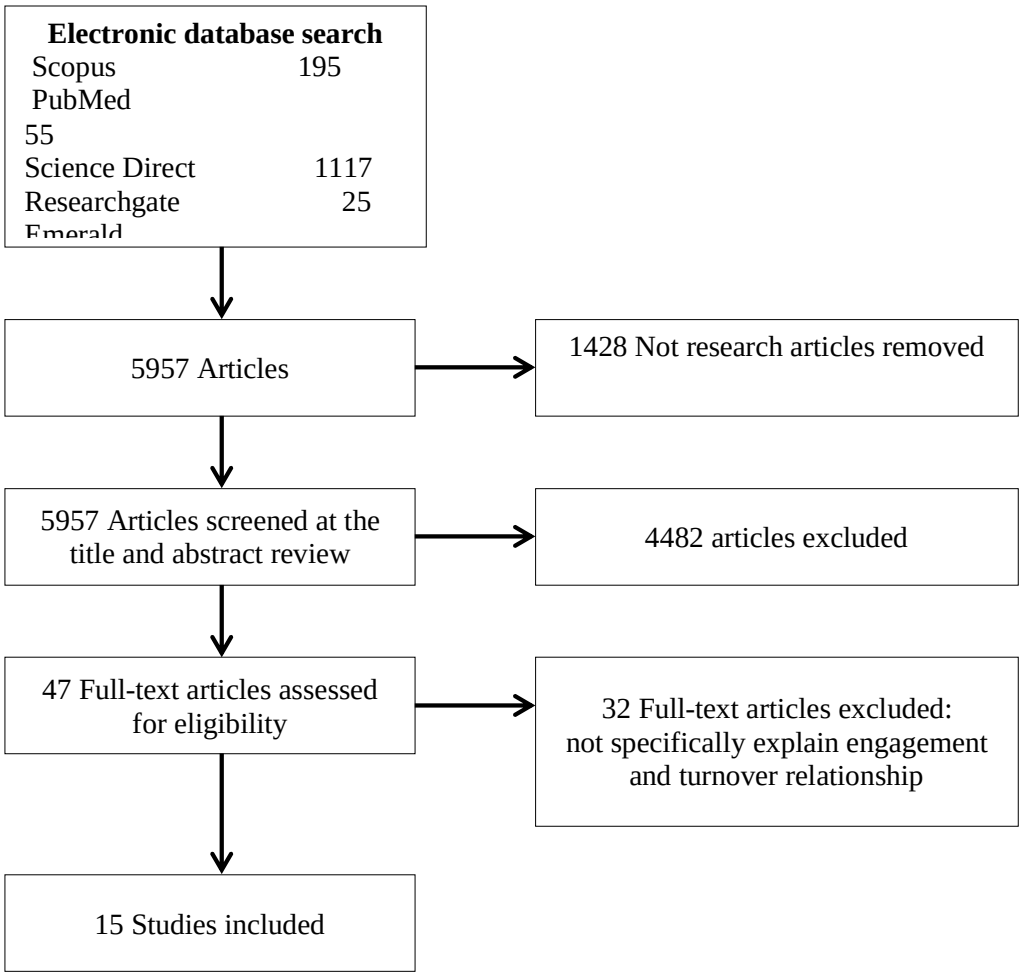

Figure 1. Search and retrieval process

3.2. Characteristic of the included study

The studies were limited to the range between 2014 and 2018. Three studies were published in 2015, 2 studies were published in 2016, 4 studies were published in 2017 and 6 studies were published in 2018. The design used for all of the studies was quantitative. Cross-sectional studies dominate quantitative studies. For the data sources, questionnaires were conducted for all studies. Three different measurement tools were used to measure engagement. The most commonly used measuring instrument was the Utrecht Work Engagement Scale (UWES) made by Schaufeli et al. in 2002 and 2006. There were two versions of UWES used in the 12 studies namely UWES with nine scoring items[1] [2] [5-11] and one with 17 items[12-14], although 1 study did not report using UWES by any method of scoring[15]. The UWES instruments in several studies had been translated into languages that were in accordance with the country of study[5] [6] [12] [13]. Other instruments used to measure engagement were HR Solutions "Sweet 16" made by HR Avatar Soutions in 2012[3] and the Work Engagement questionnaire[16]. Cronbach's alpha for the engagement tools ranged from 0.70 - 0.94. Three studies did not report on the validity[6] [13] [16] and 1 study not report the reliability[16]. Fourteen different tools were used to measure turnover intention by the employees. Cronbach's alpha for the turnover of the intention tool ranged from 0.70 to 0.96. Three studies did not report any validity tests[6] [13] [16], and five studies did not report any reliability testing[3] [7] [11] [13] [16].

Ten studies were conducted in hospital settings[3] [5-9] [12-14] [16], 4 studies were conducted in industrial areas[1] [2] [10] [11], and 1 study took place in a hotel[15]. Fourteen studies were held in multiple places[1-3] [5-13] [15] [16], and only 1 study was held in a single place[14]. The sample population came from various workplaces in this study. There were nurse participants in 10 studies[3] [5-9][12-14] [16], industrial employee participants in 4 studies[1] [2] [10] [11], hospital employee participants in 1 study[3], and hotel employee participants in 1 study[15]. In 1 study, it combined registered nurses and nurse managers[7], and in another study, it combined nurses and registered and patients[5]. The total population in this study was 24362 people consisting of 11745 nurses, 12436 employees and 181 patients. The place of research was across various countries, namely China[12], Uruguay[6], Spain[6], Japan[7], New Zealand[8], Italy[5], the United States[3], Portugal[13], North American[15], Iran[14], Cyprus[16], India[1], Malaysia[2] [10], and Australia[9]. One study did not explain in what country the research was conducted[11]. See Appendix for the characteristics of the included studies.

3.3. Theoretical frameworks

The theoretical framework was used and elaborated on to underlie the research across the 14 studies, whereas in one study, it was not described using the theoretical framework[3]. Eight different theoretical framework models were used throughout the studies, namely the Job Demand-Resources Model developed by Bakker, Demerouti, & Schaufeli in 2003[11], Bakker & Demerouti in 2007[2] [6] [8] [14], Bakker and Demerouti in 2008[16] and Bakker and Demerouti in 2011[13], thte Social Cognitive Theory developed by Bandura in 1986[5], the Career Adaptability Theory

that was developed by Savickas in 1997[15], the Social Exchange Theory that developed by Blau in 1964[2] [9] [10], the Cognitive Dissonance Theory developed by Festinger in 1957[9], the Field Theory developed by Lewin in 1951[10], Organizational Support Theory developed by Kurtessis, Eisenberger, Ford, Buffardi, Stewart, & Adisin in 2017[11], and the Causal Turnover Model developed by Price & Muller in 1981[13]. All of the above theoretical frameworks underlie how engagement affects turnover. In one study, the theoretical framework came from the review literature that discussed the nurse's intention to stay in the workplace and it did not explain in detail what the underlying theories were[7].

3.4. Study results

Research studies have identified that engagement plays a role in reducing turnover intention. Eight studies identified that engagement decreases turnover intention directly[1] [2] [5] [7–9] [14–16], 12 studies explained that engagement can also reduces turnover indirectly[2] [3] [5] [6] [8–14] [16], and in 3 studies it was explained that the role of engagement can be strengthened by other variables to reduce the turnover that is strengthened by job satisfaction [11] [15] and psychological capital (PsyCap)[1]. The role of engagement indirectly is namely as a mediator between the other variables and turnover intention. Engagement can act as a mediator partially and full mediator. The variables that are fully mediated by engagement to reduce turnover include the job characteristics[12], self-efficacy[8], greater emotional demands[8], mission fulfillment[3], respect[3], decisional involvement[13], job resources[14], personal resources[14], psychological capital[16], training satisfaction[2] and organization fit[10]. The variables that are partially mediated by engagement to reduce turnover include the work environment[12], social support[6], psychological contract fulfillment (job content and social atmosphere)[9], organizational support development[11]and managerial support[11].

4. Discussions

In conducting the systematic review, 15 of the studies evaluated how the role of management was to reduce employee turnover intention. From this systematic review, we tried to show that there is a positive role from engagement from within fifteen articles that met the criteria of adversity to reduce the turnover intention rate. The results of the studies showed that the role of engagement directly made the employees more involved and focused on their work to the point where they did not have time to think about leaving their jobs. Engagement can provide a positive and satisfying work experience, and it can also create positive thoughts and effects resulting in the condition of good health and increased work effort, where positive experiences and thoughts can produce positive performance, make the employers feel more valued, and reduce the possibility of them leaving the organization[17] [18]. Engagement can also reduce burnout, which can trigger turnover intention. In previous studies work engagement was negatively correlated with burnout[19]. Independent relationships are shown through burnout and engagement, where increasing job involvement and reducing fatigue levels can be used as a strategy to reduce turnover intention[7]. One of the things that keeps employees at work is where and when they feel valued

and involved in their workplace. Engagement can generate positive thoughts and work enthusiasm for employees so then fatigue diminishes and employee performance increases. The company will involve their employees more, which will affect the employees choice to stay in the workplace.

The second finding from this systematic review was that engagement plays a role as a mediator between the independent variables involved in decreasing turnover intention. This can happen if the variable can reduce turnover by influencing work engagement. For example, an engagement that mediates the role of job resources to minimize turnover intention[14]. This refers to the model made by Bakker and Demerouti, where the model explains that job resources can influence organizational outcomes by influencing work engagement[20]. Job resources have a component consisting of physical, psychological and social aspects. Good company organizations or organizations that can reduce work demands and physiological and psychological costs achieve their work goals functionally and trigger growth, learning, and personal development[21].

Further research by Bakker and Demerouti suggests that job resources can trigger motivation that leads to engagement which can improve performance, where engagement is directly able to reduce turnover intention[14]. Motivation in work is one aspect that can keep the employees in the workplace, and this motivation can be triggered through work resources. Employees who have a high motivation at work will automatically have good performance and high engagement so their intention to change jobs will decrease.

The latest finding from this systematic review is that engagement is reinforced by other variables when it comes to reducing turnover. This can occur if the variable has a positive correlation with increasing engagement and if it negatively correlates to turnover intention. For example, psychological capital can strengthen the role of engagement to reduce turnover intention[1], wherein this study it has been proven that psychological capital has a positive correlation with engagement and a negative correlation with turnover. It is based on the previous empirical studies which revealed that psychological capital is a component of personal resources that can provide a form of work engagement. Bakker and Leiter (2010) suggested that psychological capital has been proposed by Swetman and Luthans to be used as a fundamental resource that can increase productivity in the workplace[1]. The self-efficacy that forms psychological capital is the strong belief of the employees to do their jobs and to overcome obstacles in their work[1]. Employees who believe in their ability to channel energy to meet the demands of work will have the motivation to immerse themselves in their work and not think of leaving their jobs[22]. High psychological capital will make the employees motivated to work hard and to improve their performance and success in their workplace so then they will be more involved in their work and thus reduce their desire to leave the job.

5. Conclusion

The study result shows that engagement has an important role at helping to reduce turnover rates among employees. Here are three ways how engagement plays a role in reducing turnover intention. First, engagement can reduce turnover intention directly without intermediary variables. Secondly, engagement also plays a role in mediating between other variables to reduce intentional

intention where engagement can act as a full mediator and partial mediator, and the last is that engagement will be strengthened by the other variables to reduce turnover intention. Engagement can provide a positive and satisfying work experience, and create positive thoughts and effects with the conditions of good health and increased work effort where positive experiences and thoughts can produce a positive performance, make the employers more valued, and reduce the possibility of them leaving the organization [17] [18]. Therefore, engagement can be used as one of the strategies in the organization to help employees become more involved in their work so then they do not think about leaving the organization. Employees are valuable human resource assets of the company.
